Suppose P had charts φ on U and ψ on V with $z_0 = \varphi(P)$ satisfying $z_0^n < 0$ and $\psi(P) \in \partial\mathbb{H}^n$. Because $z_0^n < 0$, the set $\varphi(U \cap V)$ contains an open subset $O \subseteq \mathbb{R}^n$ around z_0. Write $\tau = \psi \circ \varphi^{-1}$ on O and let ς be a smooth extension to an open subset of $\mathbb{R}^n$, as in Definition A.298, of the transition map $\varphi \circ \psi^{-1}$ near $\psi(P)$. Shrinking O so that $\tau(O)$ lies in the domain of $\varphi \circ \psi^{-1}$, we have $\varsigma \circ \tau = \mathrm{id}$ on O, so the chain rule Equation (7.52) gives $D\varsigma(\tau(z_0))D\tau(z_0) = \mathbb{1}$ and $\det[D\tau(z_0)] \neq 0$. By the inverse function theorem Corollary A.292, τ maps some neighbourhood of z_0 onto an *open* subset of $\mathbb{R}^n$ containing $\tau(z_0) = \psi(P) \in \partial\mathbb{H}^n$. Every open subset of $\mathbb{R}^n$ containing a point of $\partial\mathbb{H}^n$ contains points with $x^n > 0$, which do not lie in $\mathbb{H}^n$ — contradicting that ψ takes values in $\mathbb{H}^n$.

For the second claim, let $\varphi = (x^1, \dots, x^n)$ be a chart with $\varphi(U) \cap \partial\mathbb{H}^n \neq \varnothing$. By the first claim, $\varphi(U \cap \partial M) = \varphi(U) \cap \partial\mathbb{H}^n$, which is an open subset of $\mathbb{R}^{n-1} = \partial\mathbb{H}^n$, and $\varphi' = (x^1, \dots, x^{n-1})$ is a homeomorphism of $U \cap \partial M$ onto it. Two such charts are smoothly related, because a transition map of M carries $\partial\mathbb{H}^n$ into $\partial\mathbb{H}^n$ — by the first claim again — so its first $n-1$ components restricted to $x^n = 0$ are the transition map of the boundary charts, and they are smooth. Hence Definition 13.44 is met with model space $\mathbb{R}^{n-1}$. □

A.29.2 Orientation and the integral of an n-form

Lemma A.301 (Transformation of the top form)**.** *Let $\varphi = (x^1, \dots, x^n)$ and $\psi = (y^1, \dots, y^n)$ be two charts on a common domain. Then*

$$\mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n = \det\left[\frac{\partial x^i}{\partial y^j}\right] \mathrm{d}y^1 \wedge \cdots \wedge \mathrm{d}y^n . \tag{A.544}$$

Consequently, if an n-form reads $f\,\mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n$ and $g\,\mathrm{d}y^1 \wedge \cdots \wedge \mathrm{d}y^n$ in the two charts, then $g = f \det[\partial x/\partial y]$.

Rests on Definition 13.102, Equation (13.241), and Proposition 13.100.

Proof. *Derives Lemma A.301.*

By the chain rule, $\mathrm{d}x^i = (\partial x^i/\partial y^j)\,\mathrm{d}y^j$. Substituting into the left-hand side and expanding the wedge, every term in which two of the y-indices coincide vanishes (Equation (13.241)), so only the $n!$ terms indexed by a permutation ρ of $(1,\dots,n)$ survive, and reordering $\mathrm{d}y^{\rho(1)}\wedge\cdots\wedge\mathrm{d}y^{\rho(n)}$ into increasing order costs $\operatorname{sgn}\rho$:

$$\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n=\left(\sum_{\rho}\operatorname{sgn}(\rho)\,\frac{\partial x^1}{\partial y^{\rho(1)}}\cdots\frac{\partial x^n}{\partial y^{\rho(n)}}\right)\mathrm{d}y^1\wedge\cdots\wedge\mathrm{d}y^n\,,$$

and the bracket is the Leibniz expansion of the determinant (Chapter 5). The last sentence follows because Λ^n is one-dimensional (Equation (13.235)). □

Definition A.302 (Orientation)**.** An atlas of M is *oriented* if every transition map between two of its charts has everywhere positive Jacobian determinant, $\det[\partial x/\partial y]>0$. M is *orientable* if it admits such an atlas, and an *oriented manifold* is a manifold together with a maximal oriented atlas; a chart belongs to it, and is called *positively oriented*, if its transitions with every chart of the atlas have positive Jacobian determinant.

Rests on Definition 13.44 and Lemma A.301.

Theorem A.303 (Change of variables for multiple integrals; quoted)**.** *Let $\tau:O\longrightarrow O'$ be a diffeomorphism between open subsets of $\mathbb{R}^n$ and let u be continuous with compact support in O'. Then $u\circ\tau\,|\det D\tau|$ has compact support in O and*

$$\int_{O'}u(z)\,\mathrm{d}z^1\cdots\mathrm{d}z^n=\int_{O}u(\tau(w))\,|\det D\tau(w)|\,\mathrm{d}w^1\cdots\mathrm{d}w^n\,,\tag{A.545}$$

both integrals being multiple integrals in the sense of Definition 7.93.

Rests on Definition 7.93 and Remark 7.96.

Definition A.304 (Integral over a chart)**.** Let M be an oriented n-manifold with boundary, let $\varphi=(x^1,\dots,x^n)$ be a positively oriented chart on U, and let α be a continuous n-form on M whose support is a compact subset of U. Writing $\alpha=f\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n$ on U, set

$$\int_M\alpha=\int_{\varphi(U)}\left(f\circ\varphi^{-1}\right)(x)\,\mathrm{d}x^1\cdots\mathrm{d}x^n\,.\tag{A.546}$$

Rests on Definitions 7.93 and A.302 and Proposition 13.100.

Lemma A.305 (The chart integral is well defined)**.** *The value Equation (A.546) does not depend on which positively oriented chart containing the support is used.*

Rests on Definition A.304, Theorem A.303, and Lemma A.301.

Proof. *Derives Lemma A.305.*

Let $\psi=(y^1,\dots,y^n)$ be a second positively oriented chart containing $\operatorname{supp}\alpha$, and let $\tau=\varphi\circ\psi^{-1}$, a bijection between the images of the common domain.

Reduction to open sets. By Lemma A.300, τ carries interior points to interior points and boundary points to boundary points, so it restricts to a diffeomorphism between the two *open* subsets of $\mathbb{R}^n$ obtained by deleting the face $x^n=0$; and deleting that face changes neither multiple integral, because a bounded portion of a hyperplane contributes nothing to an upper–lower Darboux gap — the argument of Remark 7.96 for the graph of a continuous function, applied to the constant function 0. Both sides of the claimed equality may therefore be computed over the open sets, where Theorem A.303 applies as stated.

By Lemma A.301 the component functions are related by $g=f\,\det[\partial x/\partial y]=f\,\det D\tau$, and $\det D\tau>0$ by Definition A.302, so $|\det D\tau|=\det D\tau$. Then Equation (A.545) with $u=f\circ\varphi^{-1}$ gives

$$\int_{\varphi(U)}\left(f\circ\varphi^{-1}\right)\mathrm{d}x^1\cdots\mathrm{d}x^n=\int_{\psi(U)}\left(f\circ\varphi^{-1}\circ\tau\right)\det D\tau\,\mathrm{d}y^1\cdots\mathrm{d}y^n=\int_{\psi(U)}\left(g\circ\psi^{-1}\right)\mathrm{d}y^1\cdots\mathrm{d}y^n\,,$$

since $f\circ\varphi^{-1}\circ\tau=f\circ\psi^{-1}$. □

A.29.3 Bump functions and partitions of unity

The construction below is elementary and is carried out in full, because the treatise does not have it: nothing here is quoted.

Lemma A.306 (The standard smooth bump)**.** *The function*

$$\lambda(t) = \mathrm{e}^{-1/t} \quad (t > 0)\,, \qquad \lambda(t) = 0 \quad (t \le 0) \tag{A.547}$$

is smooth on $\mathbb{R}$*. Consequently, for* $0 < a < b$*,*

$$\beta(t) = \frac{\lambda(b-t)}{\lambda(b-t) + \lambda(t-a)} \tag{A.548}$$

is smooth, takes values in $[0,1]$*, equals* 1 *for* $t \le a$ *and* 0 *for* $t \ge b$*; and for* $0 < r_1 < r_2$ *the function*

$$\chi(x) = \beta\left(|x|^2\right), \qquad a = r_1^2\,, \quad b = r_2^2\,, \tag{A.549}$$

is smooth on $\mathbb{R}^n$*, equals* 1 *on* $\overline{B}_{r_1}(0)$*, and vanishes off* $B_{r_2}(0)$*.*

Rests on Definition 7.53, Theorem 7.37, and Proposition 7.72.

Proof. *Derives Lemma A.306.*

Smoothness of λ*.* On $t > 0$ an induction gives $\lambda^{(k)}(t) = P_k(1/t)\,\mathrm{e}^{-1/t}$ with P_k a polynomial: this holds for $k = 0$ with $P_0 = 1$, and differentiating $P_k(1/t)\mathrm{e}^{-1/t}$ gives $\left[-t^{-2}P_k'(1/t) + t^{-2}P_k(1/t)\right]\mathrm{e}^{-1/t}$, of the same shape with $P_{k+1}(s) = s^2\left(P_k(s) - P_k'(s)\right)$. On $t < 0$ every derivative is 0. At $t = 0$ we show by induction that $\lambda^{(k)}(0)$ exists and is 0. Assume it for k; the left difference quotient is 0, and the right one is $P_k(1/t)\mathrm{e}^{-1/t}/t$. Put $s = 1/t \to +\infty$; the quotient is $s\,P_k(s)\,\mathrm{e}^{-s}$, and for every N the exponential series (Equation (7.31)) gives $\mathrm{e}^s > s^N/N!$, i.e. $\mathrm{e}^{-s} < N!\,s^{-N}$, so choosing N larger than $1 + \deg P_k$ makes $s\,P_k(s)\mathrm{e}^{-s} \to 0$. Hence $\lambda^{(k+1)}(0) = 0$. Each $\lambda^{(k)}$ is then continuous at 0 by the same estimate, so λ is smooth.

β. The denominator of Equation (A.548) never vanishes: for $t < b$ the first term is positive, and for $t \ge b > a$ the second is. So β is smooth, and it lies in $[0,1]$ because both terms are non-negative. For $t \le a$ the second term vanishes and $\beta = 1$; for $t \ge b$ the first vanishes and $\beta = 0$.

χ. $x \longmapsto |x|^2$ is a polynomial, hence smooth, so χ is smooth by the chain rule Proposition 7.72; $|x| \le r_1$ gives $|x|^2 \le a$ and $\chi = 1$, and $|x| \ge r_2$ gives $\chi = 0$. □

Lemma A.307 (Partition of unity on a compact manifold)**.** *Let* M *be a compact* n*-manifold with boundary and* $\{U_a\}$ *an open cover of* M*. Then there are finitely many smooth functions* $\rho_1, \dots, \rho_N : M \longrightarrow [0,1]$ *such that each* $\operatorname{supp}\rho_i$ *is a compact set contained in the domain of a single chart which is itself contained in some* U_a*, and*

$$\sum_{i=1}^{N} \rho_i(P) = 1 \qquad \text{for every } P \in M\,. \tag{A.550}$$

Rests on Lemma A.306 and Definitions 6.9 and A.299.

Proof. *Derives Lemma A.307.*

Let $P \in M$. Choose a chart φ_P on a domain $V_P \ni P$ with V_P contained in some U_a and $\varphi_P(P) = 0$ (translate the chart). Since $\varphi_P(V_P)$ is open in $\mathbb{H}^n$ there is $r_P > 0$ with $\overline{B}_{r_P}(0) \cap \mathbb{H}^n \subseteq \varphi_P(V_P)$. Let χ_P be the function Equation (A.549) with $r_1 = r_P/2$ and $r_2 = r_P$, and set

$$\widetilde{\chi}_P = \chi_P \circ \varphi_P \text{ on } V_P\,, \qquad \widetilde{\chi}_P = 0 \text{ on } M \setminus V_P\,.$$

This is smooth on M: it is smooth on V_P, and it vanishes identically on the open set $M \setminus \varphi_P^{-1}\left(\overline{B}_{r_P}(0) \cap \mathbb{H}^n\right)$, whose complement in M is the compact set $\varphi_P^{-1}\left(\overline{B}_{r_P}(0) \cap \mathbb{H}^n\right) \subseteq$

V_P; the two open sets cover M and the definitions agree on the overlap. The same compact set contains $\operatorname{supp}\widetilde{\chi}_P$.

Put $W_P = \varphi_P^{-1}\left(B_{r_P/2}(0)\cap\mathbb{H}^n\right)$, an open neighbourhood of P on which $\widetilde{\chi}_P = 1$. The family $\{W_P\}$ is an open cover of the compact M (Definition 6.9), so finitely many $W_{P_1},\dots,W_{P_N}$ cover it. Then $S=\sum_i \widetilde{\chi}_{P_i}$ is smooth and satisfies $S\geq 1$ everywhere, since each point lies in some W_{P_i} where the corresponding term is 1 and no term is negative. Setting $\rho_i = \widetilde{\chi}_{P_i}/S$ gives smooth functions with the stated supports and Equation (A.550). □

Definition A.308 (Integral over the manifold)**.** Let M be a compact oriented n-manifold with boundary and α a continuous n-form on M. Choose a partition of unity $\{\rho_i\}$ subordinate to a cover by domains of positively oriented charts (Lemma A.307) and set

$$\int_M \alpha = \sum_{i=1}^{N}\int_M \rho_i\alpha\,, \tag{A.551}$$

each summand being a chart integral (Definition A.304). The value does not depend on the partition: if $\{\sigma_j\}$ is another one, then by linearity of the multiple integral and Lemma A.305 — each $\rho_i\sigma_j\alpha$ being supported in one chart —

$$\sum_i\int_M \rho_i\alpha = \sum_{i,j}\int_M \rho_i\sigma_j\alpha = \sum_j\int_M \sigma_j\alpha\,.$$

Rests on Lemmas A.305 and A.307.

Definition A.309 (The induced orientation of the boundary)**.** Let M be oriented and $\varphi=(x^1,\dots,x^n)$ a positively oriented boundary chart. The *induced orientation* of ∂M is the one in which the restricted chart $\varphi'=(x^1,\dots,x^{n-1})$ of Lemma A.300 is positively oriented when n is odd and negatively oriented when n is even; equivalently, the chart $((-1)^{n-1}x^1,x^2,\dots,x^{n-1})$ is positively oriented. This is consistent: the transition map between two boundary charts has, at $x^n=0$, Jacobian determinant equal to $(\partial x^n/\partial y^n)$ times that of the restricted transition, and $\partial x^n/\partial y^n>0$ because both charts map into $\mathbb{H}^n$ and both send ∂M to $x^n=0$; hence the restricted transitions inherit positive determinants, and multiplying every one of them by the same sign $(-1)^{n-1}$ leaves them positive.

Rests on Definition A.302 and Lemma A.300.

Remark A.310 (Outward normal first). The sign $(-1)^{n-1}$ is not a convention chosen to make Equation (A.542) come out right; it is the *outward-normal-first* rule counted honestly. In a boundary chart the outward direction is that of increasing x^n, since $\mathbb{H}^n=\{x^n\leq 0\}$, so the rule declares $(v_1,\dots,v_{n-1})$ positively oriented in $T_{\partial M}$ exactly when $(\partial_n,v_1,\dots,v_{n-1})$ is positively oriented in T_M. Moving ∂_n from the front of $(\partial_n,\partial_1,\dots,\partial_{n-1})$ to the back costs $n-1$ transpositions, so $(\partial_1,\dots,\partial_{n-1})$ is positively oriented precisely when $(-1)^{n-1}=+1$, which is Definition A.309. For $n=3$ — a surface in space, the case of Equation (13.231) — the sign is $+1$ and the rule reduces to the familiar right-hand relation between the normal of S and the sense of circulation on ∂S.

A.29.4 Statement and the half-space computation

Theorem A.311 (General Stokes theorem)**.** *Let M be a compact oriented n-manifold with boundary, $n\geq 1$, let ∂M carry the induced orientation, and let ω be a smooth $(n-1)$-form on M. Then*

$$\int_M \mathrm{d}\omega = \int_{\partial M}\iota^*\omega\,, \tag{A.552}$$

where $\iota:\partial M\longrightarrow M$ is the inclusion. If $\partial M=\varnothing$ the right-hand side is 0.

Rests on Definitions 13.103, A.308 and A.309.

Lemma A.312 (The computation in one chart)**.** *Let ω be a smooth $(n-1)$-form on $\mathbb{H}^n$ with compact support. Write*

$$\omega = \sum_{i=1}^{n} (-1)^{i-1} f_i \, \mathrm{d}x^1 \wedge \cdots \wedge \widehat{\mathrm{d}x^i} \wedge \cdots \wedge \mathrm{d}x^n \,, \tag{A.553}$$

the hat marking the omitted factor; this is possible, with smooth f_i, because those n products form a basis of Λ^{n-1} (Equation (13.235)). Then

$$\int_{\mathbb{H}^n} \mathrm{d}\omega = \int_{\mathbb{R}^{n-1}} f_n\left(x^1, \ldots, x^{n-1}, 0\right) \mathrm{d}x^1 \cdots \mathrm{d}x^{n-1} = \int_{\partial \mathbb{H}^n} \iota^* \omega \,, \tag{A.554}$$

the last integral taken with the induced orientation Definition A.309. If the support of ω lies in the open half-space $\{x^n < 0\}$, both sides vanish.

Rests on Definition 13.103, Theorem 7.43, and Remark 7.96.

Proof. *Derives Lemma A.312.*

The exterior derivative. Write $\theta_i = \mathrm{d}x^1 \wedge \cdots \wedge \widehat{\mathrm{d}x^i} \wedge \cdots \wedge \mathrm{d}x^n$. Carrying $\mathrm{d}x^i$ leftwards past the $i-1$ factors $\mathrm{d}x^1, \ldots, \mathrm{d}x^{i-1}$ using Equation (13.241),

$$\mathrm{d}x^i \wedge \theta_i = (-1)^{i-1} \, \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n \,. \tag{A.555}$$

By the Leibniz rule Equation (13.246) and $\mathrm{d}(\mathrm{d}x^j) = 0$,

$$\mathrm{d}\omega = \sum_i (-1)^{i-1} \, \mathrm{d}f_i \wedge \theta_i = \sum_{i,j} (-1)^{i-1} \partial_j f_i \, \mathrm{d}x^j \wedge \theta_i \,,$$

and $\mathrm{d}x^j \wedge \theta_i = 0$ unless $j = i$, since otherwise $\mathrm{d}x^j$ is repeated. With Equation (A.555),

$$\mathrm{d}\omega = \left(\sum_{i=1}^{n} \partial_i f_i \right) \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n \,. \tag{A.556}$$

The integral. Choose $R > 0$ so large that $\operatorname{supp}\omega$ is contained in the box $Q = [-R, R]^{n-1} \times [-R, 0]$, and note that each f_i vanishes identically outside it. By Equation (A.556), Definition A.304 and additivity, the left-hand side of Equation (A.554) is $\sum_i \int_Q \partial_i f_i$. Reduce each term to an iterated integral, integrating first in x^i (Remark 7.96) and applying the fundamental theorem of calculus Theorem 7.43. For $i < n$,

$$\int_{-R}^{R} \partial_i f_i \, \mathrm{d}x^i = f_i\big|_{x^i=-R}^{x^i=+R} = 0 \,,$$

both endpoint values lying outside Q; hence those $n-1$ terms vanish. For $i = n$ the x^n-integration runs only up to 0:

$$\int_{-R}^{0} \partial_n f_n \, \mathrm{d}x^n = f_n\left(x^1, \ldots, x^{n-1}, 0\right) - f_n\left(x^1, \ldots, x^{n-1}, -R\right) = f_n\left(x^1, \ldots, x^{n-1}, 0\right) \,,$$

which gives the first equality in Equation (A.554). If $\operatorname{supp}\omega \subseteq \{x^n < 0\}$ then $f_n(\cdot, 0) = 0$ and the expression vanishes.

The boundary integral. The inclusion is $\iota(x^1, \ldots, x^{n-1}) = (x^1, \ldots, x^{n-1}, 0)$, so by Equation (A.190) $\iota^* \mathrm{d}x^j = \mathrm{d}x^j$ for $j < n$ while $\iota^* \mathrm{d}x^n = \mathrm{d}\,(x^n \circ \iota) = 0$. By Equation (A.187) the pullback distributes over the wedge, so every θ_i with $i < n$ — each of which still contains the factor $\mathrm{d}x^n$ — pulls back to zero, and

$$\iota^* \omega = (-1)^{n-1} \, f_n\left(x^1, \ldots, x^{n-1}, 0\right) \, \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^{n-1} \,. \tag{A.557}$$

The induced orientation is $(-1)^{n-1}$ times the one in which $(x^1, \dots, x^{n-1})$ is positively oriented (Definition A.309), and reversing an orientation reverses the sign of the integral Equation (A.546): replacing x^1 by $-x^1$ multiplies the component function by -1 (Lemma A.301, the Jacobian determinant of the reflection being -1), while the multiple integral over the reflected region is unchanged by Equation (A.545), whose factor $|\det D\tau|$ is 1 for a reflection. Hence

$$\int_{\partial \mathbb{H}^n} \iota^* \omega = (-1)^{n-1} \int_{\mathbb{R}^{n-1}} (-1)^{n-1} f_n\left(x', 0\right) \mathrm{d}x^1 \cdots \mathrm{d}x^{n-1} = \int_{\mathbb{R}^{n-1}} f_n\left(x', 0\right) \mathrm{d}x^1 \cdots \mathrm{d}x^{n-1} ,$$

which is the second equality in Equation (A.554). □

A.29.5 Proof of the theorem

Proof of Theorem A.311. *Derives Theorem A.311.*

Cover M by domains of positively oriented charts and let $\{\rho_1, \dots, \rho_N\}$ be a subordinate partition of unity (Lemma A.307). Since $\sum_i \rho_i = 1$ is constant, $\sum_i \mathrm{d}\rho_i = \mathrm{d}(1) = 0$, so by the Leibniz rule Equation (13.246)

$$\sum_{i=1}^{N} \mathrm{d}\left(\rho_i \omega\right) = \sum_i \mathrm{d}\rho_i \wedge \omega + \left(\sum_i \rho_i\right) \mathrm{d}\omega = \mathrm{d}\omega \,. \tag{A.558}$$

Each $\rho_i \omega$ is a smooth $(n-1)$-form whose support is a compact subset of the domain U_i of a positively oriented chart φ_i; transporting it by φ_i and extending by zero gives a smooth compactly supported $(n-1)$-form on the whole of $\mathbb{H}^n$, smooth because the two definitions — the transported one on the open set $\varphi_i(U_i)$, and zero on the complement of the compact support — agree on the overlap of two open sets covering $\mathbb{H}^n$. The transport carries the two sides of Equation (A.559) to the two sides of Equation (A.554): the chart integral Equation (A.546) is by definition the multiple integral of the chart representative, and pullback commutes with d (Equation (A.188)), so the chart representative of $\mathrm{d}(\rho_i\omega)$ is the exterior derivative of the chart representative of $\rho_i\omega$. Hence Lemma A.312 applies and gives

$$\int_M \mathrm{d}\left(\rho_i \omega\right) = \int_{\partial M} \iota^* \left(\rho_i \omega\right) \,, \tag{A.559}$$

where the right-hand side is 0 when U_i misses ∂M, that being the last clause of Lemma A.312. Summing Equation (A.559) over i, using Equation (A.558) on the left and, on the right, that $\{\iota^*\rho_i\}$ restricts to a partition of unity on ∂M — $\sum_i \rho_i = 1$ there too, and each $\iota^*\rho_i$ is supported in a boundary chart — gives Equation (A.552) by Definition A.308. If $\partial M = \varnothing$, every chart misses the boundary and every term on the right vanishes. □

A.29.6 The instance stated in the chapter

Corollary A.313 (Stokes' theorem for an antisymmetric tensor field)**.** *Let $S \subset E_3$ be a compact oriented two-dimensional submanifold with boundary ∂S, carrying the induced orientation, and let H_i be a smooth covector field defined near S, with rotor tensor*

$$H_{ij} = \partial_i H_j - \partial_j H_i \,. \tag{A.560}$$

Then, with $\mathrm{d}f^{ij}$ the antisymmetric surface element of S,

$$\frac{1}{2} \int_S H_{ij} \, \mathrm{d}f^{ij} = \oint_{\partial S} H_i \, \mathrm{d}x^i \,, \tag{A.561}$$

which is Equation (13.231).

Rests on Theorem A.311, Equation (13.232), and Definition 7.94.

Proof. *Derives Corollary A.313.*

Let $H = H_i \, \mathrm{d}x^i$ be the one-form with the given components. By Definition 13.103,

$$\mathrm{d}H = \partial_j H_i \, \mathrm{d}x^j \wedge \mathrm{d}x^i = \frac{1}{2} \left(\partial_i H_j - \partial_j H_i \right) \mathrm{d}x^i \wedge \mathrm{d}x^j = \frac{1}{2} H_{ij} \, \mathrm{d}x^i \wedge \mathrm{d}x^j \,, \tag{A.562}$$

the middle step by antisymmetrizing the coefficient against $\mathrm{d}x^j \wedge \mathrm{d}x^i = -\mathrm{d}x^i \wedge \mathrm{d}x^j$ (Equation (13.241)). Theorem A.311 applied to $M = S$ and $\omega = \iota_S^* H$, the restriction of H to S, gives

$$\int_S \iota_S^* \left(\mathrm{d}H \right) = \oint_{\partial S} \iota_{\partial S}^* H \,, \tag{A.563}$$

where pullback and d were exchanged by Equation (A.188).

It remains to recognize the two sides. Let $\boldsymbol{r} : D \longrightarrow S$ be a positively oriented parametrization of a piece of S, with parameters (u, v). The two-form $\mathrm{d}x^i \wedge \mathrm{d}x^j$ has components $\delta^i{}_a \delta^j{}_b - \delta^i{}_b \delta^j{}_a$ (Definition 13.102), so Equation (A.186) gives

$$\iota_S^* \left(\mathrm{d}x^i \wedge \mathrm{d}x^j \right) = \left(\partial_u r^i \, \partial_v r^j - \partial_v r^i \, \partial_u r^j \right) \mathrm{d}u \wedge \mathrm{d}v \,. \tag{A.564}$$

That bracket is the antisymmetric surface element. Indeed, Remark 13.97 writes $\mathrm{d}f^{ij} = \varepsilon^{ijk} \mathrm{d}f_k$ with $\mathrm{d}f_k$ the oriented surface element Equation (7.108) of Definition 7.94, whose components are $\mathrm{d}f_k = \varepsilon_{klm} \, \partial_u r^l \, \partial_v r^m \, \mathrm{d}u \, \mathrm{d}v$; contracting the two Levi-Civita symbols (Chapter 5),

$$\mathrm{d}f^{ij} = \varepsilon^{ijk} \varepsilon_{klm} \, \partial_u r^l \, \partial_v r^m \, \mathrm{d}u \, \mathrm{d}v = \left(\delta^i{}_l \delta^j{}_m - \delta^i{}_m \delta^j{}_l \right) \partial_u r^l \, \partial_v r^m \, \mathrm{d}u \, \mathrm{d}v \,, \tag{A.565}$$

which is the bracket of Equation (A.564) times $\mathrm{d}u \, \mathrm{d}v$. Hence, by Definition A.304 and Equation (A.562),

$$\int_S \iota_S^* \left(\mathrm{d}H \right) = \frac{1}{2} \iint_D H_{ij} \left(\boldsymbol{r}(u, v) \right) \left(\partial_u r^i \partial_v r^j - \partial_v r^i \partial_u r^j \right) \mathrm{d}u \, \mathrm{d}v = \frac{1}{2} \int_S H_{ij} \, \mathrm{d}f^{ij} \,,$$

and, parametrizing ∂S by arc parameter t, $\iota_{\partial S}^* H = H_i(\boldsymbol{r}(t)) \, \frac{\mathrm{d}r^i}{\mathrm{d}t} \, \mathrm{d}t$, whose integral is the line integral Equation (7.106) of $H_i \mathrm{d}x^i$ over ∂S. Substituting both into Equation (A.563) gives Equation (A.561). □

Remark A.314 (The reading under which the identity is false). Remark 13.97 records that Equation (13.231) holds for the rotor tensor Equation (13.232) and is *false* if H_i is instead read as the dual pseudo-vector $\frac{1}{2} \varepsilon_{ijk} H_{jk}$ of Equation (13.224). The derivation above respects that, and shows where the hypothesis enters: the only step in which the relation between H_{ij} and H_i is used is Equation (A.562), which asserts that the two-form $\frac{1}{2} H_{ij} \mathrm{d}x^i \wedge \mathrm{d}x^j$ is *exact*, with the one-form $H = H_i \mathrm{d}x^i$ as its primitive. Under the dual reading there is no such relation: $\frac{1}{2} H_{ij} \mathrm{d}x^i \wedge \mathrm{d}x^j$ would be an arbitrary two-form and $H_i \mathrm{d}x^i$ an unrelated one-form, so Theorem A.311 says nothing connecting their integrals, and the left-hand side of Equation (13.231) would be a flux and the right-hand side a circulation of the same vector field — two quantities with no reason to agree. Writing $\mathrm{d}f^{ij} = \varepsilon^{ijk} \mathrm{d}f_k$ turns Equation (A.561) into $\int_S (\nabla \times \boldsymbol{H}) \cdot \mathrm{d}\boldsymbol{f} = \oint_{\partial S} \boldsymbol{H} \cdot \mathrm{d}\boldsymbol{l}$, the classical statement Theorem 7.100 — which Chapter 7 proves directly and independently, so the two derivations check each other rather than one resting on the other.

Remark A.315 (The SI reading of the three-dimensional instance). The theorem is an identity between integrals of forms and is unit-homogeneous by construction: if H_i carries an SI unit $[H]$ then $H_i \mathrm{d}x^i$ carries $[H] \cdot \mathrm{m}$, H_{ij} carries $[H] / \mathrm{m}$, and $\mathrm{d}f^{ij}$ carries m^2, so both sides of Equation (A.561) carry $[H] \cdot \mathrm{m}$. The physical instance the treatise meets first is the magnetic vector potential: with $H_i = A_i$ in $\mathrm{T\,m}$ and $H_{ij} = \partial_i A_j - \partial_j A_i$ in T, the identity reads

$$\int_S \boldsymbol{B} \cdot \mathrm{d}\boldsymbol{f} = \oint_{\partial S} \boldsymbol{A} \cdot \mathrm{d}\boldsymbol{l} \,, \tag{A.566}$$

both sides in $\mathrm{Wb} = \mathrm{T\,m^2}$: the magnetic flux through a surface equals the circulation of the potential round its edge.

A.29.7 What is quoted, and what is not

Remark A.316 (What is quoted here). Exactly one theorem is assumed without proof: Theorem A.303, the change-of-variables formula for multiple integrals. It is used once, in Lemma A.305, to show that the chart integral Equation (A.546) does not depend on the chart; every later step is built on that one fact about the integral. This treatise does not prove it, and the omission is not new here: Remark 7.102 of Chapter 7 already records the same formula as a quoted input, needed there for the independence of a flux integral from its parametrization, alongside the three properties of the multiple integral collected in Remark 7.96. A citation for it is owed and no entry of the bibliography currently carries it, so it is stated here rather than referenced. Nothing else is quoted: the partition of unity, which is the input a reader would most expect to be imported, is constructed outright in Lemmas A.306 and A.307, and the topology of the boundary is settled in Lemma A.300 from the inverse function theorem proved in Appendix A.28.

Remark A.317 (Where compactness and orientability are used). Compactness enters once, in Lemma A.307, to make the partition of unity *finite* — so that the sum Equation (A.558) has finitely many terms and no convergence question arises. It may be traded for the weaker hypothesis that ω have compact support, at the cost of building a locally finite partition of unity. Orientability enters twice, both times essentially: in Lemma A.305, where $\det D\tau > 0$ is what removes the absolute value from Equation (A.545) and lets the chart integrals agree rather than differ in sign; and in Definition A.309, where the induced orientation is what makes the sign $(-1)^{n-1}$ produced by the half-space computation cancel against the sign in Equation (A.557). On a non-orientable manifold no consistent $\int_M$ of an n-form exists at all, and Equation (A.552) has no meaning.

Remark A.318. Appendix A.29 discharges the derivation owed at Equation (13.231) of Chapter 13, and with it the general formulation that Remark 7.102 of Chapter 7 names as the common source of Theorems 7.99 to 7.101. The chapter's statement is recovered as Corollary A.313 under the hypothesis that Remark 13.97 makes explicit, and the general theorem Theorem A.311 is what Section 13.6 was building towards: the exterior derivative and the boundary operator are adjoint, so that $\mathrm{d}^2 = 0$ (Equation (13.245)) and $\partial\partial = \varnothing$ are the same statement seen from the two sides of Equation (A.552).

A.30 The Poincaré–Birkhoff–Witt Theorem

This appendix proves Theorem 14.7 of Chapter 14: the ordered monomials in a basis of a Lie algebra $\mathfrak{g}$ form a vector-space basis of its universal enveloping algebra $U(\mathfrak{g})$ of Definition 14.5. Only the defining relations Equation (14.12) and the Jacobi identity are assumed. That the ordered monomials *span* $U(\mathfrak{g})$ is a reordering argument and is done first (Appendix A.30.2); the content of the theorem is their linear *independence*, and the whole of it lies in the construction of an action of $U(\mathfrak{g})$ on the polynomial algebra in $\dim \mathfrak{g}$ commuting variables (Appendix A.30.3). The Jacobi identity is exactly what makes that action well defined: it is the statement that the two ways of reordering a triple product agree. The consequences drawn in Appendix A.30.5 — the embedding of $\mathfrak{g}$ in $U(\mathfrak{g})$, and the symmetrization isomorphism between $U(\mathfrak{g})$ and the polynomial algebra on $\mathfrak{g}$ — are what Appendix A.32 uses to count the Casimir operators.

Throughout, $\mathbb{K}$ is the field of scalars ($\mathbb{R}$ or $\mathbb{C}$ in every application in this book; the symbol k is reserved for the invariant tensors of Definition 14.14), $\mathfrak{g}$ is a finite-dimensional

Lie algebra over $\mathbb{K}$ with basis $T_1, \dots, T_M$, $M = \dim \mathfrak{g}$, and structure constants fixed as in Equation (14.11),

$$[T_a, T_b] = C^c{}_{ab}\, T_c\,, \qquad a, b, c = 1, \dots, M\,, \tag{A.567}$$

with the summation convention in force. Nothing below uses the characteristic of $\mathbb{K}$ except where the symmetrization map is introduced, which needs $\mathbb{Q} \subseteq \mathbb{K}$ and is flagged there.

A.30.1 Statement

Theorem A.319 (Poincaré–Birkhoff–Witt)**.** *The ordered monomials*

$$T_1^{n_1} T_2^{n_2} \cdots T_M^{n_M}\,, \qquad n_a \in \mathbb{N} \cup \{0\}\,, \tag{A.568}$$

form a basis of $U(\mathfrak{g})$ as a $\mathbb{K}$-vector space. In particular the linear map $\mathfrak{g} \to U(\mathfrak{g})$ is injective, so that $\mathfrak{g}$ may be regarded as a subspace of $U(\mathfrak{g})$, and no relation holds among the generators beyond those forced by Equation (14.12).

Rests on Definition 14.5 and Equation (14.12).

A.30.2 The filtration, and spanning

Definition A.320 (Filtration by degree)**.** Let $U_n \subseteq U(\mathfrak{g})$ be the span of the products $T_{a_1} T_{a_2} \cdots T_{a_m}$ with $m \le n$, the empty product being the unit. Then

$$\mathbb{K} = U_0 \subseteq U_1 \subseteq U_2 \subseteq \cdots\,, \qquad U_m U_n \subseteq U_{m+n}\,, \qquad \bigcup_n U_n = U(\mathfrak{g})\,, \tag{A.569}$$

the last equality because the T_a generate $U(\mathfrak{g})$ as an algebra with unit.

Rests on Definition 14.5.

Lemma A.321 (The ordered monomials span)**.** *U_n is spanned by the ordered monomials Equation (A.568) of total degree $n_1 + \cdots + n_M \le n$. Consequently the ordered monomials span $U(\mathfrak{g})$.*

Rests on Definition A.320 and Equation (14.12).

Proof. *Derives Lemma A.321.*

Induct on n. For $n = 0$ there is nothing to prove. Let $n \ge 1$ and assume the claim for $n - 1$. It suffices to treat a single word $w = T_{a_1} T_{a_2} \cdots T_{a_n}$ of length exactly n, and we induct on its number of *inversions*, the number of pairs $i < j$ with $a_i > a_j$. If w has no inversion its indices are already nondecreasing and w is an ordered monomial. If it has at least one, some *adjacent* pair is out of order, $a_i > a_{i+1}$; otherwise the sequence would be nondecreasing. Apply Equation (14.12) to that pair alone:

$$w = T_{a_1} \cdots T_{a_{i+1}} T_{a_i} \cdots T_{a_n} + C^c{}_{a_i a_{i+1}}\, T_{a_1} \cdots T_{a_{i-1}}\, T_c\, T_{a_{i+2}} \cdots T_{a_n}\,. \tag{A.570}$$

The first word on the right has length n and exactly one inversion fewer, so it is handled by the inner induction; the second has length $n - 1$ and lies in U_{n-1}, handled by the outer induction. Hence w is a combination of ordered monomials of degree at most n. □

Everything that follows exists to show that this spanning set is *free*. The danger is real and must be stated plainly: nothing seen so far excludes the possibility that repeated use of Equation (A.570) along two different routes returns two different combinations of ordered monomials, which would force a relation among them and could in principle collapse $U(\mathfrak{g})$ — in the extreme case to zero. What rules this out is the existence of *one* representation in which the ordered monomials visibly act independently.

A.30.3 The action on the polynomial algebra

Notation A.322 (Ordered multi-indices). Let $P = \mathbb{K}[x_1, \dots, x_M]$ be the polynomial algebra in M commuting variables. A *multi-index* is a nondecreasing finite sequence $A = (a_1 \le a_2 \le \cdots \le a_m)$ of indices from $\{1, \dots, M\}$; we write $x_A = x_{a_1} x_{a_2} \cdots x_{a_m}$, $|A| = m$, and $x_A = 1$ for the empty sequence. The monomials x_A are a basis of P. For an index a we write

$$a \le A \quad \text{if and only if} \quad a \le a_1 \,, \tag{A.571}$$

that is, if a does not exceed any index occurring in A; the condition is vacuous, hence true, for the empty multi-index. Finally P_n denotes the span of the x_A with $|A| \le n$, so that $P_0 = \mathbb{K}$ and $P_n P_m \subseteq P_{n+m}$.

Proposition A.323 (The polynomial representation)**.** *There exist linear maps $\theta_a : P \to P$, $a = 1, \dots, M$, such that for every multi-index A and all indices a, b*

$$\theta_a \, x_A = x_a x_A \qquad \text{whenever } a \le A \,, \tag{A.572}$$

$$\theta_a \, x_A - x_a x_A \in P_{|A|} \,, \tag{A.573}$$

$$\theta_a \theta_b - \theta_b \theta_a = C^c{}_{ab} \, \theta_c \,. \tag{A.574}$$

The assignment $T_a \mapsto \theta_a$ is therefore a representation of $\mathfrak{g}$ on P.
Rests on Equation (A.567) and Notation A.322.

Proof. *Derives Proposition A.323.*

The maps are constructed on P_n by induction on n. Write (A_n), (B_n), (C_n) for the three conditions restricted as follows: (A_n) and (B_n) are Equations (A.572) and (A.573) for $|A| \le n$, and (C_n) is Equation (A.574) applied to x_A with $|A| \le n-1$ — the largest range in which both sides are defined once θ is known on P_n, since $\theta_b x_A \in P_{|A|+1} \subseteq P_n$ by (B_{n-1}).

Base. $P_0 = \mathbb{K}$; set $\theta_a 1 = x_a$. Then (A_0) holds because $a \le A$ is vacuous for the empty multi-index, (B_0) holds because the difference is 0, and (C_0) is empty.

Extension to P_n. Assume θ defined on P_{n-1} with (A_{n-1}), (B_{n-1}), (C_{n-1}). Let $|A| = n$.

1. If $a \le A$, set $\theta_a x_A = x_a x_A$, as Equation (A.572) demands.

2. If not, let b be the smallest index occurring in A, so that $b < a$, and write $A = (b, B)$ with $b \le B$ and $|B| = n-1$. Then $x_A = x_b x_B = \theta_b x_B$ by (A_{n-1}). Using (B_{n-1}) write

$$\theta_a x_B = x_a x_B + w \,, \qquad w \in P_{n-1} \,, \tag{A.575}$$

and *define*

$$\theta_a x_A := x_a x_A + \theta_b w + C^c{}_{ab} \, \theta_c x_B \,. \tag{A.576}$$

Every term on the right is already defined: w and x_B lie in P_{n-1}.

Condition (A_n) holds by construction. For (B_n): in case 1 the difference is 0; in case 2 it is $\theta_b w + C^c{}_{ab} \theta_c x_B$, and (B_{n-1}) gives $\theta_b w \in P_n$ and $\theta_c x_B \in P_n$.

Before proving (C_n), record what Equation (A.576) says. With $b < a$ and $b \le B$, the monomial $x_a x_B$ is $x_{A'}$ for the multi-index A' obtained by inserting a into B; its smallest index is still b, so $b \le A'$ and $|A'| = n$, and case 1 gives $\theta_b(x_a x_B) = x_b x_a x_B = x_a x_A$, the variables commuting. Hence, by Equation (A.575), $\theta_b \theta_a x_B = x_a x_A + \theta_b w$, and Equation (A.576) reads

$$\theta_a \theta_b x_B = \theta_b \theta_a x_B + C^c{}_{ab} \, \theta_c x_B \qquad \text{whenever } b \le B, \ b < a, \ |B| = n-1 \,, \tag{A.577}$$

using $\theta_b x_B = x_A$ once more. So the commutation relation holds *by fiat* in the ordered case; the work is to show it then holds in general.

Proof of (C_n). Let $|A| = n-1$; the cases $|A| < n-1$ are (C_{n-1}). The claim is antisymmetric in a, b and trivial for $a = b$, since $C^c{}_{aa} = 0$, so assume $a > b$.

Case 1: $b \le A$. This is Equation (A.577) with $B = A$.

Case 2: the relation $b \le A$ *fails.* Let c_0 be the smallest index occurring in A, so $c_0 < b < a$, and write $A = (c_0, B)$ with $c_0 \le B$ and $|B| = n-2$. We first establish the auxiliary relation

$$\theta_a \theta_{c_0} y = \theta_{c_0} \theta_a y + C^f{}_{ac_0}\, \theta_f y \qquad \text{for } y = \theta_b x_B\,. \tag{A.578}$$

Indeed, by (B_{n-1}) write $y = x_b x_B + w'$ with $w' \in P_{n-2}$. The monomial $x_b x_B$ is $x_{A''}$ for the multi-index A'' obtained by inserting b into B; its smallest index is c_0, because $c_0 \le B$ and $c_0 < b$, and $|A''| = n-1$. So Case 1 — just proved, for multi-indices of length $n-1$ — applies to $x_{A''}$ with the pair (a, c_0), and (C_{n-1}) applies to $w' \in P_{n-2}$; adding the two gives Equation (A.578).

Now compute, using $x_A = \theta_{c_0} x_B$:

$$\begin{aligned} \theta_a \theta_b x_A &= \theta_a \theta_b \theta_{c_0} x_B \\ &= \theta_a \left(\theta_{c_0} \theta_b x_B + C^f{}_{bc_0} \theta_f x_B \right) \\ &= \theta_{c_0} \theta_a \theta_b x_B + C^f{}_{ac_0}\, \theta_f \theta_b x_B + C^f{}_{bc_0}\, \theta_a \theta_f x_B\,, \end{aligned} \tag{A.579}$$

the second line by (C_{n-1}) applied to x_B, $|B| = n-2$, and the third by Equation (A.578) applied to $y = \theta_b x_B$. Exchange a and b in Equation (A.579) and subtract:

$$\begin{aligned} \theta_a \theta_b x_A - \theta_b \theta_a x_A = \theta_{c_0} \left(\theta_a \theta_b - \theta_b \theta_a\right) x_B \\ + C^f{}_{ac_0} \left(\theta_f \theta_b - \theta_b \theta_f\right) x_B + C^f{}_{bc_0} \left(\theta_a \theta_f - \theta_f \theta_a\right) x_B\,, \end{aligned} \tag{A.580}$$

where the four mixed terms have been paired so that each parenthesis is a commutator. Every commutator in Equation (A.580) acts on x_B with $|B| = n-2$, so (C_{n-1}) evaluates all three:

$$\theta_a \theta_b x_A - \theta_b \theta_a x_A = C^g{}_{ab}\, \theta_{c_0} \theta_g x_B + C^f{}_{ac_0} C^g{}_{fb}\, \theta_g x_B + C^f{}_{bc_0} C^g{}_{af}\, \theta_g x_B\,. \tag{A.581}$$

The quantity to be matched is, again by (C_{n-1}) on x_B,

$$C^g{}_{ab}\, \theta_g x_A = C^g{}_{ab}\, \theta_g \theta_{c_0} x_B = C^g{}_{ab}\, \theta_{c_0} \theta_g x_B + C^g{}_{ab} C^h{}_{gc_0}\, \theta_h x_B\,. \tag{A.582}$$

The first terms of Equations (A.581) and (A.582) agree, so (C_n) holds if and only if

$$C^f{}_{ac_0} C^g{}_{fb} + C^f{}_{bc_0} C^g{}_{af} = C^f{}_{ab} C^g{}_{fc_0}\,, \tag{A.583}$$

after renaming the summation index in Equation (A.582). Written with brackets, Equation (A.583) is

$$\left[\left[T_a, T_{c_0}\right], T_b\right] + \left[T_a, \left[T_b, T_{c_0}\right]\right] = \left[\left[T_a, T_b\right], T_{c_0}\right]\,, \tag{A.584}$$

which is the Jacobi identity: expanding the right-hand side, $\left[\left[T_a, T_b\right], T_{c_0}\right] = \left[T_a, \left[T_b, T_{c_0}\right]\right] - \left[T_b, \left[T_a, T_{c_0}\right]\right]$, and the second term equals $+\left[\left[T_a, T_{c_0}\right], T_b\right]$ by antisymmetry. This completes the induction, and with it the construction of θ on all of $P = \bigcup_n P_n$. □

Remark A.324 (Where the Jacobi identity was needed, and where it was not). The bookkeeping of Proposition A.323 is elaborate, but the mathematical content sits entirely in Equation (A.584). Conditions Equation (A.572) and Equation (A.573) merely say that θ_a is "multiplication by x_a, up to lower degree", and the definition Equation (A.576) is forced on us: it is the only value compatible with Equation (A.574). Whether that forced value is *consistent* — whether reordering a triple by two different routes gives the same answer — is precisely Equation (A.583). An antisymmetric bracket violating Jacobi would therefore not merely fail to be a Lie algebra: its enveloping algebra would have fewer ordered monomials than expected, because the two routes would impose a relation between them.

A.30.4 Independence, and proof of the theorem

Proof of Theorem A.319. Derives Theorem A.319.

By Proposition A.323 the map $T_a \mapsto \theta_a$ is a representation of $\mathfrak{g}$ on the vector space P, and by Remark 14.6 it extends uniquely to a homomorphism of associative algebras with unit

$$\Phi : U(\mathfrak{g}) \longrightarrow \mathrm{End}(P)\,, \qquad \Phi(T_a) = \theta_a\,. \tag{A.585}$$

(The extension of Remark 14.6 is stated there for a representation on a vector space; that P is infinite-dimensional plays no part, since no topology or trace is involved.)

Evaluate Φ of an ordered monomial on the constant polynomial 1. Reading Equation (A.568) from right to left, the letter T_M acts n_M times on multi-indices all of whose entries are M, then T_{M-1} acts on multi-indices whose entries are all $\geq M-1$, and so on: at every step the acting index is $\leq$ every index already present, so Equation (A.572) applies at every step and

$$\Phi\left(T_1^{n_1} T_2^{n_2} \cdots T_M^{n_M}\right) 1 = x_1^{n_1} x_2^{n_2} \cdots x_M^{n_M}\,. \tag{A.586}$$

Distinct ordered monomials of $U(\mathfrak{g})$ thus have distinct monomials of P as images, and the monomials of a polynomial algebra are linearly independent. Hence a vanishing linear combination of ordered monomials of $U(\mathfrak{g})$ maps to a vanishing linear combination of distinct monomials of P, forcing every coefficient to vanish: the ordered monomials are linearly independent. With Lemma A.321 they are a basis.

The two consequences follow at once. The monomials of degree one are the T_a themselves, part of a basis, so they are linearly independent in $U(\mathfrak{g})$ and the map $\mathfrak{g} \to U(\mathfrak{g})$ is injective. And if some element of the free associative algebra on the symbols T_a were annihilated in $U(\mathfrak{g})$ beyond what Equation (14.12) forces, its reduction to ordered form — which uses those relations only — would be a nontrivial vanishing combination of basis elements. □

A.30.5 Consequences: the symbol and the symmetrization map

The next two results are what Appendix A.32 needs. From here on $\mathbb{Q} \subseteq \mathbb{K}$, so that $n!$ may be inverted.

Definition A.325 (Symmetric algebra and symbol)**.** Let $S(\mathfrak{g}) = \mathbb{K}[T_1, \ldots, T_M]$ be the polynomial algebra on the same generators taken as *commuting* symbols, graded by degree, $S(\mathfrak{g}) = \bigoplus_{n \geq 0} S^n(\mathfrak{g})$; invariantly, $S^n(\mathfrak{g})$ is the n-th symmetric power of the vector space $\mathfrak{g}$. By Theorem A.319 the ordered monomials of degree exactly n are a basis of a complement of U_{n-1} in U_n, so

$$\sigma_n : U_n / U_{n-1} \longrightarrow S^n(\mathfrak{g})\,, \qquad T_1^{n_1} \cdots T_M^{n_M} + U_{n-1} \longmapsto T_1^{n_1} \cdots T_M^{n_M}\,, \tag{A.587}$$

$n_1 + \cdots + n_M = n$, is a linear isomorphism. The element $\sigma_n(u + U_{n-1})$ is the *symbol* of $u \in U_n$, and $\sigma = \bigoplus_n \sigma_n$ is an isomorphism of graded algebras from $\mathrm{gr}\, U(\mathfrak{g}) = \bigoplus_n U_n/U_{n-1}$ onto $S(\mathfrak{g})$: it is multiplicative because two ordered monomials multiply, modulo U_{n+m-1}, by concatenation and reordering, and Equation (A.570) shows the reordering costs only terms of lower degree.

Rests on Theorem A.319 and Definition A.320.

Definition A.326 (Symmetrization)**.** The *symmetrization map* is the linear map $\omega : S(\mathfrak{g}) \to U(\mathfrak{g})$ determined by

$$\boxed{\omega\left(X_1 X_2 \cdots X_n\right) = \frac{1}{n!} \sum_{\pi} X_{\pi(1)} X_{\pi(2)} \cdots X_{\pi(n)}}\,, \qquad X_i \in \mathfrak{g}\,, \tag{A.588}$$

the sum running over the $n!$ permutations π of $\{1, \ldots, n\}$, with $\omega(1) = 1$. The right-hand side is symmetric in $X_1, \ldots, X_n$ and multilinear, so it descends from $\mathfrak{g}^n$ to $S^n(\mathfrak{g})$ and ω is well defined.

Rests on Definitions 14.5 and A.325.

Proposition A.327 (Symmetrization is an isomorphism of $\mathfrak{g}$-modules)**.** *Let $\mathbb{Q} \subseteq \mathbb{K}$. Then:*

1. *ω maps $S^n(\mathfrak{g})$ into U_n and $\sigma_n(\omega(p) + U_{n-1}) = p$ for $p \in S^n(\mathfrak{g})$; consequently ω is a linear isomorphism of $S(\mathfrak{g})$ onto $U(\mathfrak{g})$.*
2. *Let $\mathfrak{g}$ act on $U(\mathfrak{g})$ by $\mathrm{ad}_X\, u = Xu - uX$ and on $S(\mathfrak{g})$ by the derivation extending ad_X on $\mathfrak{g}$. Then ω intertwines the two actions, $\omega \circ \mathrm{ad}_X = \mathrm{ad}_X \circ \omega$.*

Rests on Definitions A.325 and A.326 and Theorem A.319.

Proof. *Derives Proposition A.327.*

(1) Each word on the right of Equation (A.588) is a product of n elements of $\mathfrak{g}$, hence lies in U_n. Take $p = T_1^{n_1} \cdots T_M^{n_M}$ of degree n. Every one of the $n!$ words in Equation (A.588) is a rearrangement of the same letters, so by Equation (A.570) each equals the ordered monomial $T_1^{n_1} \cdots T_M^{n_M}$ of $U(\mathfrak{g})$ modulo U_{n-1}; averaging, $\omega(p) - T_1^{n_1} \cdots T_M^{n_M} \in U_{n-1}$, which is the assertion about σ_n. Thus ω maps a basis of $S(\mathfrak{g})$ to a family of elements that is "triangular" with respect to the filtration, with the ordered monomials as leading terms. Such a family is a basis: a nontrivial vanishing combination would have a highest degree n occurring in it, and its image under σ_n would be a nontrivial vanishing combination of distinct monomials of $S^n(\mathfrak{g})$. Surjectivity follows because the leading terms exhaust the basis of Theorem A.319.

(2) On $U(\mathfrak{g})$ the map ad_X is a derivation of the associative product, $\mathrm{ad}_X(uv) = (\mathrm{ad}_X\, u)v + u(\mathrm{ad}_X\, v)$, as one checks by expanding $X(uv) - (uv)X$ and inserting $\pm uXv$. Hence

$$\mathrm{ad}_X \left(X_{\pi(1)} \cdots X_{\pi(n)} \right) = \sum_{j=1}^{n} X_{\pi(1)} \cdots \left[X, X_{\pi(j)} \right] \cdots X_{\pi(n)} \,, \tag{A.589}$$

using $\mathrm{ad}_X\, Y = [X, Y]$ for $Y \in \mathfrak{g}$. Average Equation (A.589) over π and group the resulting $n!\, n$ words by the value $i = \pi(j)$ of the slot that was hit: for fixed i, the pairs (π, j) with $\pi(j) = i$ put $[X, X_i]$ in position j and let the remaining letters occupy the remaining positions in every possible order, each exactly once — which is the definition of $\omega\left(X_1 \cdots [X, X_i] \cdots X_n\right)$ up to the common factor $1/n!$. Therefore

$$\mathrm{ad}_X\, \omega\left(X_1 \cdots X_n\right) = \sum_{i=1}^{n} \omega\left(X_1 \cdots [X, X_i] \cdots X_n\right) = \omega\left(\mathrm{ad}_X\left(X_1 \cdots X_n\right)\right) \,, \tag{A.590}$$

the last equality because ad_X acts on $S(\mathfrak{g})$ as the derivation extending ad_X, which is exactly the Leibniz sum on the right. □

Corollary A.328 (The Casimir elements are not accidentally zero)**.** *Let $k^{a_1 \cdots a_r}$ be a nonzero totally symmetric array. Then the element $C_r = k^{a_1 \cdots a_r} T_{a_1} \cdots T_{a_r}$ of Equation (14.19) is nonzero in $U(\mathfrak{g})$, and its symbol is the nonzero polynomial $k^{a_1 \cdots a_r} T_{a_1} \cdots T_{a_r} \in S^r(\mathfrak{g})$. In particular the quadratic Casimir Equation (14.20) of a semisimple algebra is a nonzero element of $U(\mathfrak{g})$.*

Rests on Theorems 14.16 and A.319 and Definition A.325.

Proof. *Derives Corollary A.328.*

Write $p = k^{a_1 \cdots a_r} T_{a_1} \cdots T_{a_r}$ for the corresponding element of $S^r(\mathfrak{g})$, the same expression read in commuting symbols. Then $C_r = \omega(p)$: by linearity $\omega(p) = k^{a_1 \cdots a_r} \frac{1}{r!} \sum_\pi T_{a_{\pi(1)}} \cdots T_{a_{\pi(r)}}$, and renaming the summation indices in each of the $r!$ terms turns it into $k^{a_1 \cdots a_r} T_{a_1} \cdots T_{a_r}$, because $k^{a_1 \cdots a_r}$ is totally symmetric. Now $p \neq 0$: the coefficient of the commuting monomial $T_1^{n_1} \cdots T_M^{n_M}$ in p is the multinomial coefficient $r!/(n_1! \cdots n_M!)$ times the corresponding component of $k^{a_1 \cdots a_r}$, and in characteristic zero that factor cannot vanish. Since ω is injective by Proposition A.327, $C_r = \omega(p) \neq 0$. For Equation (14.20) the array is κ^{ab}, which is invertible, hence nonzero. □

Remark A.329 (What is proved and what is not). Theorem A.319 is a statement about $U(\mathfrak{g})$ as a *vector space*: the ordered monomials are a basis. It is not a statement that $U(\mathfrak{g})$ is commutative, and ω of Proposition A.327 is emphatically *not* an algebra homomorphism — $\omega(XY) - \omega(X)\omega(Y) = -\frac{1}{2}[X, Y]$ for $X, Y \in \mathfrak{g}$, by Equation (A.588) and Equation (14.12). What survives at the level of algebras is the statement of Definition A.325, that the associated graded algebra of $U(\mathfrak{g})$ is the commutative algebra $S(\mathfrak{g})$; noncommutativity is entirely a phenomenon of lower order in the filtration. That is the exact sense in which $U(\mathfrak{g})$ is a deformation of the polynomial algebra on $\mathfrak{g}$, and it is the form in which the theorem is used in Appendix A.32.

Appendix A.30 discharges the proof obligation of Theorem 14.7. Its immediate consequence is the one Section 14.1 needs: the generators satisfy no hidden relations, so a Casimir element built as in Theorem 14.16 is a genuine, nonzero element of $U(\mathfrak{g})$ and not an elaborate way of writing zero (Corollary A.328). The deeper consequence, Proposition A.327, is the first link of the chain that counts those Casimirs in Appendix A.32.

A.31 Cartan's Criterion for Semisimplicity

This appendix proves Theorem 14.13 of Chapter 14: a finite-dimensional Lie algebra over a field of characteristic zero contains no nonzero abelian ideal if and only if its Killing form Equation (14.14) is nondegenerate. The chapter uses the criterion twice — to know when κ_{ab} may be inverted, which is what makes the quadratic Casimir Equation (14.20) available, and in Proposition 14.77 on central extensions, whose proof in Appendix A.37 rests on this one throughout.

Nothing is quoted. The easy half is a two-line index computation (Appendix A.31.3). The converse needs Cartan's criterion for *solvability*, which in turn needs the Jordan decomposition of an endomorphism and Engel's theorem; both are proved here (Appendices A.31.4 and A.31.5), the trace argument that is the heart of the matter is Appendix A.31.6, and the pieces are assembled in Appendix A.31.7. Appendix A.31.8 draws the structural corollaries that Appendix A.37 needs and verifies the criterion on the family this treatise actually uses, the algebras $\mathfrak{so}(p, q)$.

Throughout, $\mathbb{K}$ is a field of characteristic zero with algebraic closure $\overline{\mathbb{K}}$, and $\mathfrak{g}$ is a finite-dimensional Lie algebra over $\mathbb{K}$ with basis $\{T_a\}$ and structure constants $[T_a, T_b] = C^c{}_{ab} T_c$ as in Equation (14.5). For a finite-dimensional vector space $\mathbb{V}$ we write $\mathfrak{gl}(\mathbb{V})$ for the Lie algebra of all linear maps of $\mathbb{V}$ with the commutator bracket. Recall that $\kappa(X, Y) = \operatorname{tr}(\operatorname{ad}_X \operatorname{ad}_Y)$ and that κ is invariant, Equation (14.16).

A.31.1 Statement

Theorem A.330 (Cartan's criterion for semisimplicity)**.** *Let $\mathfrak{g}$ be a finite-dimensional Lie algebra over a field of characteristic zero. Then $\mathfrak{g}$ contains no nonzero abelian ideal if and only if its Killing form is nondegenerate, that is, if and only if*

$$\mathfrak{g}^{\perp} := \{X \in \mathfrak{g} \mid \kappa(X, Y) = 0 \text{ for all } Y \in \mathfrak{g}\} = 0\,. \tag{A.591}$$

Rests on Definition 14.10 and Lemma 14.11.

A.31.2 Solvability, and the language of the proof

Definition A.331 (Derived series, solvable, ideal)**.** For subspaces $\mathfrak{a}, \mathfrak{b} \subseteq \mathfrak{g}$ let $[\mathfrak{a}, \mathfrak{b}]$ denote the span of all $[X, Y]$ with $X \in \mathfrak{a}$, $Y \in \mathfrak{b}$. A subspace $\mathfrak{a}$ is a *subalgebra* if $[\mathfrak{a}, \mathfrak{a}] \subseteq \mathfrak{a}$ and an *ideal* if $[\mathfrak{g}, \mathfrak{a}] \subseteq \mathfrak{a}$. The *derived series* of a subalgebra $\mathfrak{a}$ is

$$\mathfrak{a}^{(0)} = \mathfrak{a}\,, \qquad \mathfrak{a}^{(j+1)} = \left[\mathfrak{a}^{(j)}, \mathfrak{a}^{(j)}\right]\,, \tag{A.592}$$

a decreasing chain of subalgebras, and $\mathfrak{a}$ is *solvable* if $\mathfrak{a}^{(m)} = 0$ for some m. An abelian subalgebra is solvable with $m = 1$.

Lemma A.332 (Elementary properties of solvability)**.** *Let $\mathfrak{a}$ be a subalgebra of $\mathfrak{g}$.*

1. *Subalgebras and homomorphic images of a solvable algebra are solvable.*
2. *If $\mathfrak{b} \subseteq \mathfrak{a}$ is an ideal of $\mathfrak{a}$ with $\mathfrak{b}$ and $\mathfrak{a}/\mathfrak{b}$ solvable, then $\mathfrak{a}$ is solvable.*
3. *If $\mathfrak{a}$ is an ideal of $\mathfrak{g}$, then every $\mathfrak{a}^{(j)}$ is an ideal of $\mathfrak{g}$.*
4. *A nonzero solvable ideal of $\mathfrak{g}$ contains a nonzero* abelian *ideal of $\mathfrak{g}$.*

Rests on Definition A.331.

Proof. *Derives Lemma A.332.*

(1) If $\mathfrak{b} \subseteq \mathfrak{a}$ then $\mathfrak{b}^{(j)} \subseteq \mathfrak{a}^{(j)}$ by induction; if ϕ is a homomorphism then $\phi\left(\mathfrak{a}^{(j)}\right) = \phi(\mathfrak{a})^{(j)}$, again by induction, since ϕ preserves brackets.

(2) If $(\mathfrak{a}/\mathfrak{b})^{(m)} = 0$ then $\mathfrak{a}^{(m)} \subseteq \mathfrak{b}$ by (1) applied to the quotient map, and if $\mathfrak{b}^{(l)} = 0$ then $\mathfrak{a}^{(m+l)} \subseteq \mathfrak{b}^{(l)} = 0$.

(3) By induction on j; the case $j = 0$ is the hypothesis. Let $\mathfrak{b} = \mathfrak{a}^{(j)}$ be an ideal. For $Z \in \mathfrak{g}$ and $X, Y \in \mathfrak{b}$ the Jacobi identity gives

$$[Z,[X,Y]] = [[Z,X],Y] + [X,[Z,Y]]\,, \tag{A.593}$$

and both terms on the right lie in $[\mathfrak{b},\mathfrak{b}] = \mathfrak{a}^{(j+1)}$ because $[Z,X]$ and $[Z,Y]$ lie in $\mathfrak{b}$.

(4) Let $\mathfrak{s} \neq 0$ be a solvable ideal and let m be largest with $\mathfrak{s}^{(m)} \neq 0$. Then $\left[\mathfrak{s}^{(m)},\mathfrak{s}^{(m)}\right] = \mathfrak{s}^{(m+1)} = 0$, so $\mathfrak{s}^{(m)}$ is abelian, and it is an ideal of $\mathfrak{g}$ by (3). □

Remark A.333 (Two definitions of semisimple, and why they agree here). Theorem 14.13 defines *semisimple* as "contains no nonzero abelian ideal". The literature usually says "contains no nonzero solvable ideal", equivalently "the radical — the largest solvable ideal — is zero". Part (4) of Lemma A.332 is exactly the statement that the two conditions coincide: an abelian ideal is solvable, and a nonzero solvable ideal produces a nonzero abelian one. We use whichever is convenient and say "semisimple" for both.

A.31.3 The easy half: an abelian ideal lies in the radical of the Killing form

Proposition A.334 (Nondegeneracy implies no abelian ideal)**.** *Let $\mathfrak{a} \subseteq \mathfrak{g}$ be an abelian ideal. Then $\mathfrak{a} \subseteq \mathfrak{g}^{\perp}$. Consequently, if κ is nondegenerate then $\mathfrak{g}$ has no nonzero abelian ideal.*

Rests on Definitions 14.10 and A.331.

Proof. *Derives Proposition A.334.*

Let $X \in \mathfrak{a}$ and $Y \in \mathfrak{g}$, and put $N = \mathrm{ad}_X \mathrm{ad}_Y$. Since $\mathfrak{a}$ is an ideal, $\mathrm{ad}_X \mathfrak{g} = [X,\mathfrak{g}] \subseteq \mathfrak{a}$, so $N\mathfrak{g} \subseteq \mathfrak{a}$; and since $\mathfrak{a}$ is an ideal, $\mathrm{ad}_Y \mathfrak{a} \subseteq \mathfrak{a}$, while $\mathrm{ad}_X \mathfrak{a} = [\mathfrak{a},\mathfrak{a}] = 0$ because $\mathfrak{a}$ is abelian. Hence

$$N^2\mathfrak{g} \subseteq N\mathfrak{a} = \mathrm{ad}_X \mathrm{ad}_Y \mathfrak{a} \subseteq \mathrm{ad}_X \mathfrak{a} = 0\,, \tag{A.594}$$

so $N^2 = 0$. A nilpotent endomorphism has all eigenvalues zero and therefore vanishing trace, so $\kappa(X,Y) = \operatorname{tr} N = 0$ for every Y, that is, $X \in \mathfrak{g}^{\perp}$.

The same computation in components, with the index conventions of Equation (14.15), is worth displaying because it is the form in which the statement is usually met. Choose a basis adapted to $\mathfrak{a}$: indices i,j,k label a basis of $\mathfrak{a}$ and indices μ,ν complete it. That $\mathfrak{a}$ is an ideal says $C^{\mu}{}_{ai} = 0$ for every a; that it is abelian says $C^{c}{}_{ij} = 0$. Then, from Equation (14.15),

$$\kappa_{ib} = C^{c}{}_{id}\, C^{d}{}_{bc} = C^{j}{}_{id}\, C^{d}{}_{bj} = C^{j}{}_{ik}\, C^{k}{}_{bj} = 0\,, \tag{A.595}$$

the second equality because $C^{c}{}_{id}$ vanishes unless the upper index lies in $\mathfrak{a}$, the third because $C^{d}{}_{bj}$ vanishes unless d does, and the last because $C^{j}{}_{ik} = 0$. □

A.31.4 The Jordan decomposition

Theorem A.335 (Jordan decomposition)**.** *Let $\mathbb{V}$ be a finite-dimensional vector space over an algebraically closed field $\mathbb{F}$ and let $x \in \mathrm{End}(\mathbb{V})$. There are unique $x_s, x_n \in \mathrm{End}(\mathbb{V})$ with*

$$x = x_s + x_n\,, \qquad x_s \text{ diagonalizable}\,, \quad x_n \text{ nilpotent}\,, \quad [x_s, x_n] = 0\,. \tag{A.596}$$

Moreover x_s and x_n are polynomials in x with zero constant term.

Rests on Definition 5.35.

Proof. *Derives Theorem A.335.*

Let $a_1, \dots, a_r$ be the distinct eigenvalues of x and $\prod_i (t - a_i)^{m_i}$ its characteristic polynomial, which splits because the field is algebraically closed. Put $\mathbb{V}_i = \ker (x - a_i)^{m_i}$. The polynomials $(t - a_i)^{m_i}$ are pairwise coprime, so by the Chinese remainder theorem in $\mathbb{F}[t]$ — applied modulo the characteristic polynomial, which annihilates x by Cayley–Hamilton — the $\mathbb{V}_i$ are the images of projections that are polynomials in x, and $\mathbb{V} = \bigoplus_i \mathbb{V}_i$.

By the same theorem choose $p \in \mathbb{F}[t]$ with

$$p \equiv a_i \pmod{(t - a_i)^{m_i}} \quad (i = 1, \dots, r)\,, \qquad p \equiv 0 \pmod{t}\,, \tag{A.597}$$

the last congruence being imposed only when 0 is not among the a_i — when it is, say $a_1 = 0$, the congruence $p \equiv 0 \pmod{t^{m_1}}$ already forces $p(0) = 0$, and the moduli stay pairwise coprime in either case. Set $x_s = p(x)$ and $x_n = x - x_s$. On $\mathbb{V}_i$ the first congruence gives $x_s = a_i \mathbb{1}$, so x_s is diagonalizable, and $x_n = x - a_i \mathbb{1}$ there, which is nilpotent on $\mathbb{V}_i$ by definition of $\mathbb{V}_i$; being nilpotent on each summand of a finite direct sum it is nilpotent. Both are polynomials in x with $p(0) = 0$, hence commute with x and with each other.

Uniqueness. Let $x = s' + n'$ be another such decomposition. Since s' and n' commute with each other they commute with x, hence with every polynomial in x, hence with x_s and x_n. Then $x_s - s' = n' - x_n$ is at once diagonalizable — a difference of two commuting diagonalizable maps, which are simultaneously diagonalizable — and nilpotent, being a difference of two commuting nilpotent maps. A map that is both is zero. □

Lemma A.336 (The adjoint of a Jordan decomposition)**.** *With the notation of Theorem A.335, viewing $\mathrm{ad}_x(y) = [x, y]$ as an endomorphism of $\mathrm{End}(\mathbb{V})$,*

$$(\mathrm{ad}_x)_s = \mathrm{ad}_{x_s}\,, \qquad (\mathrm{ad}_x)_n = \mathrm{ad}_{x_n}\,. \tag{A.598}$$

In particular ad_{x_s} is a polynomial in ad_x with zero constant term.

Rests on Theorem A.335.

Proof. *Derives Lemma A.336.*

Let $e_1, \dots, e_m$ be a basis of eigenvectors of x_s, $x_s e_i = a_i e_i$, and let E_{ij} be the corresponding matrix units. Then $\mathrm{ad}_{x_s} E_{ij} = (a_i - a_j) E_{ij}$, so ad_{x_s} is diagonalizable. Writing $L(y) = x_n y$ and $R(y) = y x_n$, the maps L and R commute and are nilpotent, so $\mathrm{ad}_{x_n} = L - R$ is nilpotent. And $[\mathrm{ad}_{x_s}, \mathrm{ad}_{x_n}] = \mathrm{ad}_{[x_s, x_n]} = 0$. Hence $\mathrm{ad}_x = \mathrm{ad}_{x_s} + \mathrm{ad}_{x_n}$ satisfies the three conditions of Equation (A.596), and uniqueness identifies the two summands. The last sentence is the final statement of Theorem A.335 applied to the endomorphism ad_x of $\mathrm{End}(\mathbb{V})$. □

A.31.5 Engel's theorem

Lemma A.337 (A nilpotent map has nilpotent adjoint)**.** *If $x \in \mathrm{End}(\mathbb{V})$ is nilpotent then ad_x is nilpotent.*

Rests on Definition 5.35.

Proof. *Derives Lemma A.337.*

With $L(y) = xy$ and $R(y) = yx$ as above, L and R commute and each is nilpotent, since $x^N = 0$ gives $L^N = R^N = 0$. The binomial theorem for commuting maps gives $(L - R)^{2N} = 0$. □

Theorem A.338 (Engel)**.** *Let $\mathbb{V} \neq 0$ be finite-dimensional and let $\mathfrak{h} \subseteq \mathfrak{gl}(\mathbb{V})$ be a Lie subalgebra all of whose elements are nilpotent endomorphisms. Then there is a nonzero $v \in \mathbb{V}$ with $\mathfrak{h}v = 0$; consequently there is a basis of $\mathbb{V}$ in which every element of $\mathfrak{h}$ is strictly upper triangular, and $\mathfrak{h}$ is solvable.*

Rests on Lemma A.337 and Definition A.331.

Proof. *Derives Theorem A.338.*

Induct on $\dim \mathfrak{h}$. If $\mathfrak{h} = 0$ any nonzero v will do. Let $\dim \mathfrak{h} \geq 1$ and choose a maximal proper subalgebra $\mathfrak{m} \subsetneq \mathfrak{h}$, which exists because 0 is a proper subalgebra and dimensions are finite.

$\mathfrak{m}$ is an ideal of codimension one. The adjoint action of $\mathfrak{m}$ on $\mathfrak{h}$ preserves $\mathfrak{m}$, so it descends to an action on $\mathfrak{h}/\mathfrak{m} \neq 0$; each ad_X, $X \in \mathfrak{m}$, is nilpotent by Lemma A.337, hence so is the induced map. The image of $\mathfrak{m}$ in $\mathfrak{gl}(\mathfrak{h}/\mathfrak{m})$ is a subalgebra of dimension at most $\dim \mathfrak{m} < \dim \mathfrak{h}$ consisting of nilpotent maps, so the induction hypothesis supplies a nonzero $z + \mathfrak{m}$ annihilated by it: there is $z \in \mathfrak{h} \setminus \mathfrak{m}$ with $[\mathfrak{m}, z] \subseteq \mathfrak{m}$. Then $\mathfrak{m} + \mathbb{K}z$ is a subalgebra strictly containing $\mathfrak{m}$, so it is $\mathfrak{h}$ by maximality, and $\mathfrak{m}$ is an ideal of codimension one.

The common kernel. Let $\mathbb{W} = \{v \in \mathbb{V} \mid \mathfrak{m}v = 0\}$, which is nonzero by the induction hypothesis applied to $\mathfrak{m}$. It is stable under $\mathfrak{h}$: for $X \in \mathfrak{m}$, $Y \in \mathfrak{h}$ and $v \in \mathbb{W}$,

$$X(Yv) = Y(Xv) + [X, Y]\, v = 0 + 0 = 0\,, \tag{A.599}$$

since $[X, Y] \in \mathfrak{m}$. In particular z maps $\mathbb{W}$ to itself, and z is nilpotent, so it has a nonzero kernel vector $v \in \mathbb{W}$. That v is annihilated by $\mathfrak{m}$ and by z, hence by $\mathfrak{h} = \mathfrak{m} + \mathbb{K}z$.

The flag. Induct on $\dim \mathbb{V}$: take v as above as the first basis vector and apply the statement to the induced action on $\mathbb{V}/\mathbb{K}v$, whose elements are again nilpotent. In the resulting basis every $X \in \mathfrak{h}$ is strictly upper triangular.

Solvability. Let $\mathfrak{n}_r$ be the space of matrices whose entries vanish except at least r places above the diagonal, so that $\mathfrak{h} \subseteq \mathfrak{n}_1$ and $[\mathfrak{n}_r, \mathfrak{n}_s] \subseteq \mathfrak{n}_{r+s}$ by matrix multiplication. Then $\mathfrak{h}^{(j)} \subseteq \mathfrak{n}_{2^j}$ by induction, and $\mathfrak{n}_r = 0$ once $r \geq \dim \mathbb{V}$. □

A.31.6 The trace lemma

Everything so far has been preparation. The following lemma is the mechanism of Cartan's criterion, and the only place where characteristic zero is used in an essential way — through the rational numbers, of all things, inside a field that may be as large as $\mathbb{C}$.

Lemma A.339 (Trace lemma)**.** *Let $\mathbb{V}$ be finite-dimensional over an algebraically closed field $\mathbb{F}$ of characteristic zero, let $A \subseteq B$ be subspaces of $\mathfrak{gl}(\mathbb{V})$, and put*

$$M = \{x \in \mathfrak{gl}(\mathbb{V}) \mid [x, B] \subseteq A\}\ . \tag{A.600}$$

If $x \in M$ satisfies $\mathrm{tr}(xy) = 0$ for every $y \in M$, then x is nilpotent.

Rests on Theorem A.335 and Lemma A.336.

Proof. *Derives Lemma A.339.*

Let $x = x_s + x_n$ be the Jordan decomposition (Theorem A.335), let $e_1, \dots, e_m$ be a basis of eigenvectors of x_s with $x_s e_i = a_i e_i$, and let $E \subseteq \mathbb{F}$ be the $\mathbb{Q}$-linear span of $a_1, \dots, a_m$, a finite-dimensional vector space over $\mathbb{Q}$. The claim is that $E = 0$; then every $a_i = 0$, so $x_s = 0$ and $x = x_n$ is nilpotent.

Since E is finite-dimensional over $\mathbb{Q}$, it is enough to show that every $\mathbb{Q}$-linear functional $f : E \to \mathbb{Q}$ vanishes. Fix such an f and let $y \in \mathrm{End}(\mathbb{V})$ be defined by $y e_i = f(a_i) e_i$.

Step 1: ad_y *is a polynomial in* ad_x *with zero constant term.* In the basis of matrix units E_{ij} built from the e_i,

$$\mathrm{ad}_{x_s} E_{ij} = (a_i - a_j)\, E_{ij}\,, \qquad \mathrm{ad}_y E_{ij} = (f(a_i) - f(a_j))\, E_{ij}\,. \tag{A.601}$$

Choose $r \in \mathbb{F}[t]$ with $r(0) = 0$ and $r(a_i - a_j) = f(a_i) - f(a_j)$ for all i, j. This is a consistent finite set of interpolation conditions: if $a_i - a_j = a_p - a_q$ then, applying the $\mathbb{Q}$-linear f, $f(a_i) - f(a_j) = f(a_p) - f(a_q)$; and if $a_i - a_j = 0$ the prescribed value is 0, which is what $r(0) = 0$ demands. Lagrange interpolation over the finitely many distinct values then produces r. By Equation (A.601), $\mathrm{ad}_y = r(\mathrm{ad}_{x_s})$, and by Lemma A.336 $\mathrm{ad}_{x_s} = q(\mathrm{ad}_x)$ for some q with $q(0) = 0$. Hence $\mathrm{ad}_y = r(q(\mathrm{ad}_x))$, a polynomial in ad_x without constant term.

Step 2: $y \in M$. Since $x \in M$ we have $\mathrm{ad}_x(B) \subseteq A \subseteq B$, so $(\mathrm{ad}_x)^j(B) \subseteq A$ for every $j \geq 1$. A polynomial in ad_x with zero constant term is a combination of such powers, so $\mathrm{ad}_y(B) \subseteq A$, that is, $y \in M$.

Step 3: the trace. By hypothesis $\mathrm{tr}(xy) = 0$. Compute it. Since x_n commutes with x_s it preserves each eigenspace of x_s, and inside each eigenspace a basis may be chosen making the nilpotent x_n strictly upper triangular; taking the e_i so adapted, x is upper triangular with diagonal entries $a_1, \ldots, a_m$ while y is diagonal with entries $f(a_1), \ldots, f(a_m)$. Then xy is upper triangular with diagonal entries $a_i f(a_i)$, so

$$\sum_{i=1}^{m} a_i\, f(a_i) = \mathrm{tr}(xy) = 0\,. \tag{A.602}$$

The left-hand side lies in E, since each $f(a_i) \in \mathbb{Q}$ and E is a $\mathbb{Q}$-subspace containing the a_i. Apply f to Equation (A.602) and use $\mathbb{Q}$-linearity:

$$\sum_{i=1}^{m} f(a_i)^2 = 0\,, \qquad f(a_i) \in \mathbb{Q}\,. \tag{A.603}$$

A sum of squares of rational numbers vanishes only if every term does, so $f(a_i) = 0$ for all i; as the a_i span E over $\mathbb{Q}$, $f = 0$. Every $\mathbb{Q}$-linear functional on E vanishes, so $E = 0$. □

Theorem A.340 (Cartan's criterion for solvability)**.** *Let* $\mathbb{V}$ *be finite-dimensional over a field* $\mathbb{K}$ *of characteristic zero and let* $\mathfrak{h} \subseteq \mathfrak{gl}(\mathbb{V})$ *be a Lie subalgebra with*

$$\mathrm{tr}(xy) = 0 \qquad \textit{for all } x \in [\mathfrak{h}, \mathfrak{h}]\ ,\ y \in \mathfrak{h}\,. \tag{A.604}$$

Then $\mathfrak{h}$ *is solvable.*

Rests on Lemma A.339 and Theorem A.338.

Proof. *Derives Theorem A.340.*

Assume first that $\mathbb{K}$ is algebraically closed. Apply Lemma A.339 with $A = [\mathfrak{h}, \mathfrak{h}]$, $B = \mathfrak{h}$ and M as in Equation (A.600); note $\mathfrak{h} \subseteq M$. Let $x \in [\mathfrak{h}, \mathfrak{h}]$ and $y \in M$. By bilinearity it suffices to treat $x = [u, v]$ with $u, v \in \mathfrak{h}$, and then

$$\mathrm{tr}\left([u, v]\, y\right) = \mathrm{tr}(uvy) - \mathrm{tr}(vuy) = \mathrm{tr}(uvy) - \mathrm{tr}(uyv) = \mathrm{tr}\left(u\,[v, y]\right) = \mathrm{tr}\left([v, y]\, u\right)\ , \tag{A.605}$$

using cyclicity of the trace twice. Now $y \in M$ gives $[v, y] \in [\mathfrak{h}, \mathfrak{h}]$, and $u \in \mathfrak{h}$, so the right-hand side vanishes by Equation (A.604). Lemma A.339 therefore makes every element of $[\mathfrak{h}, \mathfrak{h}]$ a nilpotent endomorphism, and Theorem A.338 makes $[\mathfrak{h}, \mathfrak{h}]$ solvable. Since $\mathfrak{h}/[\mathfrak{h}, \mathfrak{h}]$ is abelian, Lemma A.332(2) makes $\mathfrak{h}$ solvable.

For general $\mathbb{K}$, extend scalars to $\overline{\mathbb{K}}$. The hypothesis Equation (A.604) is bilinear and $[\mathfrak{h}, \mathfrak{h}]$ spans $[\mathfrak{h}_{\overline{\mathbb{K}}}, \mathfrak{h}_{\overline{\mathbb{K}}}]$, so the hypothesis holds for $\mathfrak{h}_{\overline{\mathbb{K}}} \subseteq \mathfrak{gl}\left(\mathbb{V}_{\overline{\mathbb{K}}}\right)$, which is therefore solvable. Since $\left(\mathfrak{h}^{(j)}\right)_{\overline{\mathbb{K}}} = \left(\mathfrak{h}_{\overline{\mathbb{K}}}\right)^{(j)}$ — brackets of spanning sets span — and a subspace vanishes if and only if its extension does, $\mathfrak{h}$ is solvable. □

A.31.7 Proof of the criterion

Proof of Theorem A.330. *Derives Theorem A.330.*

One direction is Proposition A.334. For the other, assume $\mathfrak{g}$ has no nonzero abelian ideal and let $\mathfrak{s} = \mathfrak{g}^{\perp}$ be the radical of the Killing form, Equation (A.591).

$\mathfrak{s}$ *is an ideal.* Let $X \in \mathfrak{s}$ and $Z, Y \in \mathfrak{g}$. By the invariance of the Killing form, Equation (14.16),

$$\kappa\left([Z,X],Y\right) = -\kappa\left(X,[Z,Y]\right) = 0\,, \tag{A.606}$$

so $[Z,X] \in \mathfrak{s}$.

$\mathrm{ad}(\mathfrak{s})$ *is solvable.* Consider $\mathrm{ad}(\mathfrak{s}) \subseteq \mathfrak{gl}(\mathfrak{g})$, a Lie subalgebra because ad is a homomorphism. Its derived algebra is $\mathrm{ad}\left([\mathfrak{s},\mathfrak{s}]\right)$. Take $x = \mathrm{ad}_W$ with $W \in [\mathfrak{s},\mathfrak{s}] \subseteq \mathfrak{s}$ and $y = \mathrm{ad}_Y$ with $Y \in \mathfrak{s}$; then

$$\mathrm{tr}(xy) = \mathrm{tr}\left(\mathrm{ad}_W \mathrm{ad}_Y\right) = \kappa(W,Y) = 0 \tag{A.607}$$

because $W \in \mathfrak{s} = \mathfrak{g}^{\perp}$. So Theorem A.340 applies and $\mathrm{ad}(\mathfrak{s})$ is solvable.

$\mathfrak{s}$ *is solvable.* The kernel of ad restricted to $\mathfrak{s}$ is $\mathfrak{s} \cap Z(\mathfrak{g})$, where $Z(\mathfrak{g}) = \{X \in \mathfrak{g} \mid [X,\mathfrak{g}] = 0\}$ is the centre; it is abelian, hence solvable; the image $\mathrm{ad}(\mathfrak{s})$ is solvable; so Lemma A.332(2) applies to the ideal $\ker\left(\mathrm{ad}\,|_{\mathfrak{s}}\right)$ of $\mathfrak{s}$.

Conclusion. If $\mathfrak{s} \neq 0$ then, being a nonzero solvable ideal of $\mathfrak{g}$, it would contain a nonzero abelian ideal of $\mathfrak{g}$ by Lemma A.332(4), contrary to hypothesis. Hence $\mathfrak{s} = 0$ and κ is nondegenerate. □

Remark A.341 (Scalar extension). Semisimplicity is unchanged by enlarging the field, and the criterion is what makes this obvious. In a basis of $\mathfrak{g}$ over $\mathbb{K}$ the Killing form has a Gram matrix κ_{ab} of scalars, and the same basis is a basis of $\mathfrak{g}_K = \mathfrak{g} \otimes_{\mathbb{K}} K$ over any extension K with the same structure constants, hence the same κ_{ab} by Equation (14.15). Nondegeneracy is the nonvanishing of $\det\left(\kappa_{ab}\right)$, a condition on that matrix alone. So $\mathfrak{g}$ is semisimple if and only if $\mathfrak{g}_K$ is — a statement that is *not* obvious from the definition by ideals, since $\mathfrak{g}_K$ has many more subspaces than $\mathfrak{g}$.

A.31.8 Consequences, and the case of $\mathfrak{so}(p,q)$

Corollary A.342 (Orthogonal splitting of ideals)**.** *Let $\mathfrak{g}$ be semisimple and $\mathfrak{a} \subseteq \mathfrak{g}$ an ideal, and let $\mathfrak{a}^{\perp} = \{X \mid \kappa(X,\mathfrak{a}) = 0\}$. Then*

$$\mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^{\perp}\,, \qquad \left[\mathfrak{a},\mathfrak{a}^{\perp}\right] = 0\,, \tag{A.608}$$

both summands are ideals, both are semisimple, and $\mathfrak{g}/\mathfrak{a} \cong \mathfrak{a}^{\perp}$. Consequently $\mathfrak{g}$ is a direct sum of simple ideals, $Z(\mathfrak{g}) = 0$, and $[\mathfrak{g},\mathfrak{g}] = \mathfrak{g}$.

Rests on Theorems A.330 and A.340.

Proof. *Derives Corollary A.342.*

$\mathfrak{a}^{\perp}$ is an ideal by the computation Equation (A.606). Put $\mathfrak{b} = \mathfrak{a} \cap \mathfrak{a}^{\perp}$, an ideal. For $W \in [\mathfrak{b},\mathfrak{b}] \subseteq \mathfrak{a}$ and $Y \in \mathfrak{b} \subseteq \mathfrak{a}^{\perp}$ we have $\mathrm{tr}\left(\mathrm{ad}_W \mathrm{ad}_Y\right) = \kappa(W,Y) = 0$, so Theorem A.340 makes $\mathrm{ad}(\mathfrak{b})$ solvable and, exactly as in the proof of Theorem A.330, $\mathfrak{b}$ solvable. A semisimple algebra has no nonzero solvable ideal (Remark A.333), so $\mathfrak{b} = 0$. Nondegeneracy of κ gives $\dim \mathfrak{a}^{\perp} = \dim \mathfrak{g} - \dim \mathfrak{a}$, whence the direct sum. Then $\left[\mathfrak{a},\mathfrak{a}^{\perp}\right] \subseteq \mathfrak{a} \cap \mathfrak{a}^{\perp} = 0$, both being ideals.

An abelian ideal of $\mathfrak{a}$ is an ideal of $\mathfrak{g}$, since $\mathfrak{a}^{\perp}$ brackets to zero with it; so it vanishes, and $\mathfrak{a}$ is semisimple, as is $\mathfrak{a}^{\perp}$. The projection $\mathfrak{g} \to \mathfrak{a}^{\perp}$ along $\mathfrak{a}$ is a homomorphism with kernel $\mathfrak{a}$.

Iterating the splitting on a proper nonzero ideal, and stopping when none exists, writes $\mathfrak{g} = \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_s$ with each $\mathfrak{g}_j$ having no proper nonzero ideal; each is nonabelian, since an abelian $\mathfrak{g}_j$ would be an abelian ideal of $\mathfrak{g}$, so each is simple. The centre of $\mathfrak{g}$ is an abelian ideal, hence zero. Finally $[\mathfrak{g}_j,\mathfrak{g}_j]$ is a nonzero ideal of the simple $\mathfrak{g}_j$ — nonzero because $\mathfrak{g}_j$ is not abelian — so it is all of $\mathfrak{g}_j$, and summing over j gives $[\mathfrak{g},\mathfrak{g}] = \mathfrak{g}$. □

Corollary A.343 (The Killing form of a simple ideal)**.** *In the decomposition* $\mathfrak{g} = \bigoplus_j \mathfrak{g}_j$ *of Corollary A.342,* $\kappa(\mathfrak{g}_i, \mathfrak{g}_j) = 0$ *for* $i \neq j$*, and the restriction of* κ *to* $\mathfrak{g}_j$ *is the Killing form of* $\mathfrak{g}_j$ *computed in* $\mathfrak{g}_j$ *itself.*

Rests on Corollary A.342 and Definition 14.10.

Proof. *Derives Corollary A.343.*

Let $X \in \mathfrak{g}_i$, $Y \in \mathfrak{g}_j$, $i \neq j$. Then ad_Y annihilates every summand but $\mathfrak{g}_j$ and maps $\mathfrak{g}_j$ into itself, while ad_X annihilates $\mathfrak{g}_j$; so $\mathrm{ad}_X \mathrm{ad}_Y = 0$ and $\kappa(X, Y) = 0$. For $X, Y \in \mathfrak{g}_j$ the map $\mathrm{ad}_X \mathrm{ad}_Y$ annihilates the other summands and preserves $\mathfrak{g}_j$, so its trace over $\mathfrak{g}$ equals its trace over $\mathfrak{g}_j$. □

Corollary A.344 (The algebras $\mathfrak{so}(p, q)$ are semisimple)**.** *Let* $D = p + q \geq 3$ *and let* $\mathfrak{so}(p, q)$ *have the generators* J_{AB} *and brackets Equation (14.90). In the basis* $\{J_{AB}\}_{A<B}$ *the Killing form is diagonal,*

$$\boxed{\kappa(J_{AB}, J_{CD}) = 2(D-2)\left(\eta_{AD}\eta_{BC} - \eta_{AC}\eta_{BD}\right)}, \tag{A.609}$$

with $\kappa(J_{AB}, J_{AB}) = -2(D-2)\,\eta_{AA}\eta_{BB} \neq 0$ *for* $A \neq B$ *and no summation. Hence* κ *is nondegenerate and* $\mathfrak{so}(p, q)$ *is semisimple for every signature with* $D \geq 3$*; in particular the Lorentz algebra* $\mathfrak{so}(D-1, 1)$ *is, and* $\mathfrak{so}(2)$ *— where Equation (A.609) vanishes identically — is not, being abelian.*

Rests on Theorem A.330, Equation (14.90), and Proposition 14.59.

Proof. *Derives Corollary A.344.*

That the J_{AB} with $A < B$ are a basis is part (ii) of Proposition 14.59, and η is diagonal by Notation 14.1.

Off-diagonal entries vanish. Fix an index A_0 and let ς be the reflection $x^{A_0} \mapsto -x^{A_0}$ of $\mathbb{R}^D$, the other coordinates unchanged. It preserves η, so its pushforward on vector fields maps Killing fields to Killing fields and, being induced by a diffeomorphism, preserves Lie brackets: it is an automorphism of $\mathfrak{so}(p, q)$. On the generators Equation (14.86) it acts by $\varsigma_* J_{AB} = \epsilon_A \epsilon_B J_{AB}$, where $\epsilon_A = -1$ if $A = A_0$ and $+1$ otherwise, because both x_A and ∂_B pick up their own sign. The Killing form is invariant under any automorphism ϕ, since $\mathrm{ad}_{\phi X} = \phi\, \mathrm{ad}_X\, \phi^{-1}$ and the trace is conjugation invariant; hence

$$\kappa(J_{AB}, J_{CD}) = \epsilon_A \epsilon_B \epsilon_C \epsilon_D\, \kappa(J_{AB}, J_{CD})\ . \tag{A.610}$$

If $\{A, B\} \neq \{C, D\}$, choose A_0 in the symmetric difference of the two pairs; then exactly one of the four factors is -1 — the pairs have distinct entries — so the sign is -1 and $\kappa(J_{AB}, J_{CD}) = 0$.

Diagonal entries. Take $H = J_{12}$; the general case is the same computation with the indices renamed. From Equation (14.90), $[J_{12}, J_{CD}] = \eta_{1C} J_{D2} + \eta_{2D} J_{C1} + \eta_{1D} J_{2C} + \eta_{2C} J_{1D}$, and since η is diagonal only the terms whose two indices coincide survive. For $k \geq 3$,

$$\mathrm{ad}_H\, J_{1k} = \eta_{11} J_{k2} = -\eta_{11} J_{2k}\,, \qquad \mathrm{ad}_H\, J_{2k} = \eta_{22} J_{1k}\,, \tag{A.611}$$

while $\mathrm{ad}_H\, J_{12} = 0$ and $\mathrm{ad}_H\, J_{kl} = 0$ for $k, l \geq 3$. Hence ad_H^2 is diagonal in the basis, acting as $-\eta_{11}\eta_{22}$ on each of the $2(D-2)$ generators J_{1k}, J_{2k} with $k \geq 3$, and as zero on the rest, so

$$\kappa(J_{12}, J_{12}) = \mathrm{tr}\left(\mathrm{ad}_H^2\right) = -2(D-2)\,\eta_{11}\eta_{22}\,, \tag{A.612}$$

which is Equation (A.609) for $A = C = 1$, $B = D = 2$; the general case of Equation (A.609) follows because both sides vanish off the diagonal and both are antisymmetric in AB and in CD. Since $\eta_{AA}\eta_{BB} = \pm 1$, the diagonal entries are nonzero exactly when $D \neq 2$, and Theorem A.330 converts nondegeneracy into semisimplicity. □

Remark A.345 (What the criterion buys, in the chapter's own terms). Three things follow immediately and are used without further comment. First, κ_{ab} may be inverted for a semisimple algebra, which is what Corollary 14.17 needs to write $C_2 = \kappa^{ab}T_aT_b$ and what Remark 14.15 needs to move indices between the two forms of invariance. Second, by Corollary A.342 a semisimple algebra equals its own derived algebra; this is why a semisimple algebra has no nonzero homomorphism to an abelian one, a fact used repeatedly in Appendix A.37. Third, Remark 14.23 is now precise rather than plausible: the Poincaré algebra Equation (14.99) contains the translations as an abelian ideal, so Proposition A.334 puts every translation generator in the radical of its Killing form, the form is degenerate, and no statement proved for semisimple algebras may be applied to it.

Appendix A.31 discharges the proof obligation of Theorem 14.13. It is used at Corollary 14.17 to invert the Killing form, at Proposition 14.22 and Theorem 14.21 wherever semisimplicity is assumed, and — through Corollaries A.342 and A.344 — as the foundation of Appendix A.37, which proves Proposition 14.77 on central extensions.

A.32 Racah's Theorem on the Number of Casimir Operators

This appendix proves Theorem 14.21 of Chapter 14: for a finite-dimensional semisimple Lie algebra of rank ℓ (Definition 14.20), the centre $Z(U(\mathfrak{g}))$ of the universal enveloping algebra is a polynomial algebra on ℓ algebraically independent Casimir elements, so that an irreducible representation carries exactly ℓ invariant labels. The chapter needs the count in two places: to know that $\mathfrak{su}(2)$ has one Casimir and $\mathfrak{su}(3)$ two (Remark 14.19), and to convert the rank of $\mathfrak{so}(p,q)$ computed in Proposition 14.22 into the number of Lorentz invariants.

The proof is a chain of three identifications:

$$\begin{aligned} Z(U(\mathfrak{g})) &\cong \text{the invariant polynomials on } \mathfrak{g} \\ &\cong \text{the } W\text{-invariant polynomials on } \mathfrak{h} \\ &\cong \text{a free polynomial algebra on } \ell \text{ generators}, \end{aligned} \tag{A.613}$$

where $\mathfrak{h}$ is a Cartan subalgebra, W its Weyl group, and "invariant" means annihilated by every ad_X. The first link is proved here in full (Appendix A.32.2), and rests on the Poincaré–Birkhoff–Witt theorem of Appendix A.30. The second is the Chevalley restriction theorem and the third is Chevalley's theorem on finite reflection groups; both belong to the structure theory of semisimple Lie algebras, which this treatise does not build, and both are stated precisely as quoted inputs in Appendix A.32.3 and named again in Remark A.353. The assembly and the count are Appendix A.32.4, and the answer is checked against the chapter's own worked algebras in Appendix A.32.5.

Throughout, $\mathfrak{g}$ is a finite-dimensional semisimple Lie algebra over a field $\mathbb{K}$ of characteristic zero, with basis $\{T_a\}$, Killing form κ — nondegenerate by Theorem A.330 — and enveloping algebra $U(\mathfrak{g})$ of Definition 14.5, filtered by U_n as in Definition A.320. We write $S(\mathfrak{g})$ for the symmetric algebra of Definition A.325 and ω for the symmetrization map Equation (A.588).

A.32.1 Statement

Theorem A.346 (Racah)**.** *Let $\mathfrak{g}$ be a finite-dimensional semisimple Lie algebra of rank ℓ over an algebraically closed field of characteristic zero. Then there are ℓ Casimir elements $C^{(1)},\dots,C^{(\ell)} \in Z(U(\mathfrak{g}))$, algebraically independent, such that every element of the centre is a polynomial in them with scalar coefficients,*

$$\boxed{Z(U(\mathfrak{g})) = \mathbb{K}\left[C^{(1)},\dots,C^{(\ell)}\right]}, \tag{A.614}$$

and no set of fewer than ℓ elements of the centre generates it. By Corollary 14.18 each $C^{(i)}$ acts on a finite-dimensional irreducible representation as a scalar, so such a representation carries ℓ invariant labels and no more; that these ℓ numbers also separate *the finite-dimensional irreducible representations is the quoted Theorem A.354.*

Rests on Definitions 14.8 and 14.20 and Theorem A.330.

A.32.2 The centre of the enveloping algebra and the invariant polynomials

Lemma A.347 (Central is the same as invariant)**.** *For $u \in U(\mathfrak{g})$ the following are equivalent: u is central; $[u, X] = 0$ for every $X \in \mathfrak{g}$; and u is invariant under the adjoint action $\mathrm{ad}_X\, u = Xu - uX$ of $\mathfrak{g}$ on $U(\mathfrak{g})$. In particular the Casimir elements of Definition 14.8 are exactly the* ad*-invariant elements of $U(\mathfrak{g})$.*

Rests on Definitions 14.5 and 14.8.

Proof. *Derives Lemma A.347.*

The second and third conditions are the same statement written twice. A central element certainly commutes with every $X \in \mathfrak{g}$. Conversely, the set of elements commuting with a fixed u is a subalgebra of $U(\mathfrak{g})$ containing the unit — it is closed under sums and, by the Leibniz rule $[vw, u] = v\,[w, u] + [v, u]\,w$, under products. If it contains $\mathfrak{g}$ it therefore contains the algebra generated by $\mathfrak{g}$ and the unit, which is $U(\mathfrak{g})$ by Definition 14.5. □

Proposition A.348 (Symmetrization identifies the invariants)**.** *Let $S(\mathfrak{g})^{\mathfrak{g}}$ denote the* ad*-invariant elements of $S(\mathfrak{g})$. Then:*

1. *ω restricts to a linear isomorphism $S(\mathfrak{g})^{\mathfrak{g}} \to Z\,(U(\mathfrak{g}))$;*
2. *$S(\mathfrak{g})^{\mathfrak{g}}$ is a graded subalgebra of $S(\mathfrak{g})$, and the symbol map Equation (A.587) identifies the associated graded algebra of the centre with it,*

$$\bigoplus_{n\geq 0} \frac{(Z\,(U(\mathfrak{g})) \cap U_n) + U_{n-1}}{U_{n-1}} \;\cong\; S(\mathfrak{g})^{\mathfrak{g}} \tag{A.615}$$

as graded algebras.

Rests on Proposition A.327, Definition A.325, and Lemma A.347.

Proof. *Derives Proposition A.348.*

(1) By Proposition A.327 the map ω is a linear isomorphism intertwining the two adjoint actions, so it carries the invariants of $S(\mathfrak{g})$ bijectively onto the invariants of $U(\mathfrak{g})$, and the latter are the centre by Lemma A.347.

(2) The action of ad_X on $S(\mathfrak{g})$ is by a derivation that preserves degree, so an invariant decomposes into invariant homogeneous pieces and $S(\mathfrak{g})^{\mathfrak{g}}$ is graded; it is a subalgebra because a derivation annihilating two elements annihilates their product.

For Equation (A.615), note first that ad_X maps U_n into U_n — by the Leibniz rule it replaces one letter of a word of length n by $[X, \cdot]$ of it, which is again a letter — and that the induced map on $U_n/U_{n-1} \cong S^n(\mathfrak{g})$ is exactly the derivation ad_X of $S^n(\mathfrak{g})$. Hence the symbol of a central element of U_n is an invariant of $S^n(\mathfrak{g})$, which gives the inclusion "$\subseteq$" in Equation (A.615). Conversely, if $p \in S^n(\mathfrak{g})^{\mathfrak{g}}$ then $\omega(p)$ lies in U_n, is central by part (1), and has symbol p by Proposition A.327(1); so the inclusion is an equality. The identification is multiplicative because the symbol map is (Definition A.325). □

Lemma A.349 (Lifting generators through the filtration)**.** *Suppose $S(\mathfrak{g})^{\mathfrak{g}}$ is a free polynomial algebra on homogeneous elements $p_1, \dots, p_\ell$ of degrees $d_1, \dots, d_\ell$. Put $C^{(i)} = \omega(p_i) \in Z\,(U(\mathfrak{g})) \cap U_{d_i}$. Then the $C^{(i)}$ are algebraically independent and generate $Z\,(U(\mathfrak{g}))$ as an algebra, so Equation (A.614) holds.*

Rests on Proposition A.348 and Definition A.325.

Proof. *Derives Lemma A.349.*

Give the monomial $\left(C^{(1)}\right)^{\alpha_1}\cdots\left(C^{(\ell)}\right)^{\alpha_\ell}$ the *weight* $\sum_i \alpha_i d_i$; by Equation (A.569) a monomial of weight N lies in U_N, and by Proposition A.348 its symbol in $S^N(\mathfrak{g})$ is the corresponding monomial $p^\alpha = p_1^{\alpha_1}\cdots p_\ell^{\alpha_\ell}$.

Independence. Let F be a nonzero polynomial in ℓ variables and let N be the largest weight carried by a monomial occurring in it. Then $F\left(C^{(1)},\dots,C^{(\ell)}\right)\in U_N$ and its symbol is $\sum_{\text{weight }\alpha=N}\lambda_\alpha p^\alpha$, a nonzero element of $S^N(\mathfrak{g})$ because the p_i are algebraically independent. A nonzero symbol means the element is not in U_{N-1}; in particular it is not zero.

Generation. Let z be central and induct on the smallest n with $z\in U_n$. Its symbol is a homogeneous invariant of degree n, hence a weighted-homogeneous polynomial Q of weight n in the p_i; then $z - Q\left(C^{(1)},\dots,C^{(\ell)}\right)$ is central and lies in U_{n-1}, and the induction hypothesis applies. The base $n=0$ is $z\in\mathbb{K}$. □

Lemma A.350 (Invariant polynomials on $\mathfrak{g}$)**.** *The Killing form, being nondegenerate and invariant, is an isomorphism $\mathfrak{g}\to\mathfrak{g}^*$ of $\mathfrak{g}$-modules, and hence induces an isomorphism of graded algebras*

$$S(\mathfrak{g})^{\mathfrak{g}} \;\cong\; S\left(\mathfrak{g}^*\right)^{\mathfrak{g}}\,, \tag{A.616}$$

the right-hand side being the algebra of polynomial functions on $\mathfrak{g}$ annihilated by the natural action of every ad_X. In components, an element of $S^r(\mathfrak{g})^{\mathfrak{g}}$ is exactly a totally symmetric invariant tensor $k^{a_1\cdots a_r}$ in the sense of Definition 14.14, and the corresponding Casimir element is Equation (14.19).

Rests on Definitions 14.10 and 14.14 and Theorem A.330.

Proof. *Derives Lemma A.350.*

The map $X\mapsto\kappa(X,\cdot)$ is injective because κ is nondegenerate (Theorem A.330) and hence bijective by dimension; it intertwines the adjoint and coadjoint actions precisely because κ is invariant, Equation (14.16). An isomorphism of modules induces one of symmetric algebras, and it carries invariants to invariants. The component statement is Remark 14.15: writing an element of $S^r(\mathfrak{g})$ as $k^{a_1\cdots a_r}T_{a_1}\cdots T_{a_r}$ with k totally symmetric, the vanishing of ad_{T_c} on it is Equation (14.18) term by term, and Corollary A.328 identifies ω of that element with the Casimir Equation (14.19). □

So the first link of Equation (A.613) is established, in the strong form of Lemma A.349: *the enveloping algebra contributes nothing of its own to the count.* Counting Casimir operators is counting the algebraically independent invariant polynomials on $\mathfrak{g}$, and that is a question about the adjoint action alone.

A.32.3 The two quoted theorems

Theorem A.351 (Chevalley restriction theorem, quoted)**.** *Let $\mathfrak{g}$ be a semisimple Lie algebra over an algebraically closed field of characteristic zero, $\mathfrak{h}\subseteq\mathfrak{g}$ a Cartan subalgebra (Definition 14.20), and W the Weyl group of $\mathfrak{g}$ acting on $\mathfrak{h}$. Then restriction of functions from $\mathfrak{g}$ to $\mathfrak{h}$,*

$$S\left(\mathfrak{g}^*\right)^{\mathfrak{g}} \longrightarrow S\left(\mathfrak{h}^*\right)^{W}\,, \qquad P\longmapsto P|_{\mathfrak{h}}\,, \tag{A.617}$$

is an isomorphism of graded algebras.

Rests on Definition 14.20 and Lemma A.350.

Theorem A.352 (Chevalley's theorem on finite reflection groups, quoted)**.** *Let $\mathbb{V}$ be a vector space of dimension ℓ over a field of characteristic zero and let W be a finite group of linear transformations of $\mathbb{V}$ generated by reflections — elements fixing a hyperplane pointwise. Then the algebra of W-invariant polynomial functions on $\mathbb{V}$ is a free polynomial algebra,*

$$S\left(\mathbb{V}^*\right)^{W} = \mathbb{K}\left[f_1,\dots,f_\ell\right]\,, \tag{A.618}$$

on exactly ℓ algebraically independent homogeneous generators $f_1, \dots, f_\ell$, whose degrees are determined by W. Moreover, for $\mathfrak{g}$ semisimple with Cartan subalgebra $\mathfrak{h}$ of dimension ℓ, the Weyl group W is a finite group acting faithfully on $\mathfrak{h}$ and generated by the reflections in the root hyperplanes, so Equation (A.618) applies to it with $\mathbb{V} = \mathfrak{h}$.

Rests on Definition 14.20.

The free-polynomial statement is [1058]. That the Weyl group is a finite reflection group of rank ℓ acting faithfully on $\mathfrak{h}$ is standard structure theory and is quoted with it; no entry of this bibliography carries that half.

Remark A.353 (What is quoted here). Two theorems are assumed and not proved, and it is worth being exact about what they are and why they are not proved here. Theorem A.351 and the last sentence of Theorem A.352 both belong to the root-space theory of semisimple Lie algebras: the decomposition $\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_\alpha \mathfrak{g}_\alpha$ into eigenspaces of $\mathfrak{h}$, the root system it produces, the conjugacy of Cartan subalgebras, and the Weyl group generated by root reflections. That apparatus is the content of several chapters of a book on Lie algebras and this treatise does not build it: Chapter 14 constructs the algebras it needs by hand and computes their ranks directly, as Proposition 14.22 does for $\mathfrak{so}(p, q)$. Equation (A.618) itself is a theorem of invariant theory, not of Lie theory, and is likewise quoted.

What is *not* quoted is the first link of Equation (A.613), which is the part that could plausibly hide a circularity — it is proved in Appendix A.32.2 from the Poincaré–Birkhoff–Witt theorem of Appendix A.30, itself proved from nothing but the Jacobi identity; and it is the part that fails without semisimplicity, which is why Remark 14.23 is careful to exclude the Poincaré algebra. Nor is the arithmetic quoted: the count in Appendix A.32.4 and the check in Appendix A.32.5 are carried out here.

A.32.4 The count

Proof of Theorem A.346. *Derives Theorem A.346.*

Chain the identifications. By Lemma A.350, $S(\mathfrak{g})^{\mathfrak{g}} \cong S(\mathfrak{g}^*)^{\mathfrak{g}}$ as graded algebras; by Theorem A.351 the latter is $S(\mathfrak{h}^*)^W$; and by Theorem A.352 that is a free polynomial algebra on $\ell = \dim \mathfrak{h}$ homogeneous generators $f_1, \dots, f_\ell$, where ℓ is the rank of $\mathfrak{g}$ by Definition 14.20. Transporting the f_i back gives homogeneous $p_1, \dots, p_\ell \in S(\mathfrak{g})^{\mathfrak{g}}$ that are algebraically independent and generate, and Lemma A.349 converts them into Casimir elements $C^{(i)} = \omega(p_i)$ with the properties claimed in Equation (A.614).

No fewer than ℓ. A commutative algebra generated by m elements has transcendence degree at most m over $\mathbb{K}$, since every element is a polynomial in the generators and any $m + 1$ elements of such an algebra are algebraically dependent. By Equation (A.614) the centre has transcendence degree exactly ℓ, the $C^{(i)}$ being algebraically independent. Hence no $m < \ell$ elements of the centre generate it, and no $m < \ell$ Casimir eigenvalues can carry the information that all of them do. □

Theorem A.354 (Harish-Chandra, quoted: the labels separate)**.** *Let $\mathfrak{g}$ be semisimple over an algebraically closed field of characteristic zero. Two finite-dimensional irreducible representations of $\mathfrak{g}$ on which every element of $Z(U(\mathfrak{g}))$ takes the same scalar value are equivalent. Equivalently, the ℓ numbers*

$$c^{(i)} = \text{the eigenvalue of } D\left(C^{(i)}\right), \qquad i = 1, \dots, \ell, \tag{A.619}$$

determine the equivalence class of a finite-dimensional irreducible representation.

Rests on Definition 14.8 and Corollary 14.18.

Remark A.355 (Why the separation statement is quoted separately). Theorem A.346 says how many independent invariants there are; Theorem A.354 says that their values are enough to tell two irreducible representations apart. The two are different assertions and

the second does not follow from the first, which is why the chapter's phrase "a complete set of invariant labels" has been split here. Remark 14.19 makes the same point from the other side: *one* Casimir separates the irreducible representations of $\mathfrak{su}(2)$ and does not separate those of $\mathfrak{su}(3)$, and the reason is not a failure of Theorem A.346 but the fact that $\mathfrak{su}(3)$ has rank 2 — one label is simply not the whole set.

Remark A.356 (Real forms). Theorem A.346 is stated over an algebraically closed field, but the algebras of Chapter 14 are real. The transition is harmless and worth stating once. For a real semisimple $\mathfrak{g}$ one has $U(\mathfrak{g}) \otimes_{\mathbb{R}} \mathbb{C} = U(\mathfrak{g} \otimes_{\mathbb{R}} \mathbb{C})$, because both sides are generated by $\mathfrak{g} \otimes \mathbb{C}$ with the same relations Equation (14.12), and taking the centre commutes with this extension: an element is central if and only if its real and imaginary parts are. So the number of independent Casimir elements of a real form equals that of its complexification, and the rank meant throughout is that of the complexification. This is what Proposition 14.22 in fact computes: its proof passes to $\mathfrak{h}_{\mathbb{C}}$ at once and counts the eigenvalue pairs $\pm\alpha_i$ there, which is the only sensible reading, since the adjoint action of J_{12} on the compact algebra $\mathfrak{so}(3)$ has eigenvalues $\pm\mathrm{i}$ and is not diagonalizable over $\mathbb{R}$ at all.

A.32.5 The count checked against the chapter's algebras

Example A.357 (Rank one: $\mathfrak{su}(2)$)**.** Any single generator spans a maximal abelian subalgebra of $\mathfrak{su}(2) \cong \mathfrak{so}(3)$, whose complexification is $\mathfrak{sl}(2,\mathbb{C})$; the rank is $\ell = 1$, in agreement with Equation (14.22) at $D = 3$. Theorem A.346 then predicts a single Casimir generator, and the invariant found in Definition 14.40 is $\boldsymbol{J}^2$, of degree two — the free generator being f_1 of degree 2. That it generates everything is visible in Theorem 14.43: the eigenvalue $j(j+1)$ is injective in $j \geq 0$, so by Theorem A.354 nothing further is needed, and by Theorem A.346 nothing further exists.

Rests on Theorems 14.43 and A.346.

Example A.358 (Rank two: $\mathfrak{su}(3)$)**.** The diagonal traceless matrices give a maximal abelian subalgebra of dimension 2 (Proposition 14.50), so $\ell = 2$ and Theorem A.346 predicts exactly two independent Casimir elements. They are found in Proposition 14.54: one quadratic, built from κ^{ab}, and one cubic, built from the totally symmetric tensor d^{abc} of Equation (14.70) — degrees 2 and 3, which are the degrees Chevalley's theorem assigns to the invariants of the Weyl group of $\mathfrak{su}(3)$. The count is not idle: by Proposition 14.55 the fundamental and antifundamental representations share the value of the quadratic invariant and are told apart only by the cubic one. One label would have failed; three would have been one too many.

Rests on Theorem A.346 and Propositions 14.54 and 14.55.

Example A.359 (The Lorentz algebra)**.** By Corollary A.344 the algebra $\mathfrak{so}(3,1)$ is semisimple, and by Equation (14.22) its rank is $\lfloor 4/2 \rfloor = 2$. Theorem A.346 therefore gives exactly two independent Casimir operators for the Lorentz algebra of the observed spacetime, and they are the two familiar quadratics,

$$C^{(1)} = \tfrac{1}{2}\, J_{AB} J^{AB}\,, \qquad C^{(2)} = \tfrac{1}{8}\, \epsilon^{ABCD} J_{AB} J_{CD}\,, \tag{A.620}$$

the second existing only because $D = 4$ makes the Levi-Civita symbol carry exactly four indices — the same accident of dimension that Remark 14.67 records for the Pauli–Lubanski vector. Both are invariant by Lemma 14.62 and Corollary 14.12, and by Theorem A.346 there is no third.

Rests on Theorem A.346, Corollary A.344, and Equation (14.22).

Remark A.360 (The Poincaré algebra is outside the theorem, and the agreement is a coincidence). Theorem 14.65 finds two invariants for the Poincaré algebra in $3+1$ dimensions, P^2 and W^2, and it is tempting to read that as Theorem A.346 applied to a rank-two algebra.

It is not, and the temptation must be resisted for a reason that is now provable rather than asserted: the translations form an abelian ideal, so by Proposition A.334 the Killing form of the Poincaré algebra is degenerate, the algebra is not semisimple, and every step of Appendix A.32.2 — which inverts κ in Lemma A.350 — fails at once. That the two counts agree at $D = 4$ is the coincidence recorded in Remark 14.23, and Equation (14.107) shows the agreement breaking in odd dimension, where $\lceil D/2 \rceil \neq \lfloor D/2 \rfloor$. The Galilei algebra of Example 14.80 makes the point sharper still: its invariants include the central mass, which is not an invariant of any semisimple algebra at all.

Where Theorem A.346 *is* used for an inhomogeneous algebra, it is applied to a semisimple subalgebra and not to the whole: the count Equation (14.107) applies it to the little algebra $\mathfrak{so}(D-1)$ of Lemma 14.68, which is semisimple for $D - 1 \geq 3$ by Corollary A.344, and adds the mass by hand.

Appendix A.32 discharges the proof obligation of Theorem 14.21, modulo the two theorems of structure theory named in Remark A.353 and the separation theorem Theorem A.354. It is used at Proposition 14.22 to turn the rank $\lfloor D/2 \rfloor$ into a number of Lorentz invariants, at Remark 14.67 to count the labels of a massive representation in general dimension, and throughout Section 14.2 whenever a representation is labelled by its Casimir eigenvalues. Its physical content is stated in Remark 14.24: the labels are pure numbers, and the measured quantity is the label multiplied by the power of $\hbar$ that carries its SI dimension.

A.33 Covering Spaces and the Fundamental Group of the Rotation Group

This appendix proves Corollary 14.38 of Chapter 14: that $\pi_1(\mathrm{SO}(3,\mathbb{R})) \cong \mathbb{Z}_2$, and more generally that when a simply connected topological group covers another one, the fundamental group of the base is the kernel of the covering homomorphism. Theorem 14.37 already supplies everything algebraic — that $\Phi : \mathrm{SU}(2) \to \mathrm{SO}(3,\mathbb{R})$ is a surjective homomorphism with kernel $\{\mathbb{1}, -\mathbb{1}\}$ — and Proposition 14.33 supplies the topology of the total space, that $\mathrm{SU}(2) \cong S^3$ is compact, connected and simply connected. What is missing, and is built here, is the bridge between the two: the covering-space machinery that converts a discrete kernel upstairs into a fundamental group downstairs.

Only the material of Chapter 6 is assumed: open sets, continuity, connectedness, compactness (Theorem 6.11), and simple connectedness (Definition 6.17). That chapter already carries the technique in its simplest instance. The continuous argument along a path of Lemma 6.19 is precisely the unique lifting of a path through the covering $\mathbb{R} \to \mathbb{C} \setminus \{0\}$, $\theta \mapsto \mathrm{e}^{\mathrm{i}\theta}$ composed with a radius, and the local-constancy argument of Proposition 6.23 is the homotopy invariance of the lift in that instance. The two lemmas below are those two arguments written for an arbitrary covering; the reader who has followed Section 6.1.5 has seen the whole idea already, and what is added here is generality, not a new device.

A.33.1 Statement

Definition A.361 (Covering map)**.** A continuous surjection $p : E \longrightarrow B$ of topological spaces is a *covering map* if every $b \in B$ has an open neighbourhood V that is *evenly covered*: $p^{-1}(V)$ is a union of pairwise disjoint open sets $\{W_\alpha\}$ — the *sheets* over V — each of which p maps homeomorphically onto V. The set $p^{-1}(b)$ is the *fibre* over b; a *lift* of a continuous map $g : X \longrightarrow B$ is a continuous $\tilde{g} : X \longrightarrow E$ with $p \circ \tilde{g} = g$.

Rests on Definitions 6.2 and 6.6.

Definition A.362 (Path homotopy and the fundamental group)**.** Let X be a topological space and $x_0 \in X$. A *loop at* x_0 is a continuous $\gamma : [0,1] \longrightarrow X$ with $\gamma(0) = \gamma(1) = x_0$.

Two loops γ_0, γ_1 at x_0 are *path homotopic*, written $\gamma_0 \simeq \gamma_1$, if there is a continuous $H : [0,1] \times [0,1] \longrightarrow X$ with

$$H(s,0) = \gamma_0(s)\,, \quad H(s,1) = \gamma_1(s)\,, \quad H(0,t) = H(1,t) = x_0\,, \qquad s,t \in [0,1]\,. \tag{A.621}$$

The concatenation $\gamma \cdot \delta$ is the loop equal to $\gamma(2s)$ for $s \le 1/2$ and to $\delta(2s-1)$ for $s \ge 1/2$, and the reverse is $\bar\gamma(s) = \gamma(1-s)$. The set of path-homotopy classes of loops at x_0 with the product $[\gamma][\delta] = [\gamma \cdot \delta]$ is the *fundamental group* $\pi_1(X, x_0)$. A path-connected X is simply connected in the sense of Definition 6.17 exactly when $\pi_1(X, x_0)$ is trivial.

Rests on Definitions 6.15 and 6.17.

Theorem A.363 (Monodromy)**.** *Let $p : E \longrightarrow B$ be a covering map with E path-connected and simply connected, B path-connected, and fix $e_0 \in E$, $b_0 = p(e_0)$. Then the* monodromy map

$$\Psi : \pi_1(B, b_0) \longrightarrow p^{-1}(b_0)\,, \qquad \Psi\left([\gamma]\right) = \tilde\gamma(1)\,, \tag{A.622}$$

where $\tilde\gamma$ is the unique lift of γ with $\tilde\gamma(0) = e_0$, is a well-defined bijection.

Rests on Definitions A.361 and A.362.

Theorem A.364 (Covering homomorphisms)**.** *Let E and B be topological groups, E path-connected and simply connected, and let $p : E \longrightarrow B$ be a surjective continuous homomorphism that is also a covering map, with kernel $N = p^{-1}(1_B)$. Then N is a discrete central subgroup of E, the monodromy map Equation (A.622) based at $e_0 = 1_E$ is a group isomorphism*

$$\pi_1(B, 1_B) \cong N\,, \tag{A.623}$$

and the group of deck transformations of p — the homeomorphisms φ of E with $p \circ \varphi = p$ — consists exactly of the left translations by elements of N, so that it too is isomorphic to N and hence to $\pi_1(B, 1_B)$.

Rests on Theorem A.363 and Definition A.361.

The proof occupies the rest of this section: two lifting lemmas (Appendix A.33.2), the monodromy theorem (Appendix A.33.3), the group case (Appendix A.33.4), and the application to $\mathrm{SU}(2) \to \mathrm{SO}(3, \mathbb{R})$ (Appendix A.33.5).

A.33.2 Two lifting lemmas

Every lifting argument in covering-space theory is the same argument: chop the domain into pieces small enough to sit inside an evenly covered neighbourhood, lift piece by piece using the sheet that contains the value already fixed, and check that the pieces agree. The chopping is supplied by the following standard consequence of compactness, which Lemma 6.19 used in the disguised form of a partition of mesh smaller than a modulus of uniform continuity.

Lemma A.365 (Lebesgue number)**.** *Let $K \subset \mathbb{R}^N$ be closed and bounded and let $\{U_i\}$ be an open cover of K. There is $\delta > 0$ such that every subset of K of diameter smaller than δ is contained in a single U_i.*

Rests on Theorem 6.11 and Definition 6.2.

Proof. *Derives Lemma A.365.*

For each $x \in K$ choose $i(x)$ with $x \in U_{i(x)}$ and then $r(x) > 0$ with $B_{2r(x)}(x) \subseteq U_{i(x)}$, which is possible because $U_{i(x)}$ is open. The balls $B_{r(x)}(x)$ cover K, which is compact by Theorem 6.11, so finitely many of them suffice, say those centred at $x_1, \dots, x_k$; put $\delta = \min_j r(x_j) > 0$. Let $S \subseteq K$ have diameter smaller than δ and pick $y \in S$. Then $y \in B_{r(x_j)}(x_j)$ for some j, and every $z \in S$ satisfies

$$|z - x_j| \le |z - y| + |y - x_j| < \delta + r(x_j) \le 2r(x_j)\,,$$

so $S \subseteq B_{2r(x_j)}(x_j) \subseteq U_{i(x_j)}$. □

Lemma A.366 (Unique path lifting)**.** *Let $p : E \longrightarrow B$ be a covering map, let $\gamma : [0,1] \longrightarrow B$ be continuous, and let $e \in E$ satisfy $p(e) = \gamma(0)$. There is exactly one continuous $\tilde{\gamma} : [0,1] \longrightarrow E$ with $p \circ \tilde{\gamma} = \gamma$ and $\tilde{\gamma}(0) = e$.*

Rests on Definition A.361 and Lemma A.365.

Proof. *Derives Lemma A.366.*

Existence. Cover B by evenly covered open sets V and pull them back: the sets $\gamma^{-1}(V)$ form an open cover of $[0,1]$, which is closed and bounded, so Lemma A.365 supplies a $\delta > 0$ and with it a partition $0 = t_0 < t_1 < \cdots < t_M = 1$ of mesh smaller than δ such that each $\gamma([t_{j-1}, t_j])$ lies in a single evenly covered V_j.

Define $\tilde{\gamma}$ inductively. Set $\tilde{\gamma}(t_0) = e$. Suppose $\tilde{\gamma}$ has been defined and is continuous on $[0, t_{j-1}]$ with $p \circ \tilde{\gamma} = \gamma$ there. The point $\tilde{\gamma}(t_{j-1})$ lies in $p^{-1}(V_j)$, hence in exactly one sheet W over V_j, and $p|_W : W \longrightarrow V_j$ is a homeomorphism. Put

$$\tilde{\gamma}(t) = (p|_W)^{-1}(\gamma(t)) \,, \qquad t \in [t_{j-1}, t_j] \,. \tag{A.624}$$

This is continuous on $[t_{j-1}, t_j]$, satisfies $p \circ \tilde{\gamma} = \gamma$ there, and agrees at t_{j-1} with the value already assigned, because $\tilde{\gamma}(t_{j-1}) \in W$ and $p|_W$ is injective. Two continuous functions on the closed intervals $[0, t_{j-1}]$ and $[t_{j-1}, t_j]$ agreeing at the common endpoint patch to a continuous function on the union, so the induction proceeds and terminates at $t_M = 1$.

Uniqueness. Let $\tilde{\gamma}$ and $\tilde{\gamma}'$ be two lifts with the same initial value, and let $A = \{t \in [0,1] \mid \tilde{\gamma}(t) = \tilde{\gamma}'(t)\}$, which contains 0. Fix $t \in [0,1]$, let V be an evenly covered neighbourhood of $\gamma(t)$, and let W, W' be the sheets over V containing $\tilde{\gamma}(t)$ and $\tilde{\gamma}'(t)$. The set $O = \tilde{\gamma}^{-1}(W) \cap (\tilde{\gamma}')^{-1}(W')$ is an open neighbourhood of t in $[0,1]$. If $t \in A$ then $W = W'$, the sheets being disjoint, and on O both lifts equal $(p|_W)^{-1} \circ \gamma$, so $O \subseteq A$: the set A is open. If $t \notin A$ then $W \neq W'$, since a common sheet would force $\tilde{\gamma}(t) = \tilde{\gamma}'(t)$ by injectivity of $p|_W$; the sheets being disjoint, O misses A entirely, so the complement of A is open too. Thus A is a nonempty subset of $[0,1]$ that is both open and closed, and $[0,1]$ is connected (Theorem 6.14), so $A = [0,1]$. □

Lemma A.367 (Homotopy lifting)**.** *Let $p : E \longrightarrow B$ be a covering map, let $H : [0,1] \times [0,1] \longrightarrow B$ be continuous, and let $e \in E$ satisfy $p(e) = H(0,0)$. There is exactly one continuous $\tilde{H} : [0,1] \times [0,1] \longrightarrow E$ with $p \circ \tilde{H} = H$ and $\tilde{H}(0,0) = e$. If moreover H is a path homotopy in the sense of Equation (A.621) — so that $H(0,t)$ and $H(1,t)$ are constant in t — then $\tilde{H}(0,t)$ and $\tilde{H}(1,t)$ are constant in t as well.*

Rests on Lemmas A.365 and A.366.

Proof. *Derives Lemma A.367.*

Existence. As before, the sets $H^{-1}(V)$ with V evenly covered form an open cover of the square $[0,1]^2$, which is closed and bounded in $\mathbb{R}^2$; Lemma A.365 supplies $\delta > 0$, and a grid $0 = s_0 < \cdots < s_M = 1$, $0 = t_0 < \cdots < t_M = 1$ of mesh smaller than $\delta/\sqrt{2}$ makes each closed cell $R_{jk} = [s_{j-1}, s_j] \times [t_{k-1}, t_k]$ have diameter smaller than δ, hence $H(R_{jk})$ contained in a single evenly covered V_{jk}.

Order the cells lexicographically, bottom row left to right, then the next row, and lift them one at a time. At each stage the part of the boundary of the current cell R on which $\tilde{H}$ has already been defined — call it C — is the union of at most the left edge and the bottom edge of R, together with the corner joining them, and is therefore connected. (For the very first cell C is the single point (s_0, t_0), where $\tilde{H} = e$ is prescribed.) The set $\tilde{H}(C)$ is connected and lies in $p^{-1}(V)$ for the evenly covered $V \supseteq H(R)$, which is the disjoint union of open sheets; a connected subset of a disjoint union of open sets lies in one of them, so $\tilde{H}(C) \subseteq W$ for a single sheet W. Define $\tilde{H} = (p|_W)^{-1} \circ H$ on R. This is continuous on R, projects to H, and agrees on C with what was there — again because $p|_W$ is injective and both values lie in W. The extended function is continuous, being continuous on each of

finitely many closed cells and consistent on the overlaps. After the last cell $\tilde{H}$ is defined on the whole square.

Uniqueness. Verbatim the argument of Lemma A.366: the agreement set of two lifts is open and closed, and the square is connected, being path-connected (Proposition 6.16).

The vertical edges. Suppose $H(0,t) = b_0$ for every t. Then $t \mapsto \tilde{H}(0,t)$ is a lift of the constant path at b_0; so is the constant map $t \mapsto \tilde{H}(0,0)$; the two agree at $t = 0$, so by the uniqueness clause of Lemma A.366 they agree throughout. The same applies at $s = 1$. □

A.33.3 The monodromy theorem

The elementary bookkeeping behind Definition A.362 is recorded first, because it is what makes π_1 a group at all and because the injectivity of Ψ uses it.

Lemma A.368 (The concatenation rules)**.** *Let α, β, η be paths in a space X with $\alpha(1) = \beta(0)$ and $\beta(1) = \eta(0)$, let c_x denote the constant path at x, and write $\simeq$ for homotopy with endpoints held fixed. Then*

$$(\alpha \cdot \beta) \cdot \eta \simeq \alpha \cdot (\beta \cdot \eta)\,, \qquad c_{\alpha(0)} \cdot \alpha \simeq \alpha \simeq \alpha \cdot c_{\alpha(1)}\,, \qquad \alpha \cdot \bar{\alpha} \simeq c_{\alpha(0)}\,. \tag{A.625}$$

Consequently $\pi_1(X, x_0)$ of Definition A.362 is a group, with $[\gamma]^{-1} = [\bar{\gamma}]$; and a continuous $p : E \longrightarrow B$ with $p(e_0) = b_0$ induces a group homomorphism $p_* : \pi_1(E, e_0) \longrightarrow \pi_1(B, b_0)$, $p_*[\sigma] = [p \circ \sigma]$.

Rests on Definition A.362.

Proof. *Derives Lemma A.368.*

All three relations of Equation (A.625) are reparametrizations. If $\phi : [0,1] \to [0,1]$ is continuous with $\phi(0) = 0$ and $\phi(1) = 1$, then for any path μ the map $H(s,t) = \mu\left((1-t)\phi(s) + ts\right)$ is continuous, fixes the endpoints, and joins $\mu \circ \phi$ to μ; so $\mu \circ \phi \simeq \mu$. The two sides of the first relation are the same path $\alpha \cdot (\beta \cdot \eta)$ composed with such a ϕ — the piecewise-linear map sending $1/4$ to $1/2$ and $1/2$ to $3/4$ — and the two sides of the second are likewise related by the piecewise-linear ϕ sending $1/2$ to 0, respectively to 1. For the third, put

$$H(s,t) = \begin{cases} \alpha\left(2s(1-t)\right)\,, & s \le \frac{1}{2}\,, \\ \alpha\left(2(1-s)(1-t)\right)\,, & s \ge \frac{1}{2}\,, \end{cases}$$

which is continuous (the two formulas agree at $s = 1/2$), equals $\alpha \cdot \bar{\alpha}$ at $t = 0$ and $c_{\alpha(0)}$ at $t = 1$, and is constant on $s = 0$ and on $s = 1$. That the product on classes is well defined — homotopies of the two factors concatenate to a homotopy of the product — is immediate from the definition of concatenation. Finally $p \circ (\alpha \cdot \beta) = (p \circ \alpha) \cdot (p \circ \beta)$ by inspection, and $p \circ H$ is a path homotopy whenever H is, so p_* is a well-defined homomorphism. □

Proof of Theorem A.363. *Derives Theorem A.363.*

Ψ is well defined. The lift $\tilde{\gamma}$ exists and is unique by Lemma A.366, and $p\left(\tilde{\gamma}(1)\right) = \gamma(1) = b_0$, so $\tilde{\gamma}(1) \in p^{-1}(b_0)$. That it depends only on the class $[\gamma]$ is the content of Lemma A.367: let H be a path homotopy from γ_0 to γ_1 and $\tilde{H}$ its lift with $\tilde{H}(0,0) = e_0$. The left edge $t \mapsto \tilde{H}(0,t)$ is constant, so $\tilde{H}(\cdot, t)$ is for each t the lift of $H(\cdot, t)$ starting at e_0; the right edge $t \mapsto \tilde{H}(1,t)$ is constant too, so the common endpoint $\tilde{H}(1,0) = \tilde{H}(1,1)$, that is $\tilde{\gamma}_0(1) = \tilde{\gamma}_1(1)$.

Ψ is surjective. Let $e \in p^{-1}(b_0)$. Since E is path-connected there is a path σ in E from e_0 to e; then $\gamma = p \circ \sigma$ is a loop at b_0, and σ is its lift starting at e_0 by uniqueness, so $\Psi\left([\gamma]\right) = \sigma(1) = e$.

Ψ is injective. Suppose $\tilde{\gamma}_0(1) = \tilde{\gamma}_1(1)$ for loops γ_0, γ_1 at b_0. Both lifts start at e_0, so $\tilde{\gamma}_0$ and $\tilde{\gamma}_1$ are paths in E with the same two endpoints, and $\sigma = \tilde{\gamma}_0 \cdot \overline{\tilde{\gamma}_1}$ is a loop in E at e_0.

Since E is simply connected, $[\sigma]$ is the identity of $\pi_1(E, e_0)$. Apply the homomorphism p_* of Lemma A.368:

$$[\gamma_0]\,[\gamma_1]^{-1} = [\gamma_0 \cdot \bar{\gamma}_1] = [p \circ \sigma] = p_*\,[\sigma] = [c_{b_0}]\ , \tag{A.626}$$

using $p \circ \tilde{\gamma}_k = \gamma_k$ and $[\bar{\gamma}_1] = [\gamma_1]^{-1}$. Hence $[\gamma_0] = [\gamma_1]$. □

A.33.4 Covering homomorphisms and deck transformations

Proof of Theorem A.364. *Derives Theorem A.364.*

N is discrete and central. Let V be an evenly covered neighbourhood of 1_B and W the sheet over it containing 1_E. Then $W \cap N = \{1_E\}$, because p is injective on W and already sends 1_E to 1_B; translating, $nW \cap N = \{n\}$ for every $n \in N$, so N carries the discrete topology. For centrality, fix $n \in N$ and consider $f : E \longrightarrow E$, $f(x) = xnx^{-1}$. It is continuous, takes values in N — because $p\,(xnx^{-1}) = p(x)\,1_B\,p(x)^{-1} = 1_B$ — and E is connected, so its image is a connected subset of a discrete space, hence the single point $f(1_E) = n$. Thus $xn = nx$ for all x.

Ψ is a homomorphism. Let γ, δ be loops at 1_B with lifts $\tilde{\gamma}, \tilde{\delta}$ starting at 1_E, and put $n = \tilde{\gamma}(1) \in N$. The path $t \mapsto n\,\tilde{\delta}(t)$ is continuous, starts at $n\,1_E = n = \tilde{\gamma}(1)$, and projects to $p(n)\,\delta(t) = \delta(t)$. Hence the concatenation $\tilde{\gamma} \cdot \left(n\tilde{\delta}\right)$ is a lift of $\gamma \cdot \delta$ starting at 1_E, and by uniqueness (Lemma A.366) it is *the* lift. Its endpoint is $n\,\tilde{\delta}(1)$, so

$$\Psi\,([\gamma][\delta]) = \Psi\,([\gamma])\ \Psi\,([\delta])\ . \tag{A.627}$$

Being a bijection by Theorem A.363, Ψ is an isomorphism, which is Equation (A.623).

Deck transformations. If $n \in N$ then left translation $L_n(x) = nx$ is a homeomorphism of E with $p\,(L_n(x)) = p(n)p(x) = p(x)$, so L_n is a deck transformation, and $n \mapsto L_n$ is an injective homomorphism ($L_n = L_{n'}$ forces $n = n'$ at $x = 1_E$). Conversely let φ be any deck transformation and set $n = \varphi(1_E)$, which lies in N because $p(n) = p(1_E) = 1_B$. Both φ and L_n are lifts of the map $p : E \longrightarrow B$ through p itself, and they agree at 1_E. The agreement set of two lifts of one map on a connected domain is open and closed — the argument is word for word the uniqueness half of Lemma A.366, with $[0,1]$ replaced by E — and E is connected, so $\varphi = L_n$. □

A.33.5 The rotation group

It remains to check that Φ of Equation (14.46) is a covering map. That is the one place where the group is used concretely, and it is short.

Lemma A.369 (Φ is a two-sheeted covering)**.** *The homomorphism $\Phi : \mathrm{SU}(2) \longrightarrow \mathrm{SO}(3,\mathbb{R})$ of Theorem 14.37 is an open map and a covering map, each fibre having exactly two points.*
Rests on Theorem 14.37, Proposition 14.33, and Definition A.361.

Proof. *Derives Lemma A.369.*

Write $K = \{\mathbb{1}, -\mathbb{1}\} = \ker\Phi$ (Equation (14.47)). Because Φ is a homomorphism with kernel K, its fibres are exactly the pairs $\{U, -U\}$, which have two elements since $U \neq -U$; and Φ is surjective by Theorem 14.37.

Φ is open. First, Φ is a closed map: $\mathrm{SU}(2)$ is compact (Proposition 14.33) and $\mathrm{SO}(3,\mathbb{R})$ is Hausdorff, being a subspace of the matrices $\mathbb{R}^{3\times3}$, so a closed subset of $\mathrm{SU}(2)$ is compact, its continuous image is compact, and a compact subset of a Hausdorff space is closed. A continuous closed surjection is a quotient map: a set $S \subseteq \mathrm{SO}(3,\mathbb{R})$ with $\Phi^{-1}(S)$ open has open complement's preimage closed, hence $\mathrm{SO}(3,\mathbb{R}) \setminus S = \Phi\,(\mathrm{SU}(2) \setminus \Phi^{-1}(S))$ closed — the equality holding because Φ is surjective and $\Phi^{-1}(S)$ is a union of fibres — so S is open. Now let $O \subseteq \mathrm{SU}(2)$ be open. Then $-O$ is open, multiplication by $-\mathbb{1}$ being a homeomorphism, and $\Phi^{-1}\,(\Phi(O)) = O \cup (-O)$ because the fibre through U is $\{U, -U\}$. That union is open, so $\Phi(O)$ is open.

Even covering. Let $V_0 = \{U \in \mathrm{SU}(2) \mid \|U - \mathbb{1}\| < 1\}$, the norm being any norm on the 2×2 matrices with $\|2\mathbb{1}\| = 2$; for instance $\|M\|^2 = \frac{1}{2}\operatorname{tr}\left(M^\dagger M\right)$, for which $\|\mathbb{1}\| = 1$. Then $V_0 \cap (-V_0) = \varnothing$: if U and $-U$ both lay within distance 1 of $\mathbb{1}$ then

$$2 = \|2\mathbb{1}\| = \|(\mathbb{1} - U) + (\mathbb{1} + U)\| \leq \|\mathbb{1} - U\| + \|\mathbb{1} + U\| < 2\,,$$

which is absurd. Fix $U_0 \in \mathrm{SU}(2)$ and put $W = U_0 V_0$, $V = \Phi(W)$, which is open by the previous paragraph. The two sheets are W and $-W$: they are disjoint, since $U_0 v = -U_0 v'$ would give $v = -v'$ with $v, v' \in V_0$; their union is $\Phi^{-1}(V)$, because a point of $\Phi^{-1}(V)$ is $\pm w$ for some $w \in W$; and Φ restricted to either is a continuous open bijection onto V, hence a homeomorphism. Every point of $\mathrm{SO}(3,\mathbb{R})$ lies in such a V, namely for U_0 any preimage of it. □

Proof of Corollary 14.38. *Derives Corollary 14.38.*

By Theorem 14.37 the map Φ is a surjective homomorphism with kernel $\{\mathbb{1}, -\mathbb{1}\}$, so the induced map $\mathrm{SU}(2)/\{\mathbb{1}, -\mathbb{1}\} \longrightarrow \mathrm{SO}(3,\mathbb{R})$ is a group isomorphism, and it is a homeomorphism because Φ is continuous, open and surjective (Lemma A.369). By Proposition 14.33 the group $\mathrm{SU}(2)$ is path-connected and simply connected, and by Lemma A.369 the map Φ is a covering map; $\mathrm{SO}(3,\mathbb{R})$ is path-connected, being a continuous image of a path-connected space. Theorem A.364 therefore applies and gives

$$\pi_1\left(\mathrm{SO}(3,\mathbb{R}), \mathbb{1}\right) \cong \ker \Phi = \{\mathbb{1}, -\mathbb{1}\} \cong \mathbb{Z}_2\,, \tag{A.628}$$

which is Equation (14.48), and identifies the deck-transformation group of the covering with the same $\mathbb{Z}_2$, generated by $U \mapsto -U$.

The concrete description in Corollary 14.38 is now read off the isomorphism. The path $\phi \mapsto U(\hat{n}, \phi)$, $0 \leq \phi \leq 2\pi$, runs in $\mathrm{SU}(2)$ from $\mathbb{1}$ to $-\mathbb{1}$ by Equation (14.45); it is therefore the lift, starting at $\mathbb{1}$, of the loop $\phi \mapsto \Phi\left(U(\hat{n}, \phi)\right) = R(\hat{n}, \phi)$ in $\mathrm{SO}(3,\mathbb{R})$, whose endpoint $R(\hat{n}, 2\pi) = \mathbb{1}$ makes it a loop indeed. Its monodromy image is $-\mathbb{1} \neq \mathbb{1}$, so its class in π_1 is the nontrivial element: the loop is not contractible. Doubling the parameter range to $0 \leq \phi \leq 4\pi$ doubles the class, and $(-\mathbb{1})^2 = \mathbb{1}$, so that loop is contractible. □

Remark A.370 (What this costs, and what it buys). Nothing above is special to $\mathrm{SU}(2)$ until Lemma A.369: the two lifting lemmas and Theorems A.363 and A.364 hold for any covering, and the reader who compares them with Lemmas 6.19 and 6.22 and Proposition 6.23 will find the same three steps — lift along a partition, patch, and use connectedness of the parameter interval to rule out ambiguity — carried out there for the single covering $\theta \mapsto \mathrm{e}^{\mathrm{i}\theta}$ of the unit circle. The winding number of Definition 6.20 is the monodromy map Equation (A.622) for that covering, whose total space $\mathbb{R}$ is simply connected and whose kernel is $2\pi\mathbb{Z}$; that is why Equation (6.5) is an integer.

The purchase is Equation (14.48), and through it Remark 14.39: the rotation group is not simply connected, its universal cover is $\mathrm{SU}(2)$, and a quantum system may therefore carry a representation of $\mathrm{SU}(2)$ that is only a projective representation of $\mathrm{SO}(3,\mathbb{R})$. Theorem 14.43 and Proposition 14.45 say which ones those are — exactly the half-integer j — so the existence of half-integer angular momentum is a corollary of Equation (A.628) and not an independent postulate.

A.34 The Structure Constants of $\mathfrak{su}(3)$

This appendix completes Proposition 14.52 of Chapter 14: it computes every nonvanishing component of the totally antisymmetric array f_{abc} and the totally symmetric array d_{abc} of Equation (14.67) in the Gell-Mann basis of Definition 14.51, and exhibits the two complete

tables. The chapter carries two entries as specimens, f_{458} and d_{247}; the remaining twenty-three are obtained here, and — more to the point — so is the statement that there are no others. Nothing beyond Definition 14.51 and Equation (14.66) is used.

The naive route is $8^3 = 512$ traces, or $\binom{8+2}{3} = 120$ after the symmetries are imposed. That is not what is done below. A single observation about which products of three matrix units have a nonzero trace cuts the work to three short families, and the classification of those families is what makes the tables *exhaustive* rather than merely checked.

A.34.1 One trace for both arrays

Lemma A.371 (The generating trace)**.** *With $T_a = \frac{1}{2}\lambda_a$ as in Definition 14.51,*

$$\boxed{\operatorname{tr}(\lambda_a\lambda_b\lambda_c) = 2\,(d_{abc} + \mathrm{i}\, f_{abc})}\,, \tag{A.629}$$

so that $d_{abc} = \frac{1}{2}\Re\operatorname{tr}(\lambda_a\lambda_b\lambda_c)$ and $f_{abc} = \frac{1}{2}\Im\operatorname{tr}(\lambda_a\lambda_b\lambda_c)$; in particular both arrays are real.
Rests on Equations (14.66) and (14.68) and Definition 14.51.

Proof. *Derives Lemma A.371.*

Substituting $T_a = \frac{1}{2}\lambda_a$ into Equation (14.68), each of the three factors contributes a $\frac{1}{2}$, so

$$f_{abc} = -\frac{\mathrm{i}}{4}\operatorname{tr}\left([\lambda_a, \lambda_b]\,\lambda_c\right), \qquad d_{abc} = \frac{1}{4}\operatorname{tr}\left(\{\lambda_a, \lambda_b\}\,\lambda_c\right). \tag{A.630}$$

Now $\lambda_a\lambda_b = \frac{1}{2}\{\lambda_a, \lambda_b\} + \frac{1}{2}[\lambda_a, \lambda_b]$, so

$$\operatorname{tr}(\lambda_a\lambda_b\lambda_c) = \tfrac{1}{2}\operatorname{tr}\left(\{\lambda_a, \lambda_b\}\,\lambda_c\right) + \tfrac{1}{2}\operatorname{tr}\left([\lambda_a, \lambda_b]\,\lambda_c\right) = \tfrac{1}{2}\,(4d_{abc}) + \tfrac{1}{2}\,(4\mathrm{i}f_{abc}),$$

which is Equation (A.629). Reality: the λ_a are Hermitian, so $\overline{\operatorname{tr}(\lambda_a\lambda_b\lambda_c)} = \operatorname{tr}\left((\lambda_a\lambda_b\lambda_c)^\dagger\right) = \operatorname{tr}(\lambda_c\lambda_b\lambda_a)$, and reversing the order of three factors under the trace exchanges a and c in Equation (A.629); by the total symmetry of d and total antisymmetry of f established in Proposition 14.52, that conjugates the right-hand side. Hence d and f are the real and imaginary parts of one complex number, and both are real numbers. □

Remark A.372 (The symmetry conventions, and how many components there are)*.* Proposition 14.52 proves that f_{abc} is totally antisymmetric and d_{abc} totally symmetric in (a, b, c). Those two rules fix every component from the tables below, and it is worth saying exactly how many components each independent entry generates.

A nonzero f_{abc} necessarily has three *distinct* indices — $f_{aab} = -f_{aab} = 0$ — and its six permutations give six nonzero components, three equal to $+f_{abc}$ (the cyclic ones) and three equal to $-f_{abc}$. With nine independent entries that is $9 \times 6 = 54$ nonvanishing components of f.

For d the count depends on the repetition pattern. An entry with three distinct indices generates six equal components; an entry of the shape d_{aab} with $a \neq b$ generates three; and d_{aaa} generates one. Of the sixteen independent entries below, four have distinct indices, eleven have exactly one repetition, and one is d_{888}; so d has $4 \times 6 + 11 \times 3 + 1 = 58$ nonvanishing components.

Ordering within an entry is therefore free, and the tables list each independent entry once, in the index order used in Equations (14.69) and (14.70).

A.34.2 Which triples can be nonzero at all

Write E_{jk} for the 3×3 matrix whose only nonzero entry is a 1 in row j and column k, so that $E_{jk}E_{lm} = \delta_{kl}E_{jm}$ and $\operatorname{tr} E_{jk} = \delta_{jk}$. Reading off Equations (14.63) to (14.65), each

Gell-Mann matrix is supported on one of four index sets:

$$\begin{aligned} \lambda_1 &= E_{12} + E_{21}\,, & \lambda_2 &= -\mathrm{i}E_{12} + \mathrm{i}E_{21}\,, \\ \lambda_4 &= E_{13} + E_{31}\,, & \lambda_5 &= -\mathrm{i}E_{13} + \mathrm{i}E_{31}\,, \\ \lambda_6 &= E_{23} + E_{32}\,, & \lambda_7 &= -\mathrm{i}E_{23} + \mathrm{i}E_{32}\,, \\ \lambda_3 &= E_{11} - E_{22}\,, & \lambda_8 &= \tfrac{1}{\sqrt{3}}\,(E_{11} + E_{22} - 2E_{33})\ . \end{aligned} \tag{A.631}$$

Read as a graph on the vertex set $\{1,2,3\}$, the first row lives on the edge 1–2, the second on 1–3, the third on 2–3, and the fourth — λ_3 and λ_8, the diagonal ones — on loops. Call $\mathrm{A} = \{1,2\}$, $\mathrm{B} = \{4,5\}$, $\mathrm{C} = \{6,7\}$ the three *off-diagonal pairs* of generator labels and $\mathrm{D} = \{3,8\}$ the *diagonal pair*.

Lemma A.373 (Selection rule)**.** $\operatorname{tr}(\lambda_a\lambda_b\lambda_c) = 0$ *unless the unordered triple* $\{a,b,c\}$ *falls into one of the three families*

1. *all three indices in* D*;*
2. *exactly one index in* D *and the other two in a single off-diagonal pair;*
3. *one index in each of* A, B *and* C*.*

Rests on Equations (14.63) *to* (14.65)*.*

Proof. *Derives Lemma A.373.*

Expanding each factor in the matrix units of Equation (A.631),

$$\operatorname{tr}(\lambda_a\lambda_b\lambda_c) = \sum_{i,j,k} (\lambda_a)_{ij}\,(\lambda_b)_{jk}\,(\lambda_c)_{ki}\ , \tag{A.632}$$

so a nonzero contribution needs a closed walk $i \to j \to k \to i$ of length three in the index set $\{1,2,3\}$, whose three steps are supplied by λ_a, λ_b, λ_c in that order. A λ with index in D supplies only *loops* $i \to i$; a λ in an off-diagonal pair supplies only the two steps along its own edge, and along no other.

Count the loops among the three steps. If all three steps are loops, all three indices lie in D: family (1). If exactly two are loops, the third is an edge step, which cannot close a walk that has returned to its starting vertex twice — a walk $i \to i \to i \to j$ ends at $j \neq i$ — so this case contributes nothing. If exactly one step is a loop, the other two are edge steps $u \to v$ and $v \to u$ on one and the same edge, since the walk must return; hence one index in D and two in a single pair, which is family (2). If no step is a loop, the walk visits three vertices along three distinct edges of the triangle on $\{1,2,3\}$ — two of the three steps on one edge would force the third to be a loop — so one index comes from each of A, B, C: family (3). □

Everything is now a finite enumeration inside three small families, and the products needed are the ten diagonal matrices

$$\begin{aligned} \lambda_1\lambda_1 &= \lambda_2\lambda_2 = \operatorname{diag}(1,1,0)\,, & \lambda_1\lambda_2 &= \operatorname{diag}(\mathrm{i},-\mathrm{i},0)\,, \\ \lambda_4\lambda_4 &= \lambda_5\lambda_5 = \operatorname{diag}(1,0,1)\,, & \lambda_4\lambda_5 &= \operatorname{diag}(\mathrm{i},0,-\mathrm{i})\,, \\ \lambda_6\lambda_6 &= \lambda_7\lambda_7 = \operatorname{diag}(0,1,1)\,, & \lambda_6\lambda_7 &= \operatorname{diag}(0,\mathrm{i},-\mathrm{i})\,, \end{aligned} \tag{A.633}$$

each read straight off Equation (A.631): for instance $\lambda_6\lambda_7 = (E_{23} + E_{32})\,(-\mathrm{i}E_{23} + \mathrm{i}E_{32}) = \mathrm{i}E_{23}E_{32} - \mathrm{i}E_{32}E_{23} = \mathrm{i}E_{22} - \mathrm{i}E_{33}$.

A.34.3 Family (1): three diagonal indices

Here λ_3 and λ_8 commute, so every commutator vanishes and $f_{abc} = 0$ throughout the family. For d the four independent triples are 333, 338, 388, 888, and Equation (A.629) needs only a trace of a product of diagonal matrices:

$$\begin{aligned}
\operatorname{tr}\left(\lambda_3^3\right) &= \operatorname{tr}\operatorname{diag}(1,-1,0) = 0\,,\\
\operatorname{tr}\left(\lambda_3^2\lambda_8\right) &= \operatorname{tr}\left[\operatorname{diag}(1,1,0)\,\tfrac{1}{\sqrt{3}}\operatorname{diag}(1,1,-2)\right] = \tfrac{1}{\sqrt{3}}\,(1+1+0) = \tfrac{2}{\sqrt{3}}\,,\\
\operatorname{tr}\left(\lambda_3\lambda_8^2\right) &= \operatorname{tr}\left[\tfrac{1}{3}\operatorname{diag}(1,-1,0)\operatorname{diag}(1,1,4)\right] = \tfrac{1}{3}\,(1-1+0) = 0\,,\\
\operatorname{tr}\left(\lambda_8^3\right) &= \tfrac{1}{3\sqrt{3}}\operatorname{tr}\operatorname{diag}(1,1,-8) = \tfrac{-6}{3\sqrt{3}} = -\tfrac{2}{\sqrt{3}}\,.
\end{aligned}$$

Halving each, the family contributes

$$d_{333} = d_{388} = 0\,, \qquad d_{338} = \frac{1}{\sqrt{3}}\,, \qquad d_{888} = -\frac{1}{\sqrt{3}}\,. \tag{A.634}$$

A.34.4 Family (2): one diagonal index and one off-diagonal pair

Put the diagonal generator last, so that the trace is that of $(\lambda_a\lambda_b)\,\lambda_\delta$ with a, b in one pair and $\delta \in \{3, 8\}$; the first factor is one of the six diagonal matrices Equation (A.633). There are $3 \times 3 \times 2 = 18$ independent triples — three pairs, three choices of (a, b) up to the symmetries, two diagonal generators — and each is one line. Writing $\lambda_3 = \operatorname{diag}(1,-1,0)$ and $\lambda_8 = \frac{1}{\sqrt{3}}\operatorname{diag}(1,1,-2)$:

Pair $\mathrm{A} = \{1,2\}$*, on* $\operatorname{diag}(\cdot,\cdot,0)$.

$$\begin{aligned}
&\operatorname{tr}(\lambda_1\lambda_1\lambda_3) = \operatorname{tr}\operatorname{diag}(1,-1,0) = 0 && \Rightarrow \quad d_{113} = d_{223} = 0\,,\\
&\operatorname{tr}(\lambda_1\lambda_1\lambda_8) = \tfrac{1}{\sqrt{3}}\operatorname{tr}\operatorname{diag}(1,1,0) = \tfrac{2}{\sqrt{3}} && \Rightarrow \quad d_{118} = d_{228} = \tfrac{1}{\sqrt{3}}\,,\\
&\operatorname{tr}(\lambda_1\lambda_2\lambda_3) = \operatorname{tr}\operatorname{diag}(\mathrm{i},\mathrm{i},0) = 2\mathrm{i} && \Rightarrow \quad d_{123} = 0\,,\ f_{123} = 1\,,\\
&\operatorname{tr}(\lambda_1\lambda_2\lambda_8) = \tfrac{1}{\sqrt{3}}\operatorname{tr}\operatorname{diag}(\mathrm{i},-\mathrm{i},0) = 0 && \Rightarrow \quad d_{128} = f_{128} = 0\,.
\end{aligned}$$

The second line covers $\lambda_2\lambda_2$ as well, since $\lambda_2^2 = \lambda_1^2$ by Equation (A.633).

Pair $\mathrm{B} = \{4,5\}$*, on* $\operatorname{diag}(\cdot,0,\cdot)$.

$$\begin{aligned}
&\operatorname{tr}(\lambda_4\lambda_4\lambda_3) = \operatorname{tr}\operatorname{diag}(1,0,0) = 1 && \Rightarrow \quad d_{344} = d_{355} = \tfrac{1}{2}\,,\\
&\operatorname{tr}(\lambda_4\lambda_4\lambda_8) = \tfrac{1}{\sqrt{3}}\operatorname{tr}\operatorname{diag}(1,0,-2) = -\tfrac{1}{\sqrt{3}} && \Rightarrow \quad d_{448} = d_{558} = -\tfrac{1}{2\sqrt{3}}\,,\\
&\operatorname{tr}(\lambda_4\lambda_5\lambda_3) = \operatorname{tr}\operatorname{diag}(\mathrm{i},0,0) = \mathrm{i} && \Rightarrow \quad d_{345} = 0\,,\ f_{345} = \tfrac{1}{2}\,,\\
&\operatorname{tr}(\lambda_4\lambda_5\lambda_8) = \tfrac{1}{\sqrt{3}}\operatorname{tr}\operatorname{diag}(\mathrm{i},0,2\mathrm{i}) = \mathrm{i}\sqrt{3} && \Rightarrow \quad d_{458} = 0\,,\ f_{458} = \tfrac{\sqrt{3}}{2}\,.
\end{aligned}$$

The last line reproduces the specimen computed in Proposition 14.52.

Pair $\mathrm{C} = \{6,7\}$*, on* $\operatorname{diag}(0,\cdot,\cdot)$.

$$\begin{aligned}
&\operatorname{tr}(\lambda_6\lambda_6\lambda_3) = \operatorname{tr}\operatorname{diag}(0,-1,0) = -1 && \Rightarrow \quad d_{366} = d_{377} = -\tfrac{1}{2}\,,\\
&\operatorname{tr}(\lambda_6\lambda_6\lambda_8) = \tfrac{1}{\sqrt{3}}\operatorname{tr}\operatorname{diag}(0,1,-2) = -\tfrac{1}{\sqrt{3}} && \Rightarrow \quad d_{668} = d_{778} = -\tfrac{1}{2\sqrt{3}}\,,\\
&\operatorname{tr}(\lambda_6\lambda_7\lambda_3) = \operatorname{tr}\operatorname{diag}(0,-\mathrm{i},0) = -\mathrm{i} && \Rightarrow \quad d_{367} = 0\,,\ f_{367} = -\tfrac{1}{2}\,,\\
&\operatorname{tr}(\lambda_6\lambda_7\lambda_8) = \tfrac{1}{\sqrt{3}}\operatorname{tr}\operatorname{diag}(0,\mathrm{i},2\mathrm{i}) = \mathrm{i}\sqrt{3} && \Rightarrow \quad d_{678} = 0\,,\ f_{678} = \tfrac{\sqrt{3}}{2}\,.
\end{aligned}$$

Every entry follows from Equation (A.629) by halving the real part for d and the imaginary part for f; the index order has been rearranged into the one used in Equations (14.69) and (14.70), which is legitimate by Remark A.372 — note that $f_{367} = f_{673}$ and $f_{345} = f_{453}$, both cyclic and therefore sign-preserving.

A.34.5 Family (3): one index from each pair

This family is eight triples (a,b,c) with $a\in\{1,2\}$, $b\in\{4,5\}$, $c\in\{6,7\}$, and all eight fall out of a single observation: in Equation (A.632) only *one* closed walk survives. The first factor lies on the edge 1–2, the second on 1–3, the third on 2–3; a walk $i\to j\to k\to i$ must therefore start with a step of the first edge, and the only choice compatible with the second step lying on 1–3 is $j=1$, hence $i=2$, $k=3$. So

$$\operatorname{tr}(\lambda_a\lambda_b\lambda_c)=(\lambda_a)_{21}\,(\lambda_b)_{13}\,(\lambda_c)_{32}\,, \tag{A.635}$$

and Equation (A.631) supplies the three factors:

$$(\lambda_1)_{21}=1\,,\quad (\lambda_2)_{21}=\mathrm{i}\,,\qquad (\lambda_4)_{13}=1\,,\quad (\lambda_5)_{13}=-\mathrm{i}\,,\qquad (\lambda_6)_{32}=1\,,\quad (\lambda_7)_{32}=\mathrm{i}\,. \tag{A.636}$$

Multiplying out the eight products of Equation (A.636) and halving real and imaginary parts as in Equation (A.629):

$$\begin{aligned}
&\operatorname{tr}(\lambda_1\lambda_4\lambda_6)=1 &&\Rightarrow\ d_{146}=\tfrac12\,,\ f_{146}=0\,, &&\operatorname{tr}(\lambda_2\lambda_4\lambda_6)=\mathrm{i} &&\Rightarrow\ f_{246}=\tfrac12\,,\\
&\operatorname{tr}(\lambda_1\lambda_4\lambda_7)=\mathrm{i} &&\Rightarrow\ f_{147}=\tfrac12\,, &&\operatorname{tr}(\lambda_2\lambda_4\lambda_7)=-1 &&\Rightarrow\ d_{247}=-\tfrac12\,,\\
&\operatorname{tr}(\lambda_1\lambda_5\lambda_6)=-\mathrm{i} &&\Rightarrow\ f_{156}=-\tfrac12\,, &&\operatorname{tr}(\lambda_2\lambda_5\lambda_6)=1 &&\Rightarrow\ d_{256}=\tfrac12\,,\\
&\operatorname{tr}(\lambda_1\lambda_5\lambda_7)=1 &&\Rightarrow\ d_{157}=\tfrac12\,, &&\operatorname{tr}(\lambda_2\lambda_5\lambda_7)=\mathrm{i} &&\Rightarrow\ f_{257}=\tfrac12\,,
\end{aligned} \tag{A.637}$$

the unlisted partner of each entry vanishing. The value $d_{247}=-\frac12$ reproduces the second specimen of Proposition 14.52.

A.34.6 The tables

Collecting Equation (A.634), the three blocks of Appendix A.34.4 and Equation (A.637) gives Tables A.2 and A.3. By Lemma A.373 no triple outside the three families can contribute, and inside them the enumeration was exhaustive; the tables are therefore complete, and reproduce Equations (14.69) and (14.70).

Table A.2: The nine independent nonvanishing components of the antisymmetric structure constants f_{abc} of $\mathfrak{su}(3)$ in the Gell-Mann basis of Definition 14.51, with the family of Lemma A.373 each belongs to and the trace from which it was read. Total antisymmetry generates six nonzero components from each entry, fifty-four in all; every other component vanishes.

abc	f_{abc}	family	generating trace
123	1	(2), pair $\{1,2\}$	$\operatorname{tr}(\lambda_1\lambda_2\lambda_3)=2\mathrm{i}$
147	$\frac12$	(3)	$\operatorname{tr}(\lambda_1\lambda_4\lambda_7)=\mathrm{i}$
156	$-\frac12$	(3)	$\operatorname{tr}(\lambda_1\lambda_5\lambda_6)=-\mathrm{i}$
246	$\frac12$	(3)	$\operatorname{tr}(\lambda_2\lambda_4\lambda_6)=\mathrm{i}$
257	$\frac12$	(3)	$\operatorname{tr}(\lambda_2\lambda_5\lambda_7)=\mathrm{i}$
345	$\frac12$	(2), pair $\{4,5\}$	$\operatorname{tr}(\lambda_4\lambda_5\lambda_3)=\mathrm{i}$
367	$-\frac12$	(2), pair $\{6,7\}$	$\operatorname{tr}(\lambda_6\lambda_7\lambda_3)=-\mathrm{i}$
458	$\frac{\sqrt3}{2}$	(2), pair $\{4,5\}$	$\operatorname{tr}(\lambda_4\lambda_5\lambda_8)=\mathrm{i}\sqrt3$
678	$\frac{\sqrt3}{2}$	(2), pair $\{6,7\}$	$\operatorname{tr}(\lambda_6\lambda_7\lambda_8)=\mathrm{i}\sqrt3$

Two entries of Equation (14.70) deserve a word, because the chapter lists them in an order that hides where they come from. $d_{338}=\frac{1}{\sqrt3}$ is a family-(1) entry, computed from three diagonal matrices, while d_{118} and d_{228} are family-(2) entries computed from $\lambda_1^2=\lambda_2^2=\operatorname{diag}(1,1,0)$; the three come out equal because λ_3^2 equals that same matrix. That coincidence is the reason the chapter can write $d_{118}=d_{228}=d_{338}$ in one line.

Table A.3: The sixteen independent nonvanishing components of the symmetric tensor d_{abc} of $\mathfrak{su}(3)$, grouped by the family of Lemma A.373. Total symmetry generates six equal components from each of the four entries with distinct indices, three from each of the eleven with one repetition, and one from d_{888}: fifty-eight nonvanishing components in all.

abc	d_{abc}	abc	d_{abc}
Family (1): indices in $\{3,8\}$			
338	$\frac{1}{\sqrt{3}}$	888	$-\frac{1}{\sqrt{3}}$
Family (2): one index in $\{3,8\}$*, two in one pair*			
118	$\frac{1}{\sqrt{3}}$	448	$-\frac{1}{2\sqrt{3}}$
228	$\frac{1}{\sqrt{3}}$	558	$-\frac{1}{2\sqrt{3}}$
344	$\frac{1}{2}$	668	$-\frac{1}{2\sqrt{3}}$
355	$\frac{1}{2}$	778	$-\frac{1}{2\sqrt{3}}$
366	$-\frac{1}{2}$	377	$-\frac{1}{2}$
Family (3): one index from each pair			
146	$\frac{1}{2}$	247	$-\frac{1}{2}$
157	$\frac{1}{2}$	256	$\frac{1}{2}$

A.34.7 A Jacobi check

The tables are a computation, and a computation deserves an independent test. The Jacobi identity for the brackets Equation (14.67) is such a test, and it is nontrivial on a triple that involves several different entries at once. Take (T_1, T_4, T_5):

$$[T_1,[T_4,T_5]] + [T_4,[T_5,T_1]] + [T_5,[T_1,T_4]] = 0\,. \tag{A.638}$$

The first inner bracket has *two* nonzero components, which is the trap: $[T_4,T_5] = \mathrm{i} f_{45c} T_c = \mathrm{i}\left(\frac{1}{2}T_3 + \frac{\sqrt{3}}{2}T_8\right)$, by $f_{453} = f_{345} = \frac{1}{2}$ and $f_{458} = \frac{\sqrt{3}}{2}$ from Table A.2. Since $f_{18c} = 0$ for every c — no entry of Table A.2 contains both 1 and 8 — the T_8 piece drops, and with $f_{132} = -f_{123} = -1$,

$$[T_1,[T_4,T_5]] = \frac{\mathrm{i}}{2}\,[T_1,T_3] = \frac{\mathrm{i}}{2}\,(\mathrm{i} f_{132} T_2) = \frac{\mathrm{i}}{2}\,(-\mathrm{i} T_2) = \frac{1}{2}\,T_2\,.$$

For the second term, $f_{516} = -f_{156} = \frac{1}{2}$ gives $[T_5,T_1] = \frac{\mathrm{i}}{2}T_6$, and $f_{462} = f_{246} = \frac{1}{2}$ gives

$$[T_4,[T_5,T_1]] = \frac{\mathrm{i}}{2}\,[T_4,T_6] = \frac{\mathrm{i}}{2}\left(\frac{\mathrm{i}}{2}T_2\right) = -\frac{1}{4}\,T_2\,.$$

For the third, $f_{147} = \frac{1}{2}$ gives $[T_1,T_4] = \frac{\mathrm{i}}{2}T_7$, and $f_{572} = f_{257} = \frac{1}{2}$ gives

$$[T_5,[T_1,T_4]] = \frac{\mathrm{i}}{2}\,[T_5,T_7] = \frac{\mathrm{i}}{2}\left(\frac{\mathrm{i}}{2}T_2\right) = -\frac{1}{4}\,T_2\,.$$

The three add to $\left(\frac{1}{2} - \frac{1}{4} - \frac{1}{4}\right)T_2 = 0$, so Equation (A.638) holds. The check consumes f_{123}, f_{147}, f_{156}, f_{246}, f_{257}, f_{345} and f_{458} — seven of the nine independent entries, drawn from both families that carry a nonzero f — and it fails if any one of them is altered. Had the f_{453} contribution to $[T_4,T_5]$ been overlooked, leaving only the f_{458} piece that the chapter's specimen computes, the identity would have returned $-\frac{1}{2}T_2$ instead of zero.

Remark A.374. Tables A.2 and A.3 discharge the tabulation asserted in Proposition 14.52 and used throughout Chapter 14: in Proposition 14.53, where the entry $\kappa_{33} = 3$ is checked against

the f_{3cd} read off Table A.2; in Proposition 14.54, whose cubic Casimir $C_3 = d_{abc}T_aT_bT_c$ is built from Table A.3 and whose invariance identity Equation (14.76) couples the two tables; and in Proposition 14.55, where the adjoint generators are $\left(T_a^{\mathrm{ad}}\right)_{bc} = -\mathrm{i}f_{abc}$. The completeness established by Lemma A.373 is what licenses the sums over c and d in those places to be evaluated by listing the entries of the tables and stopping.

A.35 Simplicity of $\mathfrak{su}(3)$

This appendix proves what Chapter 14 quotes in two places: that $\mathfrak{su}(3)$ is a simple Lie algebra. The statement is used in Proposition 14.53, where the nondegeneracy of the Killing form is announced as the semisimplicity demanded by Theorem 14.13, and — more substantially — in Theorem 14.57, whose proof identifies the eight-dimensional summand of $\mathbf{3} \otimes \bar{\mathbf{3}}$ with the adjoint representation and calls it irreducible *because an invariant subspace would be an ideal of a simple Lie algebra.* That last inference is what is discharged here.

The proof is the standard one and is short: complexify, split a putative ideal into eigenspaces of the two-dimensional Cartan subalgebra, and then walk around the root hexagon of Equation (14.80), using the fact that any two roots at 120 degrees add to a third. A single root vector inside the ideal therefore drags in all six, and with them the Cartan directions.

Two remarks on what is *not* used, because both matter for circularity. First, nothing below quotes the classification of simple Lie algebras; only Definition 14.51 and the multiplication table of the 3×3 matrix units enter. Second, nothing below uses Proposition 14.53. That is deliberate: the chapter computes the Killing form of $\mathfrak{su}(3)$ *directly*, precisely so as not to lean on the uniqueness of an invariant form on a simple algebra, and the present appendix repays the compliment by not leaning on the Killing form.

A.35.1 Statement

Definition A.375 (Simple Lie algebra)**.** A Lie algebra $\mathfrak{g}$ over a field is *simple* if it is not abelian and its only ideals are $\{0\}$ and $\mathfrak{g}$ itself; an *ideal* is a subspace $\mathfrak{i}$ with $[\mathfrak{g}, \mathfrak{i}] \subseteq \mathfrak{i}$.
Rests on Definition 14.49.

Theorem A.376 ($\mathfrak{su}(3)$ is simple)**.** *The real Lie algebra $\mathfrak{su}(3)$ of Definition 14.49 is simple, and so is its complexification $\mathfrak{sl}(3,\mathbb{C})$, the algebra of traceless complex 3×3 matrices.*
Rests on Definitions 14.49 and A.375 and Proposition 14.50.

Corollary A.377 (The adjoint representation is irreducible)**.** *The adjoint representation of $\mathfrak{su}(3)$ on itself, and equally the representation $M \mapsto UMU^\dagger$ of $\mathrm{SU}(3)$ on the traceless complex 3×3 matrices, has no invariant subspace other than $\{0\}$ and the whole space.*
Rests on Theorem A.376 and Proposition 14.55.

A.35.2 Complexification

Lemma A.378 (Real ideals and complex ideals)**.** *As a real vector space,*

$$\mathfrak{sl}(3,\mathbb{C}) = \mathfrak{su}(3) \oplus \mathrm{i}\,\mathfrak{su}(3)\,, \tag{A.639}$$

the sum being direct. If $\mathfrak{i} \subseteq \mathfrak{su}(3)$ is an ideal of the real algebra, then $\mathfrak{i}_{\mathbb{C}} = \mathfrak{i} + \mathrm{i}\,\mathfrak{i}$ is a complex ideal of $\mathfrak{sl}(3,\mathbb{C})$ with $\dim_{\mathbb{C}} \mathfrak{i}_{\mathbb{C}} = \dim_{\mathbb{R}} \mathfrak{i}$.
Rests on Definition 14.49 and Proposition 14.50.

Proof. *Derives Lemma A.378.*

The splitting. Let X be traceless. Put $X_- = \frac{1}{2}\left(X - X^\dagger\right)$ and $X_+ = \frac{1}{2}\left(X + X^\dagger\right)$, so that $X = X_- + X_+$. Both are traceless, since $\operatorname{tr} X^\dagger = \overline{\operatorname{tr} X} = 0$; X_- is anti-Hermitian,

hence in $\mathfrak{su}(3)$ by Definition 14.49; and X_+ is Hermitian, so $-\mathrm{i}X_+$ is anti-Hermitian and $X_+ = \mathrm{i}\,(-\mathrm{i}X_+) \in \mathrm{i}\,\mathfrak{su}(3)$. The sum is direct: if $Y \in \mathfrak{su}(3) \cap \mathrm{i}\,\mathfrak{su}(3)$, write $Y = \mathrm{i}Z$ with Z anti-Hermitian; then $Y^\dagger = -\mathrm{i}Z^\dagger = \mathrm{i}Z = Y$, so Y is Hermitian as well as anti-Hermitian, and $Y = 0$.

Ideals. The bracket of $\mathfrak{sl}(3,\mathbb{C})$ is $\mathbb{C}$-bilinear, so for $X = A + \mathrm{i}B$ with $A, B \in \mathfrak{su}(3)$ and $Y = P + \mathrm{i}Q$ with $P, Q \in \mathfrak{i}$,

$$[X,Y] = ([A,P] - [B,Q]) + \mathrm{i}\,([A,Q] + [B,P])\ ,$$

and all four brackets lie in $\mathfrak{i}$ because $\mathfrak{i}$ is an ideal of $\mathfrak{su}(3)$. So $[X,Y] \in \mathfrak{i}_{\mathbb{C}}$, and $\mathfrak{i}_{\mathbb{C}}$ is closed under multiplication by i hence a complex subspace. Finally $\mathfrak{i} \cap \mathrm{i}\,\mathfrak{i} = 0$, being contained in $\mathfrak{su}(3) \cap \mathrm{i}\,\mathfrak{su}(3) = 0$, so $\mathfrak{i}_{\mathbb{C}} = \mathfrak{i} \oplus \mathrm{i}\,\mathfrak{i}$ has real dimension $2\dim_{\mathbb{R}}\mathfrak{i}$ and complex dimension $\dim_{\mathbb{R}}\mathfrak{i}$. □

A.35.3 The root decomposition

Write E_{jk} for the matrix unit with a single 1 in row j and column k, so that $E_{jk}E_{lm} = \delta_{kl}E_{jm}$. Let

$$\mathfrak{h} = \{\mathrm{diag}(a_1,a_2,a_3) \mid a_1 + a_2 + a_3 = 0\}\ , \tag{A.640}$$

the traceless diagonal matrices, which is two-dimensional and is the complex span of the T_3 and T_8 of Definition 14.51; it is the Cartan subalgebra whose existence Proposition 14.50 established, of rank $\ell = 2$. For $H = \mathrm{diag}(a_1,a_2,a_3)$ a one-line computation with the matrix units gives

$$[H, E_{jk}] = (a_j - a_k)\,E_{jk}\,, \qquad j \neq k\,, \tag{A.641}$$

so that $\mathfrak{sl}(3,\mathbb{C})$ decomposes as

$$\mathfrak{sl}(3,\mathbb{C}) = \mathfrak{h} \oplus \bigoplus_{j\neq k} \mathbb{C}\,E_{jk}\,, \tag{A.642}$$

a direct sum of $2 + 6 = 8$ pieces, each an eigenspace of every ad_H, and each of the six off-diagonal pieces one-dimensional. The linear functional $\alpha_{jk} \in \mathfrak{h}^*$, $\alpha_{jk}(H) = a_j - a_k$, is the *root* carried by E_{jk}.

Remark A.379 (These are the six vectors of the hexagon). Evaluating α_{jk} on the two Cartan generators of Definition 14.51 gives the coordinates used in Remark 14.56. With $T_3 = \frac{1}{2}\,\mathrm{diag}(1,-1,0)$ and $T_8 = \frac{1}{2\sqrt{3}}\,\mathrm{diag}(1,1,-2)$,

$$E_{12} : (\alpha(T_3),\alpha(T_8)) = (1,0)\,,\quad E_{13} : \left(\tfrac{1}{2},\tfrac{\sqrt{3}}{2}\right)\,,\quad E_{23} : \left(-\tfrac{1}{2},\tfrac{\sqrt{3}}{2}\right)\,, \tag{A.643}$$

and E_{21}, E_{31}, E_{32} carry the negatives. These are exactly the six vectors of Equation (14.80): unit vectors at 60 degrees to one another, the regular hexagon. What the proof below uses is the one geometric property that hexagon has, namely that the sum of two roots at 120 degrees is again a root — $|\gamma| = |\delta| = 1$ and $\gamma\cdot\delta = -\frac{1}{2}$ give $|\gamma+\delta|^2 = 1$, and the sum bisects the angle. In matrix units that property reads $[E_{jk}, E_{kl}] = E_{jl}$ for j,k,l distinct, which is the form in which it will be applied.

Lemma A.380 (An ideal is a sum of eigenspaces)**.** *Let $\mathfrak{i}$ be an ideal of $\mathfrak{sl}(3,\mathbb{C})$ and let $x = h + \sum_{j\neq k} c_{jk}E_{jk} \in \mathfrak{i}$ be the decomposition of an element according to Equation (A.642). Then $h \in \mathfrak{i}$ and $c_{jk}E_{jk} \in \mathfrak{i}$ for every pair; in particular each E_{jk} with $c_{jk} \neq 0$ lies in $\mathfrak{i}$.*

Rests on Equation (A.642) and Definition A.375.

Proof. *Derives Lemma A.380.*

Take the particular Cartan element $H_0 = \mathrm{diag}(3,-1,-2) \in \mathfrak{h}$. Its six root values are

$$\alpha_{12}(H_0) = 4\,,\quad \alpha_{13}(H_0) = 5\,,\quad \alpha_{23}(H_0) = 1\,, \tag{A.644}$$

together with $-4, -5, -1$: six *distinct and nonzero* numbers, which is the only property of H_0 that is used. Enumerate the six ordered pairs as $\mu = 1, \dots, 6$, write E_μ for the corresponding matrix unit and $\lambda_\mu \in \{\pm 1, \pm 4, \pm 5\}$ for its root value, so that $x = h + \sum_\mu c_\mu E_\mu$. Because $\mathfrak{i}$ is an ideal and $[H_0, h] = 0$, all six elements

$$\operatorname{ad}_{H_0}^n x = \sum_\mu \lambda_\mu^n \, c_\mu E_\mu \in \mathfrak{i}\,, \qquad n = 1, \dots, 6\,,$$

lie in $\mathfrak{i}$, by Equation (A.641). The 6×6 coefficient matrix $\left(\lambda_\mu^n\right)$ has determinant $\left(\prod_\mu \lambda_\mu\right)$ times the Vandermonde determinant $\prod_{\mu<\nu}(\lambda_\nu - \lambda_\mu)$, which is nonzero because the λ_μ are nonzero and pairwise distinct. Inverting it expresses each $c_\mu E_\mu$ as a linear combination of the $\operatorname{ad}_{H_0}^n x$, so $c_\mu E_\mu \in \mathfrak{i}$; and then $h = x - \sum_\mu c_\mu E_\mu \in \mathfrak{i}$. Since $\mathbb{C}E_\mu$ is one-dimensional, $c_\mu \neq 0$ forces $E_\mu \in \mathfrak{i}$. □

A.35.4 Walking round the hexagon

Lemma A.381 (One root vector generates everything)**.** *Let $\mathfrak{i}$ be an ideal of $\mathfrak{sl}(3, \mathbb{C})$ containing E_{jk} for one pair $j \neq k$. Then $\mathfrak{i} = \mathfrak{sl}(3, \mathbb{C})$.*
Rests on Equations (A.641) and (A.642).

Proof. *Derives Lemma A.381.*

Let l be the remaining index, so that $\{j, k, l\} = \{1, 2, 3\}$. Every bracket below is a bracket of an element of $\mathfrak{sl}(3, \mathbb{C})$ with an element of $\mathfrak{i}$, and therefore lies in $\mathfrak{i}$.

The opposite root vector. From $E_{kj}E_{jk} = E_{kk}$ and $E_{jk}E_{kj} = E_{jj}$,

$$[E_{jk}, E_{kj}] = E_{jj} - E_{kk} =: H_{jk} \in \mathfrak{i}\,, \tag{A.645}$$

and H_{jk} is the diagonal matrix with entries $+1$ at j, -1 at k and 0 at l, so Equation (A.641) gives $[H_{jk}, E_{kj}] = (-1-1)E_{kj} = -2E_{kj}$. Hence $E_{kj} \in \mathfrak{i}$. In the language of Remark A.379: the root γ and the coroot direction it generates carry the ideal to $-\gamma$, the opposite vertex of the hexagon.

The two neighbouring roots. Because $k \neq l$ and $l \neq j$,

$$[E_{lj}, E_{jk}] = E_{lk} \in \mathfrak{i}\,, \qquad [E_{jk}, E_{kl}] = E_{jl} \in \mathfrak{i}\,, \tag{A.646}$$

the second term of each commutator vanishing — $E_{jk}E_{lj} = 0$ since $k \neq l$, and $E_{kl}E_{jk} = 0$ since $l \neq j$. These are the two roots at 60 degrees from the starting one, reached by adding the roots of E_{lj} and of E_{kl}, each at 120 degrees to it.

Closing. Apply the first step to E_{lk} and to E_{jl}: it returns $E_{kl}, H_{lk} \in \mathfrak{i}$ and $E_{lj}, H_{jl} \in \mathfrak{i}$. All six matrix units are now in $\mathfrak{i}$, which is the whole hexagon. The diagonal part follows from Equation (A.645): $H_{jk} = E_{jj} - E_{kk}$ and $H_{lk} = E_{ll} - E_{kk}$ are linearly independent elements of the two-dimensional $\mathfrak{h}$ of Equation (A.640), so they span it. By Equation (A.642), $\mathfrak{i} = \mathfrak{sl}(3, \mathbb{C})$. □

A.35.5 Proof of the theorem

Proof of Theorem A.376. *Derives Theorem A.376.*

The complex algebra. $\mathfrak{sl}(3, \mathbb{C})$ is not abelian, since $[E_{12}, E_{21}] = E_{11} - E_{22} \neq 0$. Let $\mathfrak{i} \neq \{0\}$ be an ideal and pick $x \in \mathfrak{i}$ nonzero. By Lemma A.380 either some E_{jk} lies in $\mathfrak{i}$ — in which case $\mathfrak{i} = \mathfrak{sl}(3, \mathbb{C})$ by Lemma A.381 — or every c_{jk} vanishes for every element of $\mathfrak{i}$, so that $\mathfrak{i} \subseteq \mathfrak{h}$ and $x = h \neq 0$ is a nonzero traceless diagonal matrix. In that second case Equation (A.641) gives $[h, E_{jk}] = \alpha_{jk}(h)\, E_{jk} \in \mathfrak{i}$; the right-hand side lies in $\mathbb{C}E_{jk}$, which meets $\mathfrak{h}$ only in 0, so $\alpha_{jk}(h) = 0$ for all six pairs. Writing $h = \operatorname{diag}(a_1, a_2, a_3)$ this reads $a_1 = a_2 = a_3$, which with $\sum a_i = 0$ gives $h = 0$ — contradicting the choice of x. (Equivalently: the roots

Equation (A.643) span $\mathfrak{h}^*$, since $(1,0)$ and $\left(-\frac{1}{2},\frac{\sqrt{3}}{2}\right)$ are independent, so a Cartan element annihilated by all of them is zero.) The second case is therefore empty, and $\mathfrak{sl}(3,\mathbb{C})$ is simple.

The real algebra. $\mathfrak{su}(3)$ is not abelian: the generators T_1, T_2, T_3 of Definition 14.51 satisfy $[T_1, T_2] = \mathrm{i}T_3 \neq 0$ by Equation (14.69), and $\mathrm{i}T_a$ is the anti-Hermitian element of $\mathfrak{su}(3)$ attached to the Hermitian generator T_a. Let $\mathfrak{i} \neq \{0\}$ be an ideal of $\mathfrak{su}(3)$. By Lemma A.378, $\mathfrak{i}_{\mathbb{C}}$ is a nonzero complex ideal of $\mathfrak{sl}(3,\mathbb{C})$, hence all of it by the previous paragraph, so

$$\dim_{\mathbb{R}} \mathfrak{i} = \dim_{\mathbb{C}} \mathfrak{i}_{\mathbb{C}} = \dim_{\mathbb{C}} \mathfrak{sl}(3,\mathbb{C}) = 8 = \dim_{\mathbb{R}} \mathfrak{su}(3)\,,$$

the last equality being Proposition 14.50. A subspace of full dimension is the whole space, so $\mathfrak{i} = \mathfrak{su}(3)$. □

Proof of Corollary A.377. *Derives Corollary A.377.*

An invariant subspace V of the adjoint representation of a Lie algebra $\mathfrak{g}$ on itself satisfies $[\mathfrak{g}, V] \subseteq V$ by definition, which is exactly the statement that V is an ideal (Definition A.375); so Theorem A.376 leaves only $\{0\}$ and $\mathfrak{su}(3)$.

For the group statement, note first that the space of traceless complex 3×3 matrices is $\mathfrak{sl}(3,\mathbb{C})$ and that $M \mapsto UMU^\dagger = UMU^{-1}$ is the adjoint action of SU(3) on it, as Proposition 14.55 and the proof of Theorem 14.57 record. A subspace V invariant under the group is invariant under the algebra: for $X \in \mathfrak{su}(3)$ and $M \in V$, the curve $t \mapsto \mathrm{e}^{tX} M \mathrm{e}^{-tX}$ lies in V, which is a closed subspace of a finite-dimensional space, and its derivative at $t = 0$ is $[X, M]$, so $[X, M] \in V$. Complex-linearity extends this from $\mathfrak{su}(3)$ to $\mathfrak{sl}(3,\mathbb{C})$ by Equation (A.639), and the first paragraph applies. □

Remark A.382. Theorem A.376 discharges the two quotations named at the head of this section. In Proposition 14.53 it justifies the phrase "which is simple and hence semisimple": the Killing form $\kappa_{ab} = 3\delta_{ab}$ computed there is nondegenerate, as Theorem 14.13 requires of a semisimple algebra, and the implication now runs in the direction the chapter states rather than resting on an unproved assertion. In Theorem 14.57 it supplies the irreducibility of the eight-dimensional summand of $\mathbf{3} \otimes \bar{\mathbf{3}}$, so that the decomposition $3 \times 3 = 1 + 8$ of Equation (14.81) is proved and not merely counted; Corollary A.377 is the form in which it is used there.

One limitation is worth stating plainly. What is proved is the simplicity of this one algebra, by an argument that inspects its root system directly. The general theorem — that a complex simple Lie algebra is determined by its root system, and that the possible root systems are the classified Dynkin diagrams — is not proved here and is not needed: the whole of Chapter 14 uses $\mathfrak{su}(2)$ and $\mathfrak{su}(3)$ and nothing else, and both are handled by hand.

A.36 From the Little Algebra to the Labels of a Massive Representation

This appendix supplies the step left owed after Lemma 14.68 of Chapter 14: the passage from the *algebra* that fixes a timelike momentum to the *count of labels* of a massive irreducible representation of the inhomogeneous algebra, and with it the arithmetic of Equation (14.107),

$$1 + \left\lfloor \frac{D-1}{2} \right\rfloor = \left\lceil \frac{D}{2} \right\rceil . \tag{A.647}$$

What Lemma 14.68 establishes is that the subalgebra annihilating a timelike p is $\mathfrak{so}(D-1)$, of rank $\lfloor (D-1)/2 \rfloor$. What is owed is the representation theory that converts a rank into a count: that a massive irreducible representation is determined by the mass *together with* an irreducible representation of that subalgebra, and that no further invariant of the enveloping algebra escapes those labels.

The construction is Wigner's method of induced representations [849]. Chapter 94 carries it out in the observed four dimensions — Theorem 94.27 is the construction and Theorem 94.29 the result — and this appendix does the same in general D, with two differences of emphasis: the geometric ingredients (transitivity of the Lorentz group on the mass shell, the standard boost, the invariant measure) are proved here rather than quoted, and the arithmetic of the label count is separated cleanly from the classification theorem it rests on. That classification theorem is the one genuine import, and Remark A.393 says exactly what it is.

Under rule 7 of this treatise the general-D statement is the natural mathematical one and is stated as such; every worked instantiation below is $3+1$.

A.36.1 Conventions, and what is assumed

Indices $A, B, \dots$ run from 1 to D and $\eta_{AB} = \mathrm{diag}(+1, \dots, +1, -1)$ is the flat metric of signature $(D-1, 1)$ in the ordering of Notation 14.1, so that the time direction is the last one and $x^D = ct$, as in Remark 14.88. A vector p is *timelike* when $\eta_{AB} p^A p^B < 0$, which is the convention of Lemma 14.68.

The symmetry group is the connected inhomogeneous group

$$G = \mathbb{R}^D \rtimes \mathrm{SO}(D-1,1)^{\uparrow}, \qquad (\Lambda', a')(\Lambda, a) = (\Lambda'\Lambda,\ a' + \Lambda' a), \tag{A.648}$$

whose Lie algebra is $\mathfrak{iso}(D-1,1)$ of Equation (14.99), with brackets Equations (14.84), (14.90) and (14.97); the translation a carries the SI unit m. A quantum symmetry is a projective unitary representation, and by Theorem 94.3 — proved in Appendix A.9 — each symmetry is implemented by a unitary or antiunitary operator unique up to a phase, while Corollary 94.4 rules out the antiunitary branch for a connected group. Bargmann's analysis then replaces the projective representations of G by the ordinary unitary representations of its universal cover $\tilde{G}$ [1029], whose Lorentz factor is $\mathrm{Spin}(D-1,1)$. Everything below is written for G; for the half-integer labels every Λ is read as its lift to $\mathrm{Spin}(D-1,1)$ and every little-group element as an element of $\mathrm{Spin}(D-1)$, exactly as Theorem 94.27 does in four dimensions.

The generators are normalized as in Remark 14.66: with $P_A = \partial_A$ from Equation (14.82) the momentum operator is $\hat{P}_A = -\mathrm{i}\hbar P_A$, of SI unit kg m/s, and with J_{AB} from Equation (14.86) the angular-momentum operator is $\hat{J}_{AB} = -\mathrm{i}\hbar J_{AB}$, of unit J s.

Remark A.383 (A sign of signature). In the mostly-plus ordering fixed above, a timelike momentum satisfies $\eta_{AB} p^A p^B = -m^2c^2$ and therefore $\hat{P}^2 = -m^2c^2$ on a momentum eigenstate. Equation (14.105) records the same content with the opposite overall sign, being written in the mostly-minus convention customary in Chapter 94; the two differ by $\eta \mapsto -\eta$ and nothing else. Only $\left|\hat{P}^2\right| = m^2c^2$ is used below, and the ratio Equation (14.106) is unaffected by the choice, both invariants changing sign together.

A.36.2 Statement

Definition A.384 (The mass shell and the standard momentum)**.** For $m > 0$ put

$$\mathcal{M}_m = \left\{ p \in \mathbb{R}^D \mid \eta_{AB} p^A p^B = -m^2c^2,\ p^D > 0 \right\}, \qquad k^A = mc\,\delta^A_D, \tag{A.649}$$

so that $k \in \mathcal{M}_m$ is the rest momentum, of components $\boldsymbol{p} = 0$ and $p^D = mc$. The *little group* is the stabilizer $G_k = \left\{ \Lambda \in \mathrm{SO}(D-1,1)^{\uparrow} \mid \Lambda k = k \right\}$.

Rests on Notation 14.1 and Lemma 14.68.

Theorem A.385 (Labels of a massive representation)**.** *Let $D \geq 4$ and $m > 0$. The unitary equivalence classes of irreducible, strongly continuous, positive-energy unitary representations*

U of $\tilde{G}$ with $\hat{P}^2 = -m^2c^2\,\mathbb{1}$ are in bijection with the unitary equivalence classes of irreducible unitary representations σ of $\mathrm{Spin}(D-1)$*, the bijection being $U \cong U^{(m,\sigma)}$ with $U^{(m,\sigma)}$ the induced representation Equation (A.654) below. Consequently the class of U is fixed by the mass m together with the $\lfloor (D-1)/2 \rfloor$ invariant labels of σ furnished by Theorem 14.21, and by no fewer numbers; a massive irreducible representation therefore carries exactly $\lceil D/2 \rceil$ labels, which is Equation (A.647). Every central element of the enveloping algebra acts on U as a scalar that is a function of those labels.*

Rests on Lemma 14.68, Theorem 14.21, and Definition A.384.

The bijection itself — the classification — is the imported ingredient; the geometry that makes it meaningful, the construction of $U^{(m,\sigma)}$, and the arithmetic of the count are proved here.

A.36.3 The geometry of the mass shell

Lemma A.386 (The little group)**.** *$G_k = \mathrm{SO}(D-1)$, acting on the first $D-1$ coordinates, and its Lie algebra is the $\mathfrak{so}(D-1)$ of Lemma 14.68. It is compact.*

Rests on Definition A.384, Equation (14.23), and Lemma 14.68.

Proof. *Derives Lemma A.386.*

Let $\Lambda k = k$, that is $\Lambda e_D = e_D$ where e_D is the unit vector in the time direction. Since Λ preserves η, it preserves the orthogonal complement $e_D^{\perp} = \mathbb{R}^{D-1}$, on which η restricts to the Euclidean metric; so the restriction lies in $\mathrm{O}(D-1)$. Its determinant equals $\det \Lambda = 1$ because Λ acts as the identity on the remaining direction, whence $\Lambda|_{\mathbb{R}^{D-1}} \in \mathrm{SO}(D-1)$; conversely every such rotation, extended by $e_D \mapsto e_D$, preserves η, has determinant 1 and is orthochronous. Compactness is that of a closed bounded subset of $\mathbb{R}^{(D-1)\times(D-1)}$: the rows of an orthogonal matrix are unit vectors, and orthogonality is a closed condition. Differentiating a curve through the identity gives exactly the subalgebra of Lemma 14.68, namely the elements of $\mathfrak{so}(D-1,1)$ annihilating k. □

Lemma A.387 (Standard boost and transitivity)**.** *For $p \in \mathcal{M}_m$ write $\boldsymbol{p} = (p^1, \dots, p^{D-1})$ and $|\boldsymbol{p}|$ for its Euclidean length, so that $p^D = \sqrt{|\boldsymbol{p}|^2 + m^2c^2}$. The matrix*

$$L(p)^i{}_j = \delta^i{}_j + \frac{p^i p^j}{|\boldsymbol{p}|^2}\left(\frac{p^D}{mc} - 1\right), \qquad L(p)^i{}_D = L(p)^D{}_i = \frac{p^i}{mc}, \qquad L(p)^D{}_D = \frac{p^D}{mc}, \tag{A.650}$$

with $i, j = 1, \dots, D-1$, is a proper orthochronous Lorentz transformation, depends continuously on p with $L(k) = \mathbb{1}$, and satisfies $L(p)k = p$. In particular $\mathrm{SO}(D-1,1)^{\uparrow}$ acts transitively on $\mathcal{M}_m$, and $\mathcal{M}_m$ is a single orbit.

Rests on Definition A.384 and Equation (14.23).

Proof. *Derives Lemma A.387.*

Put $\hat{n}^i = p^i/|\boldsymbol{p}|$, $\cosh\zeta = p^D/(mc)$ and $\sinh\zeta = |\boldsymbol{p}|/(mc)$; these are consistent because $\cosh^2\zeta - \sinh^2\zeta = \left((p^D)^2 - |\boldsymbol{p}|^2\right)/(mc)^2 = 1$ by Equation (A.649), and $\zeta \geq 0$ is determined. In these terms Equation (A.650) reads

$$L(p) = \mathbb{1} + (\cosh\zeta - 1)\left(\hat{n}\hat{n}^{\mathsf{T}} + e_D\, e_D^{\mathsf{T}}\right) + \sinh\zeta\left(\hat{n}\, e_D^{\mathsf{T}} + e_D\, \hat{n}^{\mathsf{T}}\right), \tag{A.651}$$

$\hat{n}$ being regarded as a vector in $\mathbb{R}^D$ with vanishing last component. Reading off the entries confirms that this is Equation (A.650): the $\hat{n}\hat{n}^{\mathsf{T}}$ term gives $L^i{}_j$, the two mixed terms give $L^i{}_D = L^D{}_i = \sinh\zeta\,\hat{n}^i = p^i/(mc)$, and the $e_D e_D^{\mathsf{T}}$ term raises $L^D{}_D$ from 1 to $\cosh\zeta = p^D/(mc)$. It is the identity on the $(D-2)$-dimensional subspace orthogonal to both $\hat{n}$ and e_D, and on the plane they span it is $\begin{pmatrix} \cosh\zeta & \sinh\zeta \\ \sinh\zeta & \cosh\zeta \end{pmatrix}$ in the basis $(\hat{n}, e_D)$. Restricted

to that plane η is $\mathrm{diag}(+1,-1)$, and $\cosh^2\zeta-\sinh^2\zeta=1$ is exactly the statement that the matrix preserves it; on the complement $L(p)$ is the identity and the two blocks are η-orthogonal. So Equation (14.23) holds at the group level and $L(p)\in \mathrm{O}(D-1,1)$. Its determinant is $\cosh^2\zeta-\sinh^2\zeta=1$ and its (D,D) entry is $\cosh\zeta\geq 1>0$, so it is proper and orthochronous.

It maps k to p. From Equation (A.650), $(L(p)k)^i=L(p)^i{}_D\,mc=p^i$ and $(L(p)k)^D=L(p)^D{}_D\,mc=p^D$.

Continuity at $\boldsymbol{p}=0$. The only term in Equation (A.650) whose form is singular there is $p^ip^j\left(p^D/(mc)-1\right)/|\boldsymbol{p}|^2$, and

$$\frac{p^D}{mc}-1=\frac{\sqrt{|\boldsymbol{p}|^2+m^2c^2}-mc}{mc}=\frac{|\boldsymbol{p}|^2}{mc\left(\sqrt{|\boldsymbol{p}|^2+m^2c^2}+mc\right)},$$

so the quotient by $|\boldsymbol{p}|^2$ is bounded and tends to 0; the whole term vanishes with $\boldsymbol{p}$, leaving $L(k)=\mathbb{1}$. The remaining entries are manifestly continuous.

Transitivity. For $p,q\in\mathcal{M}_m$ the element $L(q)L(p)^{-1}$ is in $\mathrm{SO}(D-1,1)^\uparrow$ and carries p to q. Conversely a Lorentz transformation preserves $\eta_{AB}p^Ap^B$, and an orthochronous one preserves the sign of p^D on timelike vectors, so it maps $\mathcal{M}_m$ into itself. □

Lemma A.388 (The invariant measure)**.** *The measure*

$$\mathrm{d}\mu(p)=\frac{\mathrm{d}^{D-1}\boldsymbol{p}}{p^D},\qquad p^D=\sqrt{|\boldsymbol{p}|^2+m^2c^2},\tag{A.652}$$

on $\mathcal{M}_m$ is invariant under $\mathrm{SO}(D-1,1)^\uparrow$.

Rests on Definition A.384 and Lemma A.387.

Proof. *Derives Lemma A.388.*

Consider on $\mathbb{R}^D$ the measure

$$\mathrm{d}\nu(p)=\mathrm{d}^Dp\;\delta\left(\eta_{AB}p^Ap^B+m^2c^2\right)\theta\left(p^D\right),$$

with θ the unit step. Every factor is invariant: d^Dp because $|\det\Lambda|=1$, the delta because its argument is a Lorentz scalar, and the step because Λ is orthochronous. Now carry out the p^D integration. Writing $f(p^D)=|\boldsymbol{p}|^2-(p^D)^2+m^2c^2$, the only zero with $p^D>0$ is $p^D=\sqrt{|\boldsymbol{p}|^2+m^2c^2}$, at which $|f'|=2p^D$; so $\delta(f)\,\theta(p^D)\,\mathrm{d}p^D$ integrates to $1/\left(2p^D\right)$ and $\mathrm{d}\nu=\mathrm{d}^{D-1}\boldsymbol{p}/(2p^D)=\frac{1}{2}\mathrm{d}\mu$. A constant multiple of an invariant measure is invariant. □

Remark A.389 (The SI dimension of the measure). Each p^i carries the unit $\mathrm{kg\,m/s}$, so $\mathrm{d}\mu$ of Equation (A.652) carries $(\mathrm{kg\,m/s})^{D-2}$; in the observed $D=4$ that is $\mathrm{kg^2\,m^2/s^2}$. A wave function on the mass shell therefore carries the reciprocal of the square root of that unit, so that $\int\mathrm{d}\mu(p)\,|\psi(p)|^2$ is a pure number, as a probability must be. One may of course divide $\mathrm{d}\mu$ by $(mc)^{D-2}$ to obtain a dimensionless measure; nothing below depends on the choice, and the unnormalized form is kept because it is the one in which Lemma A.388 is transparent.

A.36.4 The induced representation

Proposition A.390 (Construction)**.** *Let σ be a unitary representation of $G_k=\mathrm{SO}(D-1)$ — or of $\mathrm{Spin}(D-1)$, for the covering group — on a finite-dimensional Hilbert space V_σ. On*

$$\mathcal{H}_\sigma=L^2(\mathcal{M}_m,\mathrm{d}\mu;V_\sigma)\tag{A.653}$$

define, for $a \in \mathbb{R}^D$ *and* $\Lambda \in \mathrm{SO}(D-1,1)^{\uparrow}$,

$$\left(U^{(m,\sigma)}(\mathbb{1},a)\psi\right)(p) = \mathrm{e}^{-\mathrm{i}\,\eta_{AB}p^A a^B/\hbar}\,\psi(p)\,, \qquad \left(U^{(m,\sigma)}(\Lambda,0)\psi\right)(p) = \sigma\Big(W(\Lambda,\Lambda^{-1}p)\Big)\,\psi\Big(\Lambda^{-1}p\Big)\,, \tag{A.654}$$

with the Wigner rotation

$$W(\Lambda,q) = L(\Lambda q)^{-1}\,\Lambda\,L(q)\,, \qquad q \in \mathcal{M}_m\,, \tag{A.655}$$

and $U^{(m,\sigma)}(\Lambda,a) = U^{(m,\sigma)}(\mathbb{1},a)\,U^{(m,\sigma)}(\Lambda,0)$. *Then* $W(\Lambda,q) \in G_k$, *and* $U^{(m,\sigma)}$ *is a strongly continuous unitary representation of* G *with*

$$\hat{P}_A\psi(p) = p_A\,\psi(p)\,, \qquad \hat{P}^2 = -m^2c^2\,\mathbb{1}\,, \tag{A.656}$$

and positive energy, $p^D > 0$ *throughout the spectrum.*

Rests on Lemmas A.386 to A.388.

Proof. *Derives Proposition A.390.*

The Wigner rotation lies in the little group. Using $L(q)k = q$ from Lemma A.387,

$$W(\Lambda,q)\,k = L(\Lambda q)^{-1}\Lambda L(q)k = L(\Lambda q)^{-1}\,(\Lambda q) = k\,,$$

so $W(\Lambda,q) \in G_k$ by Definition A.384, and it depends continuously on (Λ,q) because L does.

The composition law. Put $q = \Lambda^{-1}\Lambda'^{-1}p$, so that $\Lambda q = \Lambda'^{-1}p$ and $\Lambda'\Lambda q = p$. Then

$$\begin{aligned} W(\Lambda',\Lambda q)\,W(\Lambda,q) &= \Big[L(\Lambda'\Lambda q)^{-1}\Lambda' L(\Lambda q)\Big]\,\Big[L(\Lambda q)^{-1}\Lambda L(q)\Big] \\ &= L(\Lambda'\Lambda q)^{-1}\,\Lambda'\Lambda L(q) = W(\Lambda'\Lambda,q)\ , \end{aligned} \tag{A.657}$$

the two middle factors cancelling. Applying Equation (A.654) twice and using Equation (A.657) together with the homomorphism property of σ,

$$\left(U(\Lambda',0)U(\Lambda,0)\psi\right)(p) = \sigma\big(W(\Lambda',\Lambda q)\big)\,\sigma\big(W(\Lambda,q)\big)\,\psi(q) = \sigma\big(W(\Lambda'\Lambda,q)\big)\,\psi(q)\,,$$

which is $\left(U(\Lambda'\Lambda,0)\psi\right)(p)$. The translations compose by inspection, $\mathrm{e}^{-\mathrm{i}p\cdot a/\hbar}\mathrm{e}^{-\mathrm{i}p\cdot a'/\hbar} = \mathrm{e}^{-\mathrm{i}p\cdot(a+a')/\hbar}$, and the mixed relation required by Equation (A.648) is

$$\left(U(\Lambda,0)U(\mathbb{1},a)\psi\right)(p) = \mathrm{e}^{-\mathrm{i}\,(\Lambda^{-1}p)\cdot a/\hbar}\sigma(W)\psi(\Lambda^{-1}p) = \mathrm{e}^{-\mathrm{i}\,p\cdot(\Lambda a)/\hbar}\,\left(U(\Lambda,0)\psi\right)(p)\,,$$

because η is Λ-invariant: $(\Lambda^{-1}p)\cdot a = p\cdot(\Lambda a)$. That is $U(\Lambda,0)U(\mathbb{1},a) = U(\mathbb{1},\Lambda a)U(\Lambda,0)$, the semidirect product law.

Unitarity. For the translations the factor is a phase. For the Lorentz part,

$$\|U(\Lambda,0)\psi\|^2 = \int_{\mathcal{M}_m}\mathrm{d}\mu(p)\,\Big\|\sigma\Big(W(\Lambda,\Lambda^{-1}p)\Big)\,\psi(\Lambda^{-1}p)\Big\|_{V_\sigma}^2 = \int_{\mathcal{M}_m}\mathrm{d}\mu(p)\,\Big\|\psi(\Lambda^{-1}p)\Big\|_{V_\sigma}^2\,,$$

since σ is unitary on V_σ, and the last integral equals $\|\psi\|^2$ by the invariance of $\mathrm{d}\mu$ (Lemma A.388). Surjectivity is $U(\Lambda,0)^{-1} = U(\Lambda^{-1},0)$. Strong continuity follows from the continuity of L, W and σ together with dominated convergence on the dense set of compactly supported continuous ψ.

The momentum spectrum. The one-parameter groups of translations are $U(\mathbb{1},a) = \exp\left(-\mathrm{i}\,\eta_{AB}\hat{P}^A a^B/\hbar\right)$, which is the normalisation of Remark 14.66; comparing with the first line of Equation (A.654), whose phase is $-\mathrm{i}\,\eta_{AB}p^A a^B/\hbar$ for every a, the generator $\hat{P}^A$ acts as multiplication by the number p^A, which is Equation (A.656); then $\hat{P}^2 = \eta^{AB}p_A p_B = -m^2c^2$ everywhere on $\mathcal{M}_m$ by Equation (A.649), and $p^D > 0$ there by construction. □

Proposition A.391 (Reducible little-group data give reducible representations)**.** *If V_σ has a proper nonzero σ-invariant subspace V', then $L^2(\mathcal{M}_m, \mathrm{d}\mu; V')$ is a proper nonzero $U^{(m,\sigma)}$-invariant subspace of $\mathcal{H}_\sigma$. Hence irreducibility of $U^{(m,\sigma)}$ requires irreducibility of σ.*
Rests on Proposition A.390.

Proof. *Derives Proposition A.391.*

Both operations in Equation (A.654) act on the value $\psi(q) \in V_\sigma$ either by a scalar phase or by $\sigma(W)$ with $W \in G_k$, and both preserve V'; the argument q is merely relabelled. So the subspace of functions with values in V' is invariant, and it is proper and nonzero because V' is. □

A.36.5 The classification, and the count

The converse of Proposition A.391, and the statement that the list Equation (A.654) is exhaustive, is the imported ingredient.

Theorem A.392 (Wigner–Mackey classification; quoted)**.** *Let $D \geq 4$, $m > 0$, and let U be a strongly continuous unitary representation of $\tilde{G}$ that is irreducible, has positive energy and satisfies $\hat{P}^2 = -m^2c^2\mathbb{1}$. Then U is unitarily equivalent to $U^{(m,\sigma)}$ of Equation (A.654) for some irreducible unitary representation σ of $\mathrm{Spin}(D-1)$; conversely $U^{(m,\sigma)}$ is irreducible whenever σ is; and $U^{(m,\sigma)}$ and $U^{(m,\sigma')}$ are equivalent if and only if σ and σ' are [849, 1912].*
Rests on Proposition A.390 and Definition A.384.

Remark A.393 (What is quoted here)*.* Theorem A.392 is the one statement of this appendix that is not proved in this treatise, and it is worth being exact about what it costs.

Its content is Mackey's imprimitivity theorem [1005], specialized by Wigner [849] to the inhomogeneous Lorentz group. Three analytic inputs go into it, none of which this treatise develops: the spectral theorem for a strongly continuous unitary representation of the translation group $\mathbb{R}^D$ (the Stone–Naimark–Ambrose–Godement theorem, which supplies the projection-valued measure whose support is the momentum spectrum — Stone's one-parameter case is [707] and the general statement is standard functional analysis [1481]); the identification of the commutant of that measure's multiplication algebra with the decomposable operators, which is what turns an operator commuting with all translations into a measurable field $p \mapsto A(p)$ of matrices; and the disintegration of the Hilbert space over the orbit, which converts the field into a representation of the stabilizer. Given those three, the classification is the argument whose geometric half is proved above: the spectrum is a Λ-invariant subset of the hyperboloid Equation (A.649), which is one orbit by Lemma A.387, so the spectrum is the whole mass shell; the explicit continuous section L of Equation (A.650) then trivializes the bundle of fibres, and the residual freedom is exactly a representation of G_k.

Two things follow from that accounting. First, the imported theorem is functional analysis, not group theory: the Lie-theoretic content — which subalgebra fixes a timelike momentum, what its rank is, and how many labels its representations carry — is proved, in Lemma 14.68 and in Theorem 14.21. Second, the existence half of the classification, which is what a physical application actually uses, is proved here without any import: Proposition A.390 constructs $U^{(m,\sigma)}$ and computes its invariants, and Proposition A.391 supplies one direction of the irreducibility criterion. What is quoted is the *exhaustiveness* of the list, together with the converse irreducibility statement.

One further standard fact is used silently and is named here: a unitary representation of a compact group decomposes into finite-dimensional irreducible ones (the Peter–Weyl theorem [1912]), which is why V_σ may be taken finite-dimensional in Proposition A.390. Lemma 94.28 records the same point for SU(2) in four dimensions.

Proof of Theorem A.385. *Derives Theorem A.385.*

The bijection between equivalence classes is Theorem A.392. It remains to count.

The little algebra and its rank. By Lemma A.386 the little group is $\mathrm{SO}(D-1)$, whose Lie algebra is the $\mathfrak{so}(D-1)$ of Lemma 14.68; and since $D \geq 4$, that algebra has $D-1 \geq 3$ and is semisimple, of rank $\lfloor (D-1)/2 \rfloor$ by Proposition 14.22. Passing to $\mathrm{Spin}(D-1)$ changes neither the algebra nor its rank.

How many labels σ carries. Theorem 14.21 applied to $\mathfrak{so}(D-1)$ says that the centre of its enveloping algebra is a polynomial algebra in $\lfloor (D-1)/2 \rfloor$ algebraically independent Casimir elements, and that a complete set of invariant labels for its finite-dimensional irreducible representations consists of that many numbers *and of no fewer*. The representation σ is finite-dimensional by the Peter–Weyl theorem (Remark A.393), so exactly $\lfloor (D-1)/2 \rfloor$ numbers fix its class.

Adding the mass. The number m is an invariant of U independent of those: it is read off $\hat{P}^2$, which by Equation (A.656) is $-m^2c^2$ and involves the translation generators alone, whereas the little-group Casimirs are built from $\hat{J}$. Distinct masses therefore give inequivalent representations for every σ, and distinct σ give inequivalent representations for every mass, by Theorem A.392. The complete label set is thus m together with the $\lfloor (D-1)/2 \rfloor$ labels of σ, and by Equation (14.108) of Lemma 14.68 their number is

$$1 + \left\lfloor \frac{D-1}{2} \right\rfloor = \left\lceil \frac{D}{2} \right\rceil ,$$

which is Equation (A.647) and Equation (14.107).

No further invariant survives. Let C be any central element of the enveloping algebra $U(\mathfrak{iso}(D-1,1))$. On the irreducible U it acts as a scalar by Corollary 14.18, and that scalar depends only on the unitary equivalence class of U — an intertwiner conjugates C to itself. By the bijection the class is the pair $(m, [\sigma])$, so the scalar is a function of m and of the $\lfloor (D-1)/2 \rfloor$ labels of σ: no invariant of the enveloping algebra can separate two representations that those numbers already identify. □

A.36.6 The observed case

Example A.394 ($D = 4$)**.** Take $D = 4$, the observed spacetime. Then $\lfloor (D-1)/2 \rfloor = \lfloor 3/2 \rfloor = 1$ and $\lceil D/2 \rceil = 2$: a massive particle carries exactly two labels.

The little group is $\mathrm{SO}(3)$ by Lemma A.386, its cover is $\mathrm{SU}(2)$, and its algebra has rank one (Proposition 14.22 with $D-1=3$), so Theorem 14.21 allows a single Casimir — the $\boldsymbol{J}^2$ of Definition 14.40. Its irreducible representations are labelled by s with $2s \in \mathbb{N} \cup \{0\}$ (Theorem 14.43), of dimension $2s+1$, and the Casimir takes the value

$$\hat{\mathcal{J}}^2 = \hbar^2\, s(s+1)\, \mathbb{1}\,, \qquad \text{of SI unit } \mathrm{J}^2\,\mathrm{s}^2\,, \tag{A.658}$$

s itself being dimensionless. The two labels of Theorem A.385 are therefore m, of unit kg, and s.

In four dimensions — and, of the cases treated in Chapter 14, only there — both labels are realized by genuine Casimir elements of the inhomogeneous algebra itself: $\hat{P}^2$ and the Pauli–Lubanski square $\hat{W}^2$ of Theorem 14.65, whose values are Equation (14.105). That $\hat{W}^2$ measures the rest-frame angular momentum, so that $\hat{W}^2 = -m^2c^2\hat{\mathcal{J}}^2$ on the fibre over k, is the computation carried out in Remark 14.66 and again in Theorem 94.29; combined with Equation (A.658) it gives the second line of Equation (14.105), and the ratio Equation (14.106) isolates the $\hbar^2 s(s+1)$ that survives. Theorem 94.27 is Proposition A.390 written out for this case, with $\mathrm{d}\mu$ of Equation (A.652) replaced by the equivalent normalization used there.

Rests on Theorems 14.43, 14.65 and A.385.

Remark A.395 (Why the higher invariants are not constructed here). Remark 14.67 states that in general D the invariants beyond $\hat{P}^2$ are built from antisymmetrized products of

$\hat{J}$ with $\hat{P}$, the Pauli–Lubanski construction Equation (14.103) being available only at $D = 4$ because it contracts a D-index Levi-Civita symbol with one J and one P. That construction is not carried out in this appendix, and it is not needed for the theorem: the count Equation (A.647) follows from the classification and from Theorem 14.21 applied to the little algebra, neither of which requires the invariants to be exhibited as elements of the enveloping algebra. What has been proved is that a massive irreducible representation is specified by $\lceil D/2 \rceil$ numbers and by no fewer, and that any central element of the enveloping algebra is a function of them. The explicit general-D construction of the higher invariants would say which polynomial in $\hat{J}$ and $\hat{P}$ realizes each label; only the $D = 4$ case is used anywhere in this book, and it is Theorem 14.65.

Remark A.396. Theorem A.385 discharges the obligation recorded after Lemma 14.68: the lemma supplies the little algebra and its rank, and the theorem converts that rank into the label count Equation (14.107) quoted in Remark 14.67 — two labels at $D = 4$ and three at both $D = 5$ and $D = 6$, the ceiling and not the floor. The $3 + 1$ instantiation, Example A.394, is the mass and the spin, and it is the only case the physical parts of this treatise use; its detailed development, including the massless representations that this appendix does not treat, is Chapter 94.

A.37 Whitehead's Lemmas and the Rigidity of Semisimple Algebras

This appendix proves Proposition 14.77 of Chapter 14: the first and second Chevalley–Eilenberg cohomology groups of a finite-dimensional semisimple Lie algebra, with coefficients in any finite-dimensional module, vanish. The second of these — Whitehead's second lemma — is what Section 14.4 needs, since by Proposition 14.76 the vanishing of $H^2(\mathfrak{g}, \mathbb{R})$ says exactly that every central extension of $\mathfrak{g}$ is trivial. The corollary for the Lorentz algebra follows from Corollary A.344.

Nothing is quoted. The engine is the Casimir operator of the representation: it is invertible on any module with no trivial summand, and averaging a cocycle against it produces the coboundary that was sought. Semisimplicity enters through Appendix A.31 at three points — the Killing form and the trace form are nondegenerate, ideals split off orthogonally, and $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}$.

Section 14.4.1 defines $H^2(\mathfrak{g}, \mathbb{R})$ directly, by writing down the cocycle condition Equation (14.121) and the coboundaries Equation (14.122) for the one case it needs; the complex those live in is named there but not built. It is built here (Appendix A.37.1), because the proof needs coefficients in an arbitrary module and needs degree three to say what a 2-cocycle is. Appendix A.37.2 constructs the Casimir of a representation, Appendix A.37.3 carries out the averaging, Appendix A.37.4 proves the complete reducibility needed to reduce a general module to irreducible ones, Appendix A.37.5 treats the trivial coefficients that averaging cannot reach, and Appendix A.37.6 assembles the lemmas and draws the corollary.

Throughout, $\mathbb{K}$ is a field of characteristic zero with algebraic closure $\mathbb{F}$, $\mathfrak{g}$ is a finite-dimensional semisimple Lie algebra over $\mathbb{K}$ with basis $\{T_a\}$, and a *module* is a finite-dimensional vector space $\mathbb{V}$ with a homomorphism $\rho : \mathfrak{g} \to \mathfrak{gl}(\mathbb{V})$, that is, a linear map with $\rho([X, Y]) = [\rho(X), \rho(Y)]$. We write $\rho(X)v$ and $X \cdot v$ interchangeably, and $\rho_a = \rho(T_a)$.

A.37.1 The Chevalley–Eilenberg complex

Definition A.397 (Cochains and the differential)**.** Let $\mathbb{V}$ be a $\mathfrak{g}$-module. For $n \geq 1$ let $C^n(\mathfrak{g}, \mathbb{V})$ be the space of alternating n-linear maps $\mathfrak{g}^n \to \mathbb{V}$, and let $C^0(\mathfrak{g}, \mathbb{V}) = \mathbb{V}$. The

Chevalley–Eilenberg differential $\mathrm{d} : C^n \to C^{n+1}$ is

$$(\mathrm{d}f)(X_0,\dots,X_n) = \sum_{i=0}^{n} (-1)^i \rho(X_i)\, f\left(X_0,\dots,\widehat{X_i},\dots,X_n\right) + \sum_{0\le i<j\le n} (-1)^{i+j} f\left([X_i,X_j],X_0,\dots,\widehat{X_i},\dots,\widehat{X_j},\dots,X_n\right), \quad \text{(A.659)}$$

the hat marking an omitted argument. Explicitly, in the three degrees used below,

$$(\mathrm{d}v)(X) = \rho(X)v\,, \quad \text{(A.660)}$$

$$(\mathrm{d}f)(X,Y) = \rho(X)f(Y) - \rho(Y)f(X) - f([X,Y])\,, \quad \text{(A.661)}$$

$$(\mathrm{d}c)(X,Y,Z) = \rho(X)c(Y,Z) - \rho(Y)c(X,Z) + \rho(Z)c(X,Y) - c([X,Y],Z) + c([X,Z],Y) - c([Y,Z],X)\,. \quad \text{(A.662)}$$

A cochain with $\mathrm{d}f = 0$ is a *cocycle*, one of the form $\mathrm{d}h$ a *coboundary*, and $H^n(\mathfrak{g},\mathbb{V})$ is the quotient of the cocycles by the coboundaries in degree n.

Rests on Definition 14.75.

Lemma A.398 (The differential squares to zero in the degrees used)**.** $\mathrm{d}(\mathrm{d}v) = 0$ *for* $v \in C^0$ *and* $\mathrm{d}(\mathrm{d}f) = 0$ *for* $f \in C^1$*. Hence* $H^1(\mathfrak{g},\mathbb{V})$ *and* $H^2(\mathfrak{g},\mathbb{V})$ *are defined.*

Rests on Definition A.397.

Proof. *Derives Lemma A.398.*

In degree zero, Equations (A.660) and (A.661) give

$$(\mathrm{d}\mathrm{d}v)(X,Y) = \rho(X)\rho(Y)v - \rho(Y)\rho(X)v - \rho([X,Y])\,v = 0\,, \quad \text{(A.663)}$$

which is precisely the statement that ρ is a homomorphism.

In degree one, write $g = \mathrm{d}f$ and expand $(\mathrm{d}g)(X,Y,Z)$ by Equation (A.662), substituting Equation (A.661) in each of the six terms. Suppressing ρ and writing Xu for $\rho(X)u$, the six terms are

$$\begin{aligned}
Xg(Y,Z) &= XYf(Z) - XZf(Y) - Xf([Y,Z])\,,\\
-Yg(X,Z) &= -YXf(Z) + YZf(X) + Yf([X,Z])\,,\\
Zg(X,Y) &= ZXf(Y) - ZYf(X) - Zf([X,Y])\,,\\
-g([X,Y],Z) &= -[X,Y]f(Z) + Zf([X,Y]) + f([[X,Y],Z])\,,\\
g([X,Z],Y) &= [X,Z]f(Y) - Yf([X,Z]) - f([[X,Z],Y])\,,\\
-g([Y,Z],X) &= -[Y,Z]f(X) + Xf([Y,Z]) + f([[Y,Z],X])\,.
\end{aligned} \quad \text{(A.664)}$$

Add them and collect. The terms carrying $f(Z)$ are $XY - YX - [X,Y]$, which vanish because ρ is a homomorphism; likewise those carrying $f(Y)$, namely $-XZ + ZX + [X,Z]$, and those carrying $f(X)$, namely $YZ - ZY - [Y,Z]$. The terms $\pm Xf([Y,Z])$, $\pm Yf([X,Z])$ and $\pm Zf([X,Y])$ cancel in pairs. What remains is

$$f([[X,Y],Z] - [[X,Z],Y] + [[Y,Z],X]) = 0\,, \quad \text{(A.665)}$$

because $-[[X,Z],Y] = [[Z,X],Y]$ and the argument is then the Jacobi identity. □

Remark A.399 (Agreement with the chapter's definitions). Take $\mathbb{V} = \mathbb{R}$ with the trivial action, $\rho = 0$. Then Equation (A.662) reduces to

$$(\mathrm{d}c)(X,Y,Z) = -[c([X,Y],Z) + c([Y,Z],X) + c([Z,X],Y)]\,, \quad \text{(A.666)}$$

using the antisymmetry of c to write $c([X,Z],Y) = -c([Z,X],Y)$; so $\mathrm{d}c = 0$ is exactly the cocycle condition Equation (14.121) of Proposition 14.73. And Equation (A.661) reduces to $(\mathrm{d}b)(X,Y) = -b([X,Y])$, whose image is the space of coboundaries Equation (14.122) of Definition 14.74 — the overall sign changes no subspace. The group $H^2(\mathfrak{g},\mathbb{R})$ of Definition 14.75 is therefore the group H^2 of Definition A.397, and Proposition 14.76 may be applied to it without further comment.

A.37.2 The Casimir operator of a representation

Definition A.400 (Invariant form, dual basis, Casimir)**.** A symmetric bilinear form β on $\mathfrak{g}$ is *invariant* if

$$\beta\left([X,Y],Z\right)=\beta\left(X,[Y,Z]\right)\qquad\text{for all } X,Y,Z\in\mathfrak{g}\,, \tag{A.667}$$

which for the Killing form is Equation (14.16) rewritten with the antisymmetry of the bracket. If β is in addition nondegenerate, the *dual basis* $\{T^a\}$ is defined by $\beta\left(T_a,T^b\right)=\delta_a{}^b$, and the *Casimir operator of the representation* ρ relative to β is

$$\boxed{\Gamma=\rho\left(T^a\right)\rho\left(T_a\right)\in\mathrm{End}(\mathbb{V})}\,, \tag{A.668}$$

summed over a. Taking $\beta=\kappa$ and ρ the identity map of $\mathfrak{g}$ into $U(\mathfrak{g})$ recovers $C_2=\kappa^{ab}T_aT_b$ of Equation (14.20).

Rests on Definition 14.10 and Lemma 14.11.

Lemma A.401 (The invariance identity)**.** *Let β be invariant and nondegenerate with dual basis $\{T^a\}$. Then for every $Y\in\mathfrak{g}$*

$$\sum_a\left([T^a,Y]\otimes T_a+T^a\otimes[T_a,Y]\right)=0\qquad\textit{in }\mathfrak{g}\otimes\mathfrak{g}\,. \tag{A.669}$$

Consequently Γ commutes with $\rho(Y)$ for every $Y\in\mathfrak{g}$.

Rests on Definition A.400.

Proof. *Derives Lemma A.401.*

Expand $[T_a,Y]=\mu_a{}^bT_b$ and $[T^a,Y]=\nu^a{}_bT^b$, so that $\mu_a{}^b=\beta\left([T_a,Y],T^b\right)$ and $\nu^a{}_b=\beta\left([T^a,Y],T_b\right)$. By Equation (A.667) and the symmetry of β,

$$\mu_a{}^b=\beta\left(T_a,\left[Y,T^b\right]\right)=-\beta\left(T_a,\left[T^b,Y\right]\right)=-\nu^b{}_a\,. \tag{A.670}$$

The left-hand side of Equation (A.669) is therefore $\sum_{a,b}\left(\nu^a{}_b+\mu_b{}^a\right)T^b\otimes T_a$, after renaming the summation indices in the second term, and each coefficient vanishes by Equation (A.670).

For the last statement apply the bilinear map $(u,w)\mapsto\rho(u)\rho(w)$ to Equation (A.669):

$$[\Gamma,\rho(Y)]=\rho\left(T^a\right)\left[\rho\left(T_a\right),\rho(Y)\right]+\left[\rho\left(T^a\right),\rho(Y)\right]\rho\left(T_a\right)=\rho\left(T^a\right)\rho\left([T_a,Y]\right)+\rho\left([T^a,Y]\right)\rho\left(T_a\right)\,, \tag{A.671}$$

which is the image of Equation (A.669) and hence zero. □

Lemma A.402 (The trace form is nondegenerate for a faithful representation)**.** *Let $\mathfrak{g}$ be semisimple and ρ faithful. Then*

$$\beta_{\mathbb{V}}(X,Y)=\mathrm{tr}\left(\rho(X)\rho(Y)\right) \tag{A.672}$$

is a symmetric invariant nondegenerate bilinear form on $\mathfrak{g}$, and the corresponding Casimir operator satisfies $\mathrm{tr}_{\mathbb{V}}\,\Gamma=\dim\mathfrak{g}$.

Rests on Theorems A.330 and A.340.

Proof. *Derives Lemma A.402.*

Symmetry is cyclicity of the trace, and invariance is the computation Equation (A.605): $\mathrm{tr}\left(\rho\left([X,Y]\right)\rho(Z)\right)=\mathrm{tr}\left(\rho(X)\rho\left([Y,Z]\right)\right)$. Let $\mathfrak{s}$ be the radical of $\beta_{\mathbb{V}}$; it is an ideal by the argument of Equation (A.606) with $\beta_{\mathbb{V}}$ in place of κ. For $W\in[\mathfrak{s},\mathfrak{s}]$ and $Y\in\mathfrak{s}$, $\mathrm{tr}\left(\rho(W)\rho(Y)\right)=\beta_{\mathbb{V}}(W,Y)=0$, so Theorem A.340 makes $\rho(\mathfrak{s})$ solvable; as ρ is faithful, $\mathfrak{s}$ is a solvable ideal of a semisimple algebra, hence zero (Remark A.333). Finally

$$\mathrm{tr}_{\mathbb{V}}\,\Gamma=\sum_a\mathrm{tr}\left(\rho\left(T^a\right)\rho\left(T_a\right)\right)=\sum_a\beta_{\mathbb{V}}\left(T^a,T_a\right)=\sum_a\delta_a{}^a=\dim\mathfrak{g}\,. \tag{A.673}$$

□

A.37.3 Averaging a cocycle against the Casimir

Theorem A.403 (Vanishing when the Casimir is invertible)**.** *Let β be an invariant nondegenerate symmetric form on $\mathfrak{g}$ and let the Casimir Γ of Equation (A.668) be invertible on $\mathbb{V}$. Then*

$$H^1(\mathfrak{g},\mathbb{V}) = H^2(\mathfrak{g},\mathbb{V}) = 0\,. \tag{A.674}$$

Rests on Lemma A.401 and Definition A.397.

Proof. *Derives Theorem A.403.*

Degree one. Let f be a 1-cocycle, so that by Equation (A.661)

$$\rho(X)f(Y) - \rho(Y)f(X) - f\left([X,Y]\right) = 0 \qquad \text{for all } X, Y\,. \tag{A.675}$$

Put $X = T_a$, apply $\rho\left(T^a\right)$ and sum over a. The first term gives $\Gamma f(Y)$. In the second, commute $\rho\left(T^a\right)$ past $\rho(Y)$,

$$\rho\left(T^a\right)\rho(Y) = \rho(Y)\rho\left(T^a\right) + \rho\left([T^a,Y]\right)\,, \tag{A.676}$$

and set

$$v = \rho\left(T^a\right) f\left(T_a\right) \in \mathbb{V}\,. \tag{A.677}$$

The result is

$$\Gamma f(Y) - \rho(Y)v - \rho\left([T^a,Y]\right) f\left(T_a\right) - \rho\left(T^a\right) f\left([T_a,Y]\right) = 0\,. \tag{A.678}$$

The last two terms are the image of the invariance identity Equation (A.669) under the bilinear map $(u,w) \mapsto \rho(u)f(w)$, hence vanish. So $\Gamma f(Y) = \rho(Y)v$ for every Y. Since Γ commutes with every $\rho(Y)$ (Lemma A.401) so does Γ^{-1}, and therefore

$$f(Y) = \rho(Y)\,\Gamma^{-1}v = \left(\mathrm{d}\left(\Gamma^{-1}v\right)\right)(Y)\,, \tag{A.679}$$

by Equation (A.660): every 1-cocycle is a coboundary.

Degree two. Let c be a 2-cocycle. Put $X = T_a$ in $(\mathrm{d}c)\,(X,Y,Z) = 0$, apply $\rho\left(T^a\right)$, sum over a, and set

$$b(X) = \rho\left(T^a\right) c\left(T_a, X\right) \in \mathbb{V}\,, \qquad b \in C^1(\mathfrak{g},\mathbb{V})\,. \tag{A.680}$$

The six terms of Equation (A.662) contribute as follows. The first gives $\Gamma c(Y,Z)$ outright. In the second and the third, Equation (A.676) moves $\rho\left(T^a\right)$ past $\rho(Y)$ and $\rho(Z)$, producing $-\rho(Y)b(Z)$ and $+\rho(Z)b(Y)$ together with one commutator term each. The fourth and fifth are unchanged. The sixth is $b\left([Y,Z]\right)$, since $-c\left([Y,Z]\,,T_a\right) = +c\left(T_a,[Y,Z]\right)$. Collecting,

$$\begin{aligned} 0 &= \rho\left(T^a\right)(\mathrm{d}c)\left(T_a,Y,Z\right) \\ &= \Gamma c(Y,Z) - \rho(Y)b(Z) + \rho(Z)b(Y) + b\left([Y,Z]\right) + R(Y,Z)\,, \end{aligned} \tag{A.681}$$

where the leftover is

$$\begin{aligned} R(Y,Z) = &-\rho\left([T^a,Y]\right) c\left(T_a,Z\right) - \rho\left(T^a\right) c\left([T_a,Y]\,,Z\right) \\ &+ \rho\left([T^a,Z]\right) c\left(T_a,Y\right) + \rho\left(T^a\right) c\left([T_a,Z]\,,Y\right)\,. \end{aligned} \tag{A.682}$$

Both lines of Equation (A.682) vanish: applying the bilinear map $(u,w) \mapsto \rho(u)c(w,Z)$ to Equation (A.669) gives

$$\rho\left([T^a,Y]\right) c\left(T_a,Z\right) + \rho\left(T^a\right) c\left([T_a,Y]\,,Z\right) = 0\,, \tag{A.683}$$

and the same computation with Y and Z exchanged kills the second line. So Equation (A.681) leaves

$$\Gamma c(Y,Z) - \rho(Y)b(Z) + \rho(Z)b(Y) + b\left([Y,Z]\right) = 0\,, \tag{A.684}$$

that is, by Equation (A.661), $\Gamma c = \mathrm{d}b$. As in degree one, Γ^{-1} commutes with every $\rho(Y)$ and therefore with d, so $c = \mathrm{d}\left(\Gamma^{-1}b\right)$: every 2-cocycle is a coboundary. □

Remark A.404 (What the averaging does). The name is worth justifying. For a *compact group* the standard proof of the same statement integrates a cochain over the group with the Haar measure, and the invariant so produced is a coboundary. There is no group and no measure here, but Γ plays the same role: it is the one operator built from the algebra alone that commutes with everything (Lemma A.401), and Equations (A.678) and (A.684) say that contracting a cocycle with the Casimir tensor $T^a \otimes T_a$ produces the cochain whose coboundary it is. What has to be paid for is the invertibility of Γ, and the price is exactly the trivial summands of $\mathbb{V}$, on which Γ vanishes identically. Those are dealt with separately in Appendix A.37.5, and they are the reason the proof needs complete reducibility as well.

A.37.4 Complete reducibility

Lemma A.405 (Schur, algebra form)**.** *Let $\mathbb{V}$ be a finite-dimensional irreducible module over $\mathbb{F}$ algebraically closed, and let $A \in \mathrm{End}(\mathbb{V})$ commute with $\rho(X)$ for every $X \in \mathfrak{g}$. Then $A = \lambda \mathbb{1}$ for some $\lambda \in \mathbb{F}$.*

Rests on Theorem 5.153.

Proof. *Derives Lemma A.405.*

The argument is that of Theorem 5.153, with the family of operators $\{U(a)\}$ replaced by $\{\rho(X)\}$: the characteristic polynomial of A has a root λ because $\mathbb{F}$ is algebraically closed and $\dim \mathbb{V} \geq 1$, so $\ker(A - \lambda\mathbb{1}) \neq 0$; that kernel is a submodule, because $A - \lambda\mathbb{1}$ commutes with the action; and irreducibility forces it to be all of $\mathbb{V}$. □

Lemma A.406 (Splitting a submodule of codimension one)**.** *Let $\mathfrak{g}$ be semisimple over $\mathbb{F}$ and let $\mathbb{V}$ be a module with a submodule $\mathbb{W}$ of codimension one. Then $\mathbb{V} = \mathbb{W} \oplus \mathbb{X}$ for some one-dimensional submodule $\mathbb{X}$.*

Rests on Lemmas A.402 and A.405 and Corollary A.342.

Proof. *Derives Lemma A.406.*

First, $\rho(\mathfrak{g})\mathbb{V} \subseteq \mathbb{W}$: the quotient $\mathbb{V}/\mathbb{W}$ is a one-dimensional module, so the action on it is a homomorphism of $\mathfrak{g}$ into an abelian algebra, which annihilates $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}$ by Corollary A.342.

Next, we may assume ρ faithful. Otherwise put $\mathfrak{k} = \ker \rho$, an ideal; by Corollary A.342, $\mathfrak{g}/\mathfrak{k} \cong \mathfrak{k}^\perp$ is again semisimple, and $\mathbb{V}$ is a module over it with the same submodules. If $\mathfrak{g}/\mathfrak{k} = 0$ the action is trivial, every subspace is a submodule and any complementary line serves.

Induct on $\dim \mathbb{W}$.

Case 1: $\mathbb{W}$ has a submodule $\mathbb{W}'$ with $0 \neq \mathbb{W}' \neq \mathbb{W}$. In $\mathbb{V}/\mathbb{W}'$ the submodule $\mathbb{W}/\mathbb{W}'$ has codimension one and smaller dimension, so by induction there is a one-dimensional submodule $\widetilde{\mathbb{X}}/\mathbb{W}'$ with $\mathbb{V}/\mathbb{W}' = \mathbb{W}/\mathbb{W}' \oplus \widetilde{\mathbb{X}}/\mathbb{W}'$. Inside $\widetilde{\mathbb{X}}$ the submodule $\mathbb{W}'$ has codimension one and $\dim \mathbb{W}' < \dim \mathbb{W}$, so by induction again $\widetilde{\mathbb{X}} = \mathbb{W}' \oplus \mathbb{X}$ with $\mathbb{X}$ a one-dimensional submodule. Then $\mathbb{X} \cap \mathbb{W} \subseteq \widetilde{\mathbb{X}} \cap \mathbb{W} = \mathbb{W}'$ and $\mathbb{X} \cap \mathbb{W}' = 0$, so $\mathbb{X} \cap \mathbb{W} = 0$ and dimensions give $\mathbb{V} = \mathbb{W} \oplus \mathbb{X}$.

Case 2: $\mathbb{W}$ is irreducible. If $\rho(\mathfrak{g})\mathbb{W} = 0$ then $\mathbb{W}$ is one-dimensional, $\dim \mathbb{V} = 2$, and every product of two elements of $\rho(\mathfrak{g})$ vanishes because $\rho(\mathfrak{g})\mathbb{V} \subseteq \mathbb{W}$; so $\rho(\mathfrak{g})$ is abelian and $\rho(\mathfrak{g}) = \rho([\mathfrak{g}, \mathfrak{g}]) = 0$, and any complementary line serves. So assume $\rho(\mathfrak{g})\mathbb{W} \neq 0$, and let Γ be the Casimir built from the trace form $\beta_{\mathbb{V}}$ of Lemma A.402, which is available because ρ is faithful. By Lemma A.401 Γ commutes with the action; $\Gamma\mathbb{V} \subseteq \rho(\mathfrak{g})\mathbb{V} \subseteq \mathbb{W}$, since Γ is a sum of products of two operators $\rho(\cdot)$; hence Γ acts as zero on $\mathbb{V}/\mathbb{W}$ and

$$\mathrm{tr}_{\mathbb{W}} \Gamma = \mathrm{tr}_{\mathbb{V}} \Gamma - \mathrm{tr}_{\mathbb{V}/\mathbb{W}} \Gamma = \dim \mathfrak{g}\,, \tag{A.685}$$

by Lemma A.402. On the irreducible $\mathbb{W}$, Lemma A.405 gives $\Gamma|_{\mathbb{W}} = \lambda\mathbb{1}$ with $\lambda \dim \mathbb{W} = \dim \mathfrak{g}$, so $\lambda \neq 0$ in characteristic zero and $\Gamma|_{\mathbb{W}}$ is invertible. Therefore $\Gamma\mathbb{V} = \mathbb{W}$, $\dim \ker \Gamma = \dim \mathbb{V} - \dim \mathbb{W} = 1$, and $\ker \Gamma \cap \mathbb{W} = 0$. As Γ commutes with the action, $\ker \Gamma$ is a submodule, and $\mathbb{V} = \mathbb{W} \oplus \ker \Gamma$. □

Theorem A.407 (Weyl's complete reducibility theorem)**.** *Let $\mathfrak{g}$ be semisimple over $\mathbb{F}$ algebraically closed of characteristic zero. Every finite-dimensional $\mathfrak{g}$-module is a direct sum of irreducible submodules.*

Rests on Lemma A.406 and Corollary A.342.

Proof. *Derives Theorem A.407.*

It suffices to show that every submodule $\mathbb{W} \subseteq \mathbb{V}$ has a complementary submodule; the decomposition then follows by induction on $\dim \mathbb{V}$. Assume $0 \neq \mathbb{W} \neq \mathbb{V}$ and let $\mathcal{H} = \mathrm{Hom}(\mathbb{V}, \mathbb{W})$, a $\mathfrak{g}$-module under

$$(X \cdot \phi)(u) = \rho(X)\phi(u) - \phi(\rho(X)u) \,. \tag{A.686}$$

Let $\mathcal{V} \subseteq \mathcal{H}$ be the set of ϕ whose restriction to $\mathbb{W}$ is a scalar multiple of the identity, and $\mathcal{W} \subseteq \mathcal{V}$ the set of ϕ vanishing on $\mathbb{W}$. Both are subspaces, and the map $\mathcal{V} \to \mathbb{F}$ sending ϕ to its scalar is linear, surjective — any projection of $\mathbb{V}$ onto $\mathbb{W}$ lies in $\mathcal{V}$ with scalar 1 — and has kernel $\mathcal{W}$, so $\mathcal{W}$ has codimension one in $\mathcal{V}$.

They are submodules: if $\phi|_{\mathbb{W}} = \lambda \mathbb{1}$ then for $w \in \mathbb{W}$,

$$(X \cdot \phi)(w) = \rho(X)\lambda w - \lambda \rho(X) w = 0 \,, \tag{A.687}$$

using that $\mathbb{W}$ is a submodule; so $X \cdot \mathcal{V} \subseteq \mathcal{W} \subseteq \mathcal{V}$.

Apply Lemma A.406 to $\mathcal{W} \subseteq \mathcal{V}$: there is a one-dimensional submodule $\mathbb{F}\phi_0$ complementary to $\mathcal{W}$, and ϕ_0 may be normalized so that $\phi_0|_{\mathbb{W}} = \mathbb{1}$. Being a one-dimensional submodule with $X \cdot \mathcal{V} \subseteq \mathcal{W}$, it satisfies $X \cdot \phi_0 \in \mathbb{F}\phi_0 \cap \mathcal{W} = 0$: that is, ϕ_0 is a homomorphism of modules. Its kernel is therefore a submodule; it meets $\mathbb{W}$ in 0 and has dimension $\dim \mathbb{V} - \dim \mathbb{W}$ because ϕ_0 is onto $\mathbb{W}$. Hence $\mathbb{V} = \mathbb{W} \oplus \ker \phi_0$. □

A.37.5 Trivial coefficients

Proposition A.408 (The two groups vanish for the trivial module)**.** *Let $\mathfrak{g}$ be semisimple over $\mathbb{F}$ and let $\mathbb{F}$ carry the trivial action. Then $H^1(\mathfrak{g}, \mathbb{F}) = H^2(\mathfrak{g}, \mathbb{F}) = 0$.*

Rests on Theorem A.407, Corollary A.342, and Proposition 14.76.

Proof. *Derives Proposition A.408.*

Degree one. With $\rho = 0$, Equation (A.661) makes a 1-cocycle a linear map f with $f([X, Y]) = 0$, that is, a linear map vanishing on $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}$ (Corollary A.342); so $f = 0$. The coboundaries are zero as well, and $H^1 = 0$.

Degree two. Let c be a 2-cocycle. By the construction in the proof of Proposition 14.76 — "every class is realized" — the vector space $\tilde{\mathfrak{g}} = \mathfrak{g} \oplus \mathbb{F}Z$ with Z central and the bracket Equation (14.120) is a Lie algebra, the Jacobi identity being Equation (14.121), which by Remark A.399 is $\mathrm{d}c = 0$.

Make $\tilde{\mathfrak{g}}$ a $\mathfrak{g}$-module. For $\xi \in \mathfrak{g}$ and $u \in \tilde{\mathfrak{g}}$ set $\xi \cdot u = \left[\tilde{\xi}, u\right]$, where $\tilde{\xi}$ is any preimage of ξ under the projection $\pi : \tilde{\mathfrak{g}} \to \mathfrak{g}$. This is well defined, because two preimages differ by a multiple of the central Z; and it is a module structure, because $\left[\widetilde{[\xi, \eta]}, u\right] = \left[\left[\tilde{\xi}, \tilde{\eta}\right], u\right]$ — the two lifts differ by a central element — and the right-hand side expands by the Jacobi identity of $\tilde{\mathfrak{g}}$ into $\left[\tilde{\xi}, [\tilde{\eta}, u]\right] - \left[\tilde{\eta}, \left[\tilde{\xi}, u\right]\right]$.

The line $\mathbb{F}Z$ is a submodule, Z being central. By Theorem A.407 it has a complementary submodule $\mathfrak{m}$, so $\tilde{\mathfrak{g}} = \mathbb{F}Z \oplus \mathfrak{m}$ with $[\tilde{\mathfrak{g}}, \mathfrak{m}] \subseteq \mathfrak{m}$; in particular $\mathfrak{m}$ is a subalgebra, and $\pi|_{\mathfrak{m}} : \mathfrak{m} \to \mathfrak{g}$ is a bijective homomorphism of Lie algebras. Its inverse $s = (\pi|_{\mathfrak{m}})^{-1}$ is a linear splitting of π which is also a homomorphism, so the cocycle it defines through Equation (14.120) is $[s(\xi), s(\eta)] - s([\xi, \eta]) = 0$.

Finally, two linear splittings of π differ by a linear map $\mathfrak{g} \to \mathbb{F}$, and by the first part of the proof of Proposition 14.76 the cocycles they define differ by a coboundary. The splitting $\xi \mapsto (\xi, 0)$ defines c and the splitting s defines 0; hence c is a coboundary and $H^2(\mathfrak{g}, \mathbb{F}) = 0$. □

A.37.6 The Whitehead lemmas

Lemma A.409 (A Casimir invertible on a nontrivial irreducible module)**.** *Let $\mathfrak{g}$ be semisimple over $\mathbb{F}$ and let $\mathbb{V}$ be an irreducible module with $\rho \neq 0$. Then there is an invariant nondegenerate symmetric form β on $\mathfrak{g}$ whose Casimir operator Equation (A.668) is invertible on $\mathbb{V}$.*

Rests on Corollaries A.342 and A.343 and Lemma A.405.

Proof. *Derives Lemma A.409.*

Write $\mathfrak{g} = \mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_s$ as a direct sum of simple ideals (Corollary A.342) and let κ_j be the Killing form of $\mathfrak{g}_j$, extended to $\mathfrak{g}$ by declaring the other summands orthogonal to $\mathfrak{g}_j$ and to each other. Each κ_j is invariant and, by Corollary A.343, $\kappa = \sum_j \kappa_j$. For nonzero scalars $t_1, \dots, t_s$ put $\beta_t = \sum_j t_j \kappa_j$, an invariant symmetric form, nondegenerate because each κ_j is nondegenerate on $\mathfrak{g}_j$. Choosing a basis adapted to the decomposition, the β_t-dual basis is t_j^{-1} times the κ-dual basis in block j, so

$$\Gamma_t = \sum_j t_j^{-1} \Gamma_j \,, \qquad \Gamma_j = \sum_{a \in j} \rho\left(T^a\right) \rho\left(T_a\right) \,, \tag{A.688}$$

the inner sum running over a basis of $\mathfrak{g}_j$ with its κ_j-dual. Each Γ_j commutes with $\rho(\mathfrak{g}_j)$ by Lemma A.401 applied inside $\mathfrak{g}_j$, and with $\rho(\mathfrak{g}_i)$ for $i \neq j$ because $[\mathfrak{g}_i, \mathfrak{g}_j] = 0$; so it commutes with the whole action, and Lemma A.405 gives $\Gamma_j = \lambda_j \mathbb{1}$ on the irreducible $\mathbb{V}$.

The λ_j are not all zero. Let $\beta_{\mathbb{V}}$ be the trace form Equation (A.672), which is invariant but need not be nondegenerate. Its restriction to the simple ideal $\mathfrak{g}_j$ is a multiple of κ_j: writing $\beta_{\mathbb{V}}(X, Y) = \kappa_j(AX, Y)$ for $X, Y \in \mathfrak{g}_j$ with $A \in \operatorname{End}(\mathfrak{g}_j)$, invariance of both forms gives

$$\kappa_j\left(A\left[Z, X\right], Y\right) = \beta_{\mathbb{V}}\left(\left[Z, X\right], Y\right) = -\beta_{\mathbb{V}}\left(X, \left[Z, Y\right]\right) = -\kappa_j\left(AX, \left[Z, Y\right]\right) = \kappa_j\left(\left[Z, AX\right], Y\right) \tag{A.689}$$

for all $Z \in \mathfrak{g}_j$, so A commutes with every ad_Z. The adjoint representation of a simple algebra is irreducible — its submodules are its ideals — so Lemma A.405 gives $A = c_j \mathbb{1}$ and $\beta_{\mathbb{V}}|_{\mathfrak{g}_j} = c_j \kappa_j$. Now

$$\lambda_j \dim \mathbb{V} = \operatorname{tr}_{\mathbb{V}} \Gamma_j = \sum_{a \in j} \beta_{\mathbb{V}}\left(T^a, T_a\right) = c_j \sum_{a \in j} \kappa_j\left(T^a, T_a\right) = c_j \dim \mathfrak{g}_j \,. \tag{A.690}$$

If $c_j = 0$ then $\beta_{\mathbb{V}}$ vanishes on $\mathfrak{g}_j$, so $\operatorname{tr}(\rho(X)\rho(Y)) = 0$ for all $X \in [\mathfrak{g}_j, \mathfrak{g}_j] = \mathfrak{g}_j$ and $Y \in \mathfrak{g}_j$, and Theorem A.340 makes $\rho(\mathfrak{g}_j)$ solvable; being a homomorphic image of the simple $\mathfrak{g}_j$ it is either isomorphic to $\mathfrak{g}_j$, which is not solvable, or zero. So $c_j = 0$ forces $\rho(\mathfrak{g}_j) = 0$. Since $\rho \neq 0$, some $\mathfrak{g}_{j_0}$ acts nontrivially and $\lambda_{j_0} \neq 0$.

Choice of t. The eigenvalue of Γ_t on $\mathbb{V}$ is $\sum_j t_j^{-1} \lambda_j$. If $\sum_j \lambda_j \neq 0$ take every $t_j = 1$. Otherwise take $t_{j_0} = 2$ and $t_j = 1$ for $j \neq j_0$; the eigenvalue is then $\sum_j \lambda_j - \frac{1}{2}\lambda_{j_0} = -\frac{1}{2}\lambda_{j_0} \neq 0$. In either case Γ_t is a nonzero scalar on $\mathbb{V}$, hence invertible. □

Theorem A.410 (Whitehead's first and second lemmas)**.** *Let $\mathfrak{g}$ be a finite-dimensional semisimple Lie algebra over a field of characteristic zero and let $\mathbb{V}$ be any finite-dimensional $\mathfrak{g}$-module. Then*

$$\boxed{H^1(\mathfrak{g}, \mathbb{V}) = H^2(\mathfrak{g}, \mathbb{V}) = 0} \,. \tag{A.691}$$

Rests on Theorems A.403 and A.407 and Lemma A.409.

Proof. *Derives Theorem A.410.*

Reduction to an algebraically closed field. Each $C^n(\mathfrak{g}, \mathbb{V})$ is a finite-dimensional $\mathbb{K}$-vector space and d is $\mathbb{K}$-linear; extending scalars to $\mathbb{F}$ gives $C^n(\mathfrak{g}, \mathbb{V}) \otimes_{\mathbb{K}} \mathbb{F} = C^n(\mathfrak{g}_{\mathbb{F}}, \mathbb{V}_{\mathbb{F}})$, with the same differential, because a multilinear map is fixed by its values on a $\mathbb{K}$-basis. The

ranks of d in each degree are unchanged by field extension, so $H^n(\mathfrak{g},\mathbb{V})\otimes_{\mathbb{K}}\mathbb{F}=H^n\left(\mathfrak{g}_{\mathbb{F}},\mathbb{V}_{\mathbb{F}}\right)$, and a space vanishes if and only if its extension does. Moreover $\mathfrak{g}_{\mathbb{F}}$ is again semisimple by Remark A.341. It therefore suffices to prove the theorem over $\mathbb{F}$.

Reduction to irreducible coefficients. By Theorem A.407, $\mathbb{V}=\mathbb{V}_1\oplus\cdots\oplus\mathbb{V}_r$ with each $\mathbb{V}_i$ irreducible. A cochain with values in a direct sum is the same thing as a tuple of cochains with values in the summands, and d acts componentwise, so

$$H^n\left(\mathfrak{g},\mathbb{V}\right)=\bigoplus_{i=1}^{r}H^n\left(\mathfrak{g},\mathbb{V}_i\right)\,. \tag{A.692}$$

The two cases. If $\mathfrak{g}$ acts as zero on the irreducible $\mathbb{V}_i$, then every subspace is a submodule, so $\dim\mathbb{V}_i=1$ and $\mathbb{V}_i\cong\mathbb{F}$ with the trivial action; Proposition A.408 gives $H^1=H^2=0$. Otherwise Lemma A.409 supplies an invariant nondegenerate form whose Casimir is invertible on $\mathbb{V}_i$, and Theorem A.403 gives $H^1=H^2=0$. Summing over i in Equation (A.692) completes the proof. □

Corollary A.411 (Semisimple algebras admit no nontrivial extension)**.** *A finite-dimensional semisimple Lie algebra $\mathfrak{g}$ over a field of characteristic zero satisfies $H^1(\mathfrak{g},\mathbb{R})=H^2(\mathfrak{g},\mathbb{R})=0$ and admits no nontrivial central extension. In particular, for $D=p+q\geq 3$ the algebra $\mathfrak{so}(p,q)$ — and hence the Lorentz algebra $\mathfrak{so}(D-1,1)$ of Equation (14.90), and the rotation algebra $\mathfrak{so}(3)$ — admits no nontrivial central extension.*

Rests on Theorem A.410, Corollary A.344, and Proposition 14.76.

Proof. *Derives Corollary A.411.*

Take $\mathbb{V}=\mathbb{R}$ with the trivial action in Theorem A.410; by Remark A.399 the group H^2 so computed is the group $H^2(\mathfrak{g},\mathbb{R})$ of Definition 14.75, and by Proposition 14.76 its vanishing says that every central extension of $\mathfrak{g}$ by $\mathbb{R}$ is trivial, that is, isomorphic to $\mathfrak{g}\oplus\mathbb{R}$ as a Lie algebra. That $\mathfrak{so}(p,q)$ is semisimple for $D\geq 3$ is Corollary A.344, proved there by computing its Killing form and applying Theorem A.330. □

Remark A.412 (Why the hypotheses cannot be dropped). Each hypothesis of Theorem A.410 earns its place, and the counterexamples are the physical cases of Section 14.4.2. *Semisimplicity*: the abelian algebra $\mathbb{R}^{2f}$ of Example 14.79 has $H^2=\Lambda^2\left(\mathbb{R}^{2f}\right)^*$, as far from zero as possible, and the extension is the Heisenberg algebra with $Z=\mathrm{i}\hbar$; the proof fails at the first step, since $[\mathfrak{g},\mathfrak{g}]=0$ and the Killing form vanishes identically. *Finite dimension*: the Witt algebra of Example 14.81 has a one-dimensional H^2 whose extension is the Virasoro algebra, and the Casimir Equation (A.668) is an infinite sum there, with no meaning as an operator on the algebra. *Characteristic zero*: the division by λ in Lemma A.406 and by $\dim\mathbb{V}$ in Equation (A.690) both fail in characteristic p, and so does the theorem.

The Galilei algebra of Example 14.80 is the instructive intermediate case: it is finite-dimensional over $\mathbb{R}$ but not semisimple — it has the translations and the boosts as abelian subalgebras and is a contraction (Section 14.5) of an algebra that is — and it carries the mass as a central charge. So the mass is not an accident of the nonrelativistic limit that a better choice of generators could remove; it is an obstruction that exists because the algebra fails the hypothesis of this theorem.

Appendix A.37 discharges the proof obligation of Proposition 14.77. Its statement is used at Remark 14.78 to localize where nontrivial central charges can live — not in semisimple algebras, hence only in abelian algebras, in inhomogeneous semidirect sums such as Equation (14.99), in contractions (Section 14.5) and in infinite-dimensional algebras — and at Remark 14.85, where the cohomological reading of a contraction is set out. Two by-products proved along the way have independent value and are used tacitly elsewhere in the chapter: Weyl's complete reducibility theorem (Theorem A.407), which is why a finite-dimensional representation of a semisimple algebra may always be decomposed into

irreducibles as Theorem 14.47 does for $\mathfrak{su}(2)$, and the vanishing of $H^1(\mathfrak{g}, \mathbb{V})$, which is the statement that a semisimple algebra admits no nontrivial deformation of a module structure.

A.38 The Second Cohomology of the Galilei Algebra

This appendix proves the assertion left owed in Example 14.80 of Chapter 14: the second Chevalley–Eilenberg cohomology $H^2(\mathfrak{g}, \mathbb{R})$ of the ten-generator Galilei algebra of three space dimensions is *one-dimensional*, so that up to a scale the mass extension is the only central extension the algebra admits.

Exactly one half of that statement is proved elsewhere in this treatise. Proposition 25.14, in the chapter bridging Poisson brackets and quantization, shows that the mass cocycle $c(K_i, P_j) = m\,\delta_{ij}$ of Equation (25.15) is not a coboundary — that its class in H^2 is *nonzero*. It says nothing about how large H^2 is, and the chapter records the difference honestly. What is added here is the other half: that the class of the mass cocycle *exhausts* the cohomology. Nothing in Chapter 14 or in Part III needs the stronger statement, so this appendix closes a gap in the mathematics rather than supplying a missing physical input.

The computation is finite and is carried out in full. The space of alternating bilinear forms on a ten-dimensional algebra has dimension $\binom{10}{2} = 45$; the cocycle condition Equation (14.121) cuts it down to 10, the coboundaries account for 9 of those, and the survivor is the mass.

A.38.1 The algebra, and the two spaces

Definition A.413 (The Galilei algebra of three space dimensions)**.** Let $\mathfrak{g}$ be the real ten-dimensional Lie algebra spanned by rotations J_i, boosts K_i, space translations P_i $(i = 1, 2, 3)$ and the time translation H, with the isotropy relations Equation (A.161),

$$[J_i, J_j] = \epsilon_{ijk} J_k\,, \quad [J_i, K_j] = \epsilon_{ijk} K_k\,, \quad [J_i, P_j] = \epsilon_{ijk} P_k\,, \quad [J_i, H] = 0\,, \tag{A.693}$$

and the single further nonvanishing bracket

$$[K_i, H] = P_i\,, \qquad [K_i, K_j] = [P_i, P_j] = [K_i, P_j] = [P_i, H] = 0\,. \tag{A.694}$$

This is the case $(\gamma, \mu, \nu) = (0, *, 0)$ of the enumeration in Appendix A.10.5, with $\alpha = -\gamma\mu = 0$ and $\beta = \gamma\nu = 0$; the normalisation $\mu = 1$ is the one fixed there. All indices are Cartesian, repeated indices are summed, and ϵ_{ijk} is the Levi-Civita symbol.

Rests on Equations (A.161) *and* (A.165) *and Theorem 14.90.*

Theorem A.414 (H^2 of the Galilei algebra)**.** $\dim_{\mathbb{R}} H^2(\mathfrak{g}, \mathbb{R}) = 1$*, and the class is represented by the* mass cocycle

$$c_M(K_i, P_j) = \delta_{ij}\,, \qquad c_M = 0 \text{ on every other pair of basis generators}\,. \tag{A.695}$$

Every central extension of $\mathfrak{g}$ by $\mathbb{R}$ is therefore equivalent to the one with bracket $\left[\tilde{K}_i, \tilde{P}_j\right] = m\,\delta_{ij} Z$ for a single real number m, and it is trivial exactly when $m = 0$.

Rests on Definitions 14.75 and A.413 and Proposition 14.76.

A cocycle is fixed by its values on pairs of basis generators. Grouping those values by type, an alternating bilinear $c : \mathfrak{g} \times \mathfrak{g} \to \mathbb{R}$ is exactly the datum

$$\begin{aligned} &A_{ij} = c(J_i, J_j)\,, \quad B_{ij} = c(J_i, K_j)\,, \quad C_{ij} = c(J_i, P_j)\,, \quad u_i = c(J_i, H)\,, \\ &D_{ij} = c(K_i, K_j)\,, \quad E_{ij} = c(K_i, P_j)\,, \quad v_i = c(K_i, H)\,, \quad F_{ij} = c(P_i, P_j)\,, \\ &w_i = c(P_i, H)\,, \end{aligned} \tag{A.696}$$

with A, D, F antisymmetric and B, C, E unrestricted: $3+9+9+3+3+9+3+3+3 = 45$ real parameters, as it must be.

A.38.2 Three tensor lemmas

The cocycle conditions that involve one or two rotation generators are statements about SO(3)-covariance of the arrays in Equation (A.696), and all of them reduce to two identities. They are isolated here so that the enumeration below reads cleanly. Throughout, the only inputs are the standard contractions

$$\epsilon_{ijm}\epsilon_{ijl} = 2\delta_{ml}\,, \qquad \epsilon_{ijm}\epsilon_{ikl} = \delta_{jk}\delta_{ml} - \delta_{jl}\delta_{mk}\,, \qquad \epsilon_{ijl}\epsilon_{lkm} = \delta_{ik}\delta_{jm} - \delta_{im}\delta_{jk}\,. \tag{A.697}$$

Lemma A.415 (Invariant two-tensors)**.** *A real array T_{jk} satisfies*

$$\epsilon_{ijl}T_{lk} + \epsilon_{ikl}T_{jl} = 0 \qquad \text{for all } i, j, k \tag{A.698}$$

if and only if $T_{jk} = t\,\delta_{jk}$ for a real number t.
Rests on Equation (A.697)*.*

Proof. *Derives Lemma A.415.*

Necessity. Contract Equation (A.698) with ϵ_{ijm} and sum over i and j. By the first identity of Equation (A.697) the first term gives $2T_{mk}$; by the second, the remaining term gives

$$\epsilon_{ijm}\epsilon_{ikl}T_{jl} = (\delta_{jk}\delta_{ml} - \delta_{jl}\delta_{mk})\,T_{jl} = T_{km} - \delta_{mk}\,\operatorname{tr}T\,,$$

where $\operatorname{tr}T = T_{jj}$. Hence

$$2T_{mk} + T_{km} - \delta_{mk}\,\operatorname{tr}T = 0\,. \tag{A.699}$$

Exchanging m and k in Equation (A.699) and subtracting gives $T_{mk} - T_{km} = 0$, so T is symmetric; adding instead gives $3\,(T_{mk} + T_{km}) = 2\delta_{mk}\operatorname{tr}T$, that is $T_{mk} = \frac{1}{3}\,(\operatorname{tr}T)\,\delta_{mk}$.

Sufficiency. For $T = \delta$ the left side of Equation (A.698) is $\epsilon_{ijk} + \epsilon_{ikj} = 0$. □

Lemma A.416 (The mixed covariance condition)**.** *A real array T_{jk} satisfies*

$$\epsilon_{ijl}T_{lk} + \epsilon_{ikl}T_{jl} - \epsilon_{jkl}T_{il} = 0 \qquad \text{for all } i, j, k \tag{A.700}$$

if and only if T is antisymmetric, that is $T_{jk} = \epsilon_{jkm}t_m$ for a real vector t.
Rests on Equation (A.697)*.*

Proof. *Derives Lemma A.416.*

Necessity. Contract with ϵ_{ijm} as before. The first two terms give $2T_{mk}$ and $T_{km} - \delta_{mk}\operatorname{tr}T$ exactly as in Lemma A.415. For the third, use $\epsilon_{ijm}\epsilon_{jkl} = -\epsilon_{jim}\epsilon_{jkl} = -\,(\delta_{ik}\delta_{ml} - \delta_{il}\delta_{mk})$, so that

$$-\epsilon_{ijm}\epsilon_{jkl}T_{il} = (\delta_{ik}\delta_{ml} - \delta_{il}\delta_{mk})\,T_{il} = T_{km} - \delta_{mk}\,\operatorname{tr}T\,.$$

Summing the three,

$$2T_{mk} + 2T_{km} - 2\delta_{mk}\,\operatorname{tr}T = 0\,, \qquad \text{i.e.} \qquad T_{mk} + T_{km} = \delta_{mk}\,\operatorname{tr}T\,. \tag{A.701}$$

Setting $m = k$ and summing gives $2\operatorname{tr}T = 3\operatorname{tr}T$, so $\operatorname{tr}T = 0$, and then Equation (A.701) reads $T_{mk} = -T_{km}$.

Sufficiency. Put $T_{jk} = \epsilon_{jkm}t_m$ and evaluate the three terms of Equation (A.700) with the third identity of Equation (A.697), applied after cycling the symbols into the shape $\epsilon_{abl}\epsilon_{lcd}$:

$$\begin{aligned}
\epsilon_{ijl}T_{lk} &= \epsilon_{ijl}\epsilon_{lkm}t_m = \delta_{ik}t_j - \delta_{jk}t_i\,,\\
\epsilon_{ikl}T_{jl} &= \epsilon_{ikl}\epsilon_{lmj}t_m = \delta_{im}\delta_{kj}t_m - \delta_{ij}\delta_{km}t_m = \delta_{kj}t_i - \delta_{ij}t_k\,,\\
\epsilon_{jkl}T_{il} &= \epsilon_{jkl}\epsilon_{lmi}t_m = \delta_{jm}\delta_{ki}t_m - \delta_{ji}\delta_{km}t_m = \delta_{ki}t_j - \delta_{ji}t_k\,.
\end{aligned}$$

The first two add to $\delta_{ik}t_j - \delta_{ij}t_k$, which is the third; the alternating sum vanishes. □

Remark A.417 (Where the three space dimensions enter). Lemmas A.415 and A.416 are the only steps of the computation that are not pure bookkeeping, and both are statements about the invariant two-tensors of the rotation group of *three* space dimensions: they use the Levi-Civita symbol with three indices and the contraction identities Equation (A.697), which are three-dimensional. The theorem proved here is accordingly a theorem about the Galilei algebra of the observed three space dimensions, which is the only case this treatise instantiates; no claim is made, and none is needed, for any other number of space dimensions.

A.38.3 Solving the cocycle condition

Write $\delta c(x, y, z)$ for the left-hand side of Equation (14.121),

$$\delta c(x, y, z) = c\left([x, y], z\right) + c\left([y, z], x\right) + c\left([z, x], y\right) , \tag{A.702}$$

which is alternating in (x, y, z), so it suffices to impose $\delta c = 0$ on unordered triples of basis generators; a triple containing H twice gives nothing, since there is only one H. Sixteen types remain, and every one is evaluated below.

Triples with no bracket. For (K_i, K_j, K_k), (P_i, P_j, P_k), (K_i, K_j, P_k), (K_i, P_j, P_k) and (P_i, P_j, H) every bracket appearing in Equation (A.702) vanishes by Equation (A.694), so the condition is empty.

The triple (J_i, J_j, J_k). Writing $A_{ij} = \epsilon_{ijm} a_m$ and using the third identity of Equation (A.697), $\epsilon_{ijl} A_{lk} = \delta_{ik} a_j - \delta_{jk} a_i$, so the cyclic sum is

$$(\delta_{ik} a_j - \delta_{jk} a_i) + (\delta_{ji} a_k - \delta_{ki} a_j) + (\delta_{kj} a_i - \delta_{ij} a_k) = 0$$

identically. *The array A is unconstrained*, and it appears in no other triple: a term $c([\cdot, \cdot], J)$ can involve A only when the bracket produces a rotation, and only $[J, J]$ does.

The triple (J_i, J_j, K_k). Using Equation (A.693) three times,

$$\delta c = \epsilon_{ijl} B_{lk} + \epsilon_{jkl} c(K_l, J_i) - \epsilon_{ikl} c(K_l, J_j) = \epsilon_{ijl} B_{lk} + \epsilon_{ikl} B_{jl} - \epsilon_{jkl} B_{il} ,$$

which is Equation (A.700). By Lemma A.416,

$$B_{jk} = \epsilon_{jkm} \beta_m \tag{A.703}$$

for an arbitrary vector β, and nothing more.

The triple (J_i, J_j, P_k). Identical in form, with C in place of B: it forces C to be antisymmetric and imposes nothing else. It will be subsumed by the stronger condition below.

The triple (J_i, J_j, H). Since $[J_i, H] = [H, J_j] = 0$, only the first term survives: $\delta c = \epsilon_{ijl} u_l = 0$ for all i, j, hence

$$u_i = c(J_i, H) = 0 . \tag{A.704}$$

The triple (J_i, K_j, K_k). Here $[K_j, K_k] = 0$, so

$$\delta c = \epsilon_{ijl} D_{lk} - \epsilon_{ikl} D_{lj} = \epsilon_{ijl} D_{lk} + \epsilon_{ikl} D_{jl} ,$$

the second step using the antisymmetry of D. This is Equation (A.698), so $D = t\delta$ by Lemma A.415; but D is antisymmetric and δ is not, so $t = 0$ and

$$D_{ij} = c(K_i, K_j) = 0 . \tag{A.705}$$

The triple (J_i, P_j, P_k). Word for word the same with F in place of D, giving $F_{ij} = c(P_i, P_j) = 0$.

The triple (J_i, K_j, H). Now the bracket $[K_j, H] = P_j$ contributes:

$$\delta c = \epsilon_{ijl} c(K_l, H) + c(P_j, J_i) + c(0, K_j) = \epsilon_{ijl} v_l - C_{ij}\,,$$

so that

$$C_{ij} = c(J_i, P_j) = \epsilon_{ijl} v_l\,. \tag{A.706}$$

The array C is thus determined by the vector v, and is automatically antisymmetric — consistent with, and stronger than, the (J, J, P) condition.

The triple (J_i, P_j, H). Both $[P_j, H]$ and $[H, J_i]$ vanish, leaving $\delta c = \epsilon_{ijl} w_l = 0$, hence

$$w_i = c(P_i, H) = 0\,. \tag{A.707}$$

The triple (J_i, K_j, P_k). With $[K_j, P_k] = 0$,

$$\delta c = \epsilon_{ijl} E_{lk} - \epsilon_{ikl} c(P_l, K_j) = \epsilon_{ijl} E_{lk} + \epsilon_{ikl} E_{jl}\,,$$

which is Equation (A.698) again. By Lemma A.415,

$$E_{ij} = c(K_i, P_j) = e\,\delta_{ij}\,, \qquad e \in \mathbb{R}\,. \tag{A.708}$$

The triple (K_i, K_j, H). Only the brackets with H survive:

$$\delta c = c(P_j, K_i) + c(-P_i, K_j) = -E_{ij} + E_{ji} = 0\,,$$

which says E is symmetric — already true of Equation (A.708), so no new information.

The triple (K_i, P_j, H). Here $[K_i, P_j] = 0$ and $[P_j, H] = 0$, and $[H, K_i] = -P_i$, so $\delta c = c(-P_i, P_j) = -F_{ij} = 0$: again already known.

That exhausts the sixteen types. Collecting Equations (A.703) to (A.708) and the two vanishing statements for F:

Proposition A.418 (The cocycles)**.** *A bilinear form on* $\mathfrak{g}$ *is a* 2*-cocycle in the sense of Proposition 14.73 if and only if*

$$A_{ij} = \epsilon_{ijm} a_m\,, \quad B_{ij} = \epsilon_{ijm} \beta_m\,, \quad C_{ij} = \epsilon_{ijm} v_m\,, \quad E_{ij} = e\,\delta_{ij}\,, \quad c(K_i, H) = v_i\,, \tag{A.709}$$

with $u = w = 0$ *and* $D = F = 0$*, for arbitrary vectors* $a, \beta, v \in \mathbb{R}^3$ *and an arbitrary real number* e*. Hence* $\dim_{\mathbb{R}} Z^2(\mathfrak{g}, \mathbb{R}) = 3 + 3 + 3 + 1 = 10$.

Rests on Definition A.413 and Lemmas A.415 and A.416.

A.38.4 The coboundaries, and the quotient

Proposition A.419 (The coboundaries)**.** $\dim_{\mathbb{R}} B^2(\mathfrak{g}, \mathbb{R}) = 9$*, and a coboundary is exactly a cocycle Equation* (A.709) *with* $e = 0$.

Rests on Definitions 14.74 and A.413 and Proposition A.418.

Proof. *Derives Proposition A.419.*

Let $b : \mathfrak{g} \to \mathbb{R}$ be linear, with components $b(J_i) = \beta_i^J$, $b(K_i) = \beta_i^K$, $b(P_i) = \beta_i^P$ and $b(H) = \eta$. Evaluating $(\partial b)(x, y) = b([x, y])$ of Equation (14.122) on each pair of basis generators with Equations (A.693) and (A.694),

$$\begin{aligned} &(\partial b)(J_i, J_j) = \epsilon_{ijk} \beta_k^J\,, \quad (\partial b)(J_i, K_j) = \epsilon_{ijk} \beta_k^K\,, \quad (\partial b)(J_i, P_j) = \epsilon_{ijk} \beta_k^P\,, \\ &(\partial b)(K_i, H) = \beta_i^P\,, \qquad (\partial b)(J_i, H) = 0\,, \qquad (\partial b)(K_i, P_j) = 0\,, \end{aligned} \tag{A.710}$$

and $(\partial b)(K_i, K_j) = (\partial b)(P_i, P_j) = (\partial b)(P_i, H) = 0$. In the coordinates of Equation (A.709) this is

$$a = \beta^J\,, \qquad \beta = \beta^K\,, \qquad v = \beta^P\,, \qquad e = 0\,, \tag{A.711}$$

where the third entry is consistent in both places it occurs: $C_{ij} = \epsilon_{ijk}\beta^P_k$ and $c(K_i, H) = \beta^P_i$ are exactly the pair required by Equation (A.709). Two consequences follow at once. First, every coboundary *is* a cocycle with $e = 0$ — which also re-proves Proposition 14.73 for this algebra. Second, the map $b \mapsto \partial b$ carries $\left(\beta^J, \beta^K, \beta^P\right)$ onto the whole nine-dimensional subspace $\{e = 0\}$ of Z^2, bijectively, while η is annihilated. Hence $\dim B^2 = 9$.

The kernel is visible structurally as well: $\partial b = 0$ if and only if b vanishes on the derived algebra $[\mathfrak{g}, \mathfrak{g}]$, which by Equations (A.693) and (A.694) is the span of the J_i, K_i and P_i — the P_i arising both from $[J, P]$ and from $[K, H]$ — of dimension 9. No bracket produces H, so H is not in the derived algebra and the kernel is the line $\left\{\beta^J = \beta^K = \beta^P = 0\right\}$, of dimension $10 - 9 = 1$. □

Proof of Theorem A.414. *Derives Theorem A.414.*

By Propositions A.418 and A.419 the coboundaries are the hyperplane $\{e = 0\}$ inside the ten-dimensional space of cocycles, so

$$\dim_{\mathbb{R}} H^2(\mathfrak{g}, \mathbb{R}) = \dim Z^2 - \dim B^2 = 10 - 9 = 1\,, \tag{A.712}$$

and the coordinate e descends to an isomorphism $H^2(\mathfrak{g}, \mathbb{R}) \cong \mathbb{R}$. The cocycle c_M of Equation (A.695) has $a = \beta = v = 0$ and $e = 1$: it satisfies Equation (A.709), hence is a cocycle, and its class is a generator. The final statement is Proposition 14.76: central extensions of $\mathfrak{g}$ by $\mathbb{R}$ correspond to classes in H^2, so they form a one-parameter family $m\,[c_M]$, realized by $\left[\tilde{K}_i, \tilde{P}_j\right] = m\,\delta_{ij} Z$ through Equation (14.120), and by Equation (14.123) the extension is trivial precisely for the zero class, $m = 0$. □

Remark A.420 (What was already known, and what is new). Proposition 25.14 proves that the class of c_M is nonzero, by exhibiting the Poisson-bracket realisation of a free particle and showing that no shift of the generators by constants removes the defect Equation (25.15). The present appendix reproves that as the single line $e \neq 0$ in Equation (A.712) — coboundaries have $e = 0$, c_M has $e = 1$ — and adds the converse, that there is nothing else: the whole of H^2 is the mass.

Two structural readings of the computation are worth recording, because they explain the answer rather than merely producing it. The first is that the surviving parameter is the one component of c that no coboundary can reach, namely $c(K_i, P_j)$, and it is unreachable because $[K_i, P_j] = 0$ in $\mathfrak{g}$: a coboundary is a linear functional composed with the bracket, and there is no bracket there to compose with. That is exactly the argument of Proposition 25.14, and the enumeration above shows it is the *only* such place. The second is that the answer is forced to be at most one-dimensional by rotational covariance: Lemma A.415 says the surviving array $c(K_i, P_j)$ has nowhere to live but the invariant δ_{ij}, so the mass is a single number and not a tensor.

Example 14.80 may therefore be read without its final caveat, and Remark 14.88 — which describes how the mass emerges from the Inönü–Wigner limit of a trivially extended Poincaré algebra — is now accompanied by an independent statement of where the limit must land: H^2 of the contracted algebra is one-dimensional, so any nontrivial extension produced by any route is a multiple of c_M. This is a concrete instance of the phenomenon named in Remark 14.78: a contraction can create a cohomology class that the parent semisimple algebra, rigid by Proposition 14.77, did not have.

A.39 Central Extensions of Three Infinite-Dimensional Algebras

Example 14.81 of Chapter 14 lists three infinite-dimensional algebras whose central extensions are nontrivial: the Witt algebra of vector fields on the circle, whose extension is the Virasoro

algebra; the loop algebra of a simple Lie algebra, whose extension is affine Kac–Moody; and the equal-time current algebra of a field theory, whose extension is the Schwinger term. This appendix supplies the three computations.

They are of two different kinds, and the difference is the point of the section. The first two are finite algebraic computations in the sense of Definition 14.75: a cocycle is written down, the cocycle condition Equation (14.121) is solved, and the coboundaries Equation (14.122) are divided out. The third is not. There is no finite computation of a Schwinger term, because the object whose commutator is asked for — a product of operator-valued distributions at a point — does not exist until it is regularized. What can be proved, and is proved below, is a *no-go*: in any theory with a Hamiltonian bounded below, a normalizable ground state and a local conserved current, the equal-time commutator of the charge density with the current density cannot vanish, and the leading term it must carry is a central one of definite sign. Remark A.434 states exactly which hypotheses that argument consumes and which question it leaves open.

Throughout, the ground field is written F and may be taken to be $\mathbb{R}$ or $\mathbb{C}$; Definitions 14.72, 14.74 and 14.75 and Propositions 14.73 and 14.76 are stated in Section 14.4.1 for $\mathbb{R}$, and their statements and proofs use nothing but the field axioms in characteristic zero, so they hold verbatim over $\mathbb{C}$. Rule 1 of this treatise applies here as everywhere: what follows is mathematics about Lie algebras, and no claim is made about any physical theory in which these algebras have been proposed to act.

A.39.1 The Virasoro cocycle

Definition A.421 (Witt algebra)**.** The *Witt algebra* $\mathfrak{w}$ is the Lie algebra over F with basis $\{L_n\}_{n\in\mathbb{Z}}$ and brackets

$$[L_m, L_n] = (m-n)\,L_{m+n}\,, \qquad m,n\in\mathbb{Z}\,. \tag{A.713}$$

It is the algebra of polynomial vector fields on the circle: with $t=\mathrm{e}^{\mathrm{i}\theta}$ and $L_n=-t^{n+1}\frac{\mathrm{d}}{\mathrm{d}t}$ acting on $F[t,t^{-1}]$, a direct computation reproduces Equation (A.713). The Jacobi identity is the identity $(m-n)(m+n-k)+(n-k)(n+k-m)+(k-m)(k+m-n)=0$, which holds because every quadratic monomial cancels in pairs.

Rests on Definition 14.72.

Note that $\mathfrak{w}$ is infinite-dimensional, so a bilinear form on it is an arbitrary array of values $c(L_m,L_n)$; bilinearity constrains only finite linear combinations, and no continuity or boundedness is imposed anywhere below.

Theorem A.422 (The Virasoro extension)**.** *$H^2(\mathfrak{w},F)$ is one-dimensional, generated by the class of*

$$\boxed{\omega\,(L_m,L_n)=\frac{m^3-m}{12}\,\delta_{m+n,0}}\,. \tag{A.714}$$

Every central extension of $\mathfrak{w}$ by F is therefore equivalent, for exactly one $C\in F$, to the Virasoro algebra

$$[L_m,L_n]=(m-n)L_{m+n}+\frac{C}{12}\left(m^3-m\right)\delta_{m+n,0}\,Z\,, \qquad [Z,\cdot]=0\,. \tag{A.715}$$

Rests on Definitions 14.75 and A.421 and Proposition 14.76.

Proof. *Derives Theorem A.422.*

Let c be a 2-cocycle on $\mathfrak{w}$.

Step 1: normalize against L_0. Define a linear functional b on $\mathfrak{w}$ by

$$b\,(L_n)=\frac{c\,(L_n,L_0)}{n}\quad (n\neq 0)\,, \qquad b\,(L_0)=0\,. \tag{A.716}$$

Its coboundary is $(\partial b)(L_m, L_n) = b\left([L_m, L_n]\right) = (m-n)\, b(L_{m+n})$, so for $n \neq 0$

$$(\partial b)\left(L_n, L_0\right) = n\, b\left(L_n\right) = c\left(L_n, L_0\right) ,$$

while $(\partial b)(L_0, L_0) = 0 = c(L_0, L_0)$ by antisymmetry. Replacing c by $c - \partial b$ — which changes nothing in H^2 — we may and do assume

$$c\left(L_n, L_0\right) = 0 \qquad \text{for every } n \in \mathbb{Z} . \tag{A.717}$$

Step 2: only the diagonal $m+n=0$ survives. Impose the cocycle condition Equation (14.121) on the triple (L_0, L_m, L_n). With $[L_0, L_m] = -mL_m$, $[L_n, L_0] = nL_n$ and $[L_m, L_n] = (m-n)L_{m+n}$,

$$0 = -m\, c\left(L_m, L_n\right) + (m-n)\, c\left(L_{m+n}, L_0\right) + n\, c\left(L_n, L_m\right) = -(m+n)\, c\left(L_m, L_n\right) ,$$

the middle term vanishing by Equation (A.717) and the last by antisymmetry. Hence

$$c\left(L_m, L_n\right) = h(m)\, \delta_{m+n,0} , \qquad h(m) = c\left(L_m, L_{-m}\right) , \tag{A.718}$$

and antisymmetry gives $h(-m) = -h(m)$, with $h(0) = 0$.

Step 3: the recursion. A cocycle of the shape Equation (A.718) makes every term of Equation (14.121) vanish on a triple (L_m, L_n, L_k) with $m+n+k \neq 0$, since each term pairs L_{m+n} with L_k and the two indices sum to $m+n+k$. For $m+n+k=0$ the three terms are

$$\begin{aligned} (m-n)\, c\left(L_{-k}, L_k\right) + (n-k)\, c\left(L_{-m}, L_m\right) + (k-m)\, c\left(L_{-n}, L_n\right) \\ = -\left[(m-n)h(k) + (n-k)h(m) + (k-m)h(n)\right] , \end{aligned}$$

so the cocycle condition is $(m-n)h(k) + (n-k)h(m) + (k-m)h(n) = 0$ with $k = -m-n$, that is

$$(m-n)\, h(m+n) = (m+2n)\, h(m) - (2m+n)\, h(n) . \tag{A.719}$$

Setting $n = 1$,

$$(m-1)\, h(m+1) = (m+2)\, h(m) - (2m+1)\, h(1) , \tag{A.720}$$

which for $m \geq 2$ determines $h(m+1)$ from $h(m)$ and $h(1)$. Since $h(2)$ is not reached by Equation (A.720) — at $m = 1$ the left-hand side vanishes identically, and indeed the relation then reads $3h(1) = 3h(1)$ — the solution space has dimension at most 2, the free data being $h(1)$ and $h(2)$; negative arguments follow from $h(-m) = -h(m)$.

Two solutions are exhibited directly. For $h(m) = m$,

$$(m-n)(m+n) = m^2 - n^2 = \left(m^2 + 2mn\right) - \left(2mn + n^2\right) = (m+2n)m - (2m+n)n ,$$

and for $h(m) = m^3$, expanding both sides,

$$(m-n)(m+n)^3 = m^4 + 2m^3 n - 2mn^3 - n^4 = (m+2n)m^3 - (2m+n)n^3 ,$$

where the middle expression is obtained by multiplying out $(m-n)\left(m^3 + 3m^2 n + 3mn^2 + n^3\right)$ and cancelling the two $3m^2 n^2$ terms. The two are linearly independent, so the solution space of Equation (A.719) is exactly $\left\{h(m) = \alpha m + \beta m^3\right\}$.

Step 4: the linear solution is a coboundary. Take $b_\gamma\left(L_n\right) = \gamma\, \delta_{n,0}$. Then $\left(\partial b_\gamma\right)\left(L_m, L_n\right) = (m-n)\gamma\, \delta_{m+n,0} = 2m\gamma\, \delta_{m+n,0}$, which is Equation (A.718) with $h(m) = 2\gamma m$; and it respects Equation (A.717), since $\left(\partial b_\gamma\right)\left(L_n, L_0\right) = n\, b_\gamma(L_n) = 0$ for $n \neq 0$. Choosing $\gamma = \alpha/2$ removes the α term, so every class is represented by a multiple of $h(m) = m^3$, and equally by a multiple of Equation (A.714), since $(m^3 - m)/12$ is such a combination. Thus $\dim H^2(\mathfrak{w}, F) \leq 1$.

Step 5: ω is not a coboundary. Every coboundary satisfies $(\partial b)\left(L_m, L_{-m}\right) = b\left([L_m, L_{-m}]\right) = 2m\, b\left(L_0\right)$, a linear function of m. If $\omega = \partial b$ then $(m^3 - m)/12 = 2m\, b(L_0)$

for every m; at $m = 2$ this gives $b(L_0) = \frac{1}{8}$ and at $m = 3$ it gives $b(L_0) = \frac{1}{3}$, a contradiction. Hence $\dim H^2(\mathfrak{w}, F) = 1$ and ω generates it.

The last assertion is Proposition 14.76: extensions up to equivalence are in bijection with classes, the class of $C\,\omega$ corresponds to the bracket Equation (A.715) through Equation (14.120), and by Equation (14.123) the extension is trivial precisely for $C = 0$. □

Remark A.423 (Why the normalization $(m^3 - m)/12$). Step 4 shows that the representative of a class is fixed only up to a multiple of $h(m) = m$, so the choice Equation (A.714) is a convention and not a result. It is the convention that makes ω vanish on the three-dimensional subalgebra spanned by L_{-1}, L_0, L_1: those are the values $m \in \{-1, 0, 1\}$, at which $m^3 - m = 0$. That subalgebra is closed — $[L_1, L_{-1}] = 2L_0$, $[L_0, L_{\pm 1}] = \mp L_{\pm 1}$ — and is isomorphic to $\mathfrak{sl}(2, F)$, which by Proposition 14.77 admits no nontrivial central extension at all; the normalization therefore makes the restriction of the extension to it not merely trivial in cohomology but zero on the nose. The factor 12 is chosen so that the coefficient C in Equation (A.715) takes the value 1 for the smallest extension usually singled out; nothing in the mathematics depends on it.

A.39.2 The Kac–Moody cocycle

Definition A.424 (Loop algebra and residue)**.** Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra over $\mathbb{C}$ with Killing form κ (Definition 14.10). The *loop algebra* is

$$L\mathfrak{g} = \mathfrak{g} \otimes \mathbb{C}\left[t, t^{-1}\right], \qquad [x \otimes f, y \otimes g] = [x, y] \otimes fg\,, \tag{A.721}$$

which is a Lie algebra because the bracket of $\mathfrak{g}$ is and $\mathbb{C}[t, t^{-1}]$ is commutative and associative. For a Laurent polynomial $f = \sum_n a_n t^n$ the *residue* is $\operatorname{Res} f = a_{-1}$.

Rests on Definitions 14.10 and 14.72.

Lemma A.425 (The residue of a derivative vanishes)**.** $\operatorname{Res} f' = 0$ *for every* $f \in \mathbb{C}[t, t^{-1}]$, *and consequently* $\operatorname{Res}(f'g) = -\operatorname{Res}(fg')$ *for all* f, g.

Rests on Definition A.424.

Proof. *Derives Lemma A.425.*

$(t^n)' = n\,t^{n-1}$, whose exponent is -1 only for $n = 0$, where the coefficient n vanishes; so no t^{-1} term is ever produced and $\operatorname{Res} f' = 0$ by linearity. Applying this to fg and using the Leibniz rule, $0 = \operatorname{Res}(fg)' = \operatorname{Res}(f'g) + \operatorname{Res}(fg')$. □

Theorem A.426 (The Kac–Moody cocycle)**.** *The bilinear map*

$$\boxed{\omega_\kappa\,(x \otimes f,\ y \otimes g) = \kappa(x, y)\,\operatorname{Res}(f'g)}, \qquad \textit{that is} \qquad \omega_\kappa\,(x \otimes t^m,\ y \otimes t^n) = m\,\delta_{m+n,0}\,\kappa(x, y)\,, \tag{A.722}$$

is an antisymmetric 2-cocycle on $L\mathfrak{g}$ *and is not a coboundary. The corresponding central extension is the affine Kac–Moody algebra*

$$[x \otimes t^m, y \otimes t^n] = [x, y] \otimes t^{m+n} + \ell\, m\, \delta_{m+n,0}\, \kappa(x, y)\, Z\,, \tag{A.723}$$

with $\ell \in \mathbb{C}$ *the* level *and* Z *central.*

Rests on Definition A.424 and Lemmas 14.11 and A.425.

Proof. *Derives Theorem A.426.*

The two forms agree. For $f = t^m$, $g = t^n$ one has $f'g = m\,t^{m+n-1}$, whose residue is $m\,\delta_{m+n,0}$.

Antisymmetry. κ is symmetric (Definition 14.10), so

$$\omega_\kappa\,(y \otimes g,\ x \otimes f) = \kappa(x, y)\operatorname{Res}(g'f) = -\kappa(x, y)\operatorname{Res}(f'g) = -\omega_\kappa\,(x \otimes f,\ y \otimes g)$$

by Lemma A.425.

The cocycle condition. Let $u = x \otimes f$, $v = y \otimes g$, $w = z \otimes h$. By Equation (A.721),

$$\omega_\kappa\left([u,v],w\right) = \kappa\left([x,y],z\right)\operatorname{Res}\left((fg)'h\right)\ ,$$

and likewise for the two cyclic permutations. The three Killing-form factors are equal. Indeed Lemma 14.11 reads $\kappa\left([X,Y],Z\right) = -\kappa\left(Y,[X,Z]\right)$; taking $X = y$, $Y = x$, $Z = z$ and using antisymmetry of the bracket gives $\kappa\left([x,y],z\right) = \kappa\left(x,[y,z]\right)$, and the symmetry of κ turns the right side into $\kappa\left([y,z],x\right)$; applying the same step again gives $\kappa\left([z,x],y\right)$. Write $\mathcal{K}$ for the common value. The cyclic sum is therefore

$$\mathcal{K}\operatorname{Res}\left[(fg)'h + (gh)'f + (hf)'g\right]\ . \tag{A.724}$$

Expanding each derivative by the Leibniz rule,

$$(fg)'h + (gh)'f + (hf)'g = (f'gh + fg'h) + (fg'h + fgh') + (fgh' + f'gh) = 2\,(fgh)'\ ,$$

and Res of a derivative vanishes by Lemma A.425. So Equation (A.724) is zero, which is Equation (14.121).

It is not a coboundary. Since $\mathfrak{g}$ is simple, $[\mathfrak{g},\mathfrak{g}]$ is a nonzero ideal, hence all of $\mathfrak{g}$; so $\kappa \neq 0$, and there is $x \in \mathfrak{g}$ with $\kappa(x,x) \neq 0$ — were $\kappa(x,x) = 0$ for every x, the polarization identity $2\kappa(x,y) = \kappa(x+y,x+y) - \kappa(x,x) - \kappa(y,y)$ would make κ vanish identically, contradicting its nondegeneracy (Theorem 14.13). Put $u = x \otimes t$ and $v = x \otimes t^{-1}$. Then $[u,v] = [x,x] \otimes 1 = 0$, so $(\partial b)\,(u,v) = b\,([u,v]) = 0$ for every linear b, whereas $\omega_\kappa(u,v) = 1 \cdot \kappa(x,x) \neq 0$ by Equation (A.722). The extension Equation (A.723) is then Equation (14.120) for the cocycle $\ell\,\omega_\kappa$, and is nontrivial for $\ell \neq 0$ by Equation (14.123). □

The structure of Equation (A.722) is worth naming: it is the product of the unique invariant pairing on $\mathfrak{g}$ with the unique invariant pairing on $\mathbb{C}[t,t^{-1}]$ that is antisymmetric, namely $(f,g) \mapsto \operatorname{Res}(f'g)$. The next proposition makes the first "unique" precise and shows that the product is forced.

Lemma A.427 (Invariant bilinear forms on a simple algebra)**.** *Let $\mathfrak{g}$ be finite-dimensional and simple over $\mathbb{C}$. Every bilinear $B : \mathfrak{g} \times \mathfrak{g} \to \mathbb{C}$ with*

$$B\left([z,x],y\right) + B\left(x,[z,y]\right) = 0 \qquad \text{for all } x,y,z \tag{A.725}$$

is a multiple of the Killing form; in particular it is symmetric.

Rests on Lemma 14.11 and Theorems 5.153 and 14.13.

Proof. *Derives Lemma A.427.*

Give $\mathfrak{g}^*$ the coadjoint action $(z \cdot \phi)\,(y) = -\phi\,([z,y])$. For a bilinear B satisfying Equation (A.725) the map $\Phi_B : \mathfrak{g} \to \mathfrak{g}^*$, $\Phi_B(x) = B(x,\cdot)$, obeys

$$\Phi_B\left([z,x]\right)(y) = B\left([z,x],y\right) = -B\left(x,[z,y]\right) = \left(z \cdot \Phi_B(x)\right)(y)\,,$$

so Φ_B intertwines the adjoint and coadjoint actions. The Killing form satisfies Equation (A.725) by Lemma 14.11 and is nondegenerate by Theorem 14.13, so Φ_κ is an isomorphism of $\mathfrak{g}$-modules. Hence $T = \Phi_\kappa^{-1} \circ \Phi_B$ is an endomorphism of $\mathfrak{g}$ commuting with every ad_z. The adjoint representation of a simple algebra on the finite-dimensional complex space $\mathfrak{g}$ is irreducible — an invariant subspace is an ideal — so Schur's lemma, in the form of Theorem 5.153 (whose proof uses only that T commutes with an irreducible family of operators on a finite-dimensional complex space), gives $T = \lambda\,\mathbb{1}$ and therefore $B = \lambda\,\kappa$. □

Proposition A.428 (Uniqueness in degree zero)**.** *Every 2-cocycle c on $L\mathfrak{g}$ that is homogeneous of degree zero — meaning $c\left(x \otimes t^m, y \otimes t^n\right) = 0$ whenever $m + n \neq 0$ — is cohomologous to a multiple of ω_κ.*

Rests on Theorem A.426, Lemma A.427, and Proposition 14.77.

Proof. *Derives Proposition A.428.*

Write $B_m(x,y) = c\,(x \otimes t^m, y \otimes t^{-m})$. Antisymmetry of c gives

$$B_{-m}(u,v) = -B_m(v,u)\,, \tag{A.726}$$

so B_0 is an antisymmetric bilinear form on $\mathfrak{g} \otimes 1 \cong \mathfrak{g}$.

Step 1: kill B_0. The restriction of a cocycle to a subalgebra is a cocycle, so B_0 is a 2-cocycle on $\mathfrak{g}$; by Proposition 14.77, $H^2(\mathfrak{g},\mathbb{C}) = 0$, so $B_0 = \partial\beta$ for a linear β on $\mathfrak{g}$. Extend β to b on $L\mathfrak{g}$ by $b(x \otimes t^0) = \beta(x)$ and $b(x \otimes t^n) = 0$ for $n \neq 0$. Then $(\partial b)\,(x \otimes t^m, y \otimes t^n) = \delta_{m+n,0}\,\beta\,([x,y])$, which is homogeneous of degree zero, so $c - \partial b$ is still homogeneous of degree zero and now has $B_0 = 0$. Replace c by it.

Step 2: each B_m is invariant. Apply Equation (14.121) to $(z \otimes t^0,\ x \otimes t^m,\ y \otimes t^{-m})$:

$$B_m\,([z,x]\,,y) + B_0\,([x,y]\,,z) + B_{-m}\,([y,z]\,,x) = 0\,,$$

and $B_0 = 0$ while $B_{-m}\,([y,z]\,,x) = -B_m\,(x,[y,z]) = B_m\,(x,[z,y])$ by Equation (A.726). What is left is exactly Equation (A.725), so $B_m = \lambda_m\,\kappa$ by Lemma A.427. Feeding that back into Equation (A.726) and using the symmetry of κ,

$$\lambda_{-m} = -\lambda_m\,, \qquad \lambda_0 = 0\,. \tag{A.727}$$

Step 3: λ is additive. Apply Equation (14.121) to $\left(x \otimes t^a,\ y \otimes t^b,\ z \otimes t^e\right)$ with $a+b+e = 0$. The three terms pair $t^{a+b} = t^{-e}$ with t^e, and so on, giving

$$\lambda_{-e}\,\kappa\,([x,y]\,,z) + \lambda_{-a}\,\kappa\,([y,z]\,,x) + \lambda_{-b}\,\kappa\,([z,x]\,,y) = (\lambda_{-a} + \lambda_{-b} + \lambda_{-e})\,\mathcal{K} = 0\,,$$

the three Killing factors being the common value $\mathcal{K}$ computed in the proof of Theorem A.426. Some choice of x, y, z makes $\mathcal{K} \neq 0$: $\mathfrak{g} = [\mathfrak{g},\mathfrak{g}]$ for a simple algebra, so a nonzero w with $\kappa(w,z) \neq 0$ — available by nondegeneracy — is a sum of brackets, one of which must pair nontrivially with z. Hence $\lambda_p + \lambda_q + \lambda_r = 0$ whenever $p+q+r = 0$; putting $r = -p-q$ and using Equation (A.727), $\lambda_{p+q} = \lambda_p + \lambda_q$, so $\lambda_m = m\,\lambda_1$.

Therefore $c\,(x \otimes t^m, y \otimes t^n) = \lambda_1\,m\,\delta_{m+n,0}\,\kappa(x,y)$, which is $\lambda_1\omega_\kappa$ by Equation (A.722). □

Remark A.429 (The reduction to homogeneous cocycles, and what is left open). The hypothesis of Proposition A.428 is less restrictive than it looks, and it is worth saying how much less. Define, for a cocycle c and $k \in \mathbb{Z}$, the component c_k by $c_k\,(x \otimes t^m, y \otimes t^n) = c\,(x \otimes t^m, y \otimes t^n)$ when $m + n = k$ and 0 otherwise. Each c_k is bilinear and antisymmetric, and each is separately a cocycle: every term of Equation (14.121) evaluated on $\left(x \otimes t^a, y \otimes t^b, z \otimes t^e\right)$ pairs two factors whose exponents sum to $a + b + e$, so the cocycle condition never mixes degrees. Since only one component is nonzero on any given pair of basis elements, $c = \sum_k c_k$ makes sense with no convergence question. So the classification of cocycles reduces exactly to the classification of homogeneous ones, and Proposition A.428 settles the degree-zero part.

What is *not* proved here is that a homogeneous cocycle of nonzero degree is a coboundary — equivalently, that $\dim H^2(L\mathfrak{g},\mathbb{C}) = 1$. That is a theorem of Garland (*The arithmetic theory of loop groups*, Publications mathématiques de l'IHÉS **52**, 1980, 5–136), reproved in several places since. Its proof at degree $k \neq 0$ turns on the nonvanishing of the third cohomology of a simple Lie algebra, which this treatise does not develop; the present appendix therefore establishes that the level is *a* central charge and the only one that survives the natural grading, not that it is the only one whatever.

A.39.3 The Schwinger term

The third case is different in kind, and the difference is not a defect of the exposition. A current algebra is a bracket relation between operator-valued distributions at equal times. The naive canonical evaluation of that bracket multiplies two distributions at one point, which is not an operation, so the "formal" current algebra is not a Lie algebra whose cohomology one can compute; the question is instead whether the central term that any legitimate definition produces can be made to vanish. Schwinger's answer is that it cannot. The argument below is his; it is stated in J. Schwinger, *Field theory commutators*, Physical Review Letters **3** (1959), 296–297, a work for which this treatise carries no bibliography entry, so the attribution is made here in prose and the reader is warned that it is uncited.

Throughout this subsection the setting is $3+1$ dimensions, in accordance with rule 7: the argument is dimension-independent, but it is instantiated where the evidence is.

Definition A.430 (The hypotheses)**.** Assume a quantum theory on a Hilbert space $\mathcal{H}$ with

1. a self-adjoint Hamiltonian $\hat{H}$ bounded below, with a normalizable ground state $|0\rangle$, $\hat{H}\,|0\rangle = E_0\,|0\rangle$, and a complete orthonormal family of eigenstates $\{|n\rangle\}$ with $\hat{H}\,|n\rangle = E_n\,|n\rangle$ and $E_n \geq E_0$;
2. a conserved current: Hermitian operator-valued distributions $\hat{\jmath}^0(\boldsymbol{x},t)$ (charge density, of SI unit $\mathrm{C/m^3}$) and $\hat{\jmath}^k(\boldsymbol{x},t)$ (current density, $\mathrm{C/(m^2\,s)}$), satisfying the operator continuity equation
$$\frac{\partial \hat{\jmath}^0}{\partial t} + \partial_k \hat{\jmath}^k = 0\,. \tag{A.728}$$

For a real smooth compactly supported f on $\mathbb{R}^3$, dimensionless, write
$$\hat{A}_f = \int \mathrm{d}^3x\; f(\boldsymbol{x})\,\hat{\jmath}^0(\boldsymbol{x},0)\,, \tag{A.729}$$
a Hermitian operator of SI unit C.

Rests on Definition 14.72.

Lemma A.431 (Positivity of the double commutator)**.** *Under Definition A.430,*
$$\langle 0|\left[\hat{A}_f,\left[\hat{H},\hat{A}_f\right]\right]|0\rangle = 2\sum_n (E_n - E_0)\left|\langle n|\,\hat{A}_f\,|0\rangle\right|^2 \;\geq\; 0\,, \tag{A.730}$$
with equality if and only if $\hat{A}_f\,|0\rangle$ lies in the ground eigenspace of $\hat{H}$.

Rests on Definition A.430.

Proof. *Derives Lemma A.431.*

Abbreviate $\hat{A} = \hat{A}_f$. Expanding the nested commutator,
$$\left[\hat{A},\left[\hat{H},\hat{A}\right]\right] = \hat{A}\hat{H}\hat{A} - \hat{A}^2\hat{H} - \hat{H}\hat{A}^2 + \hat{A}\hat{H}\hat{A} = 2\hat{A}\hat{H}\hat{A} - \hat{A}^2\hat{H} - \hat{H}\hat{A}^2\,.$$
Taking the ground-state expectation and using $\hat{H}\,|0\rangle = E_0\,|0\rangle$ on the last two terms,
$$\langle 0|\left[\hat{A},\left[\hat{H},\hat{A}\right]\right]|0\rangle = 2\,\langle 0|\,\hat{A}\hat{H}\hat{A}\,|0\rangle - 2E_0\,\langle 0|\,\hat{A}^2\,|0\rangle\;.$$
Inserting the resolution of the identity $\sum_n |n\rangle\langle n|$ between the operators and using $\hat{A}^\dagger = \hat{A}$, which gives $\langle 0|\,\hat{A}\,|n\rangle = \overline{\langle n|\,\hat{A}\,|0\rangle}$,
$$\langle 0|\left[\hat{A},\left[\hat{H},\hat{A}\right]\right]|0\rangle = 2\sum_n (E_n - E_0)\left|\langle n|\,\hat{A}\,|0\rangle\right|^2\,,$$
which is Equation (A.730). Every summand is nonnegative because $E_n \geq E_0$, so the sum vanishes only if $\langle n|\,\hat{A}\,|0\rangle = 0$ for every n with $E_n > E_0$, that is only if $\hat{A}\,|0\rangle$ has no component outside the ground eigenspace. $\square$

Theorem A.432 (Schwinger's theorem)**.** *Under Definition A.430, suppose the equal-time commutator of the charge density with the current density has the vacuum expectation*

$$\langle 0|\left[\hat{\jmath}^0(\boldsymbol{y},0),\hat{\jmath}^k(\boldsymbol{x},0)\right]|0\rangle = \mathrm{i}\,S\,\partial_k^{(\boldsymbol{x})}\,\delta^3(\boldsymbol{x}-\boldsymbol{y})\ , \tag{A.731}$$

with S a constant (the Schwinger term*), of SI unit $\mathrm{C}^2/(\mathrm{m\,s})$. Then*

$$\hbar\,S\int \mathrm{d}^3x\ |\nabla f|^2 = 2\sum_n (E_n-E_0)\left|\langle n|\,\hat{A}_f\,|0\rangle\right|^2\ \geq\ 0 \tag{A.732}$$

for every test function f. Hence $S\geq 0$, and $S=0$ forces $\hat{\jmath}^0(\boldsymbol{x},0)\,|0\rangle$ to lie in the ground eigenspace for every $\boldsymbol{x}$ — that is, the charge density must have no vacuum fluctuations at all. In any theory in which it does, the equal-time commutator cannot vanish.

Rests on Lemma A.431 and Definition A.430.

Proof. *Derives Theorem A.432.*

The Heisenberg equation $\mathrm{i}\hbar\,\partial_t\hat{O}=\left[\hat{O},\hat{H}\right]$ and the continuity equation Equation (A.728) give

$$\left[\hat{H},\hat{\jmath}^0(\boldsymbol{x},0)\right] = -\mathrm{i}\hbar\,\frac{\partial\hat{\jmath}^0}{\partial t}(\boldsymbol{x},0) = \mathrm{i}\hbar\,\partial_k\hat{\jmath}^k(\boldsymbol{x},0)\,,$$

so that, integrating by parts against the compactly supported f,

$$\left[\hat{H},\hat{A}_f\right] = \mathrm{i}\hbar\int \mathrm{d}^3x\ f(\boldsymbol{x})\,\partial_k\hat{\jmath}^k(\boldsymbol{x},0) = -\mathrm{i}\hbar\int \mathrm{d}^3x\ \left(\partial_k f\right)(\boldsymbol{x})\,\hat{\jmath}^k(\boldsymbol{x},0)\,. \tag{A.733}$$

Therefore

$$\left[\hat{A}_f,\left[\hat{H},\hat{A}_f\right]\right] = -\mathrm{i}\hbar\int \mathrm{d}^3y\int \mathrm{d}^3x\ f(\boldsymbol{y})\left(\partial_k f\right)(\boldsymbol{x})\ \left[\hat{\jmath}^0(\boldsymbol{y},0),\hat{\jmath}^k(\boldsymbol{x},0)\right]\ ,$$

whose ground-state expectation, by Equation (A.731) and $\int \mathrm{d}^3y\,f(\boldsymbol{y})\,\partial_k^{(\boldsymbol{x})}\delta^3(\boldsymbol{x}-\boldsymbol{y}) = \left(\partial_k f\right)(\boldsymbol{x})$, is

$$-\mathrm{i}\hbar\int \mathrm{d}^3x\ \left(\partial_k f\right)(\boldsymbol{x})\ \mathrm{i}S\ \left(\partial_k f\right)(\boldsymbol{x}) = \hbar S\int \mathrm{d}^3x\ |\nabla f|^2\ ,$$

the two imaginary units combining to $-\mathrm{i}\cdot\mathrm{i}=1$. Equating this with Equation (A.730) gives Equation (A.732). Since $\int|\nabla f|^2>0$ for any nonconstant f, the sign of S follows; and $S=0$ makes the right-hand side vanish for every f, so by the equality clause of Lemma A.431 the vector $\hat{A}_f\,|0\rangle$ lies in the ground eigenspace for every f, which is the stated conclusion.

The dimensions check: $\hat{A}_f$ carries C, so the right-hand side of Equation (A.732) carries $\mathrm{J}\times\mathrm{C}^2$; on the left, $\hbar S\int|\nabla f|^2\,\mathrm{d}^3x$ carries $\mathrm{J\,s}\times\mathrm{C}^2/(\mathrm{m\,s})\times\mathrm{m}$, the same. □

Remark A.433 (The extension is central, and it is not removable)*.* Two features of Equation (A.731) put it in the frame of Section 14.4. First, the right-hand side is a *c*-number: it commutes with every operator of the theory, so as an element of the algebra generated by the smeared densities it is central, exactly as the Z of Equation (14.120). Second, it cannot be removed by redefining the generators. The would-be redefinition is a shift of each smeared density by a constant, $\hat{A}_f\mapsto\hat{A}_f+b(f)$, which changes the commutator by b of a bracket — the coboundary of Equation (14.122) — and the naive algebra has $\left[\hat{\jmath}^0,\hat{\jmath}^k\right]=0$, so that bracket is zero and no shift produces anything. The situation is formally identical to the Galilei mass of Example 14.80: a central term sitting on a pair of generators whose classical bracket vanishes, and therefore beyond the reach of any coboundary (Appendix A.38).

What Theorem A.432 adds, and what has no analogue in the two finite computations above, is that the term is *forced*. There the question was which cocycles exist; here the cocycle that appears to be zero is proved to be nonzero by an argument that never computes it — only positivity of the energy above the ground state and conservation of the current are used.

Remark A.434 (What is quoted here). Three things are imported in this section, and the three are of different weight.

(i) Whitehead's second lemma, used once, in Step 1 of Proposition A.428: $H^2(\mathfrak{g}, F) = 0$ for a finite-dimensional semisimple $\mathfrak{g}$ in characteristic zero. It is Proposition 14.77 of the chapter, whose own derivation is recorded there and not repeated here. It is used only to remove the degree-zero-in-t piece B_0, and nothing else in this appendix depends on it.

(ii) Garland's theorem, that $\dim H^2(L\mathfrak{g}, \mathbb{C}) = 1$ for simple $\mathfrak{g}$, which would upgrade Proposition A.428 from the degree-zero statement to the full one. It is not proved here and it is not used: Theorem A.426 constructs the cocycle and proves it nontrivial without it, and Remark A.429 says precisely which case remains. The Virasoro uniqueness, by contrast, is proved in full — Theorem A.422 imports nothing.

(iii) The framework in which Theorem A.432 is stated. This is the substantial one, and it is an assumption rather than a theorem. It is assumed that the charge and current densities are operator-valued distributions on a common dense domain, smearable as in Equation (A.729), and that the equal-time commutator of two of them is supported on the diagonal $\boldsymbol{x} = \boldsymbol{y}$, so that it is a finite sum of derivatives of $\delta^3(\boldsymbol{x} - \boldsymbol{y})$ with operator coefficients; the leading such term with a c-number coefficient is what Equation (A.731) isolates. That framework is the Wightman axiomatization [1297], which this treatise uses but does not construct. The spectral hypothesis of Definition A.430 — a self-adjoint Hamiltonian bounded below with a complete family of eigenstates — is likewise the standard spectral theorem for a self-adjoint operator [1481], applied in the form in which the sum over n is legitimate.

What is *proved* above, given that framework, is the inequality Equation (A.732) and its two consequences: $S \geq 0$, and $S = 0$ only in the degenerate case where the charge density does not fluctuate in the ground state. What is *not* proved, and is not attempted, is the evaluation of S in any particular theory. That evaluation requires a regularization — a point splitting of the product of two field operators, followed by the removal of the splitting — and it is a computation in quantum field theory, not in Lie algebra cohomology. This appendix therefore establishes the statement made in Example 14.81 in the exact form "a formally central extension survives regularization": the extension is central by Remark A.433, and it survives because Theorem A.432 forbids the value zero that the unregularized computation returns.

Finally, the evidential status of all three algebras is settled in Remark 14.82 and is not reopened here. Writing down a consistent central extension is a mathematical act; that remark records what is and is not measured, in particular that the Schwinger term reaches experiment only through the anomalies [1388, 1391] and their measured consequences [2361], and that this treatise records no measurement of a Virasoro central charge.

Remark A.435. Theorems A.422, A.426 and A.432 discharge the three obligations recorded after Example 14.81 of Chapter 14. Read together with Example 14.79 — where every antisymmetric form on an abelian algebra is a cocycle and none is a coboundary — and with Appendix A.38, they fill in Remark 14.78's list of the four places a central charge can live: abelian algebras, inhomogeneous algebras and their contractions, and infinite-dimensional algebras. The last is the case treated here, and the three instances differ instructively. The Witt algebra has a one-dimensional H^2 proved outright; the loop algebra has a distinguished class built from the Killing form and the residue, whose uniqueness is settled here only within the natural grading; and the current algebra has an extension that no cohomological computation produces, because the bracket it extends does not exist until the theory is regularized.

A.40 The Strengthened Jacobi Condition and Conjugate Points

This appendix proves the equivalence asserted in Remark 16.57 of Chapter 16: for a regular problem, the hypothesis of Theorem 16.56 — the existence of a solution of the Jacobi accessory equation Equation (16.49) with no zero on the closed interval $[a, b]$ — holds if and only if no point of $(a, b]$ is conjugate to a in the sense of Definition 16.53. That equivalence is what joins Jacobi's necessary condition (Theorem 16.55) to his sufficient one, and without it the two theorems test different hypotheses.

Three ingredients are needed and all three are proved here: global existence and uniqueness for the accessory equation, which is Corollary 9.9 of Chapter 9 once the equation is written as a first-order system; the continuous dependence of a solution on the point at which its initial data are posed, which is proved from the integral equation Equation (9.7) underlying the Picard–Lindelöf theorem Theorem 9.8 together with a Grönwall estimate; and the Sturm separation theorem, which is proved from the Lagrange identity Lemma 9.56. The notation is that of Section 16.4.2 throughout: P and Q are the coefficients Equation (16.46) evaluated along the extremal, the problem is *regular*, meaning $P > 0$ on $[a, b]$, and the accessory equation is

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(P(x)\,\frac{\mathrm{d}u}{\mathrm{d}x}\right) - Q(x)\,u = 0\,. \tag{A.734}$$

Only the continuity of P and Q and the positivity of P are used; in particular P is never differentiated, which is why the results below hold for every C^3 integrand and C^2 extremal without a further regularity hypothesis.

A.40.1 Statement

Theorem A.436 (Strengthened Jacobi condition and conjugate points)**.** *Let $P, Q \in C^0[a, b]$ with $P > 0$ on $[a, b]$, and let u_a denote the solution of Equation (A.734) determined by*

$$u_a(a) = 0\,, \qquad \left(P\,\frac{\mathrm{d}u_a}{\mathrm{d}x}\right)(a) = 1\,. \tag{A.735}$$

The following three statements are equivalent.

1. *There exists a solution w of Equation (A.734) with $w(x) \neq 0$ for every $x \in [a, b]$* (the strengthened Jacobi condition)*.*
2. *No point of $(a, b]$ is conjugate to a* (Definition 16.53)*.*
3. *$u_a > 0$ on $(a, b]$.*

Rests on Definition 16.53 and Equation (16.49).

Remark A.437 (The two normalisations agree). Definition 16.53 normalises the Jacobi solution by $u'(a) = 1$, whereas Equation (A.735) normalises the quantity $P\,\mathrm{d}u/\mathrm{d}x$, which is the natural momentum variable of Equation (A.734). The two differ by the positive factor $P(a)$, and a nonzero constant multiple of a solution has exactly the same zeros, so the set of points conjugate to a is the same under either normalisation. The momentum normalisation is used below because P is not assumed differentiable and $P\,\mathrm{d}u/\mathrm{d}x$, unlike $\mathrm{d}u/\mathrm{d}x$ alone, is a component of the first-order system Equation (A.736).

The proof occupies the rest of the section: the system form and the elementary structure of the zeros (Appendix A.40.2), continuous dependence on the initial point (Appendix A.40.3), the Sturm separation theorem (Appendix A.40.4), and the equivalence itself (Appendix A.40.5), after which Appendix A.40.6 recovers the exact phrasing used in the chapter, in which the initial point is displaced to the left of a.

A.40.2 The accessory equation as a first-order system

Definition A.438 (Momentum variable and the accessory system)**.** For a solution u of Equation (A.734) put $v = P\,\mathrm{d}u/\mathrm{d}x$ and $\boldsymbol{Y} = (u, v)$. Then $\boldsymbol{Y}$ solves the linear system

$$\frac{\mathrm{d}\boldsymbol{Y}}{\mathrm{d}x} = A(x)\,\boldsymbol{Y}\,, \qquad A(x) = \begin{pmatrix} 0 & 1/P(x) \\ Q(x) & 0 \end{pmatrix}, \tag{A.736}$$

whose coefficient matrix is continuous on $[a, b]$ because P and Q are continuous and P does not vanish. Conversely, if $\boldsymbol{Y} = (u, v)$ solves Equation (A.736) then u is of class C^1 with $P\,\mathrm{d}u/\mathrm{d}x = v$ of class C^1, and $\mathrm{d}\left(P\,\mathrm{d}u/\mathrm{d}x\right)/\mathrm{d}x = Qu$, which is Equation (A.734).

Rests on Equations (9.3) and (16.49).

Lemma A.439 (Existence, uniqueness, and the structure of the zeros)**.** *For every $s \in [a, b]$ and every $\boldsymbol{Y}_0 \in \mathbb{R}^2$ the system Equation (A.736) has exactly one solution on the whole of $[a, b]$ with $\boldsymbol{Y}(s) = \boldsymbol{Y}_0$. Consequently, for a solution u of Equation (A.734) that does not vanish identically:*

1. *at every zero x_0 of u one has $\left(P\,\mathrm{d}u/\mathrm{d}x\right)(x_0) \neq 0$, so the zero is simple;*
2. *the zeros of u in $[a, b]$ are isolated, and there are finitely many of them.*

Rests on Definition A.438 and Corollary 9.9.

Proof. *Derives Lemma A.439.*

The system Equation (A.736) is linear with a continuous coefficient matrix on the compact interval $[a, b]$, so Corollary 9.9 applies verbatim with $\boldsymbol{g} = \boldsymbol{0}$: there is exactly one solution on all of $[a, b]$ for each choice of s and $\boldsymbol{Y}_0$.

(1) If $u(x_0) = 0$ and $\left(P\,\mathrm{d}u/\mathrm{d}x\right)(x_0) = 0$ then $\boldsymbol{Y}(x_0) = \boldsymbol{0}$; but $\boldsymbol{Y} \equiv \boldsymbol{0}$ is a solution with those data, so uniqueness forces $\boldsymbol{Y} \equiv \boldsymbol{0}$ and hence $u \equiv 0$, which was excluded.

(2) Let x_0 be a zero. By (1) and $P > 0$ we have $\left(\mathrm{d}u/\mathrm{d}x\right)(x_0) \neq 0$, so by the definition of the derivative there is a punctured neighbourhood of x_0 in which $u(x)/(x - x_0)$ keeps the sign of $\left(\mathrm{d}u/\mathrm{d}x\right)(x_0)$ and in particular $u(x) \neq 0$: the zero is isolated. If there were infinitely many zeros in $[a, b]$, Bolzano–Weierstrass (Theorem 7.7) would give a sequence of distinct zeros converging to some $x_* \in [a, b]$; continuity of u makes x_* a zero as well, and it is not isolated — a contradiction. □

A.40.3 Continuous dependence on the initial point

The estimate below is the one place where a quantitative statement is needed rather than a qualitative one, and it is obtained from the integral form Equation (9.7) of the initial value problem, which is where the proof of Theorem 9.8 begins. Throughout, $\|\cdot\|$ is any fixed norm on $\mathbb{R}^2$ and $\|A(x)\|$ the induced operator norm, so that $\|A(x)\boldsymbol{Z}\| \le \|A(x)\|\,\|\boldsymbol{Z}\|$; put

$$L = \max_{x \in [a,b]} \|A(x)\|\,, \tag{A.737}$$

which is finite because A is continuous on a compact interval (Theorem 7.24).

Lemma A.440 (Grönwall's inequality)**.** *Let $\varphi \in C^0[a, b]$ be nonnegative, let $x_0 \in [a, b]$, and let $C \ge 0$ and $L \ge 0$ satisfy*

$$\varphi(x) \le C + L\left|\int_{x_0}^{x} \varphi(t)\,\mathrm{d}t\right| \qquad \text{for every } x \in [a, b]\,. \tag{A.738}$$

Then $\varphi(x) \le C\,\mathrm{e}^{L|x - x_0|}$ on $[a, b]$.

Rests on Theorems 7.35 and 7.42.

Proof. *Derives Lemma A.440.*

Take first $x \geq x_0$ and set $\Phi(x) = C + L\int_{x_0}^{x} \varphi(t)\,\mathrm{d}t$, which is of class C^1 with $\Phi' = L\varphi$ by the fundamental theorem of calculus (Theorem 7.42). Hypothesis Equation (A.738) reads $\varphi \leq \Phi$ on $[x_0, b]$, so $\Phi' = L\varphi \leq L\Phi$ there, and therefore

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[\Phi(x)\,\mathrm{e}^{-L(x-x_0)}\right] = \left[\Phi'(x) - L\,\Phi(x)\right]\mathrm{e}^{-L(x-x_0)} \leq 0\,.$$

By the mean value theorem (Theorem 7.35), a function whose derivative is nowhere positive on an interval satisfies $g(x) - g\,(x_0) = g'(\xi)\,(x - x_0) \leq 0$ for some interior ξ whenever $x > x_0$; applied to $g(x) = \Phi(x)\,\mathrm{e}^{-L(x-x_0)}$ this gives $\Phi(x)\,\mathrm{e}^{-L(x-x_0)} \leq \Phi(x_0) = C$, that is $\varphi(x) \leq \Phi(x) \leq C\,\mathrm{e}^{L(x-x_0)}$.

For $x \leq x_0$ apply what has just been proved to $\tilde{\varphi}(t) = \varphi\,(x_0 - t)$ on $[0, x_0 - a]$, which satisfies the same hypothesis with the same constants because the substitution $t \longmapsto x_0 - t$ turns $\left|\int_{x_0}^{x} \varphi\right|$ into $\left|\int_{0}^{x_0 - x} \tilde{\varphi}\right|$. □

Theorem A.441 (Continuous dependence on the data and on the initial point)**.** *For $s \in [a, b]$ and $\boldsymbol{Y}_0 \in \mathbb{R}^2$ write $\boldsymbol{Y}\,(\cdot\,; s, \boldsymbol{Y}_0)$ for the solution of Equation (A.736) with $\boldsymbol{Y}(s) = \boldsymbol{Y}_0$. Then, with L as in Equation (A.737), for all $s, \tilde{s} \in [a, b]$ and all $\boldsymbol{Y}_0, \tilde{\boldsymbol{Y}}_0$,*

$$\max_{x\in[a,b]} \left\|\boldsymbol{Y}\,(x; s, \boldsymbol{Y}_0) - \boldsymbol{Y}\left(x; \tilde{s}, \tilde{\boldsymbol{Y}}_0\right)\right\| \leq \left(\left\|\boldsymbol{Y}_0 - \tilde{\boldsymbol{Y}}_0\right\| + L\,\mathrm{e}^{L(b-a)}\left\|\tilde{\boldsymbol{Y}}_0\right\|\,|s - \tilde{s}|\right)\mathrm{e}^{L(b-a)}\,. \tag{A.739}$$

In particular the map $(x, s, \boldsymbol{Y}_0) \longmapsto \boldsymbol{Y}\,(x; s, \boldsymbol{Y}_0)$ is continuous on $[a, b] \times [a, b] \times \mathbb{R}^2$.

Rests on Lemmas A.439 and A.440 and Equation (9.7).

Proof. *Derives Theorem A.441.*

Write $\boldsymbol{Y} = \boldsymbol{Y}\,(\cdot\,; s, \boldsymbol{Y}_0)$ and $\boldsymbol{Z} = \boldsymbol{Y}\left(\cdot\,; \tilde{s}, \tilde{\boldsymbol{Y}}_0\right)$. Both are continuous and, by the equivalence of the initial value problem with its integral form Equation (9.7) — which is the first step of the proof of Theorem 9.8 and uses only the fundamental theorem of calculus —

$$\boldsymbol{Y}(x) = \boldsymbol{Y}_0 + \int_{s}^{x} A(t)\,\boldsymbol{Y}(t)\,\mathrm{d}t\,, \qquad \boldsymbol{Z}(x) = \tilde{\boldsymbol{Y}}_0 + \int_{\tilde{s}}^{x} A(t)\,\boldsymbol{Z}(t)\,\mathrm{d}t\,. \tag{A.740}$$

A bound for $\boldsymbol{Z}$ alone. Taking norms in the second identity of Equation (A.740),

$$\|\boldsymbol{Z}(x)\| \leq \left\|\tilde{\boldsymbol{Y}}_0\right\| + L\left|\int_{\tilde{s}}^{x} \|\boldsymbol{Z}(t)\|\,\mathrm{d}t\right|\,,$$

so Lemma A.440 with $\varphi = \|\boldsymbol{Z}\|$, $C = \left\|\tilde{\boldsymbol{Y}}_0\right\|$ and $x_0 = \tilde{s}$ gives

$$\max_{x\in[a,b]} \|\boldsymbol{Z}(x)\| \leq \left\|\tilde{\boldsymbol{Y}}_0\right\|\,\mathrm{e}^{L(b-a)}\,. \tag{A.741}$$

The difference. Subtracting the two identities of Equation (A.740) and splitting the second integral at s,

$$\boldsymbol{Y}(x) - \boldsymbol{Z}(x) = \left(\boldsymbol{Y}_0 - \tilde{\boldsymbol{Y}}_0\right) + \int_{s}^{x} A(t)\,[\boldsymbol{Y}(t) - \boldsymbol{Z}(t)]\,\mathrm{d}t - \int_{\tilde{s}}^{s} A(t)\,\boldsymbol{Z}(t)\,\mathrm{d}t\,.$$

The last term is bounded in norm by $L\,|s - \tilde{s}|\,\max_{[a,b]}\|\boldsymbol{Z}\|$, which Equation (A.741) bounds by $L\,\mathrm{e}^{L(b-a)}\left\|\tilde{\boldsymbol{Y}}_0\right\|\,|s - \tilde{s}|$. Hence, writing $\varphi = \|\boldsymbol{Y} - \boldsymbol{Z}\|$ and $C = \left\|\boldsymbol{Y}_0 - \tilde{\boldsymbol{Y}}_0\right\| + L\,\mathrm{e}^{L(b-a)}\left\|\tilde{\boldsymbol{Y}}_0\right\|\,|s - \tilde{s}|$,

$$\varphi(x) \leq C + L\left|\int_{s}^{x} \varphi(t)\,\mathrm{d}t\right|\,,$$

and Lemma A.440 gives Equation (A.739).

For the final assertion, fix $(x_1, s_1, \boldsymbol{Y}_1)$. The estimate Equation (A.739) shows that $\boldsymbol{Y}(\cdot\,; s, \boldsymbol{Y}_0)$ converges *uniformly in* x to $\boldsymbol{Y}(\cdot\,; s_1, \boldsymbol{Y}_1)$ as $(s, \boldsymbol{Y}_0) \longrightarrow (s_1, \boldsymbol{Y}_1)$, and each solution is continuous in x; a uniform limit of continuous functions is continuous, and the triangle inequality

$$\begin{aligned}\|\boldsymbol{Y}(x; s, \boldsymbol{Y}_0) - \boldsymbol{Y}(x_1; s_1, \boldsymbol{Y}_1)\| \le \max_{[a,b]} \|\boldsymbol{Y}(\cdot\,; s, \boldsymbol{Y}_0) - \boldsymbol{Y}(\cdot\,; s_1, \boldsymbol{Y}_1)\| \\ + \|\boldsymbol{Y}(x; s_1, \boldsymbol{Y}_1) - \boldsymbol{Y}(x_1; s_1, \boldsymbol{Y}_1)\|\end{aligned}$$

makes both contributions small. □

A.40.4 The Sturm separation theorem

Lemma A.442 (The Wronskian of the accessory equation is constant)**.** *Let u_1, u_2 solve Equation (A.734) on $[a, b]$ and put*

$$W = P\left(u_1 \frac{\mathrm{d}u_2}{\mathrm{d}x} - u_2 \frac{\mathrm{d}u_1}{\mathrm{d}x}\right). \tag{A.742}$$

Then W is constant on $[a, b]$, and $W = 0$ if and only if u_1 and u_2 are linearly dependent.
Rests on Lemmas 9.56 and A.439.

Proof. *Derives Lemma A.442.*

Equation (A.734) is the Sturm–Liouville equation $L[u] = 0$ of Lemma 9.56 with the data $p = P$ and $q = -Q$. The Lagrange identity Equation (9.56) therefore gives

$$\frac{\mathrm{d}W}{\mathrm{d}x} = \frac{\mathrm{d}}{\mathrm{d}x}\left[p\left(u_1 \frac{\mathrm{d}u_2}{\mathrm{d}x} - u_2 \frac{\mathrm{d}u_1}{\mathrm{d}x}\right)\right] = u_1\, L[u_2] - u_2\, L[u_1] = 0\,,$$

so W is constant. In the notation of Definition A.438, W is the determinant of the matrix with columns $\boldsymbol{Y}_1 = (u_1, v_1)$ and $\boldsymbol{Y}_2 = (u_2, v_2)$, since $u_1 v_2 - u_2 v_1 = P(u_1 u_2' - u_2 u_1')$. If $W = 0$, the two vectors are parallel at every point; picking a point x_0 at which $\boldsymbol{Y}_1(x_0) \neq \boldsymbol{0}$ — one exists unless $u_1 \equiv 0$, in which case the dependence is trivial — gives $\boldsymbol{Y}_2(x_0) = \kappa\, \boldsymbol{Y}_1(x_0)$ for a scalar κ, and uniqueness in Lemma A.439 then forces $\boldsymbol{Y}_2 = \kappa \boldsymbol{Y}_1$ identically, hence $u_2 = \kappa u_1$. Conversely $u_2 = \kappa u_1$ makes Equation (A.742) vanish outright. □

Theorem A.443 (Sturm separation theorem)**.** *Let u_1, u_2 be linearly independent solutions of Equation (A.734) on $[a, b]$. Then between any two consecutive zeros of u_1 there lies exactly one zero of u_2, and u_1, u_2 have no zero in common. In particular the zeros of the two solutions strictly interlace.*
Rests on Lemma A.442 and Theorem 7.23.

Proof. *Derives Theorem A.443.*

By Lemma A.442 the constant $W = P(u_1 u_2' - u_2 u_1')$ is nonzero. Neither solution vanishes identically, so Lemma A.439 applies to both.

No common zero. If $u_1(x_0) = u_2(x_0) = 0$ then both terms of Equation (A.742) vanish at x_0 and $W = 0$, a contradiction.

At least one zero in between. Let $x_1 < x_2$ be consecutive zeros of u_1 in $[a, b]$, so that $u_1 \neq 0$ on (x_1, x_2). Evaluating Equation (A.742) at the two ends, where u_1 vanishes,

$$W = -P(x_1)\, u_2(x_1) \left(\frac{\mathrm{d}u_1}{\mathrm{d}x}\right)(x_1) = -P(x_2)\, u_2(x_2) \left(\frac{\mathrm{d}u_1}{\mathrm{d}x}\right)(x_2)\,. \tag{A.743}$$

Both derivatives are nonzero by Lemma A.439(1), and they have opposite signs: u_1 keeps one sign, say positive, throughout (x_1, x_2), so $(\mathrm{d}u_1/\mathrm{d}x)(x_1) = \lim_{x \to x_1^+} u_1(x)/(x - x_1) \ge 0$ and hence is > 0, while $(\mathrm{d}u_1/\mathrm{d}x)(x_2) = \lim_{x \to x_2^-} u_1(x)/(x - x_2) \le 0$ and hence is < 0; if $u_1 < 0$ in between, both signs reverse. Since $W \neq 0$ is the *same* number at both ends

of Equation (A.743) and $P > 0$, the values $u_2(x_1)$ and $u_2(x_2)$ are both nonzero and of opposite sign. The intermediate value theorem (Theorem 7.23) gives a zero of u_2 in (x_1, x_2).

At most one. Suppose u_2 had two zeros $y_1 < y_2$ in (x_1, x_2); choosing them consecutive among the zeros of u_2 — possible because by Lemma A.439(2) there are finitely many — and applying the previous paragraph with the roles of u_1 and u_2 exchanged produces a zero of u_1 in $(y_1, y_2) \subset (x_1, x_2)$, contradicting the assumption that x_1 and x_2 are consecutive zeros of u_1. □

A.40.5 Proof of the equivalence

Proof of Theorem A.436. *Derives Theorem A.436.*

The three implications are proved in the cycle (1) ⇒ (2) ⇒ (3) ⇒ (1).

(1) ⇒ (2). Let w be a solution with no zero on $[a, b]$ and suppose, for contradiction, that some $c \in (a, b]$ is conjugate to a, i.e. $u_a(c) = 0$. The solution u_a does not vanish identically, since $(P\,\mathrm{d}u_a/\mathrm{d}x)(a) = 1 \neq 0$. Moreover u_a and w are linearly independent: a multiple of w cannot vanish at a as u_a does, unless the multiple is zero. By Lemma A.439(2) the zeros of u_a in $[a, b]$ are finite in number, so among those lying in $(a, c]$ there is a smallest one, c_1; then a and c_1 are consecutive zeros of u_a. The Sturm separation theorem Theorem A.443 places a zero of w in $(a, c_1) \subset [a, b]$, contradicting the hypothesis on w.

(2) ⇒ (3). Since $(P\,\mathrm{d}u_a/\mathrm{d}x)(a) = 1$ and $P(a) > 0$, we have $(\mathrm{d}u_a/\mathrm{d}x)(a) = 1/P(a) > 0$, and with $u_a(a) = 0$ this makes $u_a(x) > 0$ for $x > a$ close enough to a. By (2), u_a has no zero in $(a, b]$; were u_a negative at some point of $(a, b]$, the intermediate value theorem (Theorem 7.23) would produce a zero between that point and one where $u_a > 0$. Hence $u_a > 0$ throughout $(a, b]$.

(3) ⇒ (1). Let z be the solution of Equation (A.734) with

$$z(a) = 1\,, \qquad \left(P\,\frac{\mathrm{d}z}{\mathrm{d}x}\right)(a) = 0\,,$$

which exists by Lemma A.439, and consider the one-parameter family of solutions

$$w_\delta = u_a + \delta\, z\,, \qquad \delta > 0\,, \tag{A.744}$$

each of which solves Equation (A.734) by linearity. We show that $w_\delta > 0$ on $[a, b]$ for all small $\delta > 0$.

Write $v_a = P\,\mathrm{d}u_a/\mathrm{d}x$, a continuous function with $v_a(a) = 1$, and recall $z(a) = 1$ with z continuous. Choose $\eta > 0$ so small that

$$v_a \geq \tfrac{1}{2} \quad \text{and} \quad z \geq \tfrac{1}{2} \qquad \text{on } [a, a+\eta] \cap [a, b]\,. \tag{A.745}$$

On that subinterval $\mathrm{d}u_a/\mathrm{d}x = v_a/P > 0$, so $u_a(x) = \int_a^x (v_a/P)\,\mathrm{d}t \geq 0$ by Theorem 7.43, and therefore

$$w_\delta(x) = u_a(x) + \delta\, z(x) \geq 0 + \tfrac{\delta}{2} > 0\,, \qquad x \in [a, a+\eta] \cap [a, b]\,.$$

If $a + \eta \geq b$ this already proves the claim for every $\delta > 0$. Otherwise, on the compact interval $[a + \eta, b]$ the continuous function u_a is strictly positive by (3), so by the extreme value theorem (Theorem 7.24) it has a minimum $m > 0$ there; let $M = \max_{[a,b]} |z|$, also finite by Theorem 7.24. Choosing any δ with $0 < \delta < m/(M+1)$ gives, for $x \in [a + \eta, b]$,

$$w_\delta(x) \geq m - \delta M > m - \frac{m\,M}{M+1} = \frac{m}{M+1} > 0\,.$$

So $w = w_\delta$ has no zero on $[a, b]$, which is (1). □

Remark A.444 (What the equivalence buys). With Theorem A.436 the two halves of the second-order theory close on each other. For a regular problem, Theorem 16.55 says that a weak minimum admits no conjugate point in the *open* interval (a, b), and Theorem 16.56 says that a solution without zeros on the *closed* interval makes $\delta^2 J$ positive definite; by statement (2) of the theorem just proved, the hypothesis of the second is exactly the absence of conjugate points in $(a, b]$. The one remaining gap between them is the single point $x = b$: an extremal whose first conjugate point is the right endpoint itself satisfies the necessary condition and fails the sufficient one, and the second variation is then positive semidefinite with the Jacobi solution u_a in its null space — which is precisely the computation carried out in the proof of Theorem 16.55, where $\delta^2 J\,[y;\eta] = 0$ for the broken variation built from u_a. The threshold case is not a defect of the theory: it is the kinetic focus, and Remark 16.74 exhibits it as the exact instant $T = \pi\sqrt{m/k}$ at which the harmonic oscillator's action stops being a minimum.

A.40.6 The displaced initial point

Remark 16.57 states the equivalence in the form in which it is usually met: the Jacobi solution vanishing slightly to the *left* of a has no zero in $[a, b]$ exactly when the solution vanishing at a has none in $(a, b]$. That form presupposes that the coefficients are defined on a slightly larger interval, which happens whenever the extremal itself extends; under that hypothesis it is a corollary of Theorems A.436 and A.441, and it is the form in which continuous dependence on the initial point does real work.

Corollary A.445 (Displacing the initial point)**.** *Suppose P and Q extend continuously to $[a - \varepsilon_0, b]$ for some $\varepsilon_0 > 0$, with $P > 0$ there, and for $s \in [a - \varepsilon_0, b)$ let u_s be the solution of Equation (A.734) with $u_s(s) = 0$ and $(P\,\mathrm{d}u_s/\mathrm{d}x)\,(s) = 1$. Then the strengthened Jacobi condition holds on $[a, b]$ if and only if there is an $\varepsilon \in (0, \varepsilon_0)$ such that $u_{a-\varepsilon}$ has no zero in $[a, b]$ — and in that case no zero in $[a, b]$ for every smaller ε as well.*

Rests on Theorems A.436 and A.441.

Proof. *Derives Corollary A.445.*

Sufficiency is immediate: $u_{a-\varepsilon}$ restricted to $[a, b]$ is a solution of Equation (A.734) without zeros there, which is statement (1) of Theorem A.436.

Necessity. Assume the strengthened Jacobi condition, hence statement (3): $u_a > 0$ on $(a, b]$. Work on the extended interval $I = [a - \varepsilon_0, b]$, on which Theorem A.441 holds with the constant L of Equation (A.737) computed over I. Write $v_s = P\,\mathrm{d}u_s/\mathrm{d}x$, so that the initial vector is $\boldsymbol{Y}_0 = (0, 1)$ for every s and only the initial *point* varies; Equation (A.739) then reads

$$\max_{x \in I} \left(|u_s(x) - u_a(x)| + |v_s(x) - v_a(x)| \right) \le L\, \mathrm{e}^{2L(b-a+\varepsilon_0)}\ |s - a| \equiv \Lambda\ |s - a|\ , \tag{A.746}$$

where the norm on $\mathbb{R}^2$ has been taken to be the sum of the moduli of the components and $\|\boldsymbol{Y}_0\| = 1$.

Since v_a is continuous on I with $v_a(a) = 1$, fix $\eta > 0$ with $\eta < \varepsilon_0$ and

$$v_a \ge \tfrac{3}{4} \qquad \text{on } \ [a - \eta, a + \eta] \cap I\,.$$

If $a + \eta < b$, the function u_a is continuous and strictly positive on the compact interval $[a + \eta, b]$ and so has a minimum $m > 0$ there (Theorem 7.24); if $a + \eta \ge b$ put $m = +\infty$ and ignore the second condition below. Now choose $\varepsilon > 0$ subject to

$$\varepsilon < \eta\,, \qquad \Lambda\,\varepsilon < \tfrac{1}{4}\,, \qquad \Lambda\,\varepsilon < \tfrac{m}{2}\,.$$

By Equation (A.746) the solution $u = u_{a-\varepsilon}$ and its momentum $v = v_{a-\varepsilon}$ then satisfy

$$v \ge v_a - \tfrac{1}{4} \ge \tfrac{1}{2} \quad \text{on } \ [a - \eta, a + \eta] \cap I\,, \qquad u \ge u_a - \tfrac{m}{2} \ge \tfrac{m}{2} > 0 \quad \text{on } \ [a + \eta, b]\ .$$

On $[a-\varepsilon, a+\eta]$ the first inequality gives $\mathrm{d}u/\mathrm{d}x = v/P > 0$, so u is strictly increasing there and, since $u\,(a-\varepsilon) = 0$, it is strictly positive on $(a-\varepsilon, a+\eta]$ — in particular on $[a, a+\eta]$, because $a > a-\varepsilon$. Together with the second inequality, $u > 0$ on all of $[a, b]$, so $u_{a-\varepsilon}$ has no zero there. The argument used only the three smallness conditions on ε, each of which persists when ε is decreased, which proves the last clause. □

Remark A.446 (The geometric reading). Corollary A.445 is the analytic content of the picture in Remark 16.54. A solution of Equation (A.734) is the derivative $\partial y/\partial\alpha$ of a one-parameter family of extremals through a common initial point, so u_s describes, to first order, the spreading of the pencil of extremals issuing from the point s. The corollary says that the pencil issuing from a stays spread out over $[a, b]$ if and only if a pencil issuing from a slightly earlier point does, and Theorem A.441 is what makes "slightly earlier" a legitimate perturbation: the focusing distance depends continuously on the point of emission. On the unit sphere, where the extremals are great circles and every pencil refocuses at the antipode, the corollary reproduces the familiar statement that an arc is a minimising geodesic exactly while it is shorter than half a great circle.

Remark A.447. Theorem A.436 discharges the equivalence asserted in Remark 16.57 of Section 16.4.2, and Corollary A.445 supplies the displaced-point phrasing used there. The two conditions the equivalence links are Jacobi's necessary condition (Theorem 16.55) and the sufficiency of the second variation (Theorem 16.56); with the equivalence in hand, a regular extremal with no conjugate point in $(a, b]$ has a positive definite second variation, which is the form in which the result is used in the field-theoretic sufficiency argument of Section 16.4.4 and in the discussion of the kinetic focus of Hamilton's principle in Section 16.7.1.

A.41 Tonelli's Existence Theorem for an Integrand Depending on the Function

This appendix proves Theorem 16.73 of Chapter 16: an integrand $f\,(x, y, q)$ that is convex in the slope q and coercive in it makes the functional Equation (16.11) attain its minimum in the Sobolev class with prescribed endpoint values. The abstract half of the argument is already in the chapter — the direct method Theorem 16.70 and the convexity lemma Lemma 16.72 — and what that lemma leaves owed is the passage from an integrand $f\,(x, q)$ to one that also depends on y. That passage is what is carried out here, and it turns on one fact about the one-dimensional Sobolev space: a bounded set of $W^{1,r}(a, b)$ is precompact in the continuous functions with the uniform norm. That compact embedding is proved below in full (Theorem A.455) from the fundamental theorem of calculus, Hölder's inequality and the Arzelà–Ascoli theorem, the last of which is not available anywhere else in this treatise and is therefore also proved here (Lemma A.454).

Uniform convergence of the competitors is exactly the leverage the y-dependence needs: it makes the values $f\,(x, u_n(x), q)$ converge pointwise to $f\,(x, u(x), q)$ and confines them to a compact range of y, on which the growth hypothesis on $\partial f/\partial q$ can be applied uniformly. With that in hand the classical Scorza–Dragoni argument — which is the route taken when no such growth hypothesis is assumed — is not needed; Remark A.458 states precisely what it would supply and why it is avoided here, and Remark A.459 lists the analytic inputs that are quoted rather than proved, all of them from the Lebesgue theory and the duality of L^r which this treatise declares as imports in Remark 12.1.

A.41.1 Statement

Throughout, $1 < r < \infty$ and $r' = r/(r-1)$ is the conjugate exponent, so that $1/r + 1/r' = 1$; $a < b$ are real and y_a, y_b are the prescribed endpoint values of Equation (16.10).

Theorem A.448 (Tonelli)**.** *Let $f : [a,b] \times \mathbb{R} \times \mathbb{R} \longrightarrow \mathbb{R}$ satisfy*

(H1) f is continuous, and continuously differentiable with respect to its third argument, with derivative written $f_q = \partial f / \partial q$;

(H2) $q \longmapsto f(x,y,q)$ is convex for every (x,y);

(H3) $f(x,y,q) \geq \alpha |q|^r - \beta$ for constants $\alpha > 0$ and $\beta \in \mathbb{R}$ and all (x,y,q);

(H4) for every $R > 0$ there is a constant C_R with $|f_q(x,y,q)| \leq C_R \left(1 + |q|^{r-1}\right)$ whenever $x \in [a,b]$, $|y| \leq R$ and $q \in \mathbb{R}$.

Then the functional Equation (16.11) attains its minimum on

$$\mathcal{A}_r = \left\{ u \in W^{1,r}(a,b) \;\middle|\; u(a) = y_a,\ u(b) = y_b \right\}, \tag{A.747}$$

that is, there is $u_* \in \mathcal{A}_r$ with $J[u_*] = \inf_{\mathcal{A}_r} J$, and the infimum is finite.

Rests on Theorem 16.70, Lemma 16.72, and Equation (16.11).

Remark A.449 (Where each hypothesis comes from). (H1)–(H4) are the hypotheses of Theorem 16.73 as the chapter states it. (H2) and (H3) — convexity and coercivity in the slope — are Tonelli's own. (H1) and (H4) are the hypotheses under which the chapter's convexity lemma Lemma 16.72 was already stated in the y-free case: there f is of class C^1 in q and $|\partial f/\partial q(x,q)| \leq C\left(1 + |q|^{r-1}\right)$. (H4) is that same bound made *locally uniform in* y, which is the least that can be asked once y enters, and it is automatic for every integrand met in this book — for a mechanical Lagrangian $\mathcal{L} = \frac{1}{2} m_{ij}(q)\dot{q}^i\dot{q}^j - V(q)$ the derivative in the velocities is linear in them, so (H4) holds with $r = 2$ and C_R the maximum of the mass matrix over $|y| \leq R$. The theorem as Tonelli stated it [432] assumes only continuity and convexity; Remark A.458 says what closing that last gap costs.

A.41.2 The Sobolev space in one dimension

Definition A.450 (The space $W^{1,r}(a,b)$)**.** For $1 < r < \infty$, $W^{1,r}(a,b)$ is the set of functions $u : [a,b] \longrightarrow \mathbb{R}$ for which there exists $v \in L^r(a,b)$ with

$$u(x) = u(a) + \int_a^x v(t)\,\mathrm{d}t \qquad \text{for every } x \in [a,b], \tag{A.748}$$

normed by $\|u\|_{W^{1,r}} = \|u\|_{L^r} + \|v\|_{L^r}$. The function v is unique as an element of L^r and is written u'; every $u \in W^{1,r}(a,b)$ is continuous on $[a,b]$, by Equation (A.748) and the absolute continuity of the Lebesgue integral.

Rests on Definition 10.85 and Theorem 7.42.

Remark A.451 (Why the space is defined by the integral formula). Definition 10.85 introduces $H^1 = W^{1,2}$ through *distributional* derivatives, and in one dimension the two definitions agree: if $u \in L^r(a,b)$ has a distributional derivative $v \in L^r$, then $w(x) = \int_a^x v$ has the same distributional derivative, so $u - w$ has distributional derivative zero and is therefore almost everywhere equal to a constant — which is the du Bois-Reymond lemma Lemma 16.19 in its integrable form, the one step of this identification that needs Lebesgue theory rather than the continuous argument given in the chapter. Nothing below uses the distributional definition, so Definition A.450 is taken as the definition and the identification is recorded only to place the space where the reader expects it. In particular each element of $W^{1,r}(a,b)$ is here a genuine continuous function, not an equivalence class, so the boundary conditions in Equation (A.747) have their literal meaning.

Lemma A.452 (Young and Hölder)**.** *Let $1 < r < \infty$ and $r' = r/(r-1)$. For all $s, t \geq 0$,*

$$s\,t \leq \frac{s^r}{r} + \frac{t^{r'}}{r'}\,, \tag{A.749}$$

and consequently, for measurable g, h on (a, b),

$$\int_a^b |g\,h|\,\mathrm{d}x \leq \|g\|_{L^{r'}}\,\|h\|_{L^r}\,. \tag{A.750}$$

Rests on Theorem 7.38 and Definition A.450.

Proof. *Derives Lemma A.452.*

Young. For $s = 0$ or $t = 0$ the inequality is trivial, so let $s, t > 0$ and put $\lambda = 1/r \in (0, 1)$, so $1 - \lambda = 1/r'$. The function $\Phi = -\log$ is of class C^2 on $(0, \infty)$ with $\Phi''(\tau) = \tau^{-2} > 0$, hence convex there: writing $c = \lambda\,\sigma + (1-\lambda)\,\tau$ for $\sigma, \tau > 0$, Taylor's theorem with Lagrange remainder (Theorem 7.38) about c gives $\Phi(\sigma) = \Phi(c) + \Phi'(c)\,(\sigma - c) + \frac{1}{2}\Phi''(\xi)\,(\sigma - c)^2 \geq \Phi(c) + \Phi'(c)\,(\sigma - c)$ and the same with τ in place of σ; multiplying the first by λ, the second by $1 - \lambda$ and adding annihilates the linear terms, because $\lambda\,(\sigma - c) + (1-\lambda)\,(\tau - c) = 0$, and leaves $\lambda\,\Phi(\sigma) + (1-\lambda)\,\Phi(\tau) \geq \Phi(c)$. Taking $\sigma = s^r$ and $\tau = t^{r'}$ and undoing the minus sign,

$$\log\left(\frac{s^r}{r} + \frac{t^{r'}}{r'}\right) \geq \frac{1}{r}\log s^r + \frac{1}{r'}\log t^{r'} = \log(s\,t)\,,$$

and log is increasing, which is Equation (A.749).

Hölder. If $\|g\|_{L^{r'}} = 0$ or $\|h\|_{L^r} = 0$ then $gh = 0$ almost everywhere and there is nothing to prove; if either norm is infinite the right side is $+\infty$. Otherwise replace g by $g/\|g\|_{L^{r'}}$ and h by $h/\|h\|_{L^r}$, which reduces the claim to the case $\|g\|_{L^{r'}} = \|h\|_{L^r} = 1$. Apply Equation (A.749) pointwise with $s = |h(x)|$, $t = |g(x)|$ and integrate:

$$\int_a^b |g\,h|\,\mathrm{d}x \leq \frac{1}{r}\int_a^b |h|^r\,\mathrm{d}x + \frac{1}{r'}\int_a^b |g|^{r'}\,\mathrm{d}x = \frac{1}{r} + \frac{1}{r'} = 1\,.$$

□

Lemma A.453 (Uniform bound and uniform Hölder continuity)**.** *Let $u \in W^{1,r}(a, b)$. Then for all $x, x' \in [a, b]$,*

$$|u(x) - u(x')| \leq \|u'\|_{L^r}\,|x - x'|^{1/r'}\,, \tag{A.751}$$

and consequently

$$\max_{[a,b]} |u| \leq |u(a)| + \|u'\|_{L^r}\,(b-a)^{1/r'}\,. \tag{A.752}$$

Rests on Definition A.450 and Lemma A.452.

Proof. *Derives Lemma A.453.*

By Equation (A.748), for $x' < x$, $u(x) - u(x') = \int_{x'}^x u'(t)\,\mathrm{d}t$. Apply Equation (A.750) on the interval (x', x) with $h = u'$ and g the constant function 1, whose $L^{r'}$ norm over that interval is $(x - x')^{1/r'}$:

$$|u(x) - u(x')| \leq \int_{x'}^x |u'(t)|\,\mathrm{d}t \leq (x - x')^{1/r'}\left(\int_{x'}^x |u'|^r\,\mathrm{d}t\right)^{1/r} \leq \|u'\|_{L^r}\,(x - x')^{1/r'}\,.$$

Taking $x' = a$ and adding $|u(a)|$ gives Equation (A.752). □

A.41.3 The Arzelà–Ascoli theorem and the compact embedding

Lemma A.454 (Arzelà–Ascoli on an interval)**.** *Let (u_n) be a sequence of continuous functions on $[a,b]$ that is*

1. uniformly bounded*: $|u_n(x)| \le K$ for all n and all x; and*
2. equicontinuous*: for every $\varepsilon > 0$ there is $\delta > 0$, independent of n, such that $|x - x'| < \delta$ implies $|u_n(x) - u_n(x')| < \varepsilon$ for every n.*

Then some subsequence converges uniformly on $[a,b]$, and its limit is continuous.
Rests on Theorems 7.7 and 7.8.

Proof. *Derives Lemma A.454.*

A subsequence converging on a countable dense set. Enumerate the rational points of $[a,b]$ together with a and b as $q_1, q_2, \ldots$; the set is countable and dense in $[a,b]$. The numerical sequence $(u_n(q_1))_n$ is bounded by K, so by Bolzano–Weierstrass (Theorem 7.7) there is a subsequence $\left(u_n^{(1)}\right)$ of (u_n) for which $\left(u_n^{(1)}(q_1)\right)$ converges. Applying the same argument to $\left(u_n^{(1)}(q_2)\right)$ produces a subsequence $\left(u_n^{(2)}\right)$ of $\left(u_n^{(1)}\right)$ converging at q_1 and q_2, and so on, giving nested subsequences $\left(u_n^{(j)}\right)_n$, the j-th converging at $q_1, \ldots, q_j$. The diagonal sequence $w_k = u_k^{(k)}$ is, from its j-th term onwards, a subsequence of $\left(u_n^{(j)}\right)_n$, so $(w_k(q_j))_k$ converges for every j.

Uniform convergence. Let $\varepsilon > 0$ and take $\delta > 0$ from equicontinuity for $\varepsilon/3$. Partition $[a,b]$ into finitely many subintervals of length less than δ and pick in each one a point of the dense set, obtaining $q_{j_1}, \ldots, q_{j_m}$ such that every $x \in [a,b]$ lies within δ of some q_{j_i}. Because each of the m sequences $(w_k(q_{j_i}))_k$ converges, it is Cauchy (Theorem 7.8), and there is an N — the largest of the m thresholds — with $|w_k(q_{j_i}) - w_l(q_{j_i})| < \varepsilon/3$ for all $k, l \ge N$ and all i. For an arbitrary $x \in [a,b]$ choose i with $|x - q_{j_i}| < \delta$; then, for $k, l \ge N$,

$$|w_k(x) - w_l(x)| \le |w_k(x) - w_k(q_{j_i})| + |w_k(q_{j_i}) - w_l(q_{j_i})| + |w_l(q_{j_i}) - w_l(x)| < \varepsilon\,,$$

the outer terms by equicontinuity. The bound does not involve x, so (w_k) is uniformly Cauchy; at each fixed x it therefore converges (Theorem 7.8), to a limit $u(x)$, and letting $l \to \infty$ in the display gives $|w_k(x) - u(x)| \le \varepsilon$ for every $k \ge N$ and every x — uniform convergence.

Continuity of the limit. Given $\varepsilon > 0$, pick k with $\max_{[a,b]} |w_k - u| < \varepsilon/3$ and δ from equicontinuity for $\varepsilon/3$; then $|x - x'| < \delta$ gives

$$|u(x) - u(x')| \le |u(x) - w_k(x)| + |w_k(x) - w_k(x')| + |w_k(x') - u(x')| < \varepsilon\,.$$

□

Theorem A.455 (Compact embedding of $W^{1,r}(a,b)$ into the continuous functions)**.** *Let $(u_n) \subset W^{1,r}(a,b)$ with*

$$\sup_n \|u_n'\|_{L^r} \le M < \infty \qquad \text{and} \qquad \sup_n |u_n(a)| \le M_0 < \infty\,. \tag{A.753}$$

Then a subsequence of (u_n) converges uniformly on $[a,b]$ to a continuous limit u. If in addition $u_n' \rightharpoonup v$ weakly in $L^r(a,b)$ along that subsequence — that is, $\int_a^b g\,u_n'\,\mathrm{d}x \longrightarrow \int_a^b g\,v\,\mathrm{d}x$ for every $g \in L^{r'}(a,b)$ — then $u \in W^{1,r}(a,b)$ with $u' = v$.
Rests on Lemmas A.453 and A.454.

Proof. *Derives Theorem A.455.*

Precompactness. By Equation (A.752) the sequence is uniformly bounded by $K = M_0 + M\,(b-a)^{1/r'}$, and by Equation (A.751)

$$\left|u_n(x) - u_n\left(x'\right)\right| \le M\ \left|x - x'\right|^{1/r'}$$

for every n, so the sequence is equicontinuous: given $\varepsilon > 0$, the choice $\delta = (\varepsilon/M)^{r'}$ serves every n at once, and it is here that $r > 1$ is used, since $1/r' > 0$. Lemma A.454 now supplies a uniformly convergent subsequence, which we do not relabel, with continuous limit u.

Identification of the derivative. Fix $x \in [a,b]$ and let χ_x be the function equal to 1 on (a,x) and to 0 on (x,b). It belongs to $L^{r'}(a,b)$, being bounded on a bounded interval, so weak convergence gives

$$\int_a^x u_n'(t)\,\mathrm{d}t = \int_a^b \chi_x\, u_n'\,\mathrm{d}t \longrightarrow \int_a^b \chi_x\, v\,\mathrm{d}t = \int_a^x v(t)\,\mathrm{d}t\,.$$

On the other hand Equation (A.748) for u_n says the left side equals $u_n(x) - u_n(a)$, which converges to $u(x) - u(a)$ by uniform — indeed pointwise — convergence. Hence $u(x) = u(a) + \int_a^x v$ for every x, which is Equation (A.748) for u with v in the role of the derivative; since $v \in L^r$ by hypothesis, $u \in W^{1,r}(a,b)$ and $u' = v$. □

A.41.4 Weak lower semicontinuity with y present

Theorem A.456 (Convexity in q implies weak lower semicontinuity)**.** *Let f satisfy (H1)–(H4) of Theorem A.448. Let $(u_n) \subset W^{1,r}(a,b)$ and $u \in W^{1,r}(a,b)$ be such that*

1. $\sup_n \|u_n'\|_{L^r} < \infty$;
2. $u_n \longrightarrow u$ *uniformly on* $[a,b]$;
3. $u_n' \rightharpoonup u'$ *weakly in* $L^r(a,b)$.

Then

$$\int_a^b f\left(x,u,u'\right)\mathrm{d}x \le \liminf_{n\to\infty} \int_a^b f\left(x,u_n,u_n'\right)\mathrm{d}x\,. \tag{A.754}$$

Rests on Lemma 16.72, Equation (16.62), and Theorem A.455.

Proof. *Derives Theorem A.456.*

Write $M = \sup_n \|u_n'\|_{L^r}$ and $R = \sup_n \max_{[a,b]} |u_n|$, the latter finite because a uniformly convergent sequence of continuous functions is uniformly bounded; enlarge R if necessary so that also $\max_{[a,b]} |u| \le R$.

Step 1: the tangent inequality, taken at the limit slope. Convexity of a C^1 function of q puts its graph above every tangent, which is Equation (16.62); applied at the fixed value $y = u_n(x)$ of the second argument, with $q_1 = u'(x)$ and $q_2 = u_n'(x)$, it gives, for almost every x,

$$f\left(x,u_n,u_n'\right) \ge f\left(x,u_n,u'\right) + g_n(x)\left[u_n'(x) - u'(x)\right]\,, \qquad g_n = f_q\left(\cdot\,,u_n,u'\right)\,. \tag{A.755}$$

Note that the tangent is taken at the *limit* slope u' but at the *approximating* value u_n of the function; this is the one departure from the y-free argument of Lemma 16.72, and it is what makes both terms on the right tractable. Integrating Equation (A.755),

$$\int_a^b f\left(x,u_n,u_n'\right)\mathrm{d}x \ge \int_a^b f\left(x,u_n,u'\right)\mathrm{d}x + \int_a^b g_n\left(u_n' - u'\right)\mathrm{d}x\,. \tag{A.756}$$

Both integrals on the right are well defined: the second because $g_n \in L^{r'}$ by Step 3 below and $u_n' - u' \in L^r$, so Equation (A.750) applies; the first because its integrand is bounded below by $-\beta$ through (H3), so the integral exists in $(-\infty, +\infty]$.

Step 2: the first term. By (H1) the map $y \longmapsto f(x, y, u'(x))$ is continuous, and $u_n(x) \longrightarrow u(x)$ for every x, so

$$f(x, u_n(x), u'(x)) \longrightarrow f(x, u(x), u'(x)) \qquad \text{for almost every } x\,.$$

By (H3) the functions $f(x, u_n, u') + \beta$ are nonnegative and measurable, so Fatou's lemma applies to them and gives

$$\int_a^b f(x, u, u')\,\mathrm{d}x \le \liminf_{n\to\infty} \int_a^b f(x, u_n, u')\,\mathrm{d}x\,, \tag{A.757}$$

the constants $\beta(b-a)$ cancelling from both sides. The inequality holds in $(-\infty, +\infty]$, so nothing is assumed about the finiteness of either side.

Step 3: the second term vanishes. Put $g = f_q(\cdot, u, u')$. By (H4) with the constant C_R,

$$|g_n(x)| \le C_R\left(1 + |u'(x)|^{r-1}\right) \qquad \text{and the same bound for } |g|\,, \tag{A.758}$$

and the right-hand side lies in $L^{r'}(a,b)$, because $\left(|u'|^{r-1}\right)^{r'} = |u'|^r$ is integrable and constants are integrable on a bounded interval. In particular $g_n, g \in L^{r'}$, as promised in Step 1. Moreover $g_n \longrightarrow g$ pointwise almost everywhere, by the continuity of f_q in its second argument (H1) and the pointwise convergence $u_n \to u$. Since $|g_n - g|^{r'} \le (2C_R)^{r'}\left(1 + |u'|^{r-1}\right)^{r'} \in L^1$ and tends to 0 almost everywhere, the dominated convergence theorem gives

$$\|g_n - g\|_{L^{r'}} \longrightarrow 0\,. \tag{A.759}$$

Now split

$$\int_a^b g_n\,(u_n' - u')\,\mathrm{d}x = \int_a^b g\,(u_n' - u')\,\mathrm{d}x + \int_a^b (g_n - g)\,(u_n' - u')\,\mathrm{d}x\,.$$

The first integral tends to 0: $g \in L^{r'}$ and $u_n' \rightharpoonup u'$ in L^r, which is exactly the statement that $\int g\,u_n' \to \int g\,u'$. The second is bounded, by Hölder's inequality Equation (A.750), by

$$\|g_n - g\|_{L^{r'}}\ \|u_n' - u'\|_{L^r} \le \left(M + \|u'\|_{L^r}\right)\|g_n - g\|_{L^{r'}}\,,$$

which tends to 0 by Equation (A.759) and hypothesis (1). Hence

$$\int_a^b g_n\,(u_n' - u')\,\mathrm{d}x \longrightarrow 0\,. \tag{A.760}$$

Conclusion. Take the lower limit in Equation (A.756). The lower limit of a sum is at least the lower limit of the first summand plus the limit of the second when the latter exists, so by Equations (A.757) and (A.760)

$$\liminf_n \int_a^b f(x, u_n, u_n')\,\mathrm{d}x \ge \liminf_n \int_a^b f(x, u_n, u')\,\mathrm{d}x + 0 \ge \int_a^b f(x, u, u')\,\mathrm{d}x\,,$$

which is Equation (A.754). □

A.41.5 Proof of the theorem

Proof of Theorem A.448. *Derives Theorem A.448.*

The infimum is finite. The affine function $\ell(x) = y_a + (y_b - y_a)\,(x-a)\,/\,(b-a)$ lies in $\mathcal{A}_r$, with constant derivative, and f is continuous, so $J[\ell]$ is finite and $m = \inf_{\mathcal{A}_r} J \le J[\ell] < \infty$. By (H3), $J[u] \ge -\beta\,(b-a)$ for every admissible u, so $m > -\infty$.

Coercivity bounds a minimising sequence. Let $(u_n) \subset \mathcal{A}_r$ satisfy $J[u_n] \longrightarrow m$; discarding finitely many terms we may assume $J[u_n] \le m+1$ for every n. By (H3),

$$m + 1 \ge J[u_n] \ge \alpha \int_a^b |u_n'|^r \,\mathrm{d}x - \beta\,(b-a)\,, \tag{A.761}$$

so $\|u_n'\|_{L^r}^r \le [m+1+\beta\,(b-a)]\,/\alpha =: M^r$, a bound independent of n. Since $u_n(a) = y_a$ for every n, the hypotheses Equation (A.753) of Theorem A.455 hold with $M_0 = |y_a|$, and by Equation (A.752) the sequence is also bounded in L^r, hence bounded in $W^{1,r}(a,b)$.

Extraction of a limit. The sequence (u_n') is bounded in $L^r(a,b)$, a reflexive Banach space for $1 < r < \infty$, so some subsequence converges weakly, $u_{n_k}' \rightharpoonup v$ in $L^r(a,b)$ — this is the compactness input of Theorem 16.70, quoted there in the same form (see Remark A.459). Passing to a further subsequence, not relabelled, Theorem A.455 makes u_{n_k} converge uniformly on $[a,b]$ to a continuous u_*, and identifies $u_* \in W^{1,r}(a,b)$ with $u_*' = v$.

The limit is admissible. Uniform convergence is in particular pointwise at the endpoints, so $u_*(a) = \lim_k u_{n_k}(a) = y_a$ and $u_*(b) = \lim_k u_{n_k}(b) = y_b$: the class $\mathcal{A}_r$ is closed under this mode of convergence, which is the second place where the compact embedding earns its keep — weak convergence in $W^{1,r}$ alone says nothing about the value of a function at a point.

The limit minimises. The three hypotheses of Theorem A.456 hold for (u_{n_k}) and u_*, so

$$J[u_*] \le \liminf_k J[u_{n_k}] = m\,,$$

while $J[u_*] \ge m$ because $u_* \in \mathcal{A}_r$. Hence $J[u_*] = m$ and the infimum is attained. □

Remark A.457 (The shape of the argument, against the abstract direct-method theorem). The proof just given is the abstract direct method with each of its three ingredients made concrete, and it is worth seeing which concrete statement plays which abstract role. Coercivity of J in the sense of Theorem 16.70 is Equation (A.761), and it controls only the *derivative*; that this suffices to control the function as well is Equation (A.752), i.e. the boundary condition plus Hölder's inequality. Sequential weak lower semicontinuity is Theorem A.456. The compactness that the abstract theorem imports from reflexivity is used here in two different topologies at once — weakly in L^r for the derivatives, uniformly in C^0 for the functions — and the second is not a convenience but a necessity: without it neither the endpoint values nor the y-dependence of the integrand would survive the limit. That is the precise sense in which Lemma 16.72 left something owed.

Remark A.458 (The route not taken: Scorza-Dragoni). If (H4) is dropped and f is asked only to be continuous and convex in q — Tonelli's own hypotheses — Step 3 above breaks down, because $|f_q(x, u_n, u')|$ can then grow with n faster than any fixed $L^{r'}$ function, and the classical repair is a different one. It rests on the theorem of Scorza-Dragoni: a Carathéodory integrand — measurable in x, continuous in (y,q) — is, after the deletion from $[a,b]$ of a set of arbitrarily small measure, continuous *jointly* in all its arguments on what remains; on that set the modulus of continuity in y is then uniform in q over compacta, which is what Step 3 needs, and the deleted set is handled by the coercivity bound (H3). This treatise's bibliography carries no entry for Scorza-Dragoni's paper, and the statement above is therefore quoted here *without a citation* — the honest record of a result that is named but neither used nor verified in this book. Nothing in Theorem A.448 depends on it: the theorem proved above is the theorem under (H1)–(H4), and every integrand this treatise minimises satisfies (H4) (Remark A.449).

Remark A.459 (What is quoted here). Three analytic inputs are used and not proved in this treatise. Each belongs to the measure theory and functional analysis that Remark 12.1 of Chapter 12 already declares as imports, and all three are in Reed and Simon [1481].

1. *The Lebesgue integral and its convergence theorems.* Fatou's lemma is used once, in Equation (A.757), and the dominated convergence theorem once, in Equation (A.759). The absolute continuity of the integral, used in Definition A.450 to see that an element of $W^{1,r}$ is continuous, is of the same family.

2. *The duality* $(L^r)^* = L^{r'}$ *and the reflexivity of* L^r *for* $1 < r < \infty$, from which a bounded sequence in L^r has a weakly convergent subsequence. This is the only compactness assumption in the proof, and it is the same one Theorem 16.70 makes in the chapter, where it is named as the Eberlein–Smulian theorem; the special case $r = 2$ is the Hilbert-space statement of Chapter 12.

3. *The du Bois-Reymond lemma for integrable functions*, used only in Remark A.451 to identify Definition A.450 with the distributional definition Definition 10.85. No step of the proof uses it; the continuous version proved in the chapter, Lemma 16.19, is not strong enough for the identification, which is why the space is defined here by Equation (A.748).

Everything else — the Arzelà–Ascoli theorem, the compact embedding, Young's and Hölder's inequalities, and the semicontinuity theorem itself — is proved above from Chapter 7 and the chapter.

Remark A.460. Theorem A.448 discharges Theorem 16.73 of Section 16.5.2, completing the direct method of Theorem 16.70 for the concrete functional Equation (16.11). Its hypotheses are what Remark 16.74 tests against the Lagrangians of mechanics, and the answer given there is unchanged by anything proved here: convexity in the velocities holds for a kinetic energy with a positive definite mass matrix, while coercivity (H3) demands a potential bounded above, so the theorem certifies existence for a free or repelled particle and not for a confining one. The failure of convexity is equally untouched — the functional Equation (16.64) satisfies (H1), (H3) and (H4) but not (H2), and has no minimiser.

A.42 Completeness of the Sturm–Liouville Eigenfunctions in the Energy Norm

This appendix proves the statement quoted in Remark 16.77 of Chapter 16: the eigenfunctions of a regular Sturm–Liouville problem are complete not merely in the weighted L^2 space, but in the *energy* norm built from the quadratic form of the problem, and with that completeness the inequality Equation (16.70) sharpens into the identity Equation (16.71) for the energy form. The identity is what the Rayleigh–Ritz error estimate Corollary 16.78 needs; the inequality, which is what the variational characterisation Theorem 16.76 needs, is proved in the chapter from Bessel's inequality alone and is *independent* of everything below — a point Remark A.473 returns to, since a circular appendix would silently destroy the chapter's argument.

The route is the one the subject was born from [388]: invert the differential operator. The inverse of a regular Sturm–Liouville operator with Dirichlet data is an integral operator whose kernel is the Green function of the problem; that kernel is continuous, so the operator is compact and self-adjoint, and the Hilbert–Schmidt theorem Theorem 12.44, proved in Appendix A.23, hands back an orthonormal basis of eigenfunctions. Completeness in the weighted L^2 space — which Theorem 16.76 *assumes* — then comes out as a theorem, and completeness in the energy norm follows from it by one identity relating the two inner products.

Throughout, the data are those of Definition 16.75: p, q, r are continuous and real on $[a,b]$ with $p>0$ and $r>0$, and the boundary conditions are $y(a)=y(b)=0$. As in the proof of Theorem 16.76, fix once and for all a constant K with

$$q + Kr \geq 0 \qquad \text{on } [a,b]\,, \tag{A.762}$$

which is possible because q is continuous and $r>0$ on a compact interval, and write

$$\langle u, v\rangle_r = \int_a^b r\,u\,v\,\mathrm{d}x\,, \qquad B_K[u,v] = \int_a^b \left[p\,u'v' + (q+Kr)\,u\,v\right]\mathrm{d}x\,. \tag{A.763}$$

The operator of the problem, shifted by K, is

$$L_K[u] = -\frac{\mathrm{d}}{\mathrm{d}x}\left(p\,\frac{\mathrm{d}u}{\mathrm{d}x}\right) + (q+Kr)\,u\,, \tag{A.764}$$

so that y solves Equation (16.66) with eigenvalue λ if and only if $L_K[y] = (\lambda+K)\,r\,y$.

A.42.1 Statement

Theorem A.461 (Completeness in the weighted and in the energy norm)**.** *Let $p,q,r \in C^0[a,b]$ with $p>0$ and $r>0$. Then:*

1. *the Dirichlet problem Equation (16.66) has an infinite sequence of real eigenvalues $\lambda_1 \leq \lambda_2 \leq \cdots$ with $\lambda_n \longrightarrow +\infty$, each of finite multiplicity, and eigenfunctions y_n that are orthonormal in $\langle\cdot,\cdot\rangle_r$ and form an orthonormal basis of the weighted space $L^2_r(a,b)$;*
2. *the rescaled eigenfunctions $y_n/\sqrt{\lambda_n+K}$ form an orthonormal basis of the energy space H_E of Definition A.462 with the inner product B_K;*
3. *consequently, for every $y \in H_E$ — in particular for every $y \in C^1_0[a,b]$ — the partial sums $S_N = \sum_{n\leq N} c_n y_n$, $c_n = \langle y, y_n\rangle_r$, satisfy $B_K\left[y-S_N, y-S_N\right] \longrightarrow 0$, and*

$$\int_a^b \left(p\,y'^2 + q\,y^2\right)\mathrm{d}x = \sum_{n\geq 1} \lambda_n\,c_n^2\,, \tag{A.765}$$

the series on the right converging.

Rests on Definition 16.75, Theorem 12.44, and Equation (16.66).

Equation (A.765) is Equation (16.71). The proof occupies the rest of the section: the energy space (Appendix A.42.2), the Green function and the inverse operator (Appendix A.42.3), its compactness and the spectral decomposition (Appendix A.42.4), and the transfer to the energy norm (Appendix A.42.5).

A.42.2 The energy space

Definition A.462 (The weighted space and the energy space)**.** $L^2_r(a,b)$ is the space of square-integrable functions with the inner product $\langle\cdot,\cdot\rangle_r$ of Equation (A.763), and

$$H_E = \left\{ u \in W^{1,2}(a,b) \;\mid\; u(a) = u(b) = 0 \right\} \tag{A.766}$$

is the *energy space*, where $W^{1,2}(a,b)$ is the space of Definition A.450 with $r=2$: the continuous functions u for which there is $u' \in L^2(a,b)$ with $u(x) = u(a) + \int_a^x u'$. On H_E the energy form B_K of Equation (A.763) is used as an inner product, with norm $\|u\|_E = B_K[u,u]^{1/2}$.

Rests on Definitions 16.75 and A.450.

Lemma A.463 (Poincaré inequality; B_K is an inner product)**.** *Write* $p_- = \min_{[a,b]} p > 0$, $p_+ = \max_{[a,b]} p$, $r_- = \min_{[a,b]} r > 0$, $r_+ = \max_{[a,b]} r$ *and* $\kappa_+ = \max_{[a,b]} (q + Kr)$. *For every* $u \in H_E$,

$$\max_{[a,b]} |u| \le (b-a)^{1/2} \|u'\|_{L^2} , \qquad \langle u, u \rangle_r \le r_+ (b-a)^2 \|u'\|_{L^2}^2 , \tag{A.767}$$

and consequently

$$p_- \|u'\|_{L^2}^2 \le B_K[u,u] \le \left[p_+ + \kappa_+ (b-a)^2 \right] \|u'\|_{L^2}^2 . \tag{A.768}$$

In particular B_K *is an inner product on* H_E*: it is bilinear and symmetric by inspection, and* $B_K[u,u] = 0$ *forces* $u = 0$.

Rests on Definition A.462 and Lemma A.452.

Proof. *Derives Lemma A.463.*

For $u \in H_E$ and $x \in [a,b]$, $u(a) = 0$ gives $u(x) = \int_a^x u'$, and the Cauchy–Schwarz case $r = 2$ of Hölder's inequality Equation (A.750) bounds this by $(x-a)^{1/2} \|u'\|_{L^2} \le (b-a)^{1/2} \|u'\|_{L^2}$, which is the first inequality of Equation (A.767). Integrating its square against r over $[a,b]$ gives the second.

For Equation (A.768), the lower bound drops the term $(q + Kr)\, u^2 \ge 0$, which is nonnegative by Equation (A.762), and bounds $p \ge p_-$; the upper bound uses $p \le p_+$, $q + Kr \le \kappa_+$ and the second inequality of Equation (A.767) with r replaced by the constant 1, i.e. $\int u^2 \le (b-a)^2 \|u'\|_{L^2}^2$. If $B_K[u,u] = 0$ then $\|u'\|_{L^2} = 0$ by the lower bound, so $u' = 0$ almost everywhere and $u(x) = u(a) + \int_a^x u' = 0$. □

Lemma A.464 (H_E is a Hilbert space)**.** (H_E, B_K) *is complete, hence a Hilbert space in the sense of Definition 12.2, and the inclusion* $H_E \subset L^2_r(a,b)$ *is continuous.*

Rests on Lemma A.463 and Theorem 12.12.

Proof. *Derives Lemma A.464.*

Continuity of the inclusion is the second inequality of Equation (A.767) combined with the lower bound in Equation (A.768): $\langle u, u \rangle_r \le r_+ (b-a)^2 p_-^{-1} B_K[u,u]$.

Let (u_k) be Cauchy in $\|\cdot\|_E$. By the lower bound in Equation (A.768) the sequence (u_k') is Cauchy in $L^2(a,b)$, which is complete (Theorem 12.12), so $u_k' \longrightarrow v$ in L^2. By the first inequality of Equation (A.767) applied to $u_k - u_l$, the sequence (u_k) is uniformly Cauchy on $[a,b]$, hence converges uniformly to a continuous u with $u(a) = u(b) = 0$. Passing to the limit in $u_k(x) = \int_a^x u_k'$ — legitimate because $|\int_a^x (u_k' - v)| \le (b-a)^{1/2} \|u_k' - v\|_{L^2} \longrightarrow 0$ by Equation (A.750) — gives $u(x) = \int_a^x v$, so $u \in H_E$ with $u' = v$. Finally the upper bound in Equation (A.768) applied to $u_k - u$ gives $\|u_k - u\|_E \longrightarrow 0$. □

Remark A.465 (This is the space the chapter's trial functions live in). $C_0^1[a,b] \subset H_E$, since a continuously differentiable function vanishing at both ends satisfies Equation (A.748) with u' its classical derivative. So every statement below applies to the trial functions of Theorem 16.76 and Proposition 16.79 without further comment. The space H_E is the $H_0^1(a,b)$ of Definition 10.85: the identification of the two descriptions is Remark A.451 together with the fact that a $W^{1,2}$ function vanishing at both endpoints is a uniform limit of smooth functions of compact support, which is not needed here and is not proved.

A.42.3 The Green function and the inverse operator

Lemma A.466 (The homogeneous Dirichlet problem is trivial)**.** *Let* φ *solve* $L_K[\varphi] = 0$ *on* $[a,b]$ *with* $\varphi(a) = \varphi(b) = 0$. *Then* $\varphi \equiv 0$.

Rests on Lemma A.463 and Equation (A.764).

Proof. *Derives Lemma A.466.*

Multiply $L_K[\varphi] = 0$ by φ and integrate over $[a, b]$; one integration by parts (Equation (7.28)), whose boundary term $[p\,\varphi\,\varphi']_a^b$ vanishes because φ does at both ends, gives $B_K[\varphi, \varphi] = 0$. Since $\varphi \in C^1[a, b]$ vanishes at a, it lies in H_E, and Lemma A.463 forces $\varphi = 0$. □

Definition A.467 (Green function of the shifted problem)**.** Let ϕ and ψ be the solutions of $L_K[u] = 0$ determined by

$$\phi(a) = 0\,, \quad (p\,\phi')\,(a) = 1\,, \qquad \psi(b) = 0\,, \quad (p\,\psi')\,(b) = 1\,, \tag{A.769}$$

which exist, are unique and are defined on the whole of $[a, b]$ by Lemma A.439 applied to the system form of $L_K[u] = 0$ — the equation $(p\,u')' = (q + Kr)\,u$ is Equation (A.734) with $P = p$ and $Q = q + Kr$. Put

$$C = p\,(\phi\,\psi' - \psi\,\phi')\,, \tag{A.770}$$

a nonzero constant, and define the *Green function*

$$G\,(x, s) = -\frac{1}{C} \times \begin{cases} \phi(x)\,\psi(s) & a \le x \le s \le b\,, \\ \phi(s)\,\psi(x) & a \le s \le x \le b\,. \end{cases} \tag{A.771}$$

Rests on Lemmas A.442 and A.466.

Lemma A.468 (The kernel is well defined, symmetric and Lipschitz)**.** *The constant C of Equation (A.770) is independent of x and nonzero; G is well defined by Equation (A.771) (the two branches agree on $x = s$), symmetric, $G\,(x, s) = G\,(s, x)$, continuous on $[a, b] \times [a, b]$, and there is a constant L_G with*

$$\left|G\,(x, s) - G\,(x', s)\right| \le L_G\,\left|x - x'\right| \qquad \text{for all } x, x', s \in [a, b]\,. \tag{A.772}$$

Rests on Definition A.467 and Theorem 7.35.

Proof. *Derives Lemma A.468.*

That C is constant is Lemma A.442 applied with $P = p$ and $Q = q + Kr$. If $C = 0$ the same lemma makes ϕ and ψ linearly dependent, so ϕ would vanish at b as ψ does, and ϕ would be a nontrivial solution of the homogeneous Dirichlet problem — nontrivial because $(p\phi')\,(a) = 1$ — contradicting Lemma A.466. Hence $C \neq 0$.

The two branches of Equation (A.771) coincide when $x = s$, so G is well defined, and exchanging x and s exchanges the two branches, which is the symmetry. Both ϕ and ψ are of class C^1 on the compact interval, hence Lipschitz there by the mean value theorem (Theorem 7.35) with constants $\max|\phi'|$ and $\max|\psi'|$; each branch of Equation (A.771) is therefore Lipschitz in x uniformly in s, with $L_G = |C|^{-1} \max\{\max|\phi'|\,\max|\psi|\,, \max|\phi|\,\max|\psi'|\}$, and since the branches agree where they meet, the bound Equation (A.772) holds for x, x' on opposite sides of s as well, by splitting the increment at s. Continuity follows, jointly in (x, s), from Equation (A.772) and the symmetry. □

Theorem A.469 (The Green operator inverts L_K)**.** *Define*

$$(Tf)\,(x) = \int_a^b G\,(x, s)\,f(s)\,r(s)\,\mathrm{d}s\,, \qquad f \in L^2_r(a, b)\,. \tag{A.773}$$

Then:

1. *for continuous f, $u = Tf$ is of class C^1 with $p\,u'$ of class C^1, and it is the unique solution of*

$$L_K[u] = r\,f\,, \qquad u(a) = u(b) = 0\,. \tag{A.774}$$

2. *T maps $L^2_r(a,b)$ into H_E, with $\|Tf\|_E \le C_P \|f\|_r$ where $C_P = \left(r_+ (b-a)^2 / p_-\right)^{1/2}$, and*
$$B_K[Tf, \chi] = \langle f, \chi \rangle_r \qquad \text{for every } \chi \in H_E\,. \tag{A.775}$$

3. *T is self-adjoint and positive on $L^2_r(a,b)$, and injective.*

Rests on Definition A.467 and Lemmas A.463 and A.466.

Proof. *Derives Theorem A.469.*
(1) Split Equation (A.773) at x using Equation (A.771):
$$-C\,u(x) = \psi(x) \int_a^x \phi\, f\, r\, \mathrm{d}s + \phi(x) \int_x^b \psi\, f\, r\, \mathrm{d}s\,, \tag{A.776}$$
the first branch of Equation (A.771) governing $s \ge x$ and the second $s \le x$. Both integrals have continuous integrands, so by the fundamental theorem of calculus (Theorem 7.42) the right side is differentiable and
$$-C\,u'(x) = \psi'(x) \int_a^x \phi\, f\, r\, \mathrm{d}s + \phi'(x) \int_x^b \psi\, f\, r\, \mathrm{d}s + [\psi(x)\phi(x) - \phi(x)\psi(x)]\, f(x) r(x)\,,$$
the last bracket vanishing identically: the two boundary terms produced by differentiating the limits of integration cancel. Hence
$$-C\,p(x)u'(x) = (p\psi')(x) \int_a^x \phi\, f\, r\, \mathrm{d}s + (p\phi')(x) \int_x^b \psi\, f\, r\, \mathrm{d}s\,,$$
which is again differentiable because $p\phi'$ and $p\psi'$ are of class C^1, with $(p\phi')' = (q + Kr)\,\phi$ and likewise for ψ. Differentiating,
$$\begin{aligned} -C\,(p\,u')'(x) &= (q+Kr)\,\psi(x) \int_a^x \phi\, f\, r\, \mathrm{d}s + (q+Kr)\,\phi(x) \int_x^b \psi\, f\, r\, \mathrm{d}s \\ &\quad + [(p\psi')(x)\phi(x) - (p\phi')(x)\psi(x)]\, f(x)\, r(x) \\ &= -C\,(q+Kr)\,u(x) + C\,f(x)\,r(x)\,, \end{aligned}$$
using Equation (A.776) for the first two terms and Equation (A.770) for the bracket, which is $\phi\,(p\psi') - \psi\,(p\phi') = p\,(\phi\psi' - \psi\phi') = C$. Dividing by $-C$ gives $(p\,u')' = (q+Kr)\,u - r\,f$, that is Equation (A.774). The boundary conditions hold because $x = a$ kills the first integral in Equation (A.776) and leaves $\phi(a) = 0$ in the second, and symmetrically at $x = b$ with $\psi(b) = 0$. Uniqueness is Lemma A.466 applied to the difference of two solutions.

(2) Let first f be continuous and $u = Tf$. Then $u \in C^1[a,b]$ with $u(a) = u(b) = 0$, so $u \in H_E$, and for $\chi \in C^1_0[a,b]$ one integration by parts (Equation (7.28)) applied to Equation (A.774) gives $B_K[u,\chi] = \langle f, \chi \rangle_r$, the boundary term $[p\,u'\chi]_a^b$ vanishing because χ does. The same identity for arbitrary $\chi \in H_E$ follows because both sides are continuous in χ for $\|\cdot\|_E$ — the left side by the Cauchy–Schwarz inequality for the inner product B_K, the right by Lemma A.464 — and, by the argument of Lemma A.464 run backwards, each $\chi \in H_E$ is an $\|\cdot\|_E$-limit of members of $C^1_0[a,b]$: take $\chi_k(x) = \int_a^x v_k$ with v_k continuous, $\int_a^b v_k = 0$ and $v_k \longrightarrow \chi'$ in L^2, which is possible because the continuous functions are dense in L^2 (Remark A.474) and the mean may be subtracted off with a loss tending to zero.

Taking $\chi = u$ in Equation (A.775) and using Equation (A.767),
$$\|u\|_E^2 = \langle f, u \rangle_r \le \|f\|_r \, \|u\|_r \le C_P \, \|f\|_r \, \|u\|_E\,, \tag{A.777}$$
so $\|Tf\|_E \le C_P \|f\|_r$ for continuous f. For general $f \in L^2_r$ take continuous $f_k \longrightarrow f$ in L^2_r; by Equation (A.777) the sequence (Tf_k) is Cauchy in H_E, hence convergent

there (Lemma A.464), while by Equation (A.773) and the Cauchy–Schwarz inequality $|Tf_k(x) - Tf(x)| \le \max|G|\,(r_+(b-a))^{1/2}\,\|f_k - f\|_r$ tends to zero uniformly. The two limits agree, so $Tf \in H_E$, the bound persists, and Equation (A.775) passes to the limit.

(3) For $f, g \in L^2_r$ put $u = Tf$, $w = Tg$. Then Equation (A.775) twice, with the symmetry of B_K in between, gives

$$\langle Tf, g\rangle_r = \langle g, u\rangle_r = B_K[w,u] = B_K[u,w] = \langle f, w\rangle_r = \langle f, Tg\rangle_r \ ,$$

so T is self-adjoint; and $\langle Tf, f\rangle_r = B_K[u,u] \ge 0$, so T is positive. If $Tf = 0$ then $B_K[0,\chi] = \langle f, \chi\rangle_r = 0$ for every $\chi \in H_E$, and since H_E is dense in L^2_r — it contains the functions χ_k built above from an arbitrary continuous v, and the continuous functions are dense — this forces $f = 0$. Hence T is injective. □

A.42.4 Compactness and the spectral decomposition

Theorem A.470 (T is compact)**.** *T maps every bounded sequence of $L^2_r(a,b)$ to a sequence with a convergent subsequence in $L^2_r(a,b)$; that is, T is compact in the sense of Definition 12.41.*

Rests on Lemmas A.454 and A.468.

Proof. *Derives Theorem A.470.*

Let $\|f_n\|_r \le M$. By the Cauchy–Schwarz inequality in L^2_r applied to Equation (A.773),

$$|(Tf_n)(x)| \le \left(\int_a^b G(x,s)^2\, r(s)\,\mathrm{d}s\right)^{1/2} \|f_n\|_r \le M \max|G|\,(r_+(b-a))^{1/2} \ ,$$

so the sequence (Tf_n) is uniformly bounded, and by the Lipschitz estimate Equation (A.772),

$$|(Tf_n)(x) - (Tf_n)(x')| \le \int_a^b |G(x,s) - G(x',s)|\,|f_n(s)|\,r(s)\,\mathrm{d}s \le L_G\,(r_+(b-a))^{1/2}\,M\ |x - x'| \ ,$$

so it is equicontinuous, with a modulus independent of n. By the Arzelà–Ascoli theorem Lemma A.454 a subsequence converges uniformly on $[a,b]$, and uniform convergence implies convergence in L^2_r, since $\|w\|_r^2 \le r_+(b-a)\max|w|^2$. □

Theorem A.471 (Spectral decomposition and completeness in L^2_r)**.** *There is an orthonormal basis $\{y_n\}_{n\ge1}$ of $L^2_r(a,b)$ and numbers $\mu_n > 0$ with $\mu_n \longrightarrow 0$ such that $Ty_n = \mu_n y_n$. Setting $\lambda_n = \mu_n^{-1} - K$, each y_n is a classical solution of the Sturm–Liouville problem Equation (16.66) with eigenvalue λ_n, and $\lambda_n \longrightarrow +\infty$. Every eigenvalue has finite multiplicity, and the λ_n may be enumerated in nondecreasing order.*

Rests on Theorems 12.44, A.469 and A.470.

Proof. *Derives Theorem A.471.*

$L^2_r(a,b)$ is a Hilbert space: its inner product differs from that of $L^2(a,b)$ by the factor r, which is bounded between the positive constants r_- and r_+, so the two norms are equivalent and completeness transfers from Theorem 12.12. On it, T is bounded (by Equation (A.777) and Equation (A.767)), self-adjoint and compact, by Theorems A.469 and A.470. The Hilbert–Schmidt theorem Theorem 12.44, proved in Appendix A.23, therefore supplies real numbers $\mu_n \longrightarrow 0$ and an orthonormal system $\{y_n\}$ with

$$Tf = \sum_n \mu_n\,\langle y_n, f\rangle_r\ y_n \qquad \text{for every } f \in L^2_r(a,b)\,. \tag{A.778}$$

The system is a basis. If f is orthogonal to every y_n then Equation (A.778) gives $Tf = 0$, and T is injective by Theorem A.469(3), so $f = 0$. By Definition 12.29 the system is maximal, i.e. an orthonormal basis, and Theorem 12.30 applies to it.

The eigenvalues are positive. Taking $f = y_n$ in Equation (A.778) gives $Ty_n = \mu_n y_n$, and $\mu_n = \langle Ty_n, y_n\rangle_r \geq 0$ by positivity; $\mu_n = 0$ is excluded by injectivity. Hence $\mu_n > 0$ and $\lambda_n = \mu_n^{-1} - K$ is well defined, with $\lambda_n \longrightarrow +\infty$ because $\mu_n \longrightarrow 0^+$.

The eigenfunctions solve the differential equation. From $y_n = \mu_n^{-1} T y_n$ and Theorem A.469(2), $y_n \in H_E$; in particular y_n is continuous, so Theorem A.469(1) applies to $f = y_n$ and makes $u = Ty_n = \mu_n y_n$ a classical solution of $L_K[u] = r\, y_n$ with $u(a) = u(b) = 0$. Dividing by μ_n,

$$L_K\,[y_n] = \mu_n^{-1} r\, y_n = (\lambda_n + K)\, r\, y_n\,,$$

which, on subtracting $K\, r\, y_n$ from both sides, is Equation (16.66) with eigenvalue λ_n and Dirichlet data.

Finite multiplicity and ordering. An eigenvalue λ of Equation (16.66) corresponds to the eigenvalue $\mu = (\lambda + K)^{-1}$ of T, whose eigenspace is finite dimensional by Theorem 12.44. Since $\lambda_n \longrightarrow +\infty$, only finitely many λ_n lie below any given bound, so the sequence may be reordered nondecreasingly, and the y_n with it. □

A.42.5 From the weighted norm to the energy norm

Lemma A.472 (The pairing identity)**.** *For every $\chi \in H_E$ and every n,*

$$B_K\,[y_n, \chi] = (\lambda_n + K)\,\langle y_n, \chi\rangle_r\,. \tag{A.779}$$

In particular $B_K\,[y_m, y_n] = (\lambda_n + K)\,\delta_{mn}$, and $\lambda_n + K > 0$ for every n.
Rests on Theorems A.469 and A.471.

Proof. *Derives Lemma A.472.*

Apply Equation (A.775) with $f = y_n$: $B_K\,[Ty_n, \chi] = \langle y_n, \chi\rangle_r$. Since $Ty_n = \mu_n y_n$ and B_K is bilinear, the left side is $\mu_n B_K\,[y_n, \chi]$; dividing by $\mu_n > 0$ and writing $\mu_n^{-1} = \lambda_n + K$ gives Equation (A.779). Taking $\chi = y_m$ and using orthonormality in $\langle\cdot,\cdot\rangle_r$ gives the second statement, and $\lambda_n + K = \mu_n^{-1} > 0$. □

Proof of Theorem A.461. *Derives Theorem A.461.*

Part (1) is Theorem A.471. For (2), put

$$\tilde{y}_n = \frac{y_n}{\sqrt{\lambda_n + K}}\,. \tag{A.780}$$

By Lemma A.472 the system $\{\tilde{y}_n\}$ is orthonormal for the inner product B_K:

$$B_K\,[\tilde{y}_m, \tilde{y}_n] = \frac{(\lambda_n + K)\,\delta_{mn}}{\sqrt{(\lambda_m + K)\,(\lambda_n + K)}} = \delta_{mn}\,.$$

It is maximal in H_E: if $\chi \in H_E$ satisfies $B_K\,[\tilde{y}_n, \chi] = 0$ for every n, then Equation (A.779) gives $\langle y_n, \chi\rangle_r = 0$ for every n, and $\{y_n\}$ is an orthonormal basis of L^2_r by part (1), so $\chi = 0$ as an element of L^2_r; being continuous, χ vanishes identically. Since (H_E, B_K) is a Hilbert space (Lemma A.464), maximality is completeness: Theorem 12.30 applies and $\{\tilde{y}_n\}$ is an orthonormal basis of H_E.

For (3), let $y \in H_E$ and $c_n = \langle y, y_n\rangle_r$. The energy-Fourier coefficients of y are, by Equation (A.779),

$$B_K\,[\tilde{y}_n, y] = \frac{(\lambda_n + K)\,\langle y_n, y\rangle_r}{\sqrt{\lambda_n + K}} = \sqrt{\lambda_n + K}\; c_n\,, \tag{A.781}$$

so the N-th partial sum of the expansion of y in the basis $\{\tilde{y}_n\}$ is

$$\sum_{n\leq N} B_K\,[\tilde{y}_n, y]\,\tilde{y}_n = \sum_{n\leq N} \sqrt{\lambda_n + K}\; c_n\, \frac{y_n}{\sqrt{\lambda_n + K}} = \sum_{n\leq N} c_n y_n = S_N\,,$$

exactly the partial sum formed in the chapter. By Equation (12.18) the expansion converges in the norm of H_E, which says $B_K\,[y - S_N, y - S_N] \longrightarrow 0$, and by Parseval's identity Equation (12.19) together with Equation (A.781),

$$B_K[y,y] = \sum_{n\geq 1} (\lambda_n + K)\, c_n^2\,, \tag{A.782}$$

the series converging because it is a Parseval sum. Finally, $\{y_n\}$ is an orthonormal basis of L^2_r, so Parseval's identity there gives $\langle y, y\rangle_r = \sum_n c_n^2$; subtracting K times that from Equation (A.782) and using $B_K[y,y] = \int \left(p\,y'^2 + q\,y^2\right) \mathrm{d}x + K\,\langle y, y\rangle_r$ leaves Equation (A.765). Both series converge separately — the first as a Parseval sum, the second because $\sum_n c_n^2 = \langle y, y\rangle_r < \infty$ — so the subtraction is legitimate. □

Remark A.473 (The chapter's inequality is untouched). Remark 16.77 insists that the *inequality* Equation (16.70), which is what the variational characterisation Theorem 16.76 rests on, is independent of the identity proved here, and that remains true: nothing above is used in the chapter's proof of Theorem 16.76, which argues from Equation (16.68) and the pairing Equation (16.69) to $B_K[y,y] \geq \sum_{n\leq N} (\lambda_n + K)\, c_n^2$ for every finite N — Bessel's inequality in the energy inner product, which needs no completeness at all. Conversely nothing in this appendix uses Theorem 16.76, so there is no circle. What this appendix does remove is a hypothesis: Theorem 16.76 assumes that the eigenfunctions are complete in L^2_r, and Theorem A.471 proves it. The difference between the two statements is exactly the difference between Bessel's inequality Equation (12.15) and Parseval's identity Equation (12.19), which is the four-way criterion Theorem 12.30 in the one place where the distinction has a consequence a reader can feel: by Corollary 16.78 the Rayleigh–Ritz error is second order in the deviation *measured in the energy norm*, and the estimate is vacuous without Equation (A.765).

Remark A.474 (What is quoted here). Two inputs are used and not proved in this section, and one further result is proved elsewhere in this appendix.

1. *The completeness of* L^2 (Theorem 12.12) and, with it, the density of the continuous functions in $L^2(a,b)$. The first is quoted in Chapter 12 itself (Remark 12.1) as resting on the convergence theorems of Lebesgue integration, which this treatise does not develop; the second belongs to the same package and is used twice above, both times to pass from continuous f to $f \in L^2_r$ in Theorem A.469. Reed and Simon [1481] is the reference of record for both.

2. *Nothing else.* The Hilbert–Schmidt theorem Theorem 12.44 is not an import: it is proved, from the numerical-radius formula and sequential compactness, in Appendix A.23 of this appendix. The Arzelà–Ascoli theorem used for the compactness of T is proved in Lemma A.454, and the existence and uniqueness theory for the second-order equation defining ϕ and ψ is Lemma A.439, both in this appendix.

Remark A.475. Theorem A.461 discharges the derivation owed in Remark 16.77 of Section 16.5.3: the eigenfunctions of a regular Sturm–Liouville problem are complete in the energy norm, and Equation (16.71) holds for every admissible trial function. The identity is used in the chapter to make the error of a Ritz estimate second order (Corollary 16.78), and through that corollary it underwrites the convergence of the Ritz scheme Equation (16.72) and of its descendants — the finite element method, the linear variational method for molecular orbitals, and the variational principle for the ground-state energy of Chapter 82. The eigenvalue problem itself is that of Chapter 9, whose orthogonality theorem Theorem 9.57 is here recovered as a by-product: eigenfunctions belonging to different eigenvalues are orthogonal in $\langle\cdot,\cdot\rangle_r$ because they are eigenvectors of a self-adjoint operator for different eigenvalues.

A.43 The Plateau Problem: the Architecture of Douglas' Proof

This appendix accompanies Theorem 16.81 of Chapter 16: every rectifiable Jordan curve in $\mathbb{R}^3$ bounds a disc-type minimal surface. It differs from every other section of this appendix in what it claims. Douglas' proof [678] and Radó's [667] are each of monograph length and neither is reproduced; what is given here is the *architecture* of Douglas' argument, with every step that can be carried out inside this treatise carried out in full and every step that cannot stated precisely, as a displayed theorem, and named as an import. Remark A.495 lists the imports exactly, and the reader who wants the honest one-sentence summary should read that remark first: this section reduces Theorem 16.81 to two named results it does not prove, namely the solvability of the Dirichlet problem for the disc by the Poisson integral and Douglas' inner-variation argument for conformality, together with the classification of the conformal automorphisms of the disc.

What *is* proved here, from scratch, is the chain that makes those two imports the only ones: that the Dirichlet integral dominates the area with equality exactly for conformal maps (Proposition A.478); that the Dirichlet integral is conformally invariant, which is what makes the non-compactness of the conformal group a real obstruction rather than a technicality (Lemma A.479); that Douglas' boundary functional equals the Dirichlet integral of the harmonic extension, with the constant made explicit (Theorem A.482); that it is lower semicontinuous (Lemma A.484); that the three-point normalisation restores compactness, through the Courant–Lebesgue estimate and the Arzelà–Ascoli theorem (Appendix A.43.5); and that a harmonic conformal map has vanishing mean curvature, so that a minimiser really is a minimal surface (Proposition A.493).

A.43.1 Setting and statement

Definition A.476 (Disc-type surfaces and the two functionals)**.** Let $B = \{z \in \mathbb{C} \mid |z| < 1\}$ be the open unit disc, with $z = u + \mathrm{i}v = \rho\,\mathrm{e}^{\mathrm{i}\theta}$, and $S^1 = \partial B$ its boundary circle. A *disc-type surface* is a map $\boldsymbol{X} : \overline{B} \longrightarrow \mathbb{R}^3$, continuous on $\overline{B}$ and of class C^1 on B. Its first fundamental coefficients (Definition 13.22) are

$$E = \boldsymbol{X}_u \cdot \boldsymbol{X}_u\,, \qquad F = \boldsymbol{X}_u \cdot \boldsymbol{X}_v\,, \qquad G = \boldsymbol{X}_v \cdot \boldsymbol{X}_v\,, \tag{A.783}$$

and its *area* and *Dirichlet* functionals are

$$A\,[\boldsymbol{X}] = \int_B \sqrt{EG - F^2}\,\mathrm{d}u\,\mathrm{d}v\,, \qquad D\,[\boldsymbol{X}] = \frac{1}{2}\int_B (E+G)\,\mathrm{d}u\,\mathrm{d}v\,. \tag{A.784}$$

$\boldsymbol{X}$ is *conformal* at a point if $E = G$ and $F = 0$ there.

Rests on Definition 13.22 and Equation (16.60).

Theorem A.477 (Douglas; Radó)**.** *Let $\Gamma \subset \mathbb{R}^3$ be a rectifiable Jordan curve. Then there exists a disc-type surface $\boldsymbol{X}$, harmonic and conformal on B, whose restriction to S^1 is a monotone parametrisation of Γ and which minimises the area among all disc-type surfaces spanning Γ. Its image is a minimal surface.*

Rests on Equation (16.7) and Theorem 16.70.

The strategy is not to minimise A, which is invariant under *all* reparametrisations of the disc and therefore has no compactness whatever, but to minimise D, which is invariant only under the conformal ones — and then to arrange that the minimiser be conformal, so that the two functionals agree on it by Proposition A.478. Douglas' innovation is to push the minimisation onto the boundary circle, where the competitors are parametrisations of Γ and the functional is Equation (A.786).

A.43.2 The Dirichlet integral dominates the area

Proposition A.478 ($D \geq A$, with equality exactly for conformal maps)**.** *For every disc-type surface, $D[\boldsymbol{X}] \geq A[\boldsymbol{X}]$, with equality if and only if $\boldsymbol{X}$ is conformal almost everywhere on B.*

Rests on Definition A.476.

Proof. *Derives Proposition A.478.*

Pointwise on B, the arithmetic–geometric mean inequality $\left(\sqrt{E}-\sqrt{G}\right)^2 \geq 0$ gives $E+G \geq 2\sqrt{EG}$, with equality if and only if $E=G$; and $\sqrt{EG} \geq \sqrt{EG-F^2}$, with equality if and only if $F=0$, since $F^2 \geq 0$ and both radicands are nonnegative — indeed $EG-F^2 = |\boldsymbol{X}_u|^2\,|\boldsymbol{X}_v|^2 - (\boldsymbol{X}_u \cdot \boldsymbol{X}_v)^2 = |\boldsymbol{X}_u \times \boldsymbol{X}_v|^2 \geq 0$ by Lagrange's identity. Chaining the two,

$$\frac{1}{2}(E+G) \geq \sqrt{EG} \geq \sqrt{EG-F^2}\,, \tag{A.785}$$

and integrating over B gives $D \geq A$. Equality of the integrals of two continuous functions ordered pointwise forces equality of the functions almost everywhere, and by the two equality cases just identified that means $E=G$ and $F=0$ almost everywhere, i.e. conformality. □

Lemma A.479 (Conformal invariance of the Dirichlet integral)**.** *Let $\tau : B \longrightarrow B$ be a bijective holomorphic map, written in real coordinates as $\tau(u,v) = (\sigma(u,v), \varrho(u,v))$. Then $D[\boldsymbol{X} \circ \tau] = D[\boldsymbol{X}]$ for every disc-type surface $\boldsymbol{X}$.*

Rests on Definition A.476 and Proposition 7.31.

Proof. *Derives Lemma A.479.*

Write $\boldsymbol{Y} = \boldsymbol{X} \circ \tau$. By the chain rule (Proposition 7.31), for each of the three components,

$$\boldsymbol{Y}_u = \sigma_u\,\boldsymbol{X}_\sigma + \varrho_u\,\boldsymbol{X}_\varrho\,, \qquad \boldsymbol{Y}_v = \sigma_v\,\boldsymbol{X}_\sigma + \varrho_v\,\boldsymbol{X}_\varrho\,,$$

the derivatives of $\boldsymbol{X}$ being evaluated at $\tau(u,v)$. The Cauchy–Riemann equations for τ read $\sigma_u = \varrho_v$ and $\sigma_v = -\varrho_u$, so with $J = \sigma_u^2 + \varrho_u^2$ — which is $|\tau'|^2$ and also the Jacobian determinant $\sigma_u\varrho_v - \sigma_v\varrho_u$ — one finds

$$\begin{aligned} |\boldsymbol{Y}_u|^2 + |\boldsymbol{Y}_v|^2 &= \left(\sigma_u^2+\sigma_v^2\right)|\boldsymbol{X}_\sigma|^2 + \left(\varrho_u^2+\varrho_v^2\right)|\boldsymbol{X}_\varrho|^2 + 2\left(\sigma_u\varrho_u + \sigma_v\varrho_v\right)\boldsymbol{X}_\sigma \cdot \boldsymbol{X}_\varrho \\ &= J\left(|\boldsymbol{X}_\sigma|^2 + |\boldsymbol{X}_\varrho|^2\right), \end{aligned}$$

because $\sigma_u^2+\sigma_v^2 = \varrho_u^2+\varrho_v^2 = J$ and $\sigma_u\varrho_u + \sigma_v\varrho_v = \sigma_u\varrho_u - \varrho_u\sigma_u = 0$ by Cauchy–Riemann. Hence the integrand of $D[\boldsymbol{Y}]$ is the integrand of $D[\boldsymbol{X}]$ composed with τ and multiplied by the Jacobian J, and the change-of-variables formula for a bijective C^1 substitution gives $D[\boldsymbol{Y}] = D[\boldsymbol{X}]$. □

Remark A.480 (Why the invariance is the whole difficulty)*.* The area functional is invariant under every diffeomorphism of the disc, an infinite-dimensional group, and a minimising sequence for A may therefore be dragged about by reparametrisations without any change in the value being minimised: no compactness argument can survive that. Passing to D cuts the invariance group down to the conformal automorphisms of B, which form only a three-parameter family — but it is still a *non-compact* one, and that residual non-compactness is exactly the difficulty Douglas' three-point normalisation removes. Lemma A.485 makes the statement precise.

A.43.3 The Douglas functional

Definition A.481 (Douglas' boundary functional)**.** For a bounded measurable $\boldsymbol{g} : S^1 \longrightarrow \mathbb{R}^3$, written as a function of the angle, $\boldsymbol{g} = \boldsymbol{g}(\theta)$, put

$$\mathcal{D}[\boldsymbol{g}] = \frac{1}{16\pi} \int_0^{2\pi} \int_0^{2\pi} \frac{|\boldsymbol{g}(\theta) - \boldsymbol{g}(\varphi)|^2}{\sin^2((\theta-\varphi)/2)} \, \mathrm{d}\theta \, \mathrm{d}\varphi \quad \in [0, +\infty] \, . \tag{A.786}$$

Rests on Definition A.476.

Theorem A.482 (Douglas' identity)**.** *Let $\boldsymbol{g} \in L^2(S^1; \mathbb{R}^3)$ have Fourier coefficients $\boldsymbol{c}_n = (2\pi)^{-1} \int_0^{2\pi} \boldsymbol{g}(\theta) \, \mathrm{e}^{-\mathrm{i}n\theta} \, \mathrm{d}\theta \in \mathbb{C}^3$, and let*

$$\boldsymbol{h}(\rho, \theta) = \sum_{n \in \mathbb{Z}} \boldsymbol{c}_n \, \rho^{|n|} \, \mathrm{e}^{\mathrm{i}n\theta} \tag{A.787}$$

be its harmonic extension to B. Then

$$\mathcal{D}[\boldsymbol{g}] = \pi \sum_{n \in \mathbb{Z}} |n| \, |\boldsymbol{c}_n|^2 = D[\boldsymbol{h}] \, , \tag{A.788}$$

both sides being $+\infty$ together.

Rests on Definition A.481 and Equation (12.19).

Proof. *Derives Theorem A.482.*

Throughout, $\left\{(2\pi)^{-1/2} \, \mathrm{e}^{\mathrm{i}n\theta}\right\}_{n \in \mathbb{Z}}$ is the standard orthonormal basis of $L^2(S^1)$ (Section 9.7.4), and Parseval's identity Equation (12.19) is applied componentwise to the three components of $\boldsymbol{g}$, so that $|\boldsymbol{c}_n|^2$ denotes $\sum_{k=1}^{3} \left|c_n^k\right|^2$.

Step 1: the Dirichlet integral of the extension. In polar coordinates $\mathrm{d}u \, \mathrm{d}v = \rho \, \mathrm{d}\rho \, \mathrm{d}\theta$ and

$$E + G = |\nabla \boldsymbol{h}|^2 = |\partial_\rho \boldsymbol{h}|^2 + \frac{1}{\rho^2} |\partial_\theta \boldsymbol{h}|^2 \, .$$

Differentiating Equation (A.787) term by term — legitimate on every disc $\rho \le \rho_0 < 1$, where the series and each of its derived series are dominated termwise by $|n|^2 \, |\boldsymbol{c}_n| \, \rho_0^{|n|-2}$, whose sum converges because $|\boldsymbol{c}_n|$ is bounded and $\rho_0 < 1$, so that the Weierstrass M-test Lemma 9.6 gives uniform convergence — and integrating in θ by orthogonality,

$$\int_0^{2\pi} |\partial_\rho \boldsymbol{h}|^2 \, \mathrm{d}\theta = 2\pi \sum_n n^2 \rho^{2|n|-2} \, |\boldsymbol{c}_n|^2 \, , \qquad \int_0^{2\pi} \frac{|\partial_\theta \boldsymbol{h}|^2}{\rho^2} \, \mathrm{d}\theta = 2\pi \sum_n n^2 \rho^{2|n|-2} \, |\boldsymbol{c}_n|^2 \, .$$

The two are equal — a first sign that the extension is conformally balanced — so

$$D[\boldsymbol{h}] = \frac{1}{2} \int_0^1 4\pi \sum_n n^2 \rho^{2|n|-1} \, |\boldsymbol{c}_n|^2 \, \mathrm{d}\rho = 2\pi \sum_n n^2 \, |\boldsymbol{c}_n|^2 \, \frac{1}{2\,|n|} = \pi \sum_n |n| \, |\boldsymbol{c}_n|^2 \, , \tag{A.789}$$

the term-by-term integration in ρ being legitimate because every term is nonnegative.

Step 2: the Douglas integral. Substitute $\theta = \varphi + t$ and integrate first in φ at fixed t. The Fourier coefficients of $\varphi \longmapsto \boldsymbol{g}(\varphi + t) - \boldsymbol{g}(\varphi)$ are $\boldsymbol{c}_n \, (\mathrm{e}^{\mathrm{i}nt} - 1)$, so Parseval Equation (12.19) gives

$$\int_0^{2\pi} |\boldsymbol{g}(\varphi + t) - \boldsymbol{g}(\varphi)|^2 \, \mathrm{d}\varphi = 2\pi \sum_n |\boldsymbol{c}_n|^2 \left|\mathrm{e}^{\mathrm{i}nt} - 1\right|^2 = 4\pi \sum_n |\boldsymbol{c}_n|^2 \, (1 - \cos nt) \, ,$$

whence

$$\mathcal{D}[\boldsymbol{g}] = \frac{1}{16\pi} \int_0^{2\pi} \frac{4\pi \sum_n |\boldsymbol{c}_n|^2 \, (1 - \cos nt)}{\sin^2(t/2)} \, \mathrm{d}t = \frac{1}{4} \sum_n |\boldsymbol{c}_n|^2 \int_0^{2\pi} \frac{1 - \cos nt}{\sin^2(t/2)} \, \mathrm{d}t \, , \tag{A.790}$$

the interchange of sum and integral being legitimate because every term is nonnegative.

Step 3: the kernel integral. Using $\sin^2(t/2) = (1-\cos t)/2$ and, for $n \geq 1$, the Dirichlet kernel $\Delta_n(t) = \sum_{j=0}^{n-1} \mathrm{e}^{\mathrm{i}jt} = (\mathrm{e}^{\mathrm{i}nt}-1)/(\mathrm{e}^{\mathrm{i}t}-1)$,

$$\frac{1-\cos nt}{\sin^2(t/2)} = \frac{2(1-\cos nt)}{1-\cos t} = 2\,\frac{\left|\mathrm{e}^{\mathrm{i}nt}-1\right|^2}{\left|\mathrm{e}^{\mathrm{i}t}-1\right|^2} = 2\,\left|\Delta_n(t)\right|^2 , \tag{A.791}$$

where $\left|\mathrm{e}^{\mathrm{i}\alpha}-1\right|^2 = 2(1-\cos\alpha)$ has been used twice. By orthogonality of the exponentials, $\int_0^{2\pi} |\Delta_n|^2 \,\mathrm{d}t = 2\pi n$, so the integral in Equation (A.790) equals $4\pi|n|$ — the case $n=0$ giving 0, and negative n the same value as $|n|$ because cos is even. Substituting,

$$\mathcal{D}[\boldsymbol{g}] = \frac{1}{4}\sum_n |\boldsymbol{c}_n|^2 \, 4\pi|n| = \pi \sum_n |n|\,|\boldsymbol{c}_n|^2 ,$$

which with Equation (A.789) is Equation (A.788). Both computations produce the same nonnegative series, so one side is infinite exactly when the other is. □

Remark A.483 (What the identity accomplishes). Equation (A.788) converts a variational problem over maps of a two-dimensional domain into one over functions on a circle: by Proposition A.478 the area of a disc-type surface is at most its Dirichlet integral, and by Equation (A.788) the Dirichlet integral of the harmonic extension of a given boundary parametrisation is computable from that parametrisation alone. The harmonic extension is moreover the *minimiser* of D among all extensions of $\boldsymbol{g}$, which is the Dirichlet principle of Definition 16.67 for the disc; so the boundary functional $\mathcal{D}$ is exactly the value of the two-dimensional problem, and Douglas' competitors are parametrisations, not surfaces.

Lemma A.484 (Lower semicontinuity of the Douglas functional). *Let $\boldsymbol{g}_k \longrightarrow \boldsymbol{g}$ pointwise almost everywhere on S^1. Then $\mathcal{D}[\boldsymbol{g}] \leq \liminf_k \mathcal{D}[\boldsymbol{g}_k]$.*

Rests on Definition A.481.

Proof. *Derives Lemma A.484.*

The integrand of Equation (A.786) is nonnegative, and for almost every pair (θ,φ) it converges to the integrand built from $\boldsymbol{g}$, the denominator being independent of k and the numerator continuous in the values of the map. Fatou's lemma — quoted, as throughout this appendix (Remark A.459) — applied on the square $[0,2\pi]^2$ gives the claim. □

A.43.4 The conformal group and the three-point normalisation

Lemma A.485 (Conformal automorphisms of the disc). *For $\alpha \in B$ and $\vartheta \in \mathbb{R}$ define*

$$M_{\alpha,\vartheta}(z) = \mathrm{e}^{\mathrm{i}\vartheta}\,\frac{z-\alpha}{1-\overline{\alpha}\,z} . \tag{A.792}$$

Each $M_{\alpha,\vartheta}$ is a holomorphic bijection of B onto itself, extending to a homeomorphism of $\overline{B}$ that maps S^1 onto S^1; these maps form a group under composition; the group is not *compact; and it acts* simply transitively *on the ordered triples of distinct points of S^1 that are in positive cyclic order. The first three assertions are proved below; the fourth is quoted (Remark A.495).*

Rests on Lemma A.479.

Proof. *Derives Lemma A.485.*

The circle is preserved. For $|z|=1$, $\overline{z} = z^{-1}$, so

$$|1-\overline{\alpha}z| = |z|\,\left|z^{-1}-\overline{\alpha}\right| = |\overline{z}-\overline{\alpha}| = |z-\alpha| ,$$

whence $|M_{\alpha,\vartheta}(z)| = 1$. The denominator never vanishes on $\overline{B}$, since $|\overline{\alpha}z| \leq |\alpha| < 1$, so $M_{\alpha,\vartheta}$ is holomorphic on a neighbourhood of $\overline{B}$ and continuous on $\overline{B}$.

The disc is preserved, and the map is bijective. A direct computation gives, for $|z| < 1$,

$$1 - |M_{\alpha,\vartheta}(z)|^2 = \frac{|1-\overline{\alpha}z|^2 - |z-\alpha|^2}{|1-\overline{\alpha}z|^2} = \frac{\left(1-|\alpha|^2\right)\left(1-|z|^2\right)}{|1-\overline{\alpha}z|^2} > 0\,,$$

the middle equality by expanding both squared moduli, so $M_{\alpha,\vartheta}$ maps B into B. Its inverse is $M_{\beta,\eta}$ with $\beta = -\mathrm{e}^{-\mathrm{i}\vartheta}\alpha$ suitably normalised — explicitly, solving $w = \mathrm{e}^{\mathrm{i}\vartheta}(z-\alpha)/(1-\overline{\alpha}z)$ for z gives $z = \left(\mathrm{e}^{-\mathrm{i}\vartheta}w + \alpha\right)/\left(1+\overline{\alpha}\mathrm{e}^{-\mathrm{i}\vartheta}w\right)$, which is again of the form Equation (A.792); so each $M_{\alpha,\vartheta}$ is a bijection of B and of S^1, and the family is closed under inversion. It is closed under composition as well, since a composition of two quotients of linear polynomials is again one and it maps B bijectively onto B — that such a map must again be of the form Equation (A.792) is the classification quoted in the fourth assertion.

Non-compactness. Take $\vartheta = 0$ and $\alpha = 1 - 1/k$ along the real axis. For any fixed $z \in S^1$ with $z \neq 1$,

$$M_{\alpha,0}(z) = \frac{z-\alpha}{1-\alpha z} \longrightarrow \frac{z-1}{1-z} = -1 \qquad \text{as } k \longrightarrow \infty\,,$$

whereas $M_{\alpha,0}(1) = 1$ for every k. The sequence therefore has no subsequence converging uniformly on S^1 to a homeomorphism: its pointwise limit collapses the whole circle except one point onto the single value -1. This is precisely the degeneration a minimising sequence for $\mathcal{D}$ may undergo at no cost, since by Lemma A.479 and Equation (A.788) the value of $\mathcal{D}$ is unchanged by such a reparametrisation of the boundary. □

Definition A.486 (The normalised admissible class)**.** Fix a homeomorphism $\gamma : S^1 \longrightarrow \Gamma$ and three points $\boldsymbol{Q}_1, \boldsymbol{Q}_2, \boldsymbol{Q}_3$ on Γ, in positive cyclic order. A *monotone parametrisation* of Γ is a map $\boldsymbol{g} = \gamma \circ \psi$, where $\psi : [0, 2\pi] \longrightarrow \mathbb{R}$ is continuous and nondecreasing with $\psi(2\pi) = \psi(0) + 2\pi$, angles being read modulo 2π. The *normalised class* $\mathcal{C}^*(\Gamma)$ consists of those monotone parametrisations with

$$\boldsymbol{g}(1) = \boldsymbol{Q}_1\,, \qquad \boldsymbol{g}(\mathrm{i}) = \boldsymbol{Q}_2\,, \qquad \boldsymbol{g}(-1) = \boldsymbol{Q}_3\,. \tag{A.793}$$

Rests on Lemma A.485 and Definition A.481.

Lemma A.487 (The normalisation costs nothing)**.** $\inf\{\mathcal{D}[\boldsymbol{g}] \mid \boldsymbol{g} \in \mathcal{C}^*(\Gamma)\} = \inf\{\mathcal{D}[\boldsymbol{g}] \mid \boldsymbol{g}$ *a monotone parametrisation of* $\Gamma\}$.

Rests on Lemmas A.479 and A.485.

Proof. *Derives Lemma A.487.*

The class $\mathcal{C}^*$ is contained in the larger class, so the left infimum is at least the right one. Conversely let $\boldsymbol{g}$ be any monotone parametrisation. The three points $\boldsymbol{g}^{-1}(\boldsymbol{Q}_i)$ may be chosen as three points $\zeta_1, \zeta_2, \zeta_3$ of S^1 in positive cyclic order, because $\boldsymbol{g}$ is monotone of degree one; by the simple transitivity in Lemma A.485 there is a conformal automorphism M of B carrying $(1, \mathrm{i}, -1)$ to $(\zeta_1, \zeta_2, \zeta_3)$. Then $\boldsymbol{g} \circ M$ is again a monotone parametrisation, now satisfying Equation (A.793), and its harmonic extension is $\boldsymbol{h} \circ M$ — the composition of a harmonic map with a holomorphic one is harmonic, since $\nabla^2(\boldsymbol{h} \circ M) = |M'|^2 (\nabla^2 \boldsymbol{h}) \circ M$ by the computation of Lemma A.479 applied to second derivatives, and its boundary values are $\boldsymbol{g} \circ M$, so it *is* the harmonic extension of $\boldsymbol{g} \circ M$ by the uniqueness of the solution of the Dirichlet problem (Corollary 10.76). Hence, by Equation (A.788) and Lemma A.479,

$$\mathcal{D}[\boldsymbol{g} \circ M] = D[\boldsymbol{h} \circ M] = D[\boldsymbol{h}] = \mathcal{D}[\boldsymbol{g}]\,,$$

so every value attained on the larger class is attained on $\mathcal{C}^*$. □

A.43.5 Compactness: the Courant–Lebesgue estimate

Lemma A.488 (Small chords cut off small arcs)**.** *Let Γ be a Jordan curve with homeomorphic parametrisation $\gamma : S^1 \longrightarrow \Gamma$. For every $\varepsilon > 0$ there is $\delta > 0$ such that any two points $\boldsymbol{P}, \boldsymbol{P}'$ of Γ with $|\boldsymbol{P} - \boldsymbol{P}'| < \delta$ divide Γ into two arcs, at least one of which has diameter less than ε.*

Rests on Theorems 6.31 and 7.25.

Proof. *Derives Lemma A.488.*

By definition a Jordan curve is the image of a homeomorphism γ of S^1, so γ^{-1} exists and is continuous, and Γ is compact, being a continuous image of a compact set.

Both maps are uniformly continuous. For γ this is Theorem 7.25 applied componentwise to the angle parametrisation on $[0, 2\pi]$. For γ^{-1}, suppose not: there are $\varepsilon_0 > 0$ and points $\boldsymbol{P}_k, \boldsymbol{P}'_k \in \Gamma$ with $|\boldsymbol{P}_k - \boldsymbol{P}'_k| \longrightarrow 0$ and $|\gamma^{-1}(\boldsymbol{P}_k) - \gamma^{-1}(\boldsymbol{P}'_k)| \geq \varepsilon_0$. The circle is compact, hence sequentially compact (Theorem 6.31), so along a subsequence $\gamma^{-1}(\boldsymbol{P}_k) \longrightarrow \zeta$ and $\gamma^{-1}(\boldsymbol{P}'_k) \longrightarrow \zeta'$ with $|\zeta - \zeta'| \geq \varepsilon_0$, so $\zeta \neq \zeta'$. Applying the continuous γ, $\boldsymbol{P}_k \longrightarrow \gamma(\zeta)$ and $\boldsymbol{P}'_k \longrightarrow \gamma(\zeta')$, and $|\boldsymbol{P}_k - \boldsymbol{P}'_k| \longrightarrow 0$ then forces $\gamma(\zeta) = \gamma(\zeta')$, contradicting injectivity.

Given $\varepsilon > 0$, uniform continuity of γ supplies $\eta > 0$ such that arcs of S^1 of length below η have images of diameter below ε; uniform continuity of γ^{-1} then supplies $\delta > 0$ such that $|\boldsymbol{P} - \boldsymbol{P}'| < \delta$ forces $\gamma^{-1}(\boldsymbol{P})$ and $\gamma^{-1}(\boldsymbol{P}')$ to be at distance below $\eta/(2\pi)$ along S^1, so that the shorter of the two arcs they determine has length below η. Its image is one of the two arcs of Γ, of diameter below ε. □

Lemma A.489 (Courant–Lebesgue)**.** *Let $\boldsymbol{h}$ be harmonic on B and continuous on $\overline{B}$ with $D[\boldsymbol{h}] \leq M$, let $z_0 \in S^1$, and let $0 < \delta < 1$. Write $C_\varsigma = \{z \in B \mid |z - z_0| = \varsigma\}$. Then there is a radius $\varsigma \in \left(\delta, \sqrt{\delta}\right)$ for which the image $\boldsymbol{h}(C_\varsigma)$ has diameter at most*

$$\left(\frac{4\pi M}{\log(1/\delta)}\right)^{1/2}. \tag{A.794}$$

Rests on Definition A.476 and Lemma A.452.

Proof. *Derives Lemma A.489.*

Use polar coordinates (ς, ω) centred at z_0, in which $\mathrm{d}u\,\mathrm{d}v = \varsigma\,\mathrm{d}\varsigma\,\mathrm{d}\omega$ and $|\nabla \boldsymbol{h}|^2 = |\partial_\varsigma \boldsymbol{h}|^2 + \varsigma^{-2}|\partial_\omega \boldsymbol{h}|^2$. Writing I_ς for the set of angles ω with $z_0 + \varsigma \mathrm{e}^{\mathrm{i}\omega} \in B$ and discarding the radial term,

$$2M \geq 2D[\boldsymbol{h}] \geq \int_\delta^{\sqrt{\delta}} \left(\int_{I_\varsigma} |\partial_\omega \boldsymbol{h}|^2 \,\mathrm{d}\omega\right) \frac{\mathrm{d}\varsigma}{\varsigma} \equiv \int_\delta^{\sqrt{\delta}} \zeta(\varsigma)\,\frac{\mathrm{d}\varsigma}{\varsigma}.$$

Since $\int_\delta^{\sqrt{\delta}} \mathrm{d}\varsigma/\varsigma = \tfrac{1}{2}\log(1/\delta)$, the mean value of ζ against the measure $\mathrm{d}\varsigma/\varsigma$ on that range is at most $4M/\log(1/\delta)$, so there exists $\varsigma \in \left(\delta, \sqrt{\delta}\right)$ with $\zeta(\varsigma) \leq 4M/\log(1/\delta)$ — otherwise the integral would exceed $2M$. For that radius the length of the image curve is bounded by the Cauchy–Schwarz inequality Equation (A.750),

$$\int_{I_\varsigma} |\partial_\omega \boldsymbol{h}| \,\mathrm{d}\omega \leq |I_\varsigma|^{1/2} \left(\int_{I_\varsigma} |\partial_\omega \boldsymbol{h}|^2 \,\mathrm{d}\omega\right)^{1/2} \leq (2\pi)^{1/2} \left(\frac{4M}{\log(1/\delta)}\right)^{1/2},$$

which is Equation (A.794), and the diameter of a curve is at most its length. □

Theorem A.490 (Equicontinuity of the normalised class)**.** *Let $(\boldsymbol{g}_k) \subset \mathcal{C}^*(\Gamma)$ satisfy $\mathcal{D}[\boldsymbol{g}_k] \leq M$ for every k. Then the family is equicontinuous on S^1, and a subsequence converges uniformly to some $\boldsymbol{g} \in \mathcal{C}^*(\Gamma)$.*

Rests on Lemmas A.454, A.488 and A.489.

Proof. *Derives Theorem A.490.*

Equicontinuity. Let $\varepsilon > 0$ and take δ_0 from Lemma A.488 for this ε; shrink ε if necessary so that 2ε is smaller than the mutual distances of $\boldsymbol{Q}_1, \boldsymbol{Q}_2, \boldsymbol{Q}_3$ and of the arcs between them. Choose $\delta \in (0,1)$ with $(4\pi M/\log(1/\delta))^{1/2} < \delta_0$ and $\sqrt{\delta}$ smaller than one third of the least of those arc lengths. Let $\boldsymbol{h}_k$ be the harmonic extension of $\boldsymbol{g}_k$, which by Equation (A.788) has $D[\boldsymbol{h}_k] = \mathcal{D}[\boldsymbol{g}_k] \le M$, and which is continuous on $\overline{B}$ with boundary values $\boldsymbol{g}_k$ by the quoted solvability of the Dirichlet problem (Theorem A.491). For $z_0 \in S^1$, Lemma A.489 produces a radius $\varsigma_k \in \left(\delta, \sqrt{\delta}\right)$ for which the arc C_{ς_k} has image of diameter below δ_0; its two endpoints lie on S^1 and their images $\boldsymbol{P}, \boldsymbol{P}'$ are values of $\boldsymbol{g}_k$ at distance below δ_0. By Lemma A.488 one of the two arcs of Γ they cut off has diameter below ε; it is the one whose preimage under the monotone map $\boldsymbol{g}_k$ is the short boundary arc cut off by C_{ς_k}, because the other boundary arc has length above $2\pi - 2\sqrt{\delta}$ and its image therefore contains at least two of $\boldsymbol{Q}_1, \boldsymbol{Q}_2, \boldsymbol{Q}_3$ — which by the choice of ε cannot lie in a set of diameter ε. Hence $\boldsymbol{g}_k$ oscillates by less than ε on the boundary arc cut off at z_0, which contains all points of S^1 within δ of z_0; and δ was chosen independently of k and of z_0. That is equicontinuity.

Extraction of a limit. Write $\boldsymbol{g}_k = \gamma \circ \psi_k$ as in Definition A.486. Equicontinuity of $\boldsymbol{g}_k$ transfers to ψ_k through the uniform continuity of γ^{-1} (Lemma A.488 and its proof), and the ψ_k are uniformly bounded once normalised by $\psi_k(0) \in [0, 2\pi)$. The Arzelà–Ascoli theorem Lemma A.454 gives a uniformly convergent subsequence $\psi_k \longrightarrow \psi$; the limit is continuous, nondecreasing and satisfies $\psi(2\pi) = \psi(0) + 2\pi$, these being closed conditions under uniform convergence. Hence $\boldsymbol{g} = \gamma \circ \psi$ is again a monotone parametrisation, it satisfies Equation (A.793) because each $\boldsymbol{g}_k$ does and convergence is pointwise, and $\boldsymbol{g}_k \longrightarrow \boldsymbol{g}$ uniformly by the uniform continuity of γ. □

A.43.6 The two quoted inputs, and the conclusion

Theorem A.491 (Dirichlet problem for the disc; quoted)**.** *For every continuous $\boldsymbol{g} : S^1 \longrightarrow \mathbb{R}^3$ the Poisson integral*

$$\boldsymbol{h}(\rho,\theta) = \frac{1}{2\pi}\int_0^{2\pi} \frac{1-\rho^2}{1-2\rho\cos(\theta-\varphi)+\rho^2}\,\boldsymbol{g}(\varphi)\,\mathrm{d}\varphi \tag{A.795}$$

is harmonic on B, continuous on $\overline{B}$, and equal to $\boldsymbol{g}$ on S^1; it coincides with the series Equation (A.787), and it minimises D among all disc-type surfaces with boundary values $\boldsymbol{g}$. This treatise does not prove it: Chapter 10 develops the maximum principles and the fundamental solution but not the Poisson kernel of the disc, and Chapter 8 explicitly reserves conformal mapping. See [1222].

Rests on Definitions 10.66 and 16.67.

Theorem A.492 (Douglas' conformality theorem; quoted)**.** *Let $\boldsymbol{g}_*$ minimise $\mathcal{D}$ over $\mathcal{C}^*(\Gamma)$ and let $\boldsymbol{X} = \boldsymbol{h}_{\boldsymbol{g}_*}$ be its harmonic extension. Then $\boldsymbol{X}$ is conformal on B, that is $E = G$ and $F = 0$, except possibly at isolated branch points where $\boldsymbol{X}_u = \boldsymbol{X}_v = \boldsymbol{0}$. Equivalently, the Hopf differential $\Phi = |\boldsymbol{X}_u|^2 - |\boldsymbol{X}_v|^2 - 2\mathrm{i}\,\boldsymbol{X}_u \cdot \boldsymbol{X}_v$ vanishes identically. The proof is by* inner *variations — reparametrising the disc rather than moving the surface, which is legitimate precisely because $\mathcal{C}^*$ is a full gauge slice by Lemma A.487 — and it is not reproduced here [678].*

Rests on Definition A.481 and Lemma A.487.

Proposition A.493 (A harmonic conformal map is a minimal surface)**.** *Let $\boldsymbol{X}$ be harmonic and conformal on B, with $E = G = \Lambda^2 > 0$ and $F = 0$ at a point. Then the mean curvature $H = \frac{1}{2} g^{ij} b_{ij}$ of the surface vanishes there. Conversely a conformal parametrisation of a surface of vanishing mean curvature is harmonic.*

Rests on Definition 13.25 and Proposition 16.8.

Proof. *Derives Proposition A.493.*

Work at a point where $E = G = \Lambda^2 > 0$ and $F = 0$, with unit normal $\hat{n}$ (Equation (13.80)). Differentiating the conformality relations,

$$\boldsymbol{X}_{uu} \cdot \boldsymbol{X}_u = \tfrac{1}{2} E_u \,, \qquad \boldsymbol{X}_{vv} \cdot \boldsymbol{X}_u = \partial_v \left(\boldsymbol{X}_v \cdot \boldsymbol{X}_u \right) - \boldsymbol{X}_v \cdot \boldsymbol{X}_{uv} = F_v - \tfrac{1}{2} G_u = -\tfrac{1}{2} E_u \,,$$

using $F \equiv 0$ and $G \equiv E$. Adding, $(\boldsymbol{X}_{uu} + \boldsymbol{X}_{vv}) \cdot \boldsymbol{X}_u = 0$, and the same computation with u and v exchanged gives $(\boldsymbol{X}_{uu} + \boldsymbol{X}_{vv}) \cdot \boldsymbol{X}_v = 0$. So the Laplacian $\nabla^2 \boldsymbol{X} = \boldsymbol{X}_{uu} + \boldsymbol{X}_{vv}$ is orthogonal to both tangent vectors, hence parallel to $\hat{n}$, and by Equation (13.80) its normal component is

$$\hat{n} \cdot \nabla^2 \boldsymbol{X} = b_{11} + b_{22} \,.$$

Since $F = 0$ and $E = G = \Lambda^2$, the inverse metric is $g^{ij} = \Lambda^{-2} \delta^{ij}$ (Definition 13.23), so $2H = g^{ij} b_{ij} = \Lambda^{-2} \left(b_{11} + b_{22} \right)$ and therefore

$$\nabla^2 \boldsymbol{X} = 2 \Lambda^2 H \, \hat{n} \,. \tag{A.796}$$

If $\boldsymbol{X}$ is harmonic the left side vanishes and, Λ^2 being positive, $H = 0$; conversely $H = 0$ makes the right side vanish. By Proposition 16.8 the vanishing of the mean curvature is the minimal-surface equation Equation (16.7) wherever the surface is a graph, so the image is a minimal surface in the sense of Section 16.1.3. □

Proof of Theorem A.477, granting the two quoted theorems. *Derives Theorem A.477.*

Let $m = \inf \{ \mathcal{D}[\boldsymbol{g}] \mid \boldsymbol{g} \in \mathcal{C}^*(\Gamma) \}$. It is finite: Γ is rectifiable, and a parametrisation proportional to arc length has $|\boldsymbol{g}(\theta) - \boldsymbol{g}(\varphi)| \le \ell \, |\theta - \varphi| \, / \, (2\pi)$ with ℓ the length of Γ, so the integrand of Equation (A.786) is bounded by $\ell^2 \, |\theta - \varphi|^2 \, / \, (4\pi^2 \sin^2 ((\theta - \varphi)/2))$, which is bounded on the square, and $\mathcal{D} < \infty$ there; this is the only place where rectifiability is used, and it is used exactly to make the infimum finite.

Take a minimising sequence $(\boldsymbol{g}_k) \subset \mathcal{C}^*$, which by discarding finitely many terms satisfies $\mathcal{D}[\boldsymbol{g}_k] \le m + 1$. By Theorem A.490 a subsequence converges uniformly to some $\boldsymbol{g}_* \in \mathcal{C}^*(\Gamma)$, and by lower semicontinuity Lemma A.484, $\mathcal{D}[\boldsymbol{g}_*] \le \liminf_k \mathcal{D}[\boldsymbol{g}_k] = m$; the reverse inequality holds because $\boldsymbol{g}_* \in \mathcal{C}^*$. So the infimum is attained.

Let $\boldsymbol{X}$ be the harmonic extension of $\boldsymbol{g}_*$, which exists and is continuous on $\overline{B}$ by Theorem A.491. By Theorem A.492 it is conformal, so by Proposition A.478 $A[\boldsymbol{X}] = D[\boldsymbol{X}] = \mathcal{D}[\boldsymbol{g}_*] = m$, using Equation (A.788) for the last equality.

It remains to see that no disc-type surface spanning Γ has smaller area. Let $\boldsymbol{Y}$ be one, with boundary parametrisation $\boldsymbol{g}$, which by Lemma A.487 may be taken in $\mathcal{C}^*(\Gamma)$. The area is *reparametrisation invariant*, since $\sqrt{EG - F^2}$ transforms with the Jacobian under any C^1 change of variables, and by Proposition A.478 $A[\boldsymbol{Y}] = A[\boldsymbol{Y} \circ \tau] \le D[\boldsymbol{Y} \circ \tau]$ for every such τ; the quoted approximation step — item (4) of Remark A.495 — upgrades this to the equality

$$A[\boldsymbol{Y}] = \inf_{\tau} D[\boldsymbol{Y} \circ \tau] \,, \tag{A.797}$$

the infimum being over the reparametrisations of the disc. Each $\boldsymbol{Y} \circ \tau$ has the same boundary values as $\boldsymbol{Y}$ up to a reparametrisation of S^1, and by the Dirichlet principle of Theorem A.491 its Dirichlet integral is at least that of the harmonic extension of those boundary values, which by Equation (A.788) and Lemma A.487 is $\mathcal{D}[\boldsymbol{g}] \ge m$. Hence $A[\boldsymbol{Y}] \ge m = A[\boldsymbol{X}]$: the surface $\boldsymbol{X}$ minimises area among disc-type surfaces spanning Γ. Finally Proposition A.493 makes the image a minimal surface away from branch points. □

Remark A.494 (Radó's route, for contrast). Radó's independent proof [667], published a year before Douglas', never forms a boundary functional. It approximates Γ by inscribed *polygons* Γ_k; for a polygon the minimal surface is produced by solving finitely many Dirichlet problems on the disc and controlling the resulting sequence with the maximum principle, and

the areas A_k converge to the infimum for Γ. The compactness that Douglas buys with the three-point normalisation is bought here by a condition on the curve — Radó first assumes Γ bounds *some* surface of finite area, which for a rectifiable curve is automatic — and the limit surface is obtained from the Γ_k by a normal-family argument in the function-theoretic sense. The two proofs meet at the same place: both must produce a conformal parametrisation, and neither can avoid the Dirichlet principle for the disc. What Douglas gains is that his functional is intrinsic to the boundary, which is why it, and not Radó's construction, generalises to higher connectivity and higher genus.

Remark A.495 (What is quoted here). This section does not prove Theorem 16.81. It reduces it to named results, and the reduction is only worth what the honesty of this list is worth.

1. *The Dirichlet problem for the disc* (Theorem A.491): that the Poisson integral of a continuous boundary function is harmonic inside, continuous up to the boundary, and minimises the Dirichlet integral among all extensions. Used twice — in Theorem A.490 to have a continuous harmonic extension to apply Courant–Lebesgue to, and in the final proof. Not proved anywhere in this treatise.

2. *Douglas' conformality theorem* (Theorem A.492): that a minimiser of $\mathcal{D}$ over the normalised class has a conformal harmonic extension. This is the technical heart of the whole subject and the step for which Douglas was awarded one of the first two Fields Medals; it is stated precisely above and not proved [678].

3. *Simple transitivity of the conformal group on boundary triples* (the fourth assertion of Lemma A.485), which belongs to the conformal mapping theory that Chapter 8 explicitly reserves. Everything else in that lemma — that the maps Equation (A.792) are automorphisms and that the family is non-compact — is proved.

4. *The comparison of A with D over reparametrisations* used at the end of the final proof, i.e. that the infimum of D over all reparametrisations of a given disc-type surface equals its area. This is Douglas' and Radó's approximation argument and is quoted with them.

5. *Lebesgue integration*, as everywhere in this appendix: Fatou's lemma in Lemma A.484, and the polar- coordinate rewriting of a double integral in Lemma A.489.

Proved here in full, and used above: the pointwise inequality $D \geq A$ with its equality case, the conformal invariance of D, the identity $\mathcal{D} = D$ of the harmonic extension with its constant, lower semicontinuity, the group property and non-compactness of the Möbius family, the arc lemma, the Courant–Lebesgue estimate, the equicontinuity of the normalised class and the extraction of a limit, and the identity Equation (A.796) that turns a harmonic conformal map into a minimal surface. The reader should also carry forward Remark 16.82 of the chapter, which is about what the *theorem* claims — disc type, minimisation among disc-type maps, possible branch points — as opposed to what this section proves about it.

Remark A.496. This section accompanies Theorem 16.81 of Section 16.5.4, replacing the pending derivation there with a proof architecture and an explicit list of imports rather than with a complete derivation — the one place in this appendix where that is so, and it is flagged as such in Remark A.495. The minimal surfaces the theorem produces are the soap films of Section 16.1.3, whose equation Equation (16.7) was derived there for a graph and is recovered here in the conformal form Equation (A.796); the differential geometry is that of Chapter 13, and the physics of the surface tension that realises the area as an energy belongs to Chapter 31.

A.44 Change of Variables in a Multiple Integral

This appendix proves Theorem 7.97 of Chapter 7: that a C^1 change of coordinates $\boldsymbol{\Phi}$ transports a multiple integral with the modulus of its Jacobian determinant as the weight, Equation (7.113). It is the one property of the multiple integral that the physical parts use on almost every page — every passage to polar, cylindrical or spherical coordinates is an instance — and it is the only one Chapter 7 states without proof.

The derivation is elementary throughout: no measure theory, no Lebesgue convergence theorem, no fixed-point theorem, and nothing from outside this treatise. Two ingredients that the chapters state only in a weaker form are proved here rather than quoted — the multiplicativity of the determinant, which Chapter 5 does not record, and iterated integration in $\mathbb{R}^N$, which Remark 7.96 states for $N = 2$ and $N = 3$. One ingredient is genuinely constructed here and was not foreseen in the plan for this section: a *continuous* partition of unity, built from distance functions in Lemma A.505. Without it the passage from a local statement to a global one cannot be made for a Riemann integral over a general region, and saying that no partition of unity is used would be false. It costs half a page and quotes nothing; see Remark A.515.

Throughout, points of $\mathbb{R}^N$ are written $\boldsymbol{u} = (u^1, \dots, u^N)$, and when the last coordinate is singled out we write $\boldsymbol{u} = (\boldsymbol{u}', t)$ with $\boldsymbol{u}' \in \mathbb{R}^{N-1}$ and $t \in \mathbb{R}$. A *box* is a product $[a_1, b_1] \times \cdots \times [a_N, b_N]$ and a *cube* is a box with all edges equal. The support of a function f on an open $V \subseteq \mathbb{R}^N$ is the closure of $\{\boldsymbol{x} \mid f(\boldsymbol{x}) \neq 0\}$; we write $f \in C_c(V)$ when f is continuous and that closure is a compact subset of V, in which case the extension of f by zero is continuous on the whole of $\mathbb{R}^N$ and vanishes off a box, so $\int_{\mathbb{R}^N} f$ means the integral of that extension over any box containing the support (Definition 7.93), and is independent of the box.

A.44.1 What the derivation uses

From Chapter 7: the Darboux construction of the multiple integral (Definition 7.93), the integrability of a continuous function on a box (Theorem 7.40), uniform continuity on a compact set (Theorem 7.25), the one-variable substitution rule Equation (7.27), the mean value theorem (Theorem 7.35), the chain rule (Proposition 7.72) and the inverse function theorem (Corollary 7.81). From Chapter 5: the Leibniz expansion Equation (5.19) and the two properties read off it there — linearity in each column and antisymmetry under exchange of two columns. From Chapter 6: compactness (Definition 6.9), the Heine–Borel theorem in $\mathbb{R}^N$ (Theorem 6.12) and the Lebesgue number lemma (Lemma 6.30).

Lemma A.497 (The determinant is multiplicative)**.** *For real $N \times N$ matrices A and B, $\det(AB) = \det A \det B$.*

Rests on Equation (5.19).

Proof. *Derives Lemma A.497.*

Write $(AB)^i{}_j = \sum_k A^i{}_k B^k{}_j$ and expand Equation (5.19), distributing the product over j:

$$\det(AB) = \sum_{\sigma} \operatorname{sgn}(\sigma) \prod_{j=1}^{N} \sum_{k_j=1}^{N} A^{\sigma(j)}{}_{k_j} B^{k_j}{}_j = \sum_{k_1,\dots,k_N} \left(\prod_{j=1}^{N} B^{k_j}{}_j \right) \sum_{\sigma} \operatorname{sgn}(\sigma) \prod_{j=1}^{N} A^{\sigma(j)}{}_{k_j} , \tag{A.798}$$

the interchange being a finite rearrangement. The inner sum is, by Equation (5.19) again, the determinant of the matrix whose j-th column is the k_j-th column of A. If two of the k_j coincide that matrix has a repeated column and the determinant vanishes, so only the tuples with $k_j = \tau(j)$ for a permutation τ survive; and bringing the columns back into their

natural order costs $\operatorname{sgn}(\tau)$, by the antisymmetry recorded after Equation (5.19). Hence the inner sum equals $\operatorname{sgn}(\tau)\det A$ and

$$\det(AB) = \det A \sum_{\tau} \operatorname{sgn}(\tau) \prod_{j=1}^{N} B^{\tau(j)}{}_{j} = \det A \, \det B \,. \tag{A.799}$$

□

A.44.2 Sets of zero content

The Darboux construction ignores sets that can be covered by finitely many boxes of arbitrarily small total volume. That notion — *zero content* — is strictly stronger than the measure zero of Section 7.12, which allows countably many covering sets; it is the one a Riemann sum can see, and it is the one used here.

Definition A.498 (Zero content)**.** A bounded set $Z \subset \mathbb{R}^N$ has *zero content* if for every $\varepsilon > 0$ there are finitely many cubes of total volume less than ε whose union contains Z.
Rests on Definitions 6.9 and 7.93.

Covering by cubes rather than by boxes is no restriction: a box with edges $a_1, \dots, a_N$ is covered by cubes of side h in number at most $\prod_i (a_i/h + 1)$, of total volume at most $\prod_i (a_i + h)$, which tends to the volume of the box as $h \to 0$. A finite union of sets of zero content has zero content.

Lemma A.499 (What zero content buys)**.** *Let R be a box, $Z \subset R$ of zero content, and $f : R \to \mathbb{R}$ bounded with $|f| \le M$.*

1. *If f is continuous at every point of $R \setminus Z$, then f is integrable on R.*
2. *If f vanishes off Z, then f is integrable with $\int_R f = 0$.*
3. *If $E_1, \dots, E_m \subseteq R$ are such that each characteristic function χ_{E_i} is integrable, the E_i cover a set E and the pairwise intersections $E_i \cap E_j$ $(i \neq j)$ have zero content, then $\int_E f = \sum_i \int_{E_i} f$ for every f for which the left-hand side is defined.*

Rests on Definitions 7.93 and A.498 and Theorem 7.25.

Proof. *Derives Lemma A.499.*
(1) Given $\varepsilon > 0$, cover Z by finitely many open cubes of total volume less than ε and let K be the complement in R of their union: K is closed and bounded, hence compact (Theorem 6.12). Note that f is continuous, as a function on R, at every point of K.

We claim there is $\lambda > 0$ such that any subset of R of diameter less than λ which meets K carries an oscillation of f of at most ε. If not, then for each j there are $\boldsymbol{x}_j \in K$ and $\boldsymbol{y}_j, \boldsymbol{z}_j \in R$ within $1/j$ of $\boldsymbol{x}_j$ with $|f(\boldsymbol{y}_j) - f(\boldsymbol{z}_j)| > \varepsilon$; by compactness a subsequence $\boldsymbol{x}_j$ converges to some $\boldsymbol{x} \in K$, the corresponding $\boldsymbol{y}_j$ and $\boldsymbol{z}_j$ converge to $\boldsymbol{x}$ as well, and the continuity of f at $\boldsymbol{x}$ makes both $f(\boldsymbol{y}_j)$ and $f(\boldsymbol{z}_j)$ tend to $f(\boldsymbol{x})$ — a contradiction.

Now partition R with mesh smaller than $\lambda/\sqrt{N}$. Writing A for the union of the covering cubes, every sub-box either lies inside A or meets $K = R \setminus A$. Those of the first kind have total volume at most $\operatorname{vol}(A) < \varepsilon$ and contribute at most $2M\varepsilon$ to the gap between the upper and the lower sum; on those of the second kind the oscillation of f is at most ε, contributing at most $\varepsilon \operatorname{vol}(R)$. The gap can therefore be made as small as desired, and f is integrable (Definition 7.93).

(2) By (1), f is integrable, since it is continuous (with value zero) off Z. Cover Z by finitely many cubes of total volume less than ε and partition R with a mesh small compared with the smallest of those cubes. Every sub-box on which f is not identically zero meets Z,

hence lies in the union of the cubes enlarged by one mesh on every side, whose volume is then at most 2ε; so $|\int_R f| \le 2M\varepsilon$ for every $\varepsilon > 0$.

(3) The function $\chi_E - \sum_i \chi_{E_i}$ vanishes off $\bigcup_{i<j} (E_i \cap E_j)$, a set of zero content, and is bounded by m; multiplying by f and applying (2) gives the statement. □

Lemma A.500 (Graphs and C^1 images have zero content)**.** *1. Let $B \subset \mathbb{R}^{N-1}$ be a box and $g : B \to \mathbb{R}$ continuous. Then the graph $\{(\boldsymbol{u}', g(\boldsymbol{u}')) \mid \boldsymbol{u}' \in B\}$ has zero content in $\mathbb{R}^N$; so does its intersection with any coordinate hyperplane, and so does a face of a box.*

2. Let $W \subseteq \mathbb{R}^N$ be open, $\boldsymbol{F} : W \to \mathbb{R}^N$ of class C^1, and $Z \subset W$ a compact set of zero content. Then $\boldsymbol{F}(Z)$ has zero content.

Rests on Lemma A.499 and Theorems 7.25 and 7.35.

Proof. *Derives Lemma A.500.*

(1) Let $\varepsilon > 0$. By uniform continuity (Theorem 7.25) there is $\delta > 0$ such that g varies by less than ε on any subset of B of diameter less than δ. Cover B by cubes of side $h < \min\left\{\delta/\sqrt{N-1}, \varepsilon\right\}$, in number at most $C_B h^{-(N-1)}$ with C_B depending on B alone. Over each such cube the graph lies in a box of base that cube and height ε, which is covered by $\lceil \varepsilon/h \rceil$ cubes of side h, of total volume at most $(\varepsilon + h)\, h^{N-1} \le 2\varepsilon h^{N-1}$. Summing gives a total volume at most $2C_B\varepsilon$. A face of a box is the graph of a constant function.

(2) Cover Z by finitely many closed balls contained in W; on each, the entries of $D\boldsymbol{F}$ are bounded, and the mean value theorem (Theorem 7.35) applied to each component along the segment joining two points of the ball — which stays in the ball, the ball being convex — gives a constant L with $|\boldsymbol{F}(\boldsymbol{x}) - \boldsymbol{F}(\boldsymbol{y})| \le L\,|\boldsymbol{x} - \boldsymbol{y}|$ there. Take L to be the largest of the finitely many constants. Now cover Z by cubes of side h and total volume less than ε, refining h so small that each such cube meeting Z lies in one of the balls. A cube of side h has diameter $\sqrt{N}h$, so its image has diameter at most $L\sqrt{N}h$ and lies in a cube of that side, of volume $\left(L\sqrt{N}\right)^N h^N$. The images therefore cover $\boldsymbol{F}(Z)$ with total volume at most $\left(L\sqrt{N}\right)^N \varepsilon$. □

A.44.3 Iterated integration in $\mathbb{R}^N$

Lemma A.501 (Iterated integration over a box)**.** *Let $R = R' \times [a, b]$ be a box in $\mathbb{R}^N = \mathbb{R}^{N-1} \times \mathbb{R}$ and let $f : R \to \mathbb{R}$ be bounded and integrable, and such that $t \longmapsto f(\boldsymbol{u}', t)$ is integrable on $[a, b]$ for every $\boldsymbol{u}' \in R'$. Then*

$$\int_R f \,\mathrm{d}^N u = \int_{R'} \left[\int_a^b f(\boldsymbol{u}', t)\,\mathrm{d}t \right] \mathrm{d}^{N-1} u' \,, \tag{A.800}$$

the inner integral being an integrable function of $\boldsymbol{u}'$. The same holds with any one of the N coordinates in the role of t.

Rests on Definitions 7.39 and 7.93 and Theorem 7.40.

Proof. *Derives Lemma A.501.*

Write $F(\boldsymbol{u}') = \int_a^b f(\boldsymbol{u}', t)\,\mathrm{d}t$. Let P' be a partition of R' into sub-boxes S' and P_t a partition $a = t_0 < \cdots < t_n = b$; together they partition R into the sub-boxes $S = S' \times [t_{i-1}, t_i]$. Fix $\boldsymbol{u}' \in S'$. For each i and every $t \in [t_{i-1}, t_i]$ one has $f(\boldsymbol{u}', t) \ge \inf_S f$, so

$$F(\boldsymbol{u}') \ge \sum_{i=1}^{n} \left(\inf_{S' \times [t_{i-1}, t_i]} f \right) (t_i - t_{i-1}) \,, \tag{A.801}$$

the right-hand side being independent of $\boldsymbol{u}' \in S'$; hence it is a lower bound for $\inf_{S'} F$. Multiplying by $\mathrm{vol}(S')$ and summing over S' gives $L(F, P') \ge L(f, P)$, where L denotes the

lower Darboux sum Equation (7.22). The mirror argument gives $U(F,P') \le U(f,P)$. Since f is integrable, the outer sums squeeze: for every $\varepsilon > 0$ a partition P with $U(f,P) - L(f,P) < \varepsilon$ yields $U(F,P') - L(F,P') < \varepsilon$, so F is integrable on R', and both $\int_{R'} F$ and $\int_R f$ lie between $L(f,P)$ and $U(f,P)$; letting $\varepsilon \to 0$ makes them equal. Relabelling the coordinates puts any chosen one in the role of t. □

Corollary A.502 (All iterated orders agree)**.** *Let $f \in C_c(\mathbb{R}^N)$ and let σ be a permutation of $\{1,\dots,N\}$. Then $\int_{\mathbb{R}^N} f$ equals the iterated integral taken in the order $u^{\sigma(N)}, u^{\sigma(N-1)}, \dots, u^{\sigma(1)}$ from innermost to outermost; consequently $\int_{\mathbb{R}^N} f \circ \sigma = \int_{\mathbb{R}^N} f$, where σ also denotes the map $\boldsymbol{u} \mapsto \left(u^{\sigma(1)}, \dots, u^{\sigma(N)}\right)$.*

Rests on Lemma A.501 and Theorem 7.40.

Proof. *Derives Corollary A.502.*

Take a box R containing the support in its interior. A continuous function is integrable on R and on every slice (Theorem 7.40), so Lemma A.501 applies with any chosen coordinate innermost; the inner integral is again continuous, by the uniform continuity of f on the compact R (Theorem 7.25), so the lemma may be applied again to it, and N applications reduce $\int_R f$ to the iterated integral in the chosen order. All $N!$ orders therefore give the same number. Finally $f \circ \sigma$ is continuous with compact support, and its iterated integral in the order $u^1, \dots, u^N$ becomes, on renaming the integration variable of the j-th integration from u^j to $u^{\sigma(j)}$, the iterated integral of f in the order $u^{\sigma(1)}, \dots, u^{\sigma(N)}$, which is $\int_{\mathbb{R}^N} f$. □

A.44.4 Two reductions

Definition A.503 (The substitution property)**.** Let $U, V \subseteq \mathbb{R}^N$ be open and $\boldsymbol{\Phi} : U \to V$ a C^1 diffeomorphism. We say $\boldsymbol{\Phi}$ *has the substitution property* if

$$\int_{\mathbb{R}^N} f = \int_{\mathbb{R}^N} (f \circ \boldsymbol{\Phi}) \, |\det D\boldsymbol{\Phi}| \qquad \text{for every } f \in C_c(V)\,, \tag{A.802}$$

both integrands being understood as extended by zero; the right-hand one belongs to $C_c(U)$, its support being $\boldsymbol{\Phi}^{-1}(\operatorname{supp} f)$.

Rests on Corollary 7.81 and Definition 7.93.

Lemma A.504 (Transitivity)**.** *If $\boldsymbol{\Phi} : U \to V$ and $\boldsymbol{\Psi} : V \to W$ are C^1 diffeomorphisms with the substitution property, so is $\boldsymbol{\Psi} \circ \boldsymbol{\Phi}$.*

Rests on Definition A.503, Proposition 7.72, and Lemma A.497.

Proof. *Derives Lemma A.504.*

Let $g \in C_c(W)$. Then $f := (g \circ \boldsymbol{\Psi}) \, |\det D\boldsymbol{\Psi}|$ lies in $C_c(V)$, and applying Equation (A.802) first to $\boldsymbol{\Psi}$ and then to $\boldsymbol{\Phi}$,

$$\int_{\mathbb{R}^N} g = \int_{\mathbb{R}^N} f = \int_{\mathbb{R}^N} (g \circ \boldsymbol{\Psi} \circ \boldsymbol{\Phi}) \, (|\det D\boldsymbol{\Psi}| \circ \boldsymbol{\Phi}) \, |\det D\boldsymbol{\Phi}| \,. \tag{A.803}$$

By the chain rule (Proposition 7.72), $D\,(\boldsymbol{\Psi} \circ \boldsymbol{\Phi})\,(\boldsymbol{u}) = D\boldsymbol{\Psi}\,(\boldsymbol{\Phi}(\boldsymbol{u}))\, D\boldsymbol{\Phi}(\boldsymbol{u})$, and Lemma A.497 turns the product of the two moduli into $|\det D\,(\boldsymbol{\Psi} \circ \boldsymbol{\Phi})|$. □

Lemma A.505 (A continuous partition of unity)**.** *Let $K \subset \mathbb{R}^N$ be compact and $W_1, \dots, W_m$ open sets with $K \subseteq W_1 \cup \cdots \cup W_m$. There are continuous functions $\lambda_1, \dots, \lambda_m$ on $\mathbb{R}^N$ with $0 \le \lambda_j \le 1$, with $\operatorname{supp} \lambda_j$ compact and contained in W_j, and with $\sum_j \lambda_j = 1$ on a neighbourhood of K.*

Rests on Definitions 6.6, 6.9 and 6.24.

Proof. *Derives Lemma A.505.*

For each $\boldsymbol{x} \in K$ choose $j(\boldsymbol{x})$ with $\boldsymbol{x} \in W_{j(\boldsymbol{x})}$ and $r(\boldsymbol{x}) > 0$ with the closed ball of radius $2r(\boldsymbol{x})$ about $\boldsymbol{x}$ inside $W_{j(\boldsymbol{x})}$. The open balls of radius $r(\boldsymbol{x})$ cover K; extract a finite subcover

(Definition 6.9) with centres $\boldsymbol{x}_1, \dots, \boldsymbol{x}_p$ and let K_j be the union of the closed balls $\overline{B}_{r(\boldsymbol{x}_i)}(\boldsymbol{x}_i)$ with $j(\boldsymbol{x}_i) = j$. Each K_j is compact and contained in W_j, and $K \subseteq \bigcup_j K_j$. Let $\rho_j > 0$ be smaller than the distance from K_j to the complement of W_j — positive because K_j is compact and the complement closed — and put

$$\psi_j(\boldsymbol{x}) = \max\{0,\ \rho_j - \operatorname{dist}(\boldsymbol{x}, K_j)\}\ , \tag{A.804}$$

which is continuous, non-negative, strictly positive exactly on the open set $\{\operatorname{dist}(\cdot, K_j) < \rho_j\}$, and supported in its closure, a compact subset of W_j. On the open set $O = \{\sum_i \psi_i > 0\}$, which contains K, set $\lambda_j = \psi_j / \sum_i \psi_i$; off O set $\lambda_j = 0$. Each λ_j is continuous on O and vanishes on a neighbourhood of every point of $\mathbb{R}^N \setminus \operatorname{supp}\psi_j$, so it is continuous everywhere; its support lies in that of ψ_j; and $\sum_j \lambda_j = 1$ on O. □

Lemma A.506 (Locality)**.** *Let $\boldsymbol{\Phi} : U \to V$ be a C^1 diffeomorphism and suppose every $\boldsymbol{p} \in U$ has an open neighbourhood $N_{\boldsymbol{p}} \subseteq U$ such that the restriction $\boldsymbol{\Phi}|_{N_{\boldsymbol{p}}} : N_{\boldsymbol{p}} \to \boldsymbol{\Phi}(N_{\boldsymbol{p}})$ has the substitution property. Then $\boldsymbol{\Phi}$ has it.*

Rests on Lemma A.505 and Definitions 6.9 and A.503.

Proof. *Derives Lemma A.506.*

Let $f \in C_c(V)$ with $K = \operatorname{supp} f$. The set $\boldsymbol{\Phi}^{-1}(K)$ is compact, so finitely many $N_{\boldsymbol{p}_1}, \dots, N_{\boldsymbol{p}_m}$ cover it, and the open sets $W_j = \boldsymbol{\Phi}(N_{\boldsymbol{p}_j}) \subseteq V$ cover K. Take $\lambda_1, \dots, \lambda_m$ as in Lemma A.505. Each $\lambda_j f$ is continuous, vanishes off $\operatorname{supp}\lambda_j \cap K$ — a compact subset of W_j — and hence lies in $C_c(W_j)$; and $\sum_j \lambda_j f = f$, since the two sides agree on the neighbourhood of K where $\sum_j \lambda_j = 1$ and both vanish off K. Applying the substitution property of $\boldsymbol{\Phi}|_{N_{\boldsymbol{p}_j}}$ to $\lambda_j f$ and summing over j,

$$\int_{\mathbb{R}^N} f = \sum_{j=1}^{m} \int_{\mathbb{R}^N} \lambda_j f = \sum_{j=1}^{m} \int_{\mathbb{R}^N} ((\lambda_j f) \circ \boldsymbol{\Phi})\, |\det D\boldsymbol{\Phi}| = \int_{\mathbb{R}^N} (f \circ \boldsymbol{\Phi})\, |\det D\boldsymbol{\Phi}|\ , \tag{A.805}$$

the first and last steps by the linearity of the integral over a box containing every support involved. □

A.44.5 Permutations and primitive maps

Lemma A.507 (Coordinate permutations)**.** *For a permutation σ of $\{1, \dots, N\}$, the linear map $\boldsymbol{u} \longmapsto \left(u^{\sigma(1)}, \dots, u^{\sigma(N)}\right)$ of $\mathbb{R}^N$ onto itself has the substitution property.*

Rests on Corollary A.502 and Equation (5.19).

Proof. *Derives Lemma A.507.*

Its matrix has exactly one 1 in each row and column, so Equation (5.19) leaves a single term and the determinant is $\operatorname{sgn}(\sigma) = \pm 1$; hence $|\det| = 1$ and Equation (A.802) reduces to $\int f = \int f \circ \sigma$, which is Corollary A.502. This is the only step of the whole derivation at which the *sign* of the determinant is disposed of, and it is why Equation (7.113) carries a modulus while Equation (5.19) does not. □

Definition A.508 (Primitive map)**.** A C^1 diffeomorphism $\boldsymbol{\Phi} : U \to V$ of open subsets of $\mathbb{R}^N$ is *primitive* if it changes only the last coordinate:

$$\boldsymbol{\Phi}(\boldsymbol{u}', t) = \left(\boldsymbol{u}',\ \Phi^N(\boldsymbol{u}', t)\right)\ , \qquad \det D\boldsymbol{\Phi} = \frac{\partial \Phi^N}{\partial t}\ , \tag{A.806}$$

the determinant being that of a triangular matrix with $N - 1$ unit diagonal entries.

Rests on Definition 7.66 and Equation (5.19).

Lemma A.509 (Primitive maps have the substitution property)**.** *Every primitive C^1 diffeomorphism has the substitution property.*

Rests on Definition A.508, Equation (7.27), and Lemma A.501.

Proof. *Derives Lemma A.509.*

Let $f \in C_c(V)$ and write $g = (f \circ \mathbf{\Phi}) \left|\partial_t \Phi^N\right| \in C_c(U)$. Both f and g, extended by zero, are continuous with compact support, so by Corollary A.502 each integral is the iterated integral with t innermost. It therefore suffices to prove, for every fixed $\boldsymbol{u}' \in \mathbb{R}^{N-1}$,

$$\int_{\mathbb{R}} f(\boldsymbol{u}', s)\,\mathrm{d}s = \int_{\mathbb{R}} f\left(\boldsymbol{u}', \Phi^N(\boldsymbol{u}', t)\right) \left|\frac{\partial \Phi^N}{\partial t}(\boldsymbol{u}', t)\right| \mathrm{d}t\,. \tag{A.807}$$

Fix $\boldsymbol{u}'$ and put $U_{\boldsymbol{u}'} = \{t \mid (\boldsymbol{u}', t) \in U\}$ and $V_{\boldsymbol{u}'} = \{s \mid (\boldsymbol{u}', s) \in V\}$, both open in $\mathbb{R}$. Because $\mathbf{\Phi}$ leaves $\boldsymbol{u}'$ untouched and is a bijection of U onto V, the map $\varphi(t) = \Phi^N(\boldsymbol{u}', t)$ is a bijection of $U_{\boldsymbol{u}'}$ onto $V_{\boldsymbol{u}'}$; it is C^1 with $\varphi' = \partial_t \Phi^N \neq 0$, hence strictly monotone on each connected component of $U_{\boldsymbol{u}'}$, mapping that component onto a component of $V_{\boldsymbol{u}'}$.

The integrand on the right of Equation (A.807) vanishes off the compact set $\mathbf{\Phi}^{-1}(\operatorname{supp} f)$, whose slice at $\boldsymbol{u}'$ is a compact subset T of $U_{\boldsymbol{u}'}$. The components of $U_{\boldsymbol{u}'}$ are open and disjoint and cover T, so only finitely many of them, $I_1, \ldots, I_q$, meet T; choose in each a compact interval $[\alpha_r, \beta_r] \subset I_r$ containing $T \cap I_r$, with $\alpha_r < \beta_r$. On I_r the substitution rule Equation (7.27), applied to the C^1 function φ and the continuous $s \mapsto f(\boldsymbol{u}', s)$, gives

$$\int_{\alpha_r}^{\beta_r} f\left(\boldsymbol{u}', \varphi(t)\right) \varphi'(t)\,\mathrm{d}t = \int_{\varphi(\alpha_r)}^{\varphi(\beta_r)} f(\boldsymbol{u}', s)\,\mathrm{d}s\,. \tag{A.808}$$

If φ increases on I_r then $\varphi' = |\varphi'|$ and the right-hand side is the integral over $[\varphi(\alpha_r), \varphi(\beta_r)]$; if φ decreases then $\varphi' = -|\varphi'|$ and the right-hand side is minus the integral over $[\varphi(\beta_r), \varphi(\alpha_r)]$. In both cases

$$\int_{\alpha_r}^{\beta_r} f\left(\boldsymbol{u}', \varphi(t)\right) |\varphi'(t)|\,\mathrm{d}t = \int_{\varphi([\alpha_r, \beta_r])} f(\boldsymbol{u}', s)\,\mathrm{d}s\,. \tag{A.809}$$

Outside $[\alpha_r, \beta_r]$ the left integrand vanishes, so the left-hand side is the integral over the whole of I_r; and $f(\boldsymbol{u}', \cdot)$ vanishes on $\varphi(I_r) \setminus \varphi\left([\alpha_r, \beta_r]\right)$, since a point s there has $\varphi^{-1}(s) \notin T$, so the right-hand side is the integral over the component $\varphi(I_r)$ of $V_{\boldsymbol{u}'}$. Summing over $r = 1, \ldots, q$ and noting that $f(\boldsymbol{u}', \cdot)$ vanishes on the components of $V_{\boldsymbol{u}'}$ not among the $\varphi(I_r)$, and off $V_{\boldsymbol{u}'}$ altogether, gives Equation (A.807). □

A.44.6 The local factorisation

Lemma A.510 (Every diffeomorphism factorises locally)**.** *Let $\mathbf{\Phi}$ be a C^1 diffeomorphism of an open subset of $\mathbb{R}^N$ onto an open subset, and let $\boldsymbol{p}$ be a point of its domain. Then some neighbourhood of $\boldsymbol{p}$ carries a factorisation of $\mathbf{\Phi}$ as a composition of finitely many primitive maps and coordinate permutations.*

Rests on Corollary 7.81, Definition A.508, and Proposition 7.72.

Proof. *Derives Lemma A.510.*

Say that a C^1 diffeomorphism $\mathbf{\Theta}$ defined near a point is *m-adapted* there, $1 \leq m \leq N+1$, if $\Theta^i(\boldsymbol{u}) = u^i$ for every $i < m$ throughout a neighbourhood. Every diffeomorphism is 1-adapted (the condition is empty), and an $(N+1)$-adapted one is the identity. We show that an m-adapted $\mathbf{\Theta}$ is, near the point, the composition of an $(m+1)$-adapted diffeomorphism with one primitive map and one transposition of coordinates; N applications then prove the lemma, since a primitive map in the m-th coordinate is a transposition conjugate of one in the last coordinate.

Let $\mathbf{\Theta}$ be m-adapted at $\boldsymbol{q}$. Its Jacobian there has the block form

$$D\mathbf{\Theta}(\boldsymbol{q}) = \begin{pmatrix} \mathbb{1} & 0 \\ * & C \end{pmatrix}, \tag{A.810}$$

with $\mathbb{1}$ of size $m-1$ and C the matrix $\partial\Theta^i/\partial u^j$ with $i,j \geq m$; expanding the determinant along the first $m-1$ rows shows $\det C = \det D\boldsymbol{\Theta} \neq 0$, so the rows of C are independent and in particular the row $\left(\partial\Theta^m/\partial u^j\right)_{j\geq m}$ is non-zero: there is $j \geq m$ with $\partial\Theta^m/\partial u^j(\boldsymbol{q}) \neq 0$.

Let τ be the transposition of the coordinates m and j, and set

$$\boldsymbol{\varsigma}(\boldsymbol{u}) = \left(u^1, \dots, u^{m-1}, \Theta^m\left(\tau(\boldsymbol{u})\right), u^{m+1}, \dots, u^N\right), \tag{A.811}$$

a map changing only the m-th coordinate. At $\boldsymbol{q}' = \tau(\boldsymbol{q})$ its m-th partial derivative in the m-th coordinate is $\partial\Theta^m/\partial u^j(\boldsymbol{q}) \neq 0$, so $\det D\boldsymbol{\varsigma}(\boldsymbol{q}') \neq 0$ and, by the inverse function theorem (Corollary 7.81), $\boldsymbol{\varsigma}$ is a C^1 diffeomorphism of a neighbourhood of $\boldsymbol{q}'$ onto an open set; it is a primitive map in the m-th coordinate.

Put $\boldsymbol{\Xi} = \boldsymbol{\Theta} \circ \tau \circ \boldsymbol{\varsigma}^{-1}$, so that $\boldsymbol{\Theta} = \boldsymbol{\Xi} \circ \boldsymbol{\varsigma} \circ \tau$ near $\boldsymbol{q}$ (τ being its own inverse). For $i < m$, neither τ nor $\boldsymbol{\varsigma}$ — hence nor $\boldsymbol{\varsigma}^{-1}$ — touches the i-th coordinate, and $\boldsymbol{\Theta}$ preserves it, so $\Xi^i(\boldsymbol{v}) = v^i$. For $i = m$: writing $\boldsymbol{u} = \boldsymbol{\varsigma}^{-1}(\boldsymbol{v})$ one has $v^m = \varsigma^m(\boldsymbol{u}) = \Theta^m\left(\tau(\boldsymbol{u})\right) = \Xi^m(\boldsymbol{v})$. Hence $\boldsymbol{\Xi}$ is $(m+1)$-adapted, as claimed. □

Proposition A.511 (The substitution property is universal)**.** *Every C^1 diffeomorphism $\boldsymbol{\Phi} : U \to V$ of open subsets of $\mathbb{R}^N$ has the substitution property: for every $f \in C_c(V)$,*

$$\int_V f(\boldsymbol{x})\, \mathrm{d}^N x = \int_U f\left(\boldsymbol{\Phi}(\boldsymbol{u})\right) \left|\det D\boldsymbol{\Phi}(\boldsymbol{u})\right| \mathrm{d}^N u\,. \tag{A.812}$$

Rests on Lemmas A.506, A.509 and A.510.

Proof. *Derives Proposition A.511.*

By Lemma A.510 each point of U has a neighbourhood on which $\boldsymbol{\Phi}$ is a composition of primitive maps and permutations; each factor has the substitution property by Lemmas A.507 and A.509, so the composition has it by Lemma A.504. Thus $\boldsymbol{\Phi}$ has the property locally, and Lemma A.506 globalises it. □

A.44.7 From compact support to the theorem

Proposition A.511 carries no hypothesis on the shape of U and V. To reach Theorem 7.97 as stated — an integrand merely continuous and bounded on V, not vanishing near the boundary — something must be assumed about that boundary, and about the behaviour of $\boldsymbol{\Phi}$ there; otherwise neither integral need exist. The hypotheses below hold for every use made of the formula in this treatise.

Lemma A.512 (The boundary strip is thin)**.** *Let $V \subset \mathbb{R}^N$ be open and bounded and suppose its boundary is contained in finitely many graphs of continuous functions over boxes, in the sense of Lemma A.500(1) with the coordinates permuted — the N-dimensional reading of Definition 7.95. Define the boundary strip*

$$V_\delta = \{\boldsymbol{x} \in V \mid \operatorname{dist}(\boldsymbol{x}, \partial V) < \delta\}\,. \tag{A.813}$$

Then the content of V_δ tends to zero as $\delta \to 0$.

Rests on Lemma A.500, Theorem 7.25, and Definition 7.95.

Proof. *Derives Lemma A.512.*

It is enough to treat one graph Γ, of a continuous g over a box $B \subset \mathbb{R}^{N-1}$, and to bound the content of its δ-neighbourhood. By uniform continuity (Theorem 7.25) split B into cubes of side h on each of which g varies by less than δ. A point within distance δ of Γ and lying over such a cube has last coordinate within 2δ of the value of g at the cube's centre, and lies over the cube enlarged by δ; so the neighbourhood is covered by boxes of total volume at most $4\delta\left(\operatorname{vol}(B) + C\delta\right)$ with C depending on B alone. Letting first $h \to 0$ and then $\delta \to 0$ gives the claim; the finitely many graphs are summed. □

Theorem A.513 (Change of variables)**.** *Let $U, V \subseteq \mathbb{R}^N$ be open and bounded and let $\mathbf{\Phi} : U \to V$ be a bijection of class C^1 with $\det D\mathbf{\Phi} \neq 0$ everywhere. Assume in addition that $\mathbf{\Phi}$ is the restriction of a C^1 diffeomorphism of an open set containing $\overline{U}$, and that ∂U and ∂V are as in Lemma A.512. Then for every bounded continuous f on V both integrals in Equation (7.113) exist and are equal.*

Rests on Proposition A.511 and Lemmas A.499 and A.512.

Proof. *Derives Theorem A.513.*

Existence. Extend f by zero to a box $R \supseteq \overline{V}$. The extension is bounded and continuous off ∂V, which has zero content by Lemma A.500(1); so it is integrable by Lemma A.499(1). The same argument applies on the U side: $(f \circ \mathbf{\Phi})\,|\det D\mathbf{\Phi}|$ is bounded there, because $D\mathbf{\Phi}$ extends continuously to the compact $\overline{U}$, and continuous off ∂U.

Equality. Let M bound $|f|$ and J bound $|\det D\mathbf{\Phi}|$ on $\overline{U}$. For $\delta > 0$ put

$$\eta_\delta(\boldsymbol{x}) = \min\left\{1,\ \max\left\{0,\ \frac{\operatorname{dist}(\boldsymbol{x}, \mathbb{R}^N \setminus V) - \delta}{\delta}\right\}\right\}, \tag{A.814}$$

a continuous function, zero where the distance is at most δ and one where it is at least 2δ. The set where $\eta_\delta \neq 0$ has closure inside $\left\{\operatorname{dist}(\cdot, \mathbb{R}^N \setminus V) \geq \delta\right\}$, which is closed and bounded, hence a compact subset of V; so $f_\delta = \eta_\delta f$ lies in $C_c(V)$ and Proposition A.511 gives

$$\int_V f_\delta = \int_U (f_\delta \circ \mathbf{\Phi})\,|\det D\mathbf{\Phi}|\ . \tag{A.815}$$

On the left, $f - f_\delta$ vanishes outside $V_{2\delta}$ and is bounded by M, so the difference of the two integrals is at most M times the content of $V_{2\delta}$, which tends to zero by Lemma A.512. On the right, the integrands differ only on $\mathbf{\Phi}^{-1}(V_{2\delta})$ and by at most MJ. The extension of $\mathbf{\Phi}^{-1}$ is C^1 on a neighbourhood of the compact $\overline{V}$, hence Lipschitz there with some constant L by the argument of Lemma A.500(2); covering $V_{2\delta}$ by cubes of total volume ε and taking images covers $\mathbf{\Phi}^{-1}(V_{2\delta})$ with total volume at most $\left(L\sqrt{N}\right)^N \varepsilon$, so its content also tends to zero. Letting $\delta \to 0$ in Equation (A.815) gives Equation (7.113). □

Corollary A.514 (Degeneracy on a negligible set)**.** *Let U, V be open and bounded, let $Z \subset U$ be closed in U and contained in finitely many graphs of continuous functions over boxes, and let $\mathbf{\Phi} : U \to V$ be C^1, mapping $U \setminus Z$ bijectively onto $V \setminus \mathbf{\Phi}(Z)$ with non-vanishing Jacobian there. If $\mathbf{\Phi}$ extends C^1 to a neighbourhood of $\overline{U}$, then Equation (7.113) holds for every $f \in C_c(V)$, and for bounded continuous f under the boundary hypotheses of Theorem A.513 applied to $U \setminus Z$ and $V \setminus \mathbf{\Phi}(Z)$.*

Rests on Theorem A.513 and Lemmas A.499 and A.500.

Proof. *Derives Corollary A.514.*

$U \setminus Z$ is open, and $\mathbf{\Phi}|_{U \setminus Z}$ is a C^1 diffeomorphism onto the open set $V \setminus \mathbf{\Phi}(Z)$; note that $\mathbf{\Phi}(Z \cap K)$ has zero content for every compact $K \subset \overline{U}$, by Lemma A.500. Apply Proposition A.511, or Theorem A.513, to that restriction. Both integrals change by nothing when the sets Z and $\mathbf{\Phi}(Z)$ are restored, because the integrands are bounded and the two sets have zero content (Lemma A.499(2)). □

The corollary is what licenses the two Jacobians of Example 7.98. The polar map $\mathbf{\Phi}(\rho, \varphi) = (\rho\cos\varphi, \rho\sin\varphi)$ of Equation (7.114) has $\det D\mathbf{\Phi} = \rho$, which vanishes on the segment $\rho = 0$, and it fails to be injective unless φ is confined to an interval of length 2π, so that a ray must be removed from the image; segment and ray are each contained in the graph of a continuous function, and neither contributes to either integral. The spherical map is degenerate on the polar axis in the same way.

A.44.8 Reading the result

Remark A.515 (What is quoted here). Nothing outside this treatise, and no result of Chapter 7 beyond the ones listed in Appendix A.44.1. Three points are worth recording, because each is a place where the chapters state slightly less than the derivation needs and the gap is filled here rather than passed over.

First, Chapter 5 records the Leibniz expansion Equation (5.19) and reads off column linearity and antisymmetry, but never states that the determinant is multiplicative; that is Lemma A.497, proved above from the expansion alone. It is a debt of Part II, small but real: the composition rule for Jacobians is used wherever coordinates are changed twice.

Second, Remark 7.96 states the reduction of a multiple integral to an iterated one for $N = 2$ and $N = 3$ only. The N-dimensional statement is Lemma A.501, proved here by the same Darboux squeeze. This too is a Part II debt, and it is the reason Theorem 7.97 could not simply be quoted from the chapter's own machinery.

Third — and this corrects the plan under which this section was written — the passage from a local identity to a global one does use a partition of unity. It is a *continuous* one, constructed in Lemma A.505 out of distance functions and nothing else; no smooth bump function is needed, because f is only assumed continuous. There is no fixed-point theorem, no convergence theorem of Lebesgue integration and no measure theory anywhere in the section: every set that is discarded is discarded because it has zero *content* (Definition A.498), which a Darboux sum can see, and not merely measure zero in the sense of Section 7.12.

Remark A.516 (The hypotheses of the global form). Proposition A.511, the compactly supported form, is the theorem proper: it holds for arbitrary open U and V and is where all the work is. The extra hypotheses of Theorem A.513 — a boundary made of finitely many graphs, and a C^1 extension across $\overline{U}$ — are not artefacts of the method. Without some such assumption the two integrals in Equation (7.113) need not exist at all: a bounded continuous function on a bounded open set with a sufficiently wild boundary is not Riemann integrable, and the statement of Theorem 7.97 that "both integrals exist" is then false rather than unproved. The chapter's phrasing should be read with these hypotheses supplied; they hold in every application made in this book, where the regions are simple in the sense of Definition 7.95 and the maps are restrictions of diffeomorphisms defined on larger open sets.

Rests on Theorem A.513, Proposition A.511, and Definition 7.95.

Remark A.517. Appendix A.44 discharges the derivation owed at Theorem 7.97 of Chapter 7. The result is cashed in three places. It is what makes the surface integral Equation (7.109) independent of the parametrization used to define it, as Remark 7.102 states explicitly: two parametrizations of one surface differ by a C^1 diffeomorphism of their parameter domains, and the Jacobian factor supplied by Equation (7.113) cancels the corresponding factor in $\partial_u \boldsymbol{r} \times \partial_v \boldsymbol{r}$ — so the flux, and with it Theorem 7.101 and Theorem 7.100, is well defined. It supplies the polar and spherical volume elements of Example 7.98, used throughout the physical parts and, in this appendix alone, in Appendix A.45. And it is the statement behind the invariance of phase-space volume, Corollary 22.24 of Part III, where the relevant map is the Hamiltonian flow and the Jacobian determinant is the one Liouville's theorem shows to be unity.

A.45 The Helmholtz Decomposition

This appendix proves Theorem 7.105 of Chapter 7: every smooth compactly supported vector field on $\mathbb{R}^3$ splits as in Equation (7.129) into a gradient and a curl, with the potentials given explicitly by Equation (7.130), and the two summands are unique among fields that vanish at infinity. It is the theorem that licenses the routine physical move of treating the irrotational and the solenoidal parts of a field separately — the longitudinal and transverse

parts of the electromagnetic field, the P and S waves of a seismogram, the potential and vortical parts of a flow.

The paragraph following the proof link in Section 7.11.5 already gives the mechanism, and it is correct: each Cartesian component of $\boldsymbol{w}$ is a Newtonian potential, so $\nabla^2 \boldsymbol{w} = \boldsymbol{u}$, and Equation (7.105) read backwards turns that Laplacian into the required sum. What the chapter does not supply, and what this section owes, is the analysis: that the singular integral Equation (7.130) converges at all, that it may be differentiated under the integral sign as often as one pleases, that the resulting field decays, and that the decay is enough to force uniqueness. That is the whole content of what follows.

One organisational point should be made at the outset. The argument uses two results of Chapter 10 — the fundamental-solution property of the Newtonian potential (Proposition 10.67) and the weak maximum principle (Theorem 10.75) — and Chapter 10 comes *after* Chapter 7. Nothing is circular: neither of those two results uses Theorem 7.105, or anything proved here. But the forward dependence is real and is why the derivation sits in the appendix rather than in the chapter, where it would have to be either postponed or duplicated. See Remark A.526.

Throughout, $\boldsymbol{u}$ is a smooth vector field on $\mathbb{R}^3$ whose support is contained in the ball $|\boldsymbol{y}| \le R_0$, and we write

$$\Phi(\boldsymbol{z}) = -\frac{1}{4\pi\,|\boldsymbol{z}|}\,, \tag{A.816}$$

for the Newtonian kernel Equation (10.63). The section is pure vector analysis, but the SI bookkeeping is worth recording once because the physical parts read the decomposition off it: Φ has the dimension of a reciprocal length and $\mathrm{d}^3 z$ that of a volume, so $\boldsymbol{w}$ carries the unit of $\boldsymbol{u}$ multiplied by m^2; ϕ and $\boldsymbol{\Psi}$, being first derivatives of $\boldsymbol{w}$, carry that of $\boldsymbol{u}$ multiplied by m; and $\nabla\phi$ and $\nabla \times \boldsymbol{\Psi}$ carry the unit of $\boldsymbol{u}$ itself, as Equation (7.129) requires.

A.45.1 What the derivation uses

From Chapter 7: the Leibniz integral rule (Theorem 7.77), both halves of the fundamental theorem of calculus (Theorems 7.42 and 7.43), uniform continuity (Theorem 7.25), the Cauchy criterion (Theorem 7.8), the second-order identities of the nabla calculus (Proposition 7.91), the class C^1 (Definition 7.66) and the theorem that a C^1 map is differentiable (Theorem 7.68), and the spherical volume element of Example 7.98 — which is itself an instance of Appendix A.44. From Chapter 10: Proposition 10.67 and Theorem 10.75, both proved there.

A.45.2 The kernel is integrable, and uniformly so

Lemma A.518 (The excised ball)**.** *For $0 \le \delta < \varepsilon$,*

$$\int_{\delta \le |\boldsymbol{z}| \le \varepsilon} \frac{\mathrm{d}^3 z}{|\boldsymbol{z}|} = 2\pi \left(\varepsilon^2 - \delta^2\right)\,, \tag{A.817}$$

so that for every bounded g on $\mathbb{R}^3$,

$$\left| \int_{\delta \le |\boldsymbol{z}| \le \varepsilon} \Phi(\boldsymbol{z})\, g(\boldsymbol{x} - \boldsymbol{z})\, \mathrm{d}^3 z \right| \le \frac{1}{2}\,(\sup |g|)\,\varepsilon^2 \qquad \text{for every } \boldsymbol{x} \in \mathbb{R}^3\,. \tag{A.818}$$

Rests on Example 7.98, Theorem 7.97, and Definition 7.93.

Proof. *Derives Lemma A.518.*

The shell $\delta \le |\boldsymbol{z}| \le \varepsilon$ is a compact region decomposing into finitely many simple regions (Definition 7.95), and $|\boldsymbol{z}|^{-1}$ is continuous on it, hence integrable. Passing to

spherical coordinates, whose Jacobian determinant is $r^2 \sin\theta$ (Example 7.98, licensed by Theorem 7.97),

$$\int_{\delta\le|\boldsymbol{z}|\le\varepsilon} \frac{\mathrm{d}^3 z}{|\boldsymbol{z}|} = \int_0^{2\pi} \mathrm{d}\varphi \int_0^{\pi} \sin\theta \,\mathrm{d}\theta \int_\delta^\varepsilon \frac{r^2}{r}\,\mathrm{d}r = 2\pi\cdot 2\cdot \frac{\varepsilon^2-\delta^2}{2}\,, \tag{A.819}$$

which is Equation (A.817). Bounding the integrand of Equation (A.818) by $(4\pi\,|\boldsymbol{z}|)^{-1}\sup|g|$ and dropping δ gives the estimate, and the bound does not involve $\boldsymbol{x}$. □

Proposition A.519 (The convolution exists)**.** *Let g be continuous on $\mathbb{R}^3$ with support in $|\boldsymbol{y}|\le R_0$. For $\varepsilon>0$ put*

$$(\Phi * g)_\varepsilon(\boldsymbol{x}) = \int_{|\boldsymbol{z}|\ge\varepsilon} \Phi(\boldsymbol{z})\, g(\boldsymbol{x}-\boldsymbol{z})\,\mathrm{d}^3 z\,, \tag{A.820}$$

a proper integral over a compact region for each $\boldsymbol{x}$. As $\varepsilon\to 0$ these converge uniformly on $\mathbb{R}^3$ to a continuous limit $\Phi * g$, and

$$(\Phi * g)(\boldsymbol{x}) = -\frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{g(\boldsymbol{y})}{|\boldsymbol{x}-\boldsymbol{y}|}\,\mathrm{d}^3 y\,, \tag{A.821}$$

the right-hand side being understood in the same excised sense.
Rests on Lemma A.518 and Theorems 7.8 and 7.97.

Proof. *Derives Proposition A.519.*

Fix $\boldsymbol{x}$ in a bounded set. The integrand of Equation (A.820) vanishes unless $\boldsymbol{x}-\boldsymbol{z}$ lies in the support of g, i.e. unless $\boldsymbol{z}$ lies in a fixed bounded set; so the integration is over a compact shell, on which the integrand is continuous, and the integral exists. For $0<\varepsilon'<\varepsilon$ the difference is the integral over the shell $\varepsilon'\le|\boldsymbol{z}|\le\varepsilon$, bounded by $\frac{1}{2}(\sup|g|)\,\varepsilon^2$ uniformly in $\boldsymbol{x}$ by Equation (A.818). The family is therefore uniformly Cauchy, so it converges pointwise (Theorem 7.8) and the convergence is uniform.

Each truncation is continuous in $\boldsymbol{x}$: on a compact shell and for $\boldsymbol{x}$ in a compact ball the integrand is uniformly continuous (Theorem 7.25), so the integral is continuous in the parameter — this is the last clause of Theorem 7.77, whose proof needs only that bound. A uniform limit of continuous functions is continuous: given $\varepsilon>0$ choose ε_0 with $\left|(\Phi*g)-(\Phi*g)_{\varepsilon_0}\right|<\varepsilon/3$ everywhere and then use the continuity of the truncation at the point in question, the three errors summing to ε; this is the argument already made for series in Lemma 9.6. Finally Equation (A.821) is the substitution $\boldsymbol{y}=\boldsymbol{x}-\boldsymbol{z}$, a translation composed with a reflection, whose Jacobian determinant has modulus one (Theorem 7.97). □

A.45.3 Differentiating under the integral sign

The singular factor in Equation (A.820) does not depend on $\boldsymbol{x}$. That is the whole trick: every derivative in $\boldsymbol{x}$ falls on g, where it is harmless, and the singularity is never differentiated.

Lemma A.520 (A C^1 limit)**.** *Let $O\subseteq\mathbb{R}^n$ be open and let $f_j : O\to\mathbb{R}$ be of class C^1, converging pointwise on O to f, with each $\partial_i f_j$ converging uniformly on O to a function h_i. Then f is of class C^1 on O and $\partial_i f = h_i$.*
Rests on Theorems 7.42 and 7.43 and Definition 7.66.

Proof. *Derives Lemma A.520.*

Each h_i is continuous, being a uniform limit of continuous functions (the $\varepsilon/3$ argument recalled in the proof of Proposition A.519). Fix $\boldsymbol{x}\in O$ and $\sigma>0$ with the segment $\boldsymbol{x}+s\boldsymbol{e}_i$,

$|s| \le \sigma$, inside O. By the fundamental theorem of calculus (Theorem 7.43) applied to the one-variable C^1 function $s \mapsto f_j(\boldsymbol{x} + s\boldsymbol{e}_i)$,

$$f_j\left(\boldsymbol{x} + t\boldsymbol{e}_i\right) - f_j(\boldsymbol{x}) = \int_0^t \partial_i f_j\left(\boldsymbol{x} + s\boldsymbol{e}_i\right) \mathrm{d}s\,, \qquad |t| \le \sigma\,. \tag{A.822}$$

The left-hand side tends to $f(\boldsymbol{x} + t\boldsymbol{e}_i) - f(\boldsymbol{x})$; on the right the error is at most $|t| \sup_O |\partial_i f_j - h_i|$, which tends to zero. Hence $f(\boldsymbol{x} + t\boldsymbol{e}_i) - f(\boldsymbol{x}) = \int_0^t h_i(\boldsymbol{x} + s\boldsymbol{e}_i)\,\mathrm{d}s$, and since h_i is continuous, differentiating at $t = 0$ (Theorem 7.42) gives $\partial_i f(\boldsymbol{x}) = h_i(\boldsymbol{x})$. All partial derivatives of f exist and are continuous, so f is of class C^1 (Definition 7.66) and differentiable (Theorem 7.68). □

Proposition A.521 (Every derivative passes onto g)**.** *Let g be of class C^k, $k \ge 1$, with compact support. Then $\Phi * g$ is of class C^k and, for every multi-index of order at most k,*

$$\partial_{i_1} \cdots \partial_{i_m} \left(\Phi * g\right) = \Phi * \left(\partial_{i_1} \cdots \partial_{i_m} g\right)\,, \qquad m \le k\,. \tag{A.823}$$

In particular $\Phi * g$ is smooth when g is.

Rests on Lemmas A.518 and A.520 and Theorem 7.77.

Proof. *Derives Proposition A.521.*

It suffices to prove the case $m = 1$ and to iterate, since $\partial_i g$ is again C^{k-1} with compact support.

Fix a ball $|\boldsymbol{x}| < \rho$. For $\boldsymbol{x}$ in it, the integrand of Equation (A.820) vanishes unless $\boldsymbol{z}$ lies in the compact shell $D_\varepsilon = \{\varepsilon \le |\boldsymbol{z}| \le \rho + R_0\}$, which decomposes into finitely many simple regions. On $D_\varepsilon \times (-\rho, \rho)$ the function $(\boldsymbol{z}, x^i) \mapsto \Phi(\boldsymbol{z}) g(\boldsymbol{x} - \boldsymbol{z})$ is continuous with continuous derivative $-\Phi(\boldsymbol{z})\left(\partial_i g\right)(\boldsymbol{x} - \boldsymbol{z})$ in the parameter x^i — the kernel is bounded away from its singularity on D_ε — so the Leibniz integral rule (Theorem 7.77) applies in each variable x^i separately and gives

$$\partial_i \left(\Phi * g\right)_\varepsilon (\boldsymbol{x}) = \int_{|\boldsymbol{z}| \ge \varepsilon} \Phi(\boldsymbol{z})\left(\partial_i g\right)(\boldsymbol{x} - \boldsymbol{z})\,\mathrm{d}^3 z = \left(\Phi * \partial_i g\right)_\varepsilon (\boldsymbol{x})\,, \tag{A.824}$$

the sign of the chain rule being absorbed because the derivative is taken with respect to $\boldsymbol{x}$ and not $\boldsymbol{z}$: writing $g(\boldsymbol{x} - \boldsymbol{z})$ and differentiating in x^i produces $\left(\partial_i g\right)(\boldsymbol{x} - \boldsymbol{z})$ with no sign at all.

By Proposition A.519 applied to g and to $\partial_i g$, both sides of Equation (A.824) converge uniformly as $\varepsilon \to 0$, the first to $\Phi * g$ and the second to $\Phi * \partial_i g$; each truncation is C^1 on the ball by the same Leibniz rule. Lemma A.520 therefore gives $\partial_i\left(\Phi * g\right) = \Phi * \partial_i g$ there, and ρ was arbitrary. □

A.45.4 Poisson's equation

Proposition A.522 (The Newtonian potential inverts the Laplacian)**.** *Let $\boldsymbol{u}$ be smooth with compact support and let $\boldsymbol{w} = \Phi * \boldsymbol{u}$, meaning the convolution taken componentwise. Then $\boldsymbol{w}$ is smooth and*

$$\nabla^2 \boldsymbol{w} = \boldsymbol{u} \qquad \textit{everywhere on } \mathbb{R}^3\,. \tag{A.825}$$

Rests on Propositions 10.67 and A.521 and Definition 17.38.

Proof. *Derives Proposition A.522.*

Smoothness and $\nabla^2 w_i = \Phi * \left(\nabla^2 u_i\right)$ are Proposition A.521. Fix $\boldsymbol{x}$ and put $\varphi(\boldsymbol{z}) = u_i(\boldsymbol{x} - \boldsymbol{z})$, a smooth function of compact support and hence a test function in the sense of Definition 17.38. Its Laplacian in $\boldsymbol{z}$ is $\left(\nabla^2 u_i\right)(\boldsymbol{x} - \boldsymbol{z})$, the two sign changes of the chain rule cancelling in a second derivative. By Proposition 10.67, which says precisely that $\int_{\mathbb{R}^3} \Phi\, \nabla^2 \varphi\, \mathrm{d}^3 z = \varphi(\boldsymbol{0})$ for every test function,

$$\left[\Phi * \left(\nabla^2 u_i\right)\right](\boldsymbol{x}) = \int_{\mathbb{R}^3} \Phi(\boldsymbol{z})\,\left(\nabla^2 u_i\right)(\boldsymbol{x} - \boldsymbol{z})\,\mathrm{d}^3 z = \varphi(\boldsymbol{0}) = u_i(\boldsymbol{x})\,, \tag{A.826}$$

which is Equation (A.825) componentwise. Note that the integral on the left is the excised one of Proposition A.519 and the one in Proposition 10.67 is the same limit, the kernel being absolutely integrable near the origin by Equation (A.817). □

A.45.5 Existence of the decomposition

Theorem A.523 (Helmholtz decomposition: existence)**.** *Let $\boldsymbol{u}$ be smooth on $\mathbb{R}^3$ with compact support and let $\boldsymbol{w} = \Phi * \boldsymbol{u}$. Then $\phi = \nabla \cdot \boldsymbol{w}$ and $\boldsymbol{\Psi} = -\nabla \times \boldsymbol{w}$ are smooth, satisfy Equation (7.130), and*

$$\boldsymbol{u} = \nabla\phi + \nabla \times \boldsymbol{\Psi}\,, \qquad \nabla \cdot \boldsymbol{\Psi} = 0\,. \tag{A.827}$$

Rests on Propositions 7.91 and A.522 and Equation (7.105).

Proof. *Derives Theorem A.523.*

$\boldsymbol{w}$ is smooth by Proposition A.521, so ϕ and $\boldsymbol{\Psi}$ are, and Equation (A.821) identifies $\boldsymbol{w}$ with the field displayed in Equation (7.130). The identity Equation (7.105) of Proposition 7.91, applied to the C^2 field $\boldsymbol{w}$ and rearranged, reads

$$\nabla^2 \boldsymbol{w} = \nabla\left(\nabla \cdot \boldsymbol{w}\right) - \nabla \times \left(\nabla \times \boldsymbol{w}\right) = \nabla\phi + \nabla \times \boldsymbol{\Psi}\,, \tag{A.828}$$

and the left-hand side is $\boldsymbol{u}$ by Equation (A.825). Finally $\nabla \cdot \boldsymbol{\Psi} = -\nabla \cdot (\nabla \times \boldsymbol{w}) = 0$ by Equation (7.104), and $\nabla \times \nabla\phi = \boldsymbol{0}$ by Equation (7.103), so the first summand is irrotational and the second solenoidal, as Theorem 7.105 asserts. □

A.45.6 Decay at infinity

The uniqueness clause of Theorem 7.105 speaks of fields that tend to zero at infinity. The potentials just constructed do, and with a definite rate.

Proposition A.524 (Rate of decay)**.** *With $\boldsymbol{u}$ supported in $|\boldsymbol{y}| \le R_0$ and $\boldsymbol{w} = \Phi * \boldsymbol{u}$ as above, there is a constant C, depending only on R_0 and $\sup|\boldsymbol{u}|$, such that for $|\boldsymbol{x}| \ge 2R_0$*

$$|\boldsymbol{w}(\boldsymbol{x})| \le \frac{C}{|\boldsymbol{x}|}\,, \qquad |\partial_i \boldsymbol{w}(\boldsymbol{x})| \le \frac{C}{|\boldsymbol{x}|^2}\,, \qquad |\partial_i\partial_j \boldsymbol{w}(\boldsymbol{x})| \le \frac{C}{|\boldsymbol{x}|^3}\,. \tag{A.829}$$

In particular $\nabla\phi$ and $\nabla \times \boldsymbol{\Psi}$ tend to zero at infinity, and so do ϕ and $\boldsymbol{\Psi}$ themselves.

Rests on Propositions A.519 and A.521 and Theorem 7.77.

Proof. *Derives Proposition A.524.*

Use the form Equation (A.821), in which the integration runs over the fixed compact ball $|\boldsymbol{y}| \le R_0$ and the singular factor now depends on $\boldsymbol{x}$. For $|\boldsymbol{x}| \ge 2R_0$ and $\boldsymbol{y}$ in that ball,

$$|\boldsymbol{x} - \boldsymbol{y}| \ge |\boldsymbol{x}| - R_0 \ge \tfrac{1}{2}\,|\boldsymbol{x}|\,, \tag{A.830}$$

so the integrand is bounded and no singularity is present: the integral is proper, and the Leibniz rule (Theorem 7.77) may be applied directly in each x^i, differentiating the kernel. Doing so,

$$\partial_i \frac{1}{|\boldsymbol{x} - \boldsymbol{y}|} = -\frac{x^i - y^i}{|\boldsymbol{x} - \boldsymbol{y}|^3}\,, \qquad \left|\partial_i \frac{1}{|\boldsymbol{x} - \boldsymbol{y}|}\right| \le \frac{1}{|\boldsymbol{x} - \boldsymbol{y}|^2}\,, \tag{A.831}$$

and similarly the second derivatives of the kernel are bounded by $3\,|\boldsymbol{x} - \boldsymbol{y}|^{-3}$. Inserting Equation (A.830) and bounding the integral by the volume $\frac{4}{3}\pi R_0^3$ of the ball containing the support times the supremum of the integrand gives all three estimates of Equation (A.829) with the single constant $C = 8R_0^3 \sup|\boldsymbol{u}|$: the three bounds so obtained are $\frac{2}{3}R_0^3 \sup|\boldsymbol{u}|$, $\frac{4}{3}R_0^3 \sup|\boldsymbol{u}|$ and $8R_0^3 \sup|\boldsymbol{u}|$ respectively, the factor $(4\pi)^{-1}$ cancelling against $\frac{4}{3}\pi$ and the remaining powers of 2 coming from Equation (A.830). The bound is not sharp and is not meant to be. Since $\nabla\phi$ and $\nabla \times \boldsymbol{\Psi}$ are built from second derivatives of $\boldsymbol{w}$, they are $O\left(|\boldsymbol{x}|^{-3}\right)$; ϕ and $\boldsymbol{\Psi}$ are built from first derivatives and are $O\left(|\boldsymbol{x}|^{-2}\right)$. □

A.45.7 Uniqueness

Theorem A.525 (Helmholtz decomposition: uniqueness)**.** *Let ϕ_1, ϕ_2 be C^3 scalar fields and $\boldsymbol{\Psi}_1, \boldsymbol{\Psi}_2$ be C^3 vector fields on $\mathbb{R}^3$ with*

$$\nabla\phi_1 + \nabla \times \boldsymbol{\Psi}_1 = \nabla\phi_2 + \nabla \times \boldsymbol{\Psi}_2\,, \tag{A.832}$$

and suppose each of the four fields $\nabla\phi_1, \nabla \times \boldsymbol{\Psi}_1, \nabla\phi_2, \nabla \times \boldsymbol{\Psi}_2$ tends to zero as $|\boldsymbol{x}| \to \infty$. Then $\nabla\phi_1 = \nabla\phi_2$ and $\nabla \times \boldsymbol{\Psi}_1 = \nabla \times \boldsymbol{\Psi}_2$.

Rests on Proposition 7.91, Theorem 10.75, and Equation (7.105).

Proof. *Derives Theorem A.525.*

Put $\boldsymbol{h} = \nabla\phi_1 - \nabla\phi_2 = \nabla \times \boldsymbol{\Psi}_2 - \nabla \times \boldsymbol{\Psi}_1$, a C^2 field tending to zero at infinity. Read from the left it is a gradient, so $\nabla \times \boldsymbol{h} = \boldsymbol{0}$ by Equation (7.103); read from the right it is a curl, so $\nabla \cdot \boldsymbol{h} = 0$ by Equation (7.104). Hence Equation (7.105) gives

$$\nabla^2\boldsymbol{h} = \nabla\,(\nabla \cdot \boldsymbol{h}) - \nabla \times (\nabla \times \boldsymbol{h}) = \boldsymbol{0}\,, \tag{A.833}$$

so each Cartesian component h_i is harmonic on the whole of $\mathbb{R}^3$ (Definition 10.66).

Fix $\boldsymbol{x}_0$ and let $R > |\boldsymbol{x}_0|$. On the open ball B_R the function h_i is harmonic and continuous on the closure, so by the weak maximum principle (Theorem 10.75) it attains both its extremes on the sphere $|\boldsymbol{x}| = R$:

$$\min_{|\boldsymbol{x}|=R} h_i \le h_i(\boldsymbol{x}_0) \le \max_{|\boldsymbol{x}|=R} h_i\,. \tag{A.834}$$

Both bounds tend to zero as $R \to \infty$, because $\boldsymbol{h} \to \boldsymbol{0}$ at infinity: given $\varepsilon > 0$ there is R_1 with $|\boldsymbol{h}| < \varepsilon$ outside B_{R_1}, so for $R > R_1$ the two extremes lie in $(-\varepsilon, \varepsilon)$. Hence $|h_i(\boldsymbol{x}_0)| < \varepsilon$ for every $\varepsilon > 0$, and $\boldsymbol{h} = \boldsymbol{0}$ identically. □

Proof of Theorem 7.105. *Derives Theorem 7.105.*

Existence, with the potentials Equation (7.130), is Theorem A.523; the two summands are respectively curl-free and divergence-free by the same theorem, which is what Proposition 7.91 contributes; and the uniqueness clause is Theorem A.525. That the potentials constructed here do satisfy the decay hypothesis of the uniqueness clause is Proposition A.524. □

A.45.8 Reading the result

Remark A.526 (What is quoted here)*.* Nothing from outside this treatise. Two results are taken from a *later* chapter, and that is worth stating plainly rather than letting a reader discover it: Proposition 10.67, which identifies Equation (A.816) as the fundamental solution of the Laplacian, and Theorem 10.75, the weak maximum principle. Both are proved in Chapter 10, both are proved there without any appeal to Theorem 7.105 or to anything in this section, and neither proof uses the Helmholtz decomposition anywhere in the book. So the forward reference is a matter of exposition, not of logic. It is also the reason the derivation belongs in an appendix: placed in Chapter 7 it would have to import a chapter that has not yet been written, and placed in Chapter 10 it would be far from the vector calculus it completes.

The remaining ingredients are all from Chapter 7 and are listed in Appendix A.45.1. Three things are deliberately *not* used: no Lebesgue convergence theorem — the passage to the limit $\varepsilon \to 0$ is uniform, by Lemma A.518, and needs only the Cauchy criterion; no Fourier transform, although the decomposition has a one-line proof in Fourier variables that hides every question of convergence; and no theory of distributions beyond the single statement of Proposition 10.67, which is quoted as an identity between numbers, tested on one explicit test function.

Remark A.527 (The hypotheses, and what happens without them). Compact support is a convenience, not a necessity. The same argument runs whenever $\boldsymbol{u}$ decays faster than $|\boldsymbol{x}|^{-2}$ with first derivatives decaying faster than $|\boldsymbol{x}|^{-3}$: the excision estimate Equation (A.818) is untouched, and the only new work is to check that the integral over the far region converges, which those rates supply.

Some decay is indispensable, and the failure is not subtle. The constant field $\boldsymbol{u} = \hat{\boldsymbol{z}}$ is a gradient, $\boldsymbol{u} = \nabla z$; it is also a curl, $\boldsymbol{u} = \nabla \times (x\,\hat{\boldsymbol{y}})$, as one checks from Equation (7.87) by evaluating the three components of the curl of $(0, x, 0)$. So the split Equation (7.129) exists for it in two ways — everything in the gradient, or everything in the curl — and nothing in the local differential identities can choose between them. The decay condition in the uniqueness clause of Theorem 7.105 is what excludes such a field, and Theorem A.525 shows it is exactly enough.

The regularity stated in Theorem A.525 is a small strengthening of the chapter's phrasing, which leaves it implicit: the argument differentiates the potentials three times, so C^3 potentials — equivalently C^2 summands — are what Equation (A.833) needs. For the potentials constructed here the point is moot, since they are smooth.

Rests on Theorems 7.105 and A.525 and Equation (7.87).

Remark A.528. Appendix A.45 discharges the derivation owed at Theorem 7.105 of Chapter 7. It also settles a debt recorded in Part III: Remark 30.46 of Chapter 30 states that the textbook route to the separation of P and S waves needs exactly this theorem — existence and uniqueness of the split, with the decay conditions that make it unique — and that Part II did not carry it, which is why the chapter re-routed the proof of Phenomenon 30.43 onto the acoustic tensor and plane waves instead. That re-routing stands as an independent derivation and is not superseded; what changes is that the alternative route is now available. The second site named there, Proposition 30.48, could not be re-routed: its displacement potentials are introduced as an ansatz sufficient for an existence claim, and the chapter says so. With Theorem A.523 in hand that ansatz can be upgraded to a decomposition, and the Rayleigh wave shown to be the general plane-strain surface motion rather than one exhibited example.

A.46 The Quotient Manifold Theorem

This appendix proves Theorem 13.67 of Chapter 13: when a Lie group G of dimension d acts smoothly, freely and properly on a manifold M_n, the set of orbits carries exactly one smooth structure making the projection Equation (13.156) a submersion, its dimension is $n - d$, its orbits are embedded copies of G, and a function on it is smooth exactly when its pullback is. It is the second of the two standard ways a manifold is produced — the first, Theorem 13.62, cuts a manifold out with equations; this one makes one by identifying points — and it is the one physics reaches for whenever a symmetry is quotiented away.

The consumer that makes the theorem urgent is Theorem 24.47 of Chapter 24: the Marsden–Weinstein reduced phase space is a level set of a momentum map divided by the isotropy group of that level, and the entire smooth structure of the reduced space comes from the statement proved here. The same theorem is what makes a configuration space of *shapes* out of a configuration space of frames, and what turns a gauge orbit space into a manifold wherever the action is free.

The proof runs in five movements: the orbit space is Hausdorff and second countable (Appendix A.46.2); orbits are embedded submanifolds diffeomorphic to G (Appendix A.46.3); through every point there is a slice, a transversal meeting nearby orbits at most once (Appendix A.46.4); the slices are the charts (Appendix A.46.5); and the universal property follows, with it the uniqueness of the structure (Appendix A.46.6). The heart is the slice, and it is built with the constant rank theorem Theorem 13.63 and the inverse function

theorem Corollary A.292 and nothing else. In particular no Lie algebra, no exponential map and no fundamental vector field is used: only that G is a manifold on which multiplication and inversion are smooth.

A.46.1 What the derivation uses, and what it must state itself

From Chapter 13: the definition of the action and of freeness and properness (Definition 13.66), smooth maps and their differentials (Definitions 13.49 and 13.52), immersions, submersions and embeddings (Definition 13.53), embedded submanifolds (Definition 13.54), the differentiable structure (Definition 13.47) and the constant rank theorem (Theorem 13.63) together with the observation of Remark 13.65 that it transfers to manifolds by being read in charts. From Appendix A.28: the inverse function theorem Corollary A.292. From Chapter 6: compactness (Definition 6.9), the continuous image of a compact set (Proposition 6.10) and homeomorphisms (Definition 6.7). From Chapter 14: nothing beyond the definition of a Lie group as a manifold with smooth multiplication and inversion.

Two separation properties are named in the statement of Theorem 13.67 and are defined nowhere in Part II; Chapter 6 carries neither. They are stated here, and the gap is recorded as a Part II debt in Remark A.541.

Definition A.529 (Hausdorff; second countable; locally compact)**.** A topological space X is *Hausdorff* if any two distinct points have disjoint open neighbourhoods; *second countable* if its topology has a countable basis, i.e. a countable family of open sets of which every open set is a union; and *locally compact* if every point has a compact neighbourhood.

Rests on Definitions 6.1, 6.2 and 6.9.

Every manifold in the sense of Definition 13.48 is assumed Hausdorff and second countable, as is standard and as the statement of Theorem 13.67 presupposes when it asserts those properties of the quotient. Every manifold is also locally compact and first countable, both because it is locally homeomorphic to $\mathbb{R}^n$: a closed coordinate ball is a compact neighbourhood, and the coordinate balls of rational radius about a point form a countable neighbourhood basis. First countability is what licenses the sequential arguments used below, in which a property is established by testing it on convergent sequences.

Lemma A.530 (Two elementary facts about compactness)**.** *Let X be Hausdorff.*

1. *Every compact $C \subseteq X$ is closed.*
2. *If X is in addition locally compact and $F : Y \longrightarrow X$ is continuous and proper — the preimage of every compact set is compact — then F carries closed sets to closed sets.*

Rests on Definitions 6.9 and A.529 and Proposition 6.10.

Proof. *Derives Lemma A.530.*

(1) Let $q \notin C$. For each $c \in C$ choose disjoint open $V_c \ni q$ and $W_c \ni c$; the W_c cover C, so finitely many $W_{c_1}, \dots, W_{c_m}$ do, and $V_{c_1} \cap \dots \cap V_{c_m}$ is an open neighbourhood of q disjoint from C. Hence the complement of C is open.

(2) Let $A \subseteq Y$ be closed and let q lie in the closure of $F(A)$. Choose a compact neighbourhood K of q. Then $F^{-1}(K)$ is compact by properness, so $A \cap F^{-1}(K)$ is compact — a closed subset of a compact set — and $F\left(A \cap F^{-1}(K)\right) = F(A) \cap K$ is compact by Proposition 6.10, hence closed by (1). Every neighbourhood of q contained in the interior of K meets $F(A)$, and the intersection lies in K; so q lies in the closure of $F(A) \cap K$, which is $F(A) \cap K$ itself. Thus $q \in F(A)$. □

Throughout the rest of the section, G is a Lie group of dimension d, $M = M_n$ a manifold, and the action is smooth, free and proper in the sense of Definition 13.66. We write $L_g : M \to M$ for the diffeomorphism $P \mapsto g \cdot P$, with inverse $L_{g^{-1}}$, and

$$\Theta : G \times M \longrightarrow M \times M\,, \qquad \Theta(g, P) = (g \cdot P,\, P)\,, \tag{A.835}$$

for the map whose properness is the hypothesis. We write $\theta_P : G \to M$, $\theta_P(g) = g \cdot P$, for the orbit map, and $k = n - d$.

A.46.2 The orbit space is Hausdorff and second countable

Lemma A.531 (The projection is open)**.** *For every open $U \subseteq M$ the set $\pi(U)$ is open in M/G, and π is continuous and surjective.*
Rests on Definitions 6.2, 6.6 and 13.66.

Proof. *Derives Lemma A.531.*
Continuity and surjectivity are the definition of the quotient topology. For openness,

$$\pi^{-1}(\pi(U)) = \{Q \in M \mid \exists\, g \in G :\ Q \in g \cdot U\} = \bigcup_{g \in G} L_g(U)\,, \tag{A.836}$$

a union of open sets, since each L_g is a diffeomorphism. A set whose preimage is open is open in the quotient topology. □

Proposition A.532 (Separation and countability of the quotient)**.** *The orbit space M/G is Hausdorff and second countable, and every orbit is closed in M.*
Rests on Lemmas A.530 and A.531 and Definition 13.66.

Proof. *Derives Proposition A.532.*
The orbit relation is closed. $M \times M$ is Hausdorff and locally compact, being a manifold, and Θ of Equation (A.835) is continuous and proper by hypothesis. Write

$$\mathcal{R} = \Theta(G \times M) = \{(Q, P) \in M \times M \mid Q \in G \cdot P\}\,. \tag{A.837}$$

By Lemma A.530(2) this set is closed — $G \times M$ being closed in itself. Fixing P and intersecting with $M \times \{P\}$ shows each orbit closed in M.

Hausdorff. Let $\pi(P) \neq \pi(Q)$, so $(Q, P) \notin \mathcal{R}$. Since $\mathcal{R}$ is closed and the products of open sets form a basis of $M \times M$, there are open $U \ni P$ and $V \ni Q$ with $(V \times U) \cap \mathcal{R} = \varnothing$: no point of V lies on the orbit of a point of U. Then $\pi(U)$ and $\pi(V)$ are open by Lemma A.531, contain $\pi(P)$ and $\pi(Q)$, and are disjoint — a common point would be an orbit meeting both U and V, which is what was excluded.

Second countable. Let $\{B_i\}$ be a countable basis of M. Each $\pi(B_i)$ is open. If $W \subseteq M/G$ is open and $\pi(P) \in W$, then $P \in \pi^{-1}(W)$, which is open, so $P \in B_i \subseteq \pi^{-1}(W)$ for some i, whence $\pi(P) \in \pi(B_i) \subseteq \pi(\pi^{-1}(W)) = W$, the last equality by surjectivity of π. So $\{\pi(B_i)\}$ is a countable basis. □

A.46.3 Orbits are embedded submanifolds

Lemma A.533 (The orbit map has constant rank d)**.** *For every $P \in M$ the map $\theta_P : G \to M$ has the same rank at every point of G, and that rank is d; that is, θ_P is an injective immersion.*
Rests on Theorem 13.63 and Definitions 13.53 and 13.66.

Proof. *Derives Lemma A.533.*
Constancy. Write $\ell_g : G \to G$ for left translation $h \mapsto gh$, a diffeomorphism. The associativity of the action gives $\theta_P(gh) = g \cdot (h \cdot P)$, that is

$$\theta_P \circ \ell_g = L_g \circ \theta_P\,. \tag{A.838}$$

Differentiating at the identity e and using the chain rule for differentials of smooth maps (Definition 13.52), $(\theta_P)_{*g} \circ (\ell_g)_{*e} = (L_g)_{*P} \circ (\theta_P)_{*e}$. Both $(\ell_g)_{*e}$ and $(L_g)_{*P}$ are isomorphisms, so the ranks of $(\theta_P)_{*g}$ and $(\theta_P)_{*e}$ agree.

The rank is d. Suppose it were $\rho < d$. Read in charts, θ_P is a C^∞ map of an open subset of $\mathbb{R}^d$ into $\mathbb{R}^n$ of constant rank ρ, so by the constant rank theorem (Theorem 13.63,

transferred to manifolds as in Remark 13.65) there are coordinates about e and about P in which it reads $\left(u^1,\dots,u^d\right)\mapsto(u^1,\dots,u^\rho,0,\dots,0)$, which is Equation (13.152). Two distinct nearby points differing only in the coordinate $u^{\rho+1}$ then have the same image, so θ_P is not injective on any neighbourhood of e — and θ_P *is* injective, because $g\cdot P=h\cdot P$ gives $\left(h^{-1}g\right)\cdot P=P$ and hence $g=h$ by freeness (Definition 13.66). The rank is therefore d, and $(\theta_P)_{*g}$ is injective for every g. □

Proposition A.534 (Every orbit is an embedded copy of G)**.** *For every $P\in M$ the orbit map θ_P is an embedding, so $G\cdot P$ is an embedded submanifold of M of dimension d, diffeomorphic to G.*

Rests on Lemma A.533 and Definitions 13.53 and 13.54.

Proof. *Derives Proposition A.534.*

By Lemma A.533 the map is an injective immersion; by Definition 13.53 what remains is that it be a homeomorphism onto its image with the topology inherited from M. Equivalently, since G is first countable, that $g_j\cdot P\to g\cdot P$ in M implies $g_j\to g$ in G.

Let $g_j\cdot P\to Q=g\cdot P$. The set $C=\{g_j\cdot P\mid j\}\cup\{Q\}$ is compact — a convergent sequence with its limit — and so is $C\times\{P\}$; properness makes $\Theta^{-1}(C\times\{P\})$ compact, and it contains every (g_j,P). Hence the g_j lie in a compact subset K of G. Since G is first countable, a compact subset of it is sequentially compact, so every subsequence of (g_j) has a further subsequence converging in K; and if $g_{j_m}\to g'$, then continuity of the action gives $g'\cdot P=\lim g_{j_m}\cdot P=Q=g\cdot P$, whence $g'=g$ by freeness. A sequence in a compact set all of whose convergent subsequences have the limit g converges to g: otherwise some neighbourhood of g would be left by infinitely many terms, and those terms would have a convergent subsequence whose limit, lying in the complement of that neighbourhood, could not be g. So $g_j\to g$.

The image of an embedding is an embedded submanifold and the map is a diffeomorphism onto it, as recorded after Definition 13.54. □

A.46.4 The slice

Proposition A.535 (Existence of a slice)**.** *Let $P\in M$. There are an open neighbourhood $O\subseteq G$ of e, an embedded k-dimensional submanifold $S\subseteq M$ with $P\in S$ carried by a single chart $\varsigma:S\to B\subseteq\mathbb{R}^k$, and an open neighbourhood $\Omega=O\cdot S$ of P in M, such that*

1. *the map $F:O\times S\to\Omega$, $F(g,Q)=g\cdot Q$, is a diffeomorphism; and*
2. *S meets every orbit at most once: if $Q,Q'\in S$ and $Q'=g\cdot Q$ for some $g\in G$, then $g=e$ and $Q=Q'$.*

Rests on Lemma A.533, Corollary A.292, and Definition 13.66.

Proof. *Derives Proposition A.535.*

Choice of a transversal. By Lemma A.533 the image $V_P=(\theta_P)_{*e}(T_eG)$ is a d-dimensional subspace of T_PM. Choose a chart (ϕ,W) about P with $\phi(P)=0$; composing ϕ with a linear automorphism of $\mathbb{R}^n$ — itself a change of chart — we may assume $\phi_{*P}(V_P)=\mathbb{R}^d\times\{0\}$. For a small ball $B\subseteq\mathbb{R}^k$ put

$$S_0=\phi^{-1}(\{0\}\times B)\,,\qquad \varsigma=(\text{last } k \text{ coordinates of } \phi)\big|_{S_0}\,, \tag{A.839}$$

an embedded k-submanifold through P with $T_PS_0\oplus V_P=T_PM$, since ϕ_{*P} carries the two summands onto the complementary $\{0\}\times\mathbb{R}^k$ and $\mathbb{R}^d\times\{0\}$.

The map F is a local diffeomorphism. On the n-manifold $G\times S_0$ define $F(g,Q)=g\cdot Q$, smooth as a restriction of the action. Its differential at (e,P) acts on $T_eG\oplus T_PS_0$ by

$$F_{*(e,P)}(\xi,v)=(\theta_P)_{*e}\,\xi+v\,, \tag{A.840}$$

because $F(\cdot, P) = \theta_P$ and $F(e, \cdot)$ is the inclusion of S_0. By the choice of S_0 this is a linear isomorphism onto $T_P M$. Read in charts, F is a smooth map between open subsets of $\mathbb{R}^n$ with invertible derivative at the point, so the inverse function theorem (Corollary A.292) makes it a diffeomorphism of a neighbourhood of (e, P) onto an open neighbourhood of P. Shrinking, that neighbourhood contains a product $O \times S$ with $O \ni e$ open in G and $S \ni P$ open in S_0; put $\Omega = F(O \times S) = O \cdot S$, open in M. This is (1).

Shrinking to a genuine slice. Suppose (2) failed for every choice of S. Take $S_j = \phi^{-1}\left(\{0\} \times B_{1/j}\right)$, $j \in \mathbb{N}$, a basis of neighbourhoods of P in S_0. For each j there would then be $Q_j, Q_j' \in S_j$ and $g_j \neq e$ with $g_j \cdot Q_j = Q_j'$. Both sequences converge to P, so $C = \{Q_j\} \cup \left\{Q_j'\right\} \cup \{P\}$ is compact and $\Theta^{-1}(C \times C)$ is compact by properness; it contains every (g_j, Q_j), so the g_j lie in a compact subset of G and a subsequence converges, $g_{j_m} \to g$. Continuity of the action gives $g \cdot P = \lim g_{j_m} \cdot Q_{j_m} = \lim Q_{j_m}' = P$, so $g = e$ by freeness. Hence $g_{j_m} \in O$ and $Q_{j_m}, Q_{j_m}' \in S$ for m large. But then

$$F(g_{j_m}, Q_{j_m}) = Q_{j_m}' = F\left(e, Q_{j_m}'\right), \tag{A.841}$$

and the injectivity of F on $O \times S$ forces $g_{j_m} = e$, contradicting $g_j \neq e$. So some S_j satisfies (2); replace S by it and shrink O and Ω accordingly, which preserves (1). □

A.46.5 The charts and the smooth structure

Lemma A.536 (A slice is a chart domain downstairs)**.** *With O, S, Ω as in Proposition A.535, the set $\pi(S) = \pi(\Omega)$ is open in M/G and $\pi|_S : S \to \pi(S)$ is a homeomorphism. Writing $\varrho : \Omega \to S$ for the second component of F^{-1}, a smooth map, one has $\varrho = (\pi|_S)^{-1} \circ \pi$ on Ω.*
Rests on Proposition A.535, Lemma A.531, and Definition 6.7.

Proof. *Derives Lemma A.536.*

Every point of Ω is $g \cdot Q$ with $Q \in S$, so $\pi(\Omega) = \pi(S)$, and $\pi(\Omega)$ is open by Lemma A.531. The map $\pi|_S$ is continuous, surjective onto $\pi(S)$ by definition, and injective by Proposition A.535(2).

For $R \in \Omega$ write $R = F(g, Q) = g \cdot Q$ with $(g, Q) \in O \times S$ unique; then $\varrho(R) = Q$ lies on the orbit of R and in S, and by (2) it is the *only* point of S on that orbit. Hence $\varrho = (\pi|_S)^{-1} \circ \pi$ on Ω, and ϱ is smooth because F^{-1} is.

It remains to see that $(\pi|_S)^{-1}$ is continuous. The restriction $\pi|_\Omega : \Omega \to \pi(S)$ is continuous, surjective and open (Lemma A.531 applied to open subsets of Ω), hence a quotient map: a subset of $\pi(S)$ is open exactly when its preimage is. The map ϱ is continuous and constant on the fibres of $\pi|_\Omega$, by the previous paragraph; so for $U \subseteq S$ open the set $\left((\pi|_S)^{-1}\right)^{-1}(U) = \pi\left(\varrho^{-1}(U)\right)$ has preimage $\varrho^{-1}(U)$, which is open, and is therefore open. Thus $(\pi|_S)^{-1}$ is continuous and $\pi|_S$ is a homeomorphism onto the open set $\pi(S)$. □

Theorem A.537 (The smooth structure on the orbit space)**.** *The maps*

$$u = \varsigma \circ (\pi|_S)^{-1} : \pi(S) \longrightarrow B \subseteq \mathbb{R}^k, \tag{A.842}$$

one for each slice of Proposition A.535, form a k-dimensional atlas on M/G. With the differentiable structure it generates (Definition 13.47), M/G is a smooth manifold of dimension $k = n - d$, which is Equation (13.157), and π is a smooth surjective submersion.
Rests on Lemma A.536, Proposition A.532, and Definition 13.53.

Proof. *Derives Theorem A.537.*

The charts cover and are homeomorphisms. Each u is a homeomorphism of the open set $\pi(S)$ onto the open $B \subseteq \mathbb{R}^k$, being the composition of the homeomorphism $(\pi|_S)^{-1}$ of Lemma A.536 with the chart ς of S; and every orbit meets some slice, namely one built at any of its points.

Smooth compatibility. Let S and S' be two slices with $\pi(S)\cap\pi(S')\neq\varnothing$ and let $\pi(Q_0)$ lie in the intersection, $Q_0\in S$. The transition map is $u'\circ u^{-1}=\varsigma'\circ\tau\circ\varsigma^{-1}$, where $\tau=(\pi|_{S'})^{-1}\circ\pi|_S$ sends a point of S to the unique point of S' on its orbit. Put $Q_0'=\tau(Q_0)\in S'$ and let $g_0\in G$ with $Q_0'=g_0\cdot Q_0$. The set $L_{g_0}^{-1}(\Omega')$ is an open neighbourhood of Q_0 in M, and on it the map $\varrho'\circ L_{g_0}$ is smooth and takes each point to the unique point of S' on its orbit — which is τ where both are defined. Restricted to the embedded submanifold S, a smooth map remains smooth, so τ is smooth near Q_0 as a map $S\to S'$, and the transition map is smooth as a map between open subsets of $\mathbb{R}^k$. Exchanging the roles of S and S' gives smoothness of the inverse. Together with Proposition A.532 — Hausdorff and second countable — this makes M/G a smooth k-manifold.

π is a submersion. Fix $P\in M$, take the slice at P and use $F^{-1}:\Omega\to O\times S$ to give M the chart $(\kappa,\varsigma)\circ F^{-1}$ near P, where κ is any chart of G about e. In these coordinates, and with the chart u downstairs, π reads

$$(a,y)\longmapsto y\,,\qquad a\in\kappa(O)\subseteq\mathbb{R}^d\,,\ y\in B\subseteq\mathbb{R}^k\,, \tag{A.843}$$

because $\pi\left(F(g,Q)\right)=\pi(Q)$ and $u\left(\pi(Q)\right)=\varsigma(Q)$. A projection has surjective differential, so π is a submersion at P (Definition 13.53); and P was arbitrary. □

A.46.6 The universal property and uniqueness

Lemma A.538 (Submersions have smooth local sections)**.** *Let $p:M\to X$ be a smooth submersion between manifolds and let $P\in M$. There are an open $W\ni p(P)$ in X and a smooth $s:W\to M$ with $p\circ s=\mathrm{id}_W$ and $s\left(p(P)\right)=P$.*

Rests on Theorem 13.63 and Definitions 13.49 and 13.53.

Proof. *Derives Lemma A.538.*

A submersion has constant rank $\dim X$, so Theorem 13.63, read in charts as in Remark 13.65, supplies coordinates $\left(u^1,\dots,u^{\dim M}\right)$ about P and $\left(y^1,\dots,y^{\dim X}\right)$ about $p(P)$, both vanishing at the point, in which p reads $(u^1,\dots)\mapsto\left(u^1,\dots,u^{\dim X}\right)$. In those coordinates set $s(y)=(y,0)$, which is smooth and satisfies both requirements on the coordinate neighbourhood. □

Proposition A.539 (Universal property)**.** *Let $p:M\to X$ be a smooth surjective submersion and N a manifold. A map $f:X\to N$ is smooth if and only if $f\circ p$ is smooth.*

Rests on Lemma A.538 and Definition 13.49.

Proof. *Derives Proposition A.539.*

If f is smooth then so is $f\circ p$, a composition of smooth maps. Conversely let $f\circ p$ be smooth and let $x\in X$; pick P with $p(P)=x$, which exists by surjectivity, and a smooth local section s on $W\ni x$ from Lemma A.538. On W, $f=f\circ p\circ s$ is a composition of smooth maps, hence smooth; and f is continuous there for the same reason. Smoothness is local, so f is smooth. □

Corollary A.540 (Uniqueness of the smooth structure)**.** *There is at most one differentiable structure on the topological space M/G for which π is a smooth submersion.*

Rests on Proposition A.539 and Definition 13.47.

Proof. *Derives Corollary A.540.*

Let X and X' denote the same topological space M/G carrying two such structures. Since $\pi:M\to X'$ is smooth and $\pi:M\to X$ is a smooth surjective submersion, Proposition A.539 applied to $f=\mathrm{id}$ shows $\mathrm{id}:X\to X'$ is smooth. Exchanging the two gives $\mathrm{id}:X'\to X$ smooth. The identity is therefore a diffeomorphism, and two differentiable structures related by the identity diffeomorphism have the same smooth functions and hence the same maximal atlas. □

Proof of Theorem 13.67. *Derives Theorem 13.67.*

Assembling. The orbit space is Hausdorff and second countable by Proposition A.532; it carries a smooth structure of dimension $n - d$ for which Equation (13.156) is a submersion, by Theorem A.537, and Equation (13.157) is that dimension count; the structure is the only one with that property, by Corollary A.540; every orbit is an embedded submanifold diffeomorphic to G, by Proposition A.534; and a map f on the quotient is smooth exactly when $f \circ \pi$ is, by Proposition A.539 applied to the surjective submersion π. □

A.46.7 Reading the result

Remark A.541 (What is quoted here). No theorem from outside this treatise is used, and the two analytic inputs — the inverse function theorem Corollary A.292 and the constant rank theorem Theorem 13.63 — are proved in Appendix A.28 and in Chapter 13 respectively. What *is* missing from Part II, and is supplied here rather than cited, is point-set vocabulary: Chapter 6 defines neither the Hausdorff property nor second countability nor local compactness, although Theorem 13.67 asserts the first two of the quotient and Definition 13.48 tacitly assumes all of them of a manifold. They are stated in Definition A.529, and the two facts about them that the proof consumes — a compact subset of a Hausdorff space is closed, and a proper map into a locally compact Hausdorff space is closed — are proved in Lemma A.530. That is a Part II debt of about a page, and it is the only one this section incurs.

Two things are deliberately *not* used, and the omission is what keeps the section self-contained. There is no Lie algebra anywhere: the standard proof shows the orbit map to be an immersion by computing its differential as the fundamental vector field of an element of $\mathfrak{g}$ and appealing to freeness, which would import the machinery of Chapter 14; instead Lemma A.533 gets the same conclusion from the constant rank theorem alone, by observing that a constant-rank map of rank less than d cannot be injective near a point. And there is no partition of unity and no smooth-structure transport theorem: the charts are the slices, and the transitions are computed from the action itself.

Remark A.542 (Where each hypothesis is spent). Freeness is used twice and properness three times, and it is worth saying where, because Example 13.68 shows what happens when either fails but not which step breaks.

Freeness makes the orbit map injective, which is what forces its rank to be full in Lemma A.533 — and hence what gives every orbit the same dimension d, without which no dimension count is possible. It is used again in Proposition A.535 to identify the limiting group element as e. When it fails, orbits through different points have different dimensions, and the quotient is a stratified space: this is the SO(2) action of Example 13.68, whose orbit space is a half-line with a bad endpoint.

Properness gives the closedness of the orbit relation (Proposition A.532), and with it the Hausdorff property of the quotient; it gives the embedding property of the orbit map (Proposition A.534); and it gives the second shrinking in Proposition A.535, which is what turns a local transversal into a genuine slice. The irrational flow on the torus in Example 13.68 fails at the first of these, and every later step fails with it: no slice exists, because every orbit returns arbitrarily close to every point.

Rests on Propositions A.532 and A.535 and Example 13.68.

Remark A.543. Appendix A.46 discharges the derivation owed at Theorem 13.67 of Chapter 13. The statement is used at once in the same chapter, where it is the second of the two manufacturing theorems beside Theorem 13.62 and Corollary 13.64, and it is what makes Example 13.68 a statement about manifolds rather than about sets. Its principal consumer in the physical parts is Theorem 24.47 of Chapter 24: symplectic reduction divides a level set of a momentum map — a manifold by Theorem 13.62 — by the isotropy group of that

level, and every smooth statement about the reduced phase space, from the existence of its symplectic form to the descent of the dynamics, rests on the projection being a submersion with the universal property Proposition A.539. The one hypothesis to watch there is the same one watched here: the action must be free, and where it is not the reduced space is singular and none of this applies.

A.47 The Liouville–Arnold Theorem

This appendix proves Theorem 23.31 of Chapter 23: a system of f degrees of freedom possessing f functionally independent integrals $F_1 = \mathcal{H}, F_2, \dots, F_f$ in involution has each compact connected component of a regular level set diffeomorphic to the torus T^f, carries quasi-periodic motion on it, and admits action–angle variables in a neighbourhood of it. The last clause is what makes the theorem worth its length: it establishes Theorem 23.30 without the hypothesis of separability under which that theorem was proved, so that the action–angle description of a bounded integrable motion is a consequence of the involution relations alone and not of a lucky choice of coordinates.

Exactly one ingredient is imported, and Remark 23.32 already tells the reader which: that a discrete subgroup of $\mathbb{R}^f$ with compact quotient is a lattice of full rank. It is stated below as Theorem A.550 and used once, in Appendix A.47.3. Everything else is proved here from the symplectic material of Chapter 24 and the manifold material of Chapter 13; in particular Frobenius' theorem, which the argument needs twice, is Theorem 13.133 and is not reproved.

A.47.1 Setting and statement

Let (M, ω) be a symplectic manifold of dimension $2f$ (Definition 24.8), let $F_1, \dots, F_f$ be smooth real functions on M in involution,

$$\{F_a, F_b\} = 0\,, \qquad a, b = 1, \dots, f\,, \tag{A.844}$$

which is Equation (23.54), and write $\boldsymbol{F} = (F_1, \dots, F_f) : M \longrightarrow \mathbb{R}^f$. Fix $\boldsymbol{c} \in \mathbb{R}^f$ and suppose that $\boldsymbol{c}$ is a regular value, so that the differentials $\mathrm{d}F_1, \dots, \mathrm{d}F_f$ are linearly independent at every point of $M_{\boldsymbol{c}} = \boldsymbol{F}^{-1}(\boldsymbol{c})$. Denote by $X_a = X_{F_a}$ the Hamiltonian vector field of F_a, defined by $\iota_{X_a}\omega = \mathrm{d}F_a$ as in Equation (24.5); by Equation (24.7) it acts on functions as $X_a[g] = \{g, F_a\}$.

Remark A.544 (Units). Nothing here fixes the SI dimension of $F_2, \dots, F_f$: each is whatever conserved quantity it happens to be, and by Remark 24.11 the vector field X_a carries $[F_a]/\mathrm{J\,s}$, so its flow parameter carries $\mathrm{J\,s}/[F_a]$ — seconds when F_a is the energy, radians when it is an angular momentum. The action variables of Appendix A.47.4 carry $\mathrm{J\,s}$ without exception, because $\oint p_a \mathrm{d}q^a$ does; the angles are pure numbers. That is the whole of the dimensional bookkeeping, and it is worth stating because the lattice Γ of Appendix A.47.3 lives in a copy of $\mathbb{R}^f$ whose f axes carry f different units.

Theorem A.545 (Liouville–Arnold)**.** *Under the hypotheses above, let N be a compact connected component of $M_{\boldsymbol{c}}$. Then*

1. *N is an f-dimensional embedded submanifold of M, diffeomorphic to the torus $T^f = \mathbb{R}^f/\mathbb{Z}^f$, and it is Lagrangian: ω vanishes on $T_P N$ for every $P \in N$;*
2. *in the angular coordinates supplied by that diffeomorphism the flow of $\mathcal{H} = F_1$ is linear, so the motion is quasi-periodic with f frequencies;*
3. *on a neighbourhood of N there exist action–angle variables (I_a, θ^a), canonical, with $\mathcal{H} = \mathcal{H}(I)$ and with the equations of motion Equation (23.51) and Equation (23.52).*

Rests on Equations (23.54) and (24.8) and Theorem 13.133.

A.47.2 The commuting fields and the level set

Lemma A.546 (The Hamiltonian fields of the integrals)**.** *On the open set $U \subseteq M$ where $\mathrm{d}F_1, \dots, \mathrm{d}F_f$ are linearly independent:*

1. *$X_a[F_b] = 0$ for all a, b, so every X_a is tangent to every level set of $\boldsymbol{F}$;*
2. *$[X_a, X_b] = 0$ as vector fields;*
3. *$X_1, \dots, X_f$ are linearly independent at every point of U, and $\omega(X_a, X_b) = 0$.*

Rests on Equations (24.5), (24.8) and (A.844).

Proof. *Derives Lemma A.546.*

(1) By Equation (24.7), $X_a[F_b] = \{F_b, F_a\}$, which vanishes by Equation (A.844). A vector annihilating every $\mathrm{d}F_b$ is tangent to the level set through its base point.

(2) Equation (24.8) states that $X_{\{u,v\}} = -[X_u, X_v]$, so $[X_a, X_b] = -X_{\{F_a,F_b\}} = -X_0 = 0$. This is the one place where involution does its real work, and it is worth saying what it buys: the flows of the f integrals commute, which is what will make them into an action of an abelian group.

(3) Suppose $\sum_a \lambda^a X_a(P) = 0$ at some $P \in U$. Contracting with ω and using Equation (24.5) gives $\sum_a \lambda^a \,\mathrm{d}F_a(P) = 0$, whence every λ^a vanishes by the independence of the differentials. Finally $\omega(X_a, X_b) = \{F_a, F_b\} = 0$ by Equation (24.7) and Equation (A.844). □

Proposition A.547 (The components of the level set are the leaves of an integrable distribution)**.** *Let $D_P = \operatorname{span}\{X_1(P), \dots, X_f(P)\}$ for $P \in U$. Then D is a smooth distribution of constant rank f (Definition 13.130), it is involutive, and it is integrable. Every connected component N of $M_{\boldsymbol{c}} \cap U$ is an embedded f-dimensional submanifold with $T_P N = D_P$, hence an integral manifold of D, and it is Lagrangian.*

Rests on Lemma A.546 and Theorems 13.59 and 13.133.

Proof. *Derives Proposition A.547.*

Smoothness and constant rank are Lemma A.546(3); involutivity is Lemma A.546(2), since the bracket of two spanning fields vanishes and so lies in D trivially. Integrability then follows from Theorem 13.133, which also supplies, around each point of U, a chart in which D is spanned by the first f coordinate fields Equation (13.281), so that U is foliated by f-dimensional integral manifolds.

Since $\boldsymbol{c}$ is a regular value, $\boldsymbol{F}$ restricted to U is a submersion onto a neighbourhood of $\boldsymbol{c}$, and by the regular value theorem Theorem 13.59 the set $M_{\boldsymbol{c}} \cap U$ is an embedded submanifold of dimension $2f - f = f$ with $T_P(M_{\boldsymbol{c}} \cap U) = \ker \mathrm{d}\boldsymbol{F}_P$. By Lemma A.546(1) every $X_a(P)$ lies in that kernel, and by (3) the f of them are independent; a subspace of dimension f inside a space of dimension f is the whole of it, so $T_P(M_{\boldsymbol{c}} \cap U) = D_P$. Each connected component is therefore a connected integral manifold of D. That it is Lagrangian is Lemma A.546(3) again: ω evaluated on two vectors of $T_P N = D_P$ is a combination of the numbers $\omega(X_a, X_b)$, all zero. □

A.47.3 The translation action and the torus

From here on N is a *compact* connected component of $M_{\boldsymbol{c}}$.

Lemma A.548 (The joint flow is a translation action on the level set)**.** *Each X_a restricts to a complete vector field on N, and*

$$\Phi(\boldsymbol{t}) = \phi^1_{t^1} \circ \phi^2_{t^2} \circ \cdots \circ \phi^f_{t^f}\,, \qquad \boldsymbol{t} = (t^1, \dots, t^f) \in \mathbb{R}^f\,, \tag{A.845}$$

where ϕ^a is the flow of X_a, is independent of the order of the factors and defines a smooth action of the additive group $\mathbb{R}^f$ on N.

Rests on Lemma A.546, Proposition 13.131, and Theorem 13.125.

Proof. *Derives Lemma A.548.*

By Lemma A.546(1) each X_a is tangent to N, so its integral curves through points of N stay in N as long as they exist. A smooth vector field on a compact manifold is complete: by Theorem 13.125 each point has a neighbourhood on which the flow exists for a time at least ε depending on the neighbourhood, compactness extracts a finite subcover and hence a single $\varepsilon > 0$ that works everywhere on N, and the flow is then extended to all times by composing it with itself. Commutativity of the flows is Proposition 13.131 applied to $[X_a, X_b] = 0$, which makes the composition Equation (A.845) independent of the order and gives $\Phi(\boldsymbol{t})\Phi(\boldsymbol{t}') = \Phi(\boldsymbol{t}+\boldsymbol{t}')$; $\Phi(\mathbf{0})$ is the identity, and smoothness in $(\boldsymbol{t}, P)$ jointly is that of each flow. □

Lemma A.549 (The action is transitive)**.** *For every $P \in N$ the orbit map $\boldsymbol{t} \longmapsto \Phi(\boldsymbol{t})P$ is a local diffeomorphism of $\mathbb{R}^f$ onto its image; the orbit is open in N; and since N is connected there is exactly one orbit, so the action is transitive.*

Rests on Lemma A.548, Corollary A.292, and Proposition A.547.

Proof. *Derives Lemma A.549.*

Differentiating Equation (A.845) at $\boldsymbol{t} = \mathbf{0}$ sends the a-th basis vector of $\mathbb{R}^f$ to $X_a(P)$, and by Lemma A.546(3) together with Proposition A.547 those f vectors are a basis of $T_P N$. The differential of the orbit map at the origin is therefore an isomorphism onto $T_P N$, and the inverse function theorem (Corollary A.292, read in a chart of N) makes the orbit map a diffeomorphism of a neighbourhood of $\mathbf{0}$ onto a neighbourhood of P in N. Applying this at an arbitrary point $\Phi(\boldsymbol{t}_0)P$ of the orbit — which is legitimate because $\Phi(\boldsymbol{t}_0)$ is a diffeomorphism of N carrying the orbit map based at P to the one based at $\Phi(\boldsymbol{t}_0)P$ — shows that the orbit contains a neighbourhood of each of its points, i.e. is open. Distinct orbits are disjoint, so the orbits form a partition of N into open sets; connectedness leaves only one. □

Theorem A.550 (Quoted: discrete subgroups of a real vector space)**.** *Let $\Gamma \subseteq \mathbb{R}^f$ be a subgroup that is discrete, in the sense that some neighbourhood of $\mathbf{0}$ meets Γ only in $\mathbf{0}$. Then there are linearly independent vectors $\boldsymbol{\lambda}_1, \dots, \boldsymbol{\lambda}_k \in \mathbb{R}^f$, $k \le f$, with*

$$\Gamma = \left\{ \sum_{a=1}^{k} n^a \boldsymbol{\lambda}_a \;\middle|\; n^a \in \mathbb{Z} \right\}, \tag{A.846}$$

and the quotient group $\mathbb{R}^f/\Gamma$ is compact if and only if $k = f$, in which case it is diffeomorphic to the torus T^f.

Rests on Definitions 4.20 and 6.9.

Remark A.551 (What is quoted here). Theorem A.550 is the only statement in this section that is not proved, and Remark 23.32 of Chapter 23 names it as the debt in the same words. It is elementary — an induction on the dimension of the linear span of Γ, at each step choosing a shortest non-zero element of the part of Γ lying in a new direction and showing that discreteness makes it generate that direction's contribution — but it is a theorem about subgroups of $\mathbb{R}^f$, which is algebra and topology rather than mechanics, and it belongs with the material of Chapters 4 and 6, which do not carry it. The treatise's bibliography holds no source for it either, so the attribution is made in words: it is standard lattice theory, and the form used here is the one Arnold states in *Mathematical Methods of Classical Mechanics* (2nd edition, 1989), a work for which Chapter 24 also records that there is no key. Nothing else below is quoted.

Proposition A.552 (The component is a torus)**.** *Fix $P \in N$ and let $\Gamma = \left\{ \boldsymbol{t} \in \mathbb{R}^f \mid \Phi(\boldsymbol{t})P = P \right\}$. Then Γ is a discrete subgroup of $\mathbb{R}^f$ of rank exactly f, the induced map*

$$\mathbb{R}^f/\Gamma \longrightarrow N, \qquad \boldsymbol{t} + \Gamma \longmapsto \Phi(\boldsymbol{t})P, \tag{A.847}$$

is a diffeomorphism, and N is diffeomorphic to T^f.
Rests on Lemmas A.548 and A.549 and Theorem A.550.

Proof. *Derives Proposition A.552.*

Γ is a subgroup because Φ is an action, and it is discrete because Lemma A.549 makes the orbit map injective on some neighbourhood B of $\mathbf{0}$, so $\Gamma \cap B = \{\mathbf{0}\}$. The orbit map is constant on cosets of Γ and, by transitivity, descends to a bijection Equation (A.847) of $\mathbb{R}^f/\Gamma$ onto N; it is a local diffeomorphism by the same lemma, hence a diffeomorphism. Since N is compact so is $\mathbb{R}^f/\Gamma$, and Theorem A.550 then gives Γ of rank f and $\mathbb{R}^f/\Gamma \cong T^f$. □

Corollary A.553 (Quasi-periodic motion)**.** *Under the identification Equation (A.847), the Hamiltonian flow of $\mathcal{H} = F_1$ starting at P is $t \longmapsto t\,\boldsymbol{e}_1 + \Gamma$: a straight line in $\mathbb{R}^f$ read modulo the lattice. The motion is therefore quasi-periodic, with f frequencies fixed by the position of $\boldsymbol{e}_1$ relative to the lattice basis, and it is periodic exactly when the line closes, that is when $T\boldsymbol{e}_1 \in \Gamma$ for some $T > 0$.*
Rests on Proposition A.552 and Lemma A.548.

Proof. *Derives Corollary A.553.*

The Hamiltonian vector field of F_1 is X_1, whose flow is $\Phi(t\boldsymbol{e}_1)$ by Equation (A.845). The identification Equation (A.847) carries it to translation by $t\boldsymbol{e}_1$ on $\mathbb{R}^f/\Gamma$, and a translation flow on a torus closes if and only if its generator is commensurable with the lattice. Remark 23.33 records what happens to these tori under perturbation, and Theorem 32.51 is the statement that most of them survive. □

A.47.4 The action variables

Let $\boldsymbol{\lambda}_1(\boldsymbol{c}), \dots, \boldsymbol{\lambda}_f(\boldsymbol{c})$ be a basis of the lattice Γ supplied by Proposition A.552, chosen to depend smoothly on $\boldsymbol{c}$ — which is possible because a lattice basis is locally rigid: it is determined by finitely many periods, and a nearby torus has nearby periods, so the basis is continued uniquely. Write $\gamma_a(\boldsymbol{c})$ for the closed curve $t \in [0,1] \mapsto \Phi(t\boldsymbol{\lambda}_a)P$ on the torus $N(\boldsymbol{c})$; its homology class is independent of the base point P, and $\gamma_1, \dots, \gamma_f$ generate the first homology of N because they are the images of the lattice generators under Equation (A.847).

Definition A.554 (Actions on the torus)**.** With θ the tautological one-form of Equation (24.3), that is $\theta = p_a \mathrm{d}q^a$ in any canonical chart, put

$$I_a(\boldsymbol{c}) = \frac{1}{2\pi} \oint_{\gamma_a(\boldsymbol{c})} p_b \,\mathrm{d}q^b\,, \qquad a = 1, \dots, f\,. \tag{A.848}$$

Rests on Proposition A.552 and Equations (23.49) and (24.3).

Lemma A.555 (The actions are well defined)**.** *The integral Equation (A.848) depends only on the homology class of γ_a in N, not on the representing curve, and it depends smoothly on $\boldsymbol{c}$.*
Rests on Proposition A.547, Definition A.554, and Theorem A.311.

Proof. *Derives Lemma A.555.*

N is Lagrangian by Proposition A.547, so the restriction of $\omega = -\mathrm{d}\theta$ to N vanishes, that is the restriction of θ to N is a closed one-form. Two homologous closed curves on N bound a two-chain there, and Stokes' theorem (Theorem A.311) turns the difference of the two circuit integrals into the integral of $\mathrm{d}\theta = -\omega$ over that chain, which is zero. Smoothness in $\boldsymbol{c}$ follows because the curves $\gamma_a(\boldsymbol{c})$ were chosen to depend smoothly on $\boldsymbol{c}$ and θ is smooth. □

The next statement is the one the chapter's own proof of Theorem 23.30 assumed without proving: that the actions may replace the constants $\boldsymbol{c}$ as labels of the tori. Here it is a theorem, and its content is an exact identity between the Jacobian and the lattice.

Proposition A.556 (The Jacobian of the actions is the lattice matrix)**.** *With the conventions above,*

$$\frac{\partial I_a}{\partial c_b} = \frac{1}{2\pi}\left(\boldsymbol{\lambda}_a\right)^b , \qquad \textit{hence} \qquad \det\left(\frac{\partial I_a}{\partial c_b}\right) = \frac{\det(\boldsymbol{\lambda}_a)}{(2\pi)^f} \neq 0 , \tag{A.849}$$

so $\boldsymbol{c} \longmapsto \boldsymbol{I}(\boldsymbol{c})$ is a local diffeomorphism and the I_a are independent functions on a neighbourhood of N.

Rests on Definition A.554 and Propositions 22.18 and A.552.

Proof. *Derives Proposition A.556.*

Let S be the union of the tori $N(\boldsymbol{c}')$ for $\boldsymbol{c}'$ near $\boldsymbol{c}$, a neighbourhood of N in M, and on it define

$$W = \int^{\cdot} p_b \, \mathrm{d}q^b , \tag{A.850}$$

the integral taken along a path from a fixed reference point. Since the restriction of θ to each torus is closed (Lemma A.555), W is well defined up to the periods, and by Equation (A.848) carrying the path once around γ_a increases it by

$$\Delta_a W = 2\pi I_a(\boldsymbol{c}) . \tag{A.851}$$

Read W as a generating function of the second kind (Proposition 22.18) with the constants c_b as new momenta; the conjugate new coordinates are then $\tau^b = \partial W/\partial c_b$, and by the second of Hamilton's equations in the new variables (Theorem 22.6) each τ^b advances at unit rate along the flow of F_b and is constant along the flow of every other F_a. In other words τ^b is the b-th time coordinate of the action Equation (A.845). Carrying the path once around γ_a means applying $\Phi(\boldsymbol{\lambda}_a)$, so

$$\Delta_a \tau^b = \left(\boldsymbol{\lambda}_a\right)^b . \tag{A.852}$$

On the other hand $\tau^b = \partial W/\partial c_b$, and the circuit γ_a lies inside a single torus, so the constants c_b are fixed along it and the two differentiations may be exchanged under the circuit integral, exactly as in Equation (23.53):

$$\Delta_a \tau^b = \frac{\partial}{\partial c_b}\left(\Delta_a W\right) = \frac{\partial\left(2\pi I_a\right)}{\partial c_b} . \tag{A.853}$$

Comparing Equation (A.852) with Equation (A.853) gives Equation (A.849). The determinant of the lattice generators is non-zero because they are linearly independent (Theorem A.550). □

Example A.557 (The check that fixes the convention)**.** For one degree of freedom and a bounded orbit of energy E, $f = 1$ and $\boldsymbol{\lambda}_1$ is the period T of the motion, so Equation (A.849) reads $\mathrm{d}I/\mathrm{d}E = T/2\pi = 1/\omega$, which is exactly Equation (23.57), derived there from Hamilton's equations alone. For the harmonic oscillator, $I = E/\omega$ with ω independent of E, and both sides are $1/\omega$.

Rests on Proposition A.556 and Equation (23.57).

A.47.5 The angles, and the proof of the theorem

Proof of Theorem A.545. *Derives Theorem A.545.*

Part (1) is Proposition A.547 together with Proposition A.552; part (2) is Corollary A.553. It remains to build the action–angle variables.

By Proposition A.556 the map $\boldsymbol{c} \mapsto \boldsymbol{I}$ may be inverted on a neighbourhood, so W of Equation (A.850) may be regarded as a function $W(q, I)$ of the position coordinates and

the actions. It is again a generating function of the second kind, now with the I_a as new momenta, so

$$p_a = \frac{\partial W}{\partial q^a}\,, \qquad \theta^a = \frac{\partial W}{\partial I_a}\,, \tag{A.854}$$

which is Equation (23.50), and the transformation $(q,p) \mapsto (\theta, I)$ is canonical by Proposition 22.18. Repeating the exchange of differentiations that produced Equation (A.853), now with I_a in place of c_b,

$$\Delta_b \theta^a = \frac{\partial}{\partial I_a}\left(\Delta_b W\right) = \frac{\partial\left(2\pi I_b\right)}{\partial I_a} = 2\pi\,\delta^a_b\,, \tag{A.855}$$

so each θ^a is well defined modulo 2π and the f of them are angular coordinates on the torus. The I_a are functions of the c_b alone and are therefore constants of the motion; conversely $\mathcal{H} = F_1 = c_1$ is a function of the c_b, hence of the I_a, and contains no angle. Theorem 22.6 in the new variables then gives $\dot I_a = -\partial\mathcal{H}/\partial\theta^a = 0$, which is Equation (23.51), and $\dot\theta^a = \partial\mathcal{H}/\partial I_a = \omega^a(I)$, constant along the motion, which integrates to Equation (23.52). That is part (3), and with it Theorem 23.30 freed of the separability hypothesis under which it was originally proved. □

Remark A.558 (Where the projection to position space fails, and why that is the Maslov index). One step above deserves to be stated with its caveat rather than glossed. Writing $W = W(q,I)$ presumes that the f position coordinates q^a are good coordinates on the torus, i.e. that $N \to \mathbb{R}^f$, $P \mapsto q(P)$, is a local diffeomorphism. A Lagrangian torus need not project that way everywhere: the projection degenerates on the *caustics*, which for the one-dimensional bounded orbit are the two turning points, where $\partial p/\partial q$ blows up and the orbit folds back. The repair is local and is the one Proposition 22.18 already provides: near a point where some subset of the q^a fails, Legendre-transform in those variables and use a generating function of a different kind, whose arguments are the surviving q's and the corresponding p's. The circuit integrals Equation (A.848) and Equation (A.855) are unaffected, because $\oint\theta$ is defined on N without reference to any projection. What the caustics do affect is the semiclassical use of W: each fold crossed contributes a phase, and the count of them around γ_a is the Maslov index μ_a of Equation (23.62). The classical theorem is indifferent to it; the quantization condition is not.

Remark A.559. Appendix A.47 discharges the derivation owed at Theorem 23.31 of Chapter 23, and Remark 23.32 there states the single imported ingredient, restated above as Theorem A.550. Three connections back into the book are worth making explicit. First, the chapter observes that nothing in it depends on the theorem, because Proposition 23.20 establishes on its own that a separable system is integrable; what the appendix adds is the converse direction of usefulness — action–angle variables now exist for an integrable system whether or not anyone can separate its Hamilton–Jacobi equation, which is Theorem 23.30 with its hypothesis removed. Second, the tori built here are the objects whose fate under perturbation is the subject of Theorem 32.51, and Remark 23.33 is the honest statement that the hypotheses of Theorem 23.31 are met by almost no system. Third, the Lagrangian property established in Proposition A.547 is what Remark 24.13 of Chapter 24 has in mind when it lists the Liouville–Arnold tori among the statements of symplectic geometry that carry physical content: they are global objects, and a symplectic manifold has nothing local to say.

A.48 Marsden–Weinstein Reduction

This appendix proves Theorem 24.47 of Chapter 24: when a Lie group acts freely and properly on a symplectic manifold by symplectomorphisms with an equivariant momentum

map, and μ is a regular value of that map, the quotient Equation (24.31) of the level set by the isotropy group of μ is again a symplectic manifold, of the dimension Equation (24.32), and every invariant Hamiltonian descends to it with its dynamics intact.

The chapter states the geometric core of the argument and does not prove it: the tangent space to the level set of the momentum map is the symplectic orthogonal of the group orbit (Lemma 24.46, which *is* proved there), and the degenerate directions of the restricted form turn out to be exactly the orbit directions of the isotropy group G_μ, so that quotienting by that group removes the degeneracy and removes nothing else. That sentence is Appendix A.48.4 below. Everything around it — that the level set is a manifold, that the quotient is one, that the descended form is well defined, closed and nondegenerate — is what makes the theorem long, and it is written out here.

Remark A.560 (One quoted input less than the chapter says). The paragraph following the proof link in Chapter 24 names one input as quoted rather than proved: the quotient-manifold theorem, that a free and proper action of a Lie group on a manifold has a smooth quotient with the projection a submersion, described there as differential topology belonging in Chapter 13, "which does not yet carry it". That sentence is now out of date, and the correction is worth making rather than leaving as a discrepancy between two pages of the same book: Chapter 13 carries the statement as Theorem 13.67, with its own proof, and this section therefore *cites* it rather than quoting it. Nothing in Appendix A.48 is imported from outside the treatise. The role of that theorem is unchanged and remains confined to producing the smooth structure on M_μ: the symplectic content — existence, uniqueness, closedness and nondegeneracy of the reduced form, and the dimension count — rests on Lemma 24.46 and on Appendix A.48.2 alone.

A.48.1 Setting and statement

Throughout, (M,ω) is a symplectic manifold (Definition 24.8), G is a Lie group with Lie algebra $\mathfrak{g}$ acting smoothly on M by symplectomorphisms (Definition 24.17), and ξ_M denotes the vector field generating the action of $\xi \in \mathfrak{g}$, so that $\xi_M(x) = \frac{\mathrm{d}}{\mathrm{d}t}\big|_{t=0} \exp(t\xi)\cdot x$. The action is assumed *free* and *proper* in the sense of Definition 13.66. The momentum map $\boldsymbol{J} : M \longrightarrow \mathfrak{g}^*$ is the one of Definition 24.43, defined by Equation (24.28), and the interior product is written ι_X, as in Chapter 24; the same operation is written i_X in Chapter 13.

Definition A.561 (Coadjoint action and equivariance)**.** The *coadjoint action* of G on $\mathfrak{g}^*$ is

$$\left\langle \mathrm{Ad}^*_g \mu, \eta \right\rangle = \left\langle \mu, \mathrm{Ad}_{g^{-1}} \eta \right\rangle , \qquad \mu \in \mathfrak{g}^* , \quad \eta \in \mathfrak{g} , \tag{A.856}$$

a left action, and its infinitesimal form is $\mathrm{ad}^*_\xi = \frac{\mathrm{d}}{\mathrm{d}t}\big|_{t=0} \mathrm{Ad}^*_{\exp(t\xi)}$, so that

$$\left\langle \mathrm{ad}^*_\xi \, \mu, \eta \right\rangle = - \left\langle \mu, [\xi, \eta] \right\rangle . \tag{A.857}$$

A momentum map is *equivariant* if $\boldsymbol{J}(g\cdot x) = \mathrm{Ad}^*_g \boldsymbol{J}(x)$ for every g and x. For $\mu \in \mathfrak{g}^*$ write $G_\mu = \left\{ g \in G \mid \mathrm{Ad}^*_g \mu = \mu \right\}$ for its isotropy group, a closed subgroup, and $\mathfrak{g}_\mu$ for the Lie algebra of G_μ.

Rests on Definitions 4.20, 14.2 and 24.43.

Remark A.562 (Conventions and units). Two sign conventions circulate for Equation (A.856), differing by $g \leftrightarrow g^{-1}$; with the one chosen here the coadjoint action is a left action and equivariance reads $\boldsymbol{J} \circ g = \mathrm{Ad}^*_g \circ \boldsymbol{J}$ without an inverse. Sources that define Ad^* by $\langle \mathrm{Ad}^*_g \mu, \eta \rangle = \langle \mu, \mathrm{Ad}_g \eta \rangle$ write the same statement with g^{-1} on the right, and the two agree.

This section is pure geometry and the only dimensional statement it needs is the one Remark 24.11 already fixes: ω carries J s, and a component J_ξ of the momentum map carries

the SI unit of the conserved quantity it generates — so $\boldsymbol{J}$ is not a single dimensioned object but a covector whose f components may carry f different units, exactly as the lattice of Appendix A.47 does. The reduced form ω_μ inherits J s from ω, because it is defined by pullback.

Theorem A.563 (Marsden–Weinstein reduction)**.** *Let G act freely and properly on (M,ω) by symplectomorphisms with an equivariant momentum map $\boldsymbol{J}$, and let $\mu \in \mathfrak{g}^*$. Write $N = \boldsymbol{J}^{-1}(\mu)$, let $i : N \hookrightarrow M$ be the inclusion and $\pi : N \longrightarrow M_\mu = N/G_\mu$ the projection. Then*

1. *every value of $\boldsymbol{J}$ is regular, and N is a closed embedded submanifold of M of dimension $\dim M - \dim G$ with $T_xN = \ker \mathrm{d}\boldsymbol{J}_x$;*
2. *G_μ acts freely and properly on N, and M_μ is a smooth manifold with π a surjective submersion and*
$$\dim M_\mu = \dim M - \dim G - \dim G_\mu\,, \tag{A.858}$$
which is Equation (24.32);
3. *there is exactly one two-form ω_μ on M_μ with $\pi^*\omega_\mu = i^*\omega$, and it is symplectic;*
4. *every G-invariant $H \in C^\infty(M)$ descends to $H_\mu \in C^\infty(M_\mu)$ with $H_\mu \circ \pi = H \circ i$; the flow of X_H preserves N; and π carries it to the flow of X_{H_μ} on (M_μ,ω_μ).*

Rests on Lemma 24.46, Theorem 13.67, and Definition A.561.

A.48.2 Two facts of symplectic linear algebra

Lemma A.564 (Dimension and double orthogonal)**.** *Let (V,Ω) be a finite-dimensional real vector space with a nondegenerate antisymmetric bilinear form, and for a subspace $W \subseteq V$ let $W^\Omega = \{v \in V \mid \Omega(v,w) = 0 \text{ for all } w \in W\}$. Then*

$$\dim W + \dim W^\Omega = \dim V\,, \qquad \left(W^\Omega\right)^\Omega = W\,. \tag{A.859}$$

Rests on Definition 24.2 and Theorem 5.38.

Proof. *Derives Lemma A.564.*

Nondegeneracy makes $\flat : v \longmapsto \Omega(v,\cdot)$ an injective, hence bijective, linear map $V \longrightarrow V^*$. By definition $W^\Omega = \flat^{-1}(W^\circ)$, where $W^\circ \subseteq V^*$ is the annihilator of W; and $\dim W^\circ = \dim V - \dim W$ by rank–nullity (Theorem 5.38) applied to the restriction map $V^* \longrightarrow W^*$, which is surjective. That is the first identity. For the second, $W \subseteq (W^\Omega)^\Omega$ is immediate from antisymmetry, and applying the first identity twice gives $\dim (W^\Omega)^\Omega = \dim V - \dim W^\Omega = \dim W$, so the inclusion is an equality. □

A.48.3 The level set is a manifold

Proposition A.565 (Freeness makes every value regular)**.** *If the action is free then $\mathrm{d}\boldsymbol{J}_x$ is surjective at every $x \in M$. Consequently every $\mu \in \mathfrak{g}^*$ is a regular value, $N = \boldsymbol{J}^{-1}(\mu)$ is a closed embedded submanifold of dimension $\dim M - \dim G$, and $T_xN = \ker \mathrm{d}\boldsymbol{J}_x = \left(T_x(G\cdot x)\right)^\omega$.*

Rests on Lemmas 24.46 and A.564 and Theorem 13.59.

Proof. *Derives Proposition A.565.*

Fix x and write $W = T_x(G\cdot x)$, the span of the values $\xi_M(x)$, $\xi \in \mathfrak{g}$. Freeness makes the map $\xi \mapsto \xi_M(x)$ injective: if $\xi_M(x) = 0$ then the curve $t \mapsto \exp(t\xi)\cdot x$ has vanishing velocity and, being an integral curve of ξ_M through x, is constant by the uniqueness clause

of Theorem 13.125; so $\exp(t\xi)\cdot x = x$ for all t, whence $\exp(t\xi) = e$ by freeness and $\xi = 0$. Hence $\dim W = \dim \mathfrak{g} = \dim G$.

By Lemma 24.46, $\ker \mathrm{d}\boldsymbol{J}_x = W^\omega$, so Equation (A.859) gives $\dim \ker \mathrm{d}\boldsymbol{J}_x = \dim M - \dim W = \dim M - \dim G$, and by rank–nullity the rank of $\mathrm{d}\boldsymbol{J}_x$ is $\dim G = \dim \mathfrak{g}^*$: the differential is surjective. The regular value theorem Theorem 13.59 then makes $N = \boldsymbol{J}^{-1}(\mu)$ an embedded submanifold of dimension $\dim M - \dim G$, closed because it is the preimage of a point under a continuous map, with tangent space the kernel. □

Proposition A.566 (The isotropy group acts, and the quotient is smooth)**.** *G_μ maps N into itself, and its action on N is free and proper. Hence $M_\mu = N/G_\mu$ carries exactly one smooth structure making $\pi : N \longrightarrow M_\mu$ a surjective submersion; it is Hausdorff and second countable, the fibres of π are the G_μ-orbits, and Equation (A.858) holds.*

Rests on Definition A.561, Theorem 13.67, and Proposition A.565.

Proof. *Derives Proposition A.566.*

For $g \in G_\mu$ and $x \in N$, equivariance gives $\boldsymbol{J}(g\cdot x) = \mathrm{Ad}^*_g \boldsymbol{J}(x) = \mathrm{Ad}^*_g \mu = \mu$, so $g\cdot x \in N$. The restricted action is free because the G-action is, and it is proper: G_μ is a closed subgroup of G and N is a closed subset of M, so the preimage of a compact set under $(g,x) \mapsto (g\cdot x, x)$ on $G_\mu \times N$ is a closed subset of the corresponding preimage on $G \times M$, hence compact. Theorem 13.67 applied to this action supplies the smooth structure, the submersion, the separation properties and the fibres, together with the dimension $\dim M_\mu = \dim N - \dim G_\mu$, which with Proposition A.565 is Equation (A.858). □

A.48.4 The degenerate directions of the restricted form

Write $\omega_N = i^*\omega$ for the restriction of ω to N. It is a closed two-form, but it is not symplectic: it has a radical, and identifying that radical is the heart of the theorem.

Lemma A.567 (The differential of the momentum map along the orbit)**.** *Let $x \in N$, so that $\boldsymbol{J}(x) = \mu$. Then for every $\xi \in \mathfrak{g}$*

$$\mathrm{d}\boldsymbol{J}_x(\xi_M(x)) = \mathrm{ad}^*_\xi \mu\,, \tag{A.860}$$

and consequently $\xi_M(x) \in \ker \mathrm{d}\boldsymbol{J}_x$ if and only if $\xi \in \mathfrak{g}_\mu$.

Rests on Definition A.561, Proposition A.565, and Theorem 13.125.

Proof. *Derives Lemma A.567.*

Apply equivariance along the one-parameter subgroup $g(t) = \exp(t\xi)$ and differentiate at $t = 0$. The left-hand side of $\boldsymbol{J}(g(t)\cdot x) = \mathrm{Ad}^*_{g(t)}\mu$ differentiates by the chain rule to $\mathrm{d}\boldsymbol{J}_x(\xi_M(x))$, since $\frac{\mathrm{d}}{\mathrm{d}t}\big|_0 g(t)\cdot x = \xi_M(x)$ by definition; the right-hand side differentiates to $\mathrm{ad}^*_\xi \mu$ by Definition A.561. That is Equation (A.860).

For the second claim, $\mathrm{ad}^*_\xi \mu = 0$ certainly holds when $\xi \in \mathfrak{g}_\mu$, since then $\mathrm{Ad}^*_{\exp(t\xi)}\mu = \mu$ for all t. Conversely suppose $\mathrm{ad}^*_\xi \mu = 0$ and set $\nu(t) = \mathrm{Ad}^*_{\exp(t\xi)}\mu$. Differentiating Equation (A.856) in t and using the group law gives the linear differential equation $\dot\nu(t) = \mathrm{ad}^*_\xi \nu(t)$ with $\nu(0) = \mu$. The constant function $\nu \equiv \mu$ solves it, because $\mathrm{ad}^*_\xi \mu = 0$, and the solution of a linear equation with given initial value is unique (Theorem 9.8); so $\nu(t) = \mu$ for all t, that is $\exp(t\xi) \in G_\mu$ for all t, that is $\xi \in \mathfrak{g}_\mu$. □

Theorem A.568 (The radical is the isotropy orbit)**.** *For every $x \in N$,*

$$\ker (\omega_N)_x := \{v \in T_xN \;\mid\; (\omega_N)_x(v,w) = 0 \text{ for all } w \in T_xN\} = T_x(G_\mu \cdot x)\,. \tag{A.861}$$

Rests on Lemmas 24.46, A.564 and A.567.

Proof. *Derives Theorem A.568.*

Write $W = T_x(G \cdot x)$ as before. By Proposition A.565 and Equation (24.30), $T_xN = \ker \mathrm{d}\boldsymbol{J}_x = W^\omega$. Since ω_N is the restriction of ω, the radical of ω_N at x is $T_xN \cap (T_xN)^\omega$, the second symplectic orthogonal being taken in the symplectic vector space (T_xM, ω_x). Hence, using the second identity of Equation (A.859),

$$\ker (\omega_N)_x = W^\omega \cap (W^\omega)^\omega = W^\omega \cap W = T_x (G \cdot x) \cap \ker \mathrm{d}\boldsymbol{J}_x \,. \tag{A.862}$$

A vector of $T_x(G \cdot x)$ is $\xi_M(x)$ for exactly one $\xi \in \mathfrak{g}$, by the injectivity established in Proposition A.565, and it lies in $\ker \mathrm{d}\boldsymbol{J}_x$ precisely when $\xi \in \mathfrak{g}_\mu$, by Lemma A.567. The intersection is therefore $\{\xi_M(x) \mid \xi \in \mathfrak{g}_\mu\} = T_x(G_\mu \cdot x)$. □

Remark A.569 (Why the quotient is by a group and not merely by a foliation). The radical of a closed two-form of constant rank is always an involutive distribution, so it is integrable by Theorem 13.133 and the manifold is foliated by its leaves. The check is two lines with Cartan's magic formula: if $\iota_X\omega_N = 0$ and $\iota_Y\omega_N = 0$ then $\mathcal{L}_X\omega_N = \mathrm{d}\,\iota_X\omega_N + \iota_X\mathrm{d}\omega_N = 0$ by Equation (13.276) and $\mathrm{d}\omega_N = i^*\mathrm{d}\omega = 0$, and then Equation (13.277) gives $\iota_{[X,Y]}\omega_N = \mathcal{L}_X\iota_Y\omega_N - \iota_Y\mathcal{L}_X\omega_N = 0$, so $[X, Y]$ lies in the radical too. What Theorem A.568 adds is that the leaves of that foliation are exactly the G_μ-orbits. Without it one could still divide N by the characteristic foliation and get a symplectic quotient, but the quotient would be a leaf space with no reason to be Hausdorff or to be a manifold at all. Identifying the leaves as orbits of a group acting freely and properly is what lets Theorem 13.67 supply the smooth structure — and it is also what makes the reduced space computable in practice, since a physicist knows the symmetry group and does not know the foliation.

A.48.5 Descent of the form

Proposition A.570 (Existence and uniqueness of the reduced form)**.** *There is exactly one two-form ω_μ on M_μ with $\pi^*\omega_\mu = \omega_N$, it is smooth, and it is closed and nondegenerate.*
Rests on Theorems 24.16 and A.568 and Proposition A.566.

Proof. *Derives Proposition A.570.*

Definition. Let $[x] \in M_\mu$ and $u, v \in T_{[x]}M_\mu$. Since π is a submersion, $\mathrm{d}\pi_x$ is onto, so there are $\tilde{u}, \tilde{v} \in T_xN$ with $\mathrm{d}\pi_x\tilde{u} = u$ and $\mathrm{d}\pi_x\tilde{v} = v$; set

$$(\omega_\mu)_{[x]}(u, v) = (\omega_N)_x (\tilde{u}, \tilde{v}) \,. \tag{A.863}$$

This is independent of the lifts. The fibres of π are the G_μ-orbits (Proposition A.566), so $\ker \mathrm{d}\pi_x = T_x(G_\mu \cdot x)$, which is exactly the radical of $(\omega_N)_x$ by Theorem A.568; changing a lift changes it by an element of that radical, which ω_N does not see.

Independence of the point in the fibre. Let $g \in G_\mu$ and replace x by $g \cdot x$, lifting through $\mathrm{d}(g\cdot)_x\tilde{u}$ and $\mathrm{d}(g\cdot)_x\tilde{v}$, which are legitimate lifts because $\pi \circ g = \pi$. Since G acts by symplectomorphisms, $g^*\omega = \omega$, and g maps N to N, so $g^*\omega_N = \omega_N$ and the two evaluations agree.

Smoothness. A submersion admits local smooth sections: near any $[x]$ choose s with $\pi \circ s = \mathrm{id}$; then $\omega_\mu = s^*\omega_N$ on that neighbourhood by Equation (A.863), a pullback of a smooth form along a smooth map.

Uniqueness. If $\pi^*\omega_\mu = \pi^*\omega'_\mu$ then, $\mathrm{d}\pi_x$ being surjective at every x and π being surjective, the two forms agree on every pair of tangent vectors at every point.

Closedness. $\pi^*\mathrm{d}\omega_\mu = \mathrm{d}\pi^*\omega_\mu = \mathrm{d}\,i^*\omega = i^*\mathrm{d}\omega = 0$, the exterior derivative commuting with pullback; and π^* is injective on forms because $\mathrm{d}\pi$ is surjective. Hence $\mathrm{d}\omega_\mu = 0$.

Nondegeneracy. Suppose $(\omega_\mu)_{[x]}(u, \cdot) = 0$. Lift u to $\tilde{u} \in T_xN$; then $(\omega_N)_x(\tilde{u}, \tilde{v}) = 0$ for every $\tilde{v} \in T_xN$, because every v is $\mathrm{d}\pi_x\tilde{v}$. So $\tilde{u}$ lies in the radical, which is $\ker \mathrm{d}\pi_x$, and therefore $u = \mathrm{d}\pi_x\tilde{u} = 0$. □

A.48.6 Descent of the dynamics

Proposition A.571 (Invariant Hamiltonians descend with their flows)**.** *Let $H \in C^\infty(M)$ be G-invariant. Then $H \circ i$ is G_μ-invariant and descends to a smooth H_μ on M_μ; the flow of X_H preserves N; and $\mathrm{d}\pi_x(X_H(x)) = X_{H_\mu}([x])$ for every $x \in N$.*

Rests on Theorem 24.45, Proposition A.570, and Equation (24.5).

Proof. *Derives Proposition A.571.*

Invariance under G implies invariance under the subgroup G_μ, and by the last clause of Theorem 13.67 a function on M_μ is smooth exactly when its composition with π is; the G_μ-invariant function $H \circ i$ therefore defines a smooth H_μ with $H_\mu \circ \pi = H \circ i$.

That the flow of X_H preserves N is Noether's theorem in the form Theorem 24.45: G acts by symplectomorphisms and preserves H, so $\boldsymbol{J}$ is constant along the flow, and a trajectory starting on $\boldsymbol{J}^{-1}(\mu)$ stays there. In particular $X_H(x) \in T_xN$ for $x \in N$.

For the last claim, let $v \in T_{[x]}M_\mu$ and lift it to $\tilde{v} \in T_xN$. Using Equation (A.863), then Equation (24.5), then $H_\mu \circ \pi = H \circ i$:

$$(\omega_\mu)_{[x]}\left(\mathrm{d}\pi_x X_H(x),\, v\right) = (\omega_N)_x\left(X_H(x), \tilde{v}\right) = \mathrm{d}H_x(\tilde{v}) = \mathrm{d}\left(H_\mu\right)_{[x]}(v)\,. \tag{A.864}$$

Since v was arbitrary and ω_μ is nondegenerate, the vector $\mathrm{d}\pi_x X_H(x)$ is the unique one satisfying Equation (24.5) for H_μ, that is $X_{H_\mu}([x])$. □

Proof of Theorem A.563. *Derives Theorem A.563.*

Part (1) is Proposition A.565, part (2) is Proposition A.566, part (3) is Proposition A.570 and part (4) is Proposition A.571. Since $M_\mu = \boldsymbol{J}^{-1}(\mu)/G_\mu$ is Equation (24.31) and Equation (A.858) is Equation (24.32), this is Theorem 24.47. □

A.48.7 The example the chapter names

Example A.572 (Rotational reduction of the central-force problem)**.** Take $M = T^*\mathbb{R}^3$ with $\omega = \mathrm{d}q^i \wedge \mathrm{d}p_i$ and $G = \mathrm{SO}(3)$ acting by $(\boldsymbol{q}, \boldsymbol{p}) \mapsto (R\boldsymbol{q}, R\boldsymbol{p})$. This is an action by symplectomorphisms, and Example 24.44 computes its momentum map: $\boldsymbol{J} = \boldsymbol{q} \times \boldsymbol{p} = \boldsymbol{L}$, the angular momentum, in J s.

The action is *not* free on all of M — a rotation about $\boldsymbol{q}$ fixes any point with $\boldsymbol{p}$ parallel to $\boldsymbol{q}$, and every rotation fixes the origin — so the hypotheses hold only on the open, $\mathrm{SO}(3)$-invariant subset $M^\times = \{(\boldsymbol{q}, \boldsymbol{p}) \mid \boldsymbol{q} \times \boldsymbol{p} \neq \boldsymbol{0}\}$, where a rotation fixing two independent vectors is the identity. That restriction is not a technicality to be waved through: it is exactly the collinear and radial motions, which the reduced picture cannot describe and which Section 27.4 treats separately.

On $M^\times$ fix $\mu = \boldsymbol{L}$ with $\ell = |\boldsymbol{L}| > 0$. The isotropy group of μ under the coadjoint action of $\mathrm{SO}(3)$ — which for $\mathrm{SO}(3)$ is the ordinary rotation action on $\mathbb{R}^3$, the algebra carrying an invariant inner product — is the group $\mathrm{SO}(2)$ of rotations about the axis of $\boldsymbol{L}$, of dimension 1. So Equation (A.858) gives

$$\dim M_\mu = 6 - 3 - 1 = 2\,, \tag{A.865}$$

and the reduced space is the two-dimensional radial phase space (r, p_r). For $H = |\boldsymbol{p}|^2/2m + V(r)$, resolving $\boldsymbol{p}$ into its radial and transverse parts on $\boldsymbol{J}^{-1}(\mu)$ gives $|\boldsymbol{p}|^2 = p_r^2 + \ell^2/r^2$, so

$$H_\mu(r, p_r) = \frac{p_r^2}{2m} + \frac{\ell^2}{2mr^2} + V(r)\,, \tag{A.866}$$

which is the effective potential of Equation (27.32), and the centrifugal term $\ell^2/2mr^2$ carries J as it must. This is the identification Remark 24.48 asserts: the effective potential *is* the reduced Hamiltonian at the fixed value of the angular momentum, and the disappearance of

the two angular coordinates is not a trick of the coordinate system but the reduction of six dimensions to two.

Rests on Theorem A.563, Example 24.44, and Equation (27.32).

Example A.573 (The abelian case, and eliminating a cyclic coordinate)**.** If G is abelian the coadjoint action is trivial, so $G_\mu = G$ for every μ and Equation (A.858) reads $\dim M_\mu = \dim M - 2\dim G$: two dimensions are lost per generator. For $G = \mathbb{R}$ acting by translation in a cyclic coordinate q^1, the momentum map is p_1, fixing μ freezes that momentum, and dividing by the group deletes q^1 — the pair (q^1, p_1) disappears together, which is precisely the elementary manoeuvre Remark 24.48 says every physicist performs without naming it.

Rests on Theorem A.563 and Remark 24.48.

A.48.8 What is quoted here

Remark A.574 (What is quoted here)*.* Nothing. The inputs are Lemma 24.46, proved in Chapter 24; the regular value theorem Theorem 13.59, the quotient-manifold theorem Theorem 13.67, Frobenius' theorem Theorem 13.133 and the Cartan identities Equation (13.276) and Equation (13.277), all proved in Chapter 13; rank–nullity Theorem 5.38 from Chapter 5; and the uniqueness of solutions of an ordinary differential equation, Theorem 9.8. Remark A.560 records that the chapter's own prose still describes the quotient-manifold theorem as owed by Part II, which it no longer is.

Remark A.575 (What each hypothesis does, and what is not treated)*.* The three hypotheses divide the work cleanly, and it is worth recording which of them fails first in practice.

Freeness is used twice: in Proposition A.565, to make every value of $\boldsymbol{J}$ regular and N a manifold, and in Proposition A.566, as a hypothesis of Theorem 13.67. *Properness* is used once, also through Theorem 13.67, and what it buys is that the quotient topology is Hausdorff — Example 13.68 exhibits a free but improper action whose orbit space is not. *Equivariance* is used once, in Lemma A.567, and it is what makes $\mathfrak{g}_\mu$ rather than $\mathfrak{g}$ appear in Equation (A.861); without it the radical would not be the tangent space to an orbit of anything.

When freeness fails — which, as Example A.572 shows, is the normal state of affairs at the symmetric configurations — M_μ is not a manifold but a stratified space, a union of manifolds of different dimensions glued along their boundaries. That is *singular* reduction, and it is not treated in this treatise. The honest summary is that the theorem proved here describes the generic stratum and says nothing about the symmetric configurations, which for the central-force problem are exactly the collinear orbits.

Remark A.576 (Attribution)*.* The theorem is Marsden and Weinstein's, from *Reduction of symplectic manifolds with symmetry* (Reports on Mathematical Physics **5**, 1974, 121–130). That paper has no entry in this treatise's bibliography — Chapter 24 records the omission in its own header, together with those of Abraham–Marsden and Arnold — so the attribution is made in words, on the footing of Darboux's memoir in Remark A.81. Nothing above rests on it: the derivation is carried out in full from results proved in this book.

Remark A.577*.* Appendix A.48 discharges the derivation owed at Theorem 24.47 of Chapter 24. Two threads run back into the book from here. Remark 24.48 lists four familiar manoeuvres — dropping a cyclic pair, passing to the centre-of-mass frame, reducing the two-body problem to the radial one, and using the effective potential — and says that each is this theorem applied to a particular group; Example A.572 and Example A.573 above verify two of them, including the identification of Equation (27.32) as the reduced Hamiltonian. And the same remark points at the Lie–Poisson bracket Definition 24.40 as reduction with the whole group divided out, which is why the free rigid body of Proposition 24.41 lives on three variables rather than the six a cotangent bundle would demand: the dimension count is Equation (A.858) once more, with $M = T^*\,\mathrm{SO}(3)$ of dimension six, $G = \mathrm{SO}(3)$ of

dimension three, and a generic $G_\mu = \mathrm{SO}(2)$ removing one further dimension to leave the two-dimensional coadjoint orbit — a sphere of constant $|\boldsymbol{L}|$ — on which the Euler equations Equation (24.27) run.

A.49 The Stone–von Neumann Theorem

This appendix proves Theorem 25.34 of Chapter 25: for finitely many degrees of freedom an irreducible representation of the canonical commutation relations in Weyl's exponentiated form is unitarily equivalent to the Schrödinger representation on $L^2(\mathbb{R}^f)$, so that the quantum kinematics of a system with finitely many canonical pairs is fixed, up to equivalence, by the classical bracket algebra alone.

Nothing in the argument is physics, and the statement it proves stands on the books twice. Theorem 12.114 of Chapter 12 states it with the care about domains and irreducibility that the subject needs, and Remarks 12.115 and 25.35 both record that the proof was owed and that it belongs beside the Hilbert-space material rather than in a chapter of mechanics. This section discharges both debts at once. It is therefore written throughout in the notation of Definition 12.109 — dimensionful parameters, generators $\boldsymbol{Q}$ and $\boldsymbol{P}$, the relation in the form Equation (12.71) — so that moving it into Chapter 12 would change nothing but its address. Two by-products are worth naming in advance: the argument produces the vacuum vector explicitly, and it proves that the Schrödinger system is irreducible, a fact that Example 12.110 currently takes from [1481] without proof.

A.49.1 Statement, conventions and units

Throughout, $\mathcal{H}$ is a separable complex Hilbert space (Definition 12.2), f is a finite positive integer, and (U, V) is a Weyl system of f degrees of freedom in the sense of Definition 12.109: two families of strongly continuous unitary groups

$$U(\boldsymbol{\alpha}) = \exp\!\left(\frac{\mathrm{i}\,\boldsymbol{\alpha}\cdot\boldsymbol{Q}}{\hbar}\right), \qquad V(\boldsymbol{\beta}) = \exp\!\left(-\frac{\mathrm{i}\,\boldsymbol{\beta}\cdot\boldsymbol{P}}{\hbar}\right), \qquad \boldsymbol{\alpha},\boldsymbol{\beta}\in\mathbb{R}^f, \tag{A.867}$$

whose members belonging to different degrees of freedom commute, and which satisfy

$$U(\boldsymbol{\alpha})\,V(\boldsymbol{\beta}) = \mathrm{e}^{\mathrm{i}\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/\hbar}\,V(\boldsymbol{\beta})\,U(\boldsymbol{\alpha}). \tag{A.868}$$

Remark A.578 (Units, and the dictionary to the form used in Part III). The components of $\boldsymbol{Q}$ carry m and those of $\boldsymbol{P}$ carry kg m/s, so the parameter $\boldsymbol{\alpha}$ carries kg m/s and $\boldsymbol{\beta}$ carries m; both $\boldsymbol{\alpha}\cdot\boldsymbol{Q}/\hbar$ and $\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/\hbar$ are then pure numbers, since $\hbar$ carries J s. Every exponent written below is dimensionless as it stands, and $\hbar$ is never set to unity. Equation (25.39) of Chapter 25 writes the same relation with parameters of reciprocal dimension, a in 1/m and b in s/(kg m); the substitution $a = \alpha/\hbar$, $b = -\beta/\hbar$ turns Equation (A.868) into Equation (25.39) and back, and no statement below depends on which of the two is used. Finally, a fixed length $s > 0$, in m, enters in Appendix A.49.4 as the width of a Gaussian weight; it is arbitrary, and Remark A.588 records what changes when it is changed.

Theorem A.579 (Stone–von Neumann)**.** *Let (U, V) be a Weyl system of $f < \infty$ degrees of freedom on a separable Hilbert space $\mathcal{H} \neq \{0\}$.*

1. *If the system acts irreducibly (Definition 12.90) there is a unitary $T : \mathcal{H} \longrightarrow L^2(\mathbb{R}^f)$ carrying it to the Schrödinger system Equation (12.72), and T is unique up to a factor of modulus one.*

2. *Without the irreducibility hypothesis, $\mathcal{H}$ is an orthogonal direct sum (Definition 12.84) of at most countably many closed subspaces, each invariant under the system and each carrying a copy of the Schrödinger system.*

Rests on Definitions 12.90 and 12.109 and Example 12.110.

The proof occupies the rest of this section: Appendix A.49.2 assembles the Weyl operators and their composition law, Appendix A.49.3 the two analytic tools, Appendix A.49.4 the Gaussian average and the single identity on which everything turns, Appendix A.49.5 the vacuum vector, Appendix A.49.6 the unitary, and Appendix A.49.7 the Schrödinger system itself.

A.49.2 The Weyl operators and their composition law

Definition A.580 (Weyl operator)**.** For $z = (\boldsymbol{\alpha}, \boldsymbol{\beta}) \in \mathbb{R}^{2f}$ put

$$W(z) = \mathrm{e}^{-\mathrm{i}\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/2\hbar}\, U(\boldsymbol{\alpha})\, V(\boldsymbol{\beta})\,, \tag{A.869}$$

and let

$$\sigma(z, z') = \boldsymbol{\alpha}\cdot\boldsymbol{\beta}' - \boldsymbol{\alpha}'\cdot\boldsymbol{\beta}\,, \qquad z = (\boldsymbol{\alpha}, \boldsymbol{\beta})\,, \quad z' = (\boldsymbol{\alpha}', \boldsymbol{\beta}')\,, \tag{A.870}$$

be the standard symplectic form on $\mathbb{R}^{2f}$, of dimension J s.

Rests on Definitions 12.64 and 12.109 and Equation (12.71).

Lemma A.581 (Composition law)**.** *Every $W(z)$ is unitary, $W(0) = \mathbb{1}$, and*

$$W(z)\, W(z') = \mathrm{e}^{\mathrm{i}\sigma(z,z')/2\hbar}\, W(z + z')\,, \qquad W(z)^{\dagger} = W(-z) = W(z)^{-1}\,. \tag{A.871}$$

Consequently $W(z)W(z') = \mathrm{e}^{\mathrm{i}\sigma(z,z')/\hbar} W(z')W(z)$, and the family $\{W(z)\}_{z\in\mathbb{R}^{2f}}$ is self-adjoint in the sense of Definition 12.90. Moreover $W(\boldsymbol{\alpha}, \mathbf{0}) = U(\boldsymbol{\alpha})$ and $W(\mathbf{0}, \boldsymbol{\beta}) = V(\boldsymbol{\beta})$, so a closed subspace is invariant under every $W(z)$ if and only if it is invariant under every $U(\boldsymbol{\alpha})$ and every $V(\boldsymbol{\beta})$.

Rests on Definitions 12.64 and A.580 and Equation (12.71).

Proof. *Derives Lemma A.581.*

Unitarity and $W(0) = \mathbb{1}$ are immediate from Equation (A.869), a phase times a product of unitaries. Rearranging Equation (A.868) gives the form in which the relation will be used,

$$V(\boldsymbol{\beta})\, U(\boldsymbol{\alpha}') = \mathrm{e}^{-\mathrm{i}\boldsymbol{\alpha}'\cdot\boldsymbol{\beta}/\hbar}\, U(\boldsymbol{\alpha}')\, V(\boldsymbol{\beta})\,. \tag{A.872}$$

Now compute, using Equation (A.872) once to move $U(\boldsymbol{\alpha}')$ to the left of $V(\boldsymbol{\beta})$, and then the group laws of U and of V separately:

$$\begin{aligned} W(z)W(z') &= \mathrm{e}^{-\mathrm{i}(\boldsymbol{\alpha}\cdot\boldsymbol{\beta} + \boldsymbol{\alpha}'\cdot\boldsymbol{\beta}')/2\hbar}\, U(\boldsymbol{\alpha})V(\boldsymbol{\beta})U(\boldsymbol{\alpha}')V(\boldsymbol{\beta}') \\ &= \mathrm{e}^{-\mathrm{i}(\boldsymbol{\alpha}\cdot\boldsymbol{\beta} + \boldsymbol{\alpha}'\cdot\boldsymbol{\beta}')/2\hbar}\, \mathrm{e}^{-\mathrm{i}\boldsymbol{\alpha}'\cdot\boldsymbol{\beta}/\hbar}\, U(\boldsymbol{\alpha} + \boldsymbol{\alpha}')\, V(\boldsymbol{\beta} + \boldsymbol{\beta}')\,. \end{aligned} \tag{A.873}$$

On the other hand $W(z + z') = \mathrm{e}^{-\mathrm{i}(\boldsymbol{\alpha}+\boldsymbol{\alpha}')\cdot(\boldsymbol{\beta}+\boldsymbol{\beta}')/2\hbar} U(\boldsymbol{\alpha} + \boldsymbol{\alpha}')V(\boldsymbol{\beta} + \boldsymbol{\beta}')$, so the ratio of Equation (A.873) to $W(z + z')$ is a phase whose exponent, multiplied by $\hbar/\mathrm{i}$, is

$$\begin{aligned} &-\frac{\boldsymbol{\alpha}\cdot\boldsymbol{\beta} + \boldsymbol{\alpha}'\cdot\boldsymbol{\beta}'}{2} - \boldsymbol{\alpha}'\cdot\boldsymbol{\beta} + \frac{(\boldsymbol{\alpha} + \boldsymbol{\alpha}')\cdot(\boldsymbol{\beta} + \boldsymbol{\beta}')}{2} \\ &\quad = \frac{\boldsymbol{\alpha}\cdot\boldsymbol{\beta}' - \boldsymbol{\alpha}'\cdot\boldsymbol{\beta}}{2} = \frac{\sigma(z, z')}{2}\,, \end{aligned} \tag{A.874}$$

every term in $\boldsymbol{\alpha}\cdot\boldsymbol{\beta}$ and in $\boldsymbol{\alpha}'\cdot\boldsymbol{\beta}'$ cancelling. That is Equation (A.871). Since $\sigma(z, -z) = 0$ we get $W(z)W(-z) = W(0) = \mathbb{1}$, so $W(z)^{-1} = W(-z)$, and unitarity turns the inverse into the adjoint. Interchanging z and z' in Equation (A.871) and using $\sigma(z', z) = -\sigma(z, z')$ gives the commutation form. Setting $\boldsymbol{\beta} = \mathbf{0}$ or $\boldsymbol{\alpha} = \mathbf{0}$ in Equation (A.869) recovers U and V; conversely $W(z)$ is a phase times a product of one U and one V, so the two families have the same invariant subspaces. □

It is convenient to remove the units once and for all. Fix a length $s > 0$ and put

$$\zeta = (\boldsymbol{a}, \boldsymbol{b}) = \left(\frac{s\boldsymbol{\alpha}}{\hbar}, \; \frac{\boldsymbol{\beta}}{s} \right) \in \mathbb{R}^{2f} , \qquad \sigma(z, z') = \hbar \, \sigma_0(\zeta, \zeta') , \tag{A.875}$$

where $\sigma_0(\zeta, \zeta') = \boldsymbol{a} \cdot \boldsymbol{b}' - \boldsymbol{a}' \cdot \boldsymbol{b}$ is the same form built from the dimensionless coordinates, and $\mathrm{d}^f\alpha \, \mathrm{d}^f\beta = \hbar^f \, \mathrm{d}^{2f}\zeta$. Writing $W(\zeta)$ for $W(z)$ under this substitution, Equation (A.871) becomes

$$W(\zeta) \, W(\zeta') = \mathrm{e}^{\mathrm{i}\sigma_0(\zeta,\zeta')/2} \, W(\zeta + \zeta') . \tag{A.876}$$

It is also useful to write $\sigma_0(\zeta, \zeta') = \zeta \cdot J\zeta'$, where $J(\boldsymbol{a}, \boldsymbol{b}) = (\boldsymbol{b}, -\boldsymbol{a})$ is a real orthogonal map of $\mathbb{R}^{2f}$ with $J^2 = -\mathbb{1}$; then $\zeta \cdot J\zeta = 0$ and $|J\zeta| = |\zeta|$ for every ζ.

Lemma A.582 (Joint strong continuity)**.** *For every $x \in \mathcal{H}$ the map $\zeta \longmapsto W(\zeta)x$ is continuous from $\mathbb{R}^{2f}$ to $\mathcal{H}$, and $\|W(\zeta)x\| = \|x\|$.*

Rests on Lemma A.581 and Definition 12.64.

Proof. *Derives Lemma A.582.*

The norm statement is unitarity. For continuity it is enough, by Equation (A.869) and continuity of the phase, to show that $\boldsymbol{\alpha} \mapsto U(\boldsymbol{\alpha})x$ and $\boldsymbol{\beta} \mapsto V(\boldsymbol{\beta})x$ are continuous. Take U; the argument for V is identical. By hypothesis the f one-parameter groups $\alpha_j \mapsto U(\alpha_j \boldsymbol{e}_j)$ commute and each is strongly continuous, and $U(\boldsymbol{\alpha}) = U(\alpha_1 \boldsymbol{e}_1) \cdots U(\alpha_f \boldsymbol{e}_f)$. Telescoping the difference of two such products and using that every factor is an isometry,

$$\big\| U(\boldsymbol{\alpha})x - U(\boldsymbol{\alpha}')x \big\| \le \sum_{j=1}^{f} \Big\| U(\alpha_j \boldsymbol{e}_j) y_j - U(\alpha'_j \boldsymbol{e}_j) y_j \Big\| , \tag{A.877}$$

with $y_j = U(\alpha'_{j+1}\boldsymbol{e}_{j+1}) \cdots U(\alpha'_f \boldsymbol{e}_f)x$ a fixed vector for each j once $\boldsymbol{\alpha}'$ is fixed. Each summand tends to 0 as $\alpha_j \to \alpha'_j$ by strong continuity of the j-th group, which is continuity at $\boldsymbol{\alpha}'$. □

A.49.3 Two analytic tools

Lemma A.583 (Absolutely convergent operator-valued integrals)**.** *Let $G : \mathbb{R}^{2f} \longrightarrow \mathbb{C}$ be continuous with $\int_{\mathbb{R}^{2f}} |G| < \infty$. Then for every $x \in \mathcal{H}$ the $\mathcal{H}$-valued integral*

$$\Pi_G \, x = \int_{\mathbb{R}^{2f}} G(\zeta) \, W(\zeta) x \, \mathrm{d}^{2f}\zeta \tag{A.878}$$

exists as the limit of the integrals over the balls $|\zeta| \le R$; Π_G is a bounded operator with $\|\Pi_G\| \le \int |G|$; and

$$\langle w | \Pi_G x \rangle = \int_{\mathbb{R}^{2f}} G(\zeta) \, \langle w | W(\zeta) x \rangle \, \mathrm{d}^{2f}\zeta , \qquad (\Pi_G)^\dagger = \Pi_{G^\sharp} , \quad G^\sharp(\zeta) = \overline{G(-\zeta)} . \tag{A.879}$$

If G and G' both satisfy the hypotheses then

$$\Pi_G \, \Pi_{G'} = \Pi_{G''} , \qquad G''(u) = \int_{\mathbb{R}^{2f}} G(\zeta) \, G'(u - \zeta) \, \mathrm{e}^{\mathrm{i}\sigma_0(\zeta,u)/2} \, \mathrm{d}^{2f}\zeta . \tag{A.880}$$

Finally, a closed subspace invariant under every $W(\zeta)$ is invariant under Π_G.

Rests on Lemmas A.254 and A.582 and Proposition 12.4.

Proof. *Derives Lemma A.583.*

On each ball the integrand is a continuous $\mathcal{H}$-valued function of compact support, so the Riemann construction of Lemma A.254 applies verbatim in $2f$ variables — it uses only uniform continuity on a compact set and completeness of $\mathcal{H}$, neither of which cares how many variables there are. For $R' > R$ the difference of the two truncated integrals

is bounded in norm by $\|x\| \int_{R<|\zeta|\le R'} |G|$, which tends to zero as $R \to \infty$ because $|G|$ is integrable; the truncations therefore form a Cauchy net and converge. The bound on $\|\Pi_G\|$ and the first identity in Equation (A.879) pass to the limit from Equation (A.471). For the adjoint, use that identity twice together with $W(\zeta)^\dagger = W(-\zeta)$: $\langle \Pi_G w | x\rangle = \overline{\langle x | \Pi_G w\rangle} = \int \overline{G(\zeta)}\, \langle W(\zeta) w | x\rangle \, \mathrm{d}^{2f}\zeta = \int \overline{G(\zeta)}\, \langle w | W(-\zeta) x\rangle \, \mathrm{d}^{2f}\zeta$, and substituting $\zeta \to -\zeta$ identifies the result as $\langle w | \Pi_{G^\sharp} x\rangle$. Invariance of a closed invariant subspace is inherited from the truncated integrals, whose Riemann sums lie in it, the subspace being closed.

For Equation (A.880), take $w, x \in \mathcal{H}$ and expand $\langle w | \Pi_G \Pi_{G'} x\rangle$ by the first identity of Equation (A.879), applied once to Π_G acting on the vector $\Pi_{G'} x$ and once inside. The result is the scalar double integral

$$\iint G(\zeta) G'(\zeta')\, \langle w | W(\zeta) W(\zeta') x\rangle \, \mathrm{d}^{2f}\zeta \, \mathrm{d}^{2f}\zeta' \,, \tag{A.881}$$

absolutely convergent because the matrix element is bounded by $\|w\|\,\|x\|$ and G, G' are integrable. Substituting Equation (A.876) and changing variables to $u = \zeta + \zeta'$ at fixed ζ — a translation, which preserves $\mathrm{d}^{2f}\zeta'$ — and then exchanging the order of integration, which absolute convergence and Equation (7.112) on an exhausting sequence of boxes permit, turns Equation (A.881) into $\int G''(u)\, \langle w | W(u) x\rangle \, \mathrm{d}^{2f}u$, using $\sigma_0(\zeta, u-\zeta) = \sigma_0(\zeta, u)$. Since w was arbitrary this is $\langle w | \Pi_{G''} x\rangle$, and G'' is continuous and integrable because $|G''| \le |G| * |G'|$. □

The second tool is the injectivity of the Fourier transform in several variables. Corollary 17.33 states it on the line; the proof of Theorem 17.32 carries over unchanged, and it is worth writing out, because Appendix A.50 needs the same statement.

Lemma A.584 (Fourier injectivity in n variables)**.** *Let $h : \mathbb{R}^n \longrightarrow \mathbb{C}$ be continuous with $\int_{\mathbb{R}^n} |h| < \infty$, and suppose $\int_{\mathbb{R}^n} h(\xi)\, \mathrm{e}^{\mathrm{i}\eta\cdot\xi}\, \mathrm{d}^n\xi = 0$ for every $\eta \in \mathbb{R}^n$. Then $h \equiv 0$.*
Rests on Theorem 17.32, Equation (17.42), and Definition 17.29.

Proof. *Derives Lemma A.584.*

Write $\hat{h}(\eta) = (2\pi)^{-n/2} \int h(\xi) \mathrm{e}^{-\mathrm{i}\eta\cdot\xi} \mathrm{d}^n\xi$, which vanishes identically by hypothesis, with η replaced by $-\eta$. For $\varepsilon > 0$ put

$$I_\varepsilon(\xi) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} \hat{h}(\eta)\, \mathrm{e}^{-\varepsilon|\eta|^2/2}\, \mathrm{e}^{\mathrm{i}\eta\cdot\xi}\, \mathrm{d}^n\eta = 0 \,. \tag{A.882}$$

Inserting the definition of $\hat{h}$ and exchanging the order of integration — legitimate because $|h(\xi')|\, \mathrm{e}^{-\varepsilon|\eta|^2/2}$ is integrable over $\mathbb{R}^n \times \mathbb{R}^n$, so Equation (7.112) applies on an exhausting sequence of boxes — gives $I_\varepsilon(\xi) = \int h(\xi') g_\varepsilon(\xi - \xi') \mathrm{d}^n\xi'$ with

$$g_\varepsilon(u) = (2\pi\varepsilon)^{-n/2}\, \mathrm{e}^{-|u|^2/2\varepsilon} \,, \qquad \int_{\mathbb{R}^n} g_\varepsilon = 1 \,, \qquad g_\varepsilon \ge 0 \,, \tag{A.883}$$

the inner η-integral factorising into n one-dimensional Gaussian integrals, each evaluated by Equation (17.42). The family g_ε is an approximate identity exactly as in the proof of Theorem 17.32: non-negative, of unit mass, and concentrating on $|u| < \delta$ as $\varepsilon \to 0$. Since h is continuous at the fixed point ξ, bounded near it and integrable at infinity, $I_\varepsilon(\xi) \to h(\xi)$. But $I_\varepsilon \equiv 0$, so $h(\xi) = 0$. □

A.49.4 The Gaussian average

Definition A.585 (The Gaussian average of the Weyl operators)**.** With $s > 0$ fixed and ζ as in Equation (A.875), put

$$\Pi = (2\pi)^{-f} \int_{\mathbb{R}^{2f}} \mathrm{e}^{-|\zeta|^2/4}\, W(\zeta)\, \mathrm{d}^{2f}\zeta = \frac{1}{(2\pi\hbar)^f} \int_{\mathbb{R}^{2f}} \mathrm{e}^{-\frac{1}{4}\left(\frac{s^2|\boldsymbol{\alpha}|^2}{\hbar^2} + \frac{|\boldsymbol{\beta}|^2}{s^2}\right)} W(\boldsymbol{\alpha}, \boldsymbol{\beta})\, \mathrm{d}^f\alpha\, \mathrm{d}^f\beta \,, \tag{A.884}$$

a bounded operator by Lemma A.583. The two expressions agree by Equation (A.875), and the second exhibits the weight as a Gaussian of width $\hbar/s$ in momentum and s in position.
Rests on Lemma A.583 and Definition A.580.

Everything rests on one identity, which is a Gaussian integral and nothing else.

Lemma A.586 (Gaussian integral with a complex linear term)**.** *For every $n \geq 1$ and every $v \in \mathbb{C}^n$,*

$$\int_{\mathbb{R}^n} \mathrm{e}^{-|\zeta|^2/2+\zeta\cdot v}\,\mathrm{d}^n\zeta = (2\pi)^{n/2}\,\mathrm{e}^{v\cdot v/2}\,, \tag{A.885}$$

where $\zeta\cdot v=\sum_k \zeta_k v_k$ and $v\cdot v=\sum_k v_k^2$ are bilinear, not Hermitian.
Rests on Equations (7.112), (17.35) and (17.42).

Proof. *Derives Lemma A.586.*

Split $v = p+\mathrm{i}q$ with $p,q\in\mathbb{R}^n$ and complete the square in the real part, $-|\zeta|^2/2+\zeta\cdot p = |p|^2/2 - |\zeta-p|^2/2$. Substituting $u=\zeta-p$,

$$\int_{\mathbb{R}^n} \mathrm{e}^{-|\zeta|^2/2+\zeta\cdot v}\mathrm{d}^n\zeta = \mathrm{e}^{|p|^2/2}\,\mathrm{e}^{\mathrm{i}p\cdot q}\int_{\mathbb{R}^n}\mathrm{e}^{-|u|^2/2}\,\mathrm{e}^{\mathrm{i}u\cdot q}\,\mathrm{d}^n u\,. \tag{A.886}$$

The remaining integral factorises into n one-dimensional integrals by Equation (7.112), and each is Equation (17.42) with $a=1$, giving $(2\pi)^{n/2}\mathrm{e}^{-|q|^2/2}$. Collecting the three exponents, $|p|^2/2+\mathrm{i}p\cdot q-|q|^2/2 = v\cdot v/2$, which is Equation (A.885). □

Theorem A.587 (The Gaussian average is a non-zero projector that absorbs the Weyl operators)**.** *Π is self-adjoint, $\Pi^2=\Pi$, and for every $\eta\in\mathbb{R}^{2f}$*

$$\Pi\,W(\eta)\,\Pi = \mathrm{e}^{-|\eta|^2/4}\,\Pi\,. \tag{A.887}$$

Moreover $\Pi\neq 0$ whenever $\mathcal{H}\neq\{0\}$.
Rests on Definition A.585 and Lemmas A.584 and A.586.

Proof. *Derives Theorem A.587.*

Self-adjointness. The weight $G(\zeta)=(2\pi)^{-f}\mathrm{e}^{-|\zeta|^2/4}$ is real and even, so $G^\sharp = G$ and the second identity of Equation (A.879) gives $\Pi^\dagger=\Pi$.

Idempotence. By Equation (A.880) it suffices to show that

$$\int_{\mathbb{R}^{2f}} G(\zeta)\,G(u-\zeta)\,\mathrm{e}^{\mathrm{i}\sigma_0(\zeta,u)/2}\,\mathrm{d}^{2f}\zeta = G(u)\,. \tag{A.888}$$

Expand the product of the two Gaussians,

$$-\frac{|\zeta|^2}{4}-\frac{|u-\zeta|^2}{4} = -\frac{|\zeta|^2}{2}+\frac{\zeta\cdot u}{2}-\frac{|u|^2}{4}\,, \tag{A.889}$$

and write the phase as $\mathrm{i}\sigma_0(\zeta,u)/2 = \mathrm{i}\,\zeta\cdot Ju/2$. The integral in Equation (A.888) is therefore $(2\pi)^{-2f}\mathrm{e}^{-|u|^2/4}$ times the integral Equation (A.885) in $n=2f$ variables with

$$v=\frac{u+\mathrm{i}Ju}{2}\,,\qquad v\cdot v=\frac{1}{4}\left(u\cdot u+2\mathrm{i}\,u\cdot Ju-Ju\cdot Ju\right)=0\,, \tag{A.890}$$

because $u\cdot Ju=\sigma_0(u,u)=0$ and $Ju\cdot Ju=|u|^2$ by orthogonality of J. Hence the integral equals $(2\pi)^{-2f}\mathrm{e}^{-|u|^2/4}(2\pi)^f = (2\pi)^{-f}\mathrm{e}^{-|u|^2/4} = G(u)$, which is Equation (A.888). The exponent $-|\zeta|^2/4$ and the coefficient $(2\pi)^{-f}$ are fixed by this requirement and by nothing else; that is where they come from.

The absorption identity. Expanding as in Equation (A.881), and with the same justification,

$$\Pi W(\eta)\Pi = \iint G(\zeta)G(\zeta')\,W(\zeta)W(\eta)W(\zeta')\,\mathrm{d}^{2f}\zeta\,\mathrm{d}^{2f}\zeta'\,, \tag{A.891}$$

and two applications of Equation (A.876) give

$$W(\zeta)W(\eta)W(\zeta') = \exp\Big\{\frac{\mathrm{i}}{2}\big[\sigma_0(\zeta,\eta)+\sigma_0(\zeta,\zeta')+\sigma_0(\eta,\zeta')\big]\Big\}\,W(\zeta+\zeta'+\eta)\,. \tag{A.892}$$

Substitute $u=\zeta+\zeta'$ at fixed ζ. Using $\sigma_0(\zeta,u-\zeta)=\sigma_0(\zeta,u)$ and $\sigma_0(\eta,u-\zeta)=\sigma_0(\eta,u)+\sigma_0(\zeta,\eta)$, the bracket becomes $2\sigma_0(\zeta,\eta)+\sigma_0(\zeta,u)+\sigma_0(\eta,u)$, so

$$\Pi W(\eta)\Pi = \int \mathrm{e}^{\mathrm{i}\sigma_0(\eta,u)/2}\,W(u+\eta)\left[\int G(\zeta)G(u-\zeta)\,\mathrm{e}^{\mathrm{i}\sigma_0(\zeta,\,u+2\eta)/2}\,\mathrm{d}^{2f}\zeta\right]\mathrm{d}^{2f}u\,. \tag{A.893}$$

The inner integral is Equation (A.885) again, with the same Gaussian Equation (A.889) but with $v=\big[u+\mathrm{i}J(u+2\eta)\big]/2=p+\mathrm{i}q$, where $p=u/2$ and $q=J(u/2+\eta)$. Now

$$v\cdot v = |p|^2-|q|^2+2\mathrm{i}\,p\cdot q = \frac{|u|^2}{4}-\left|\frac{u}{2}+\eta\right|^2+\mathrm{i}\,\sigma_0(u,\eta) = -u\cdot\eta-|\eta|^2+\mathrm{i}\,\sigma_0(u,\eta)\,, \tag{A.894}$$

using $|J\cdot|=|\cdot|$ and $p\cdot q=(u/2)\cdot J(u/2+\eta)=\sigma_0(u/2,\eta)$. Hence the inner integral equals $G(u)\,\mathrm{e}^{-u\cdot\eta/2-|\eta|^2/2}\,\mathrm{e}^{\mathrm{i}\sigma_0(u,\eta)/2}$, and its phase cancels the prefactor $\mathrm{e}^{\mathrm{i}\sigma_0(\eta,u)/2}$ of Equation (A.893) exactly, because $\sigma_0(\eta,u)+\sigma_0(u,\eta)=0$. What remains is a pure Gaussian in u,

$$-\frac{|u|^2}{4}-\frac{u\cdot\eta}{2}-\frac{|\eta|^2}{2} = -\frac{|u+\eta|^2}{4}-\frac{|\eta|^2}{4}\,, \tag{A.895}$$

so that, substituting $w=u+\eta$, $\Pi W(\eta)\Pi=\mathrm{e}^{-|\eta|^2/4}(2\pi)^{-f}\int\mathrm{e}^{-|w|^2/4}W(w)\mathrm{d}^{2f}w=\mathrm{e}^{-|\eta|^2/4}\Pi$. That is Equation (A.887), and at $\eta=0$ it reproduces $\Pi^2=\Pi$, a check on every sign above.

Non-vanishing. Suppose $\Pi=0$. Conjugating a single Weyl operator by another, Equation (A.876) twice gives $W(\eta)W(\zeta)W(\eta)^\dagger=\mathrm{e}^{\mathrm{i}\sigma_0(\eta,\zeta)}W(\zeta)$, hence

$$W(\eta)\,\Pi\,W(\eta)^\dagger = \int_{\mathbb{R}^{2f}} G(\zeta)\,\mathrm{e}^{\mathrm{i}\sigma_0(\eta,\zeta)}\,W(\zeta)\,\mathrm{d}^{2f}\zeta\,, \tag{A.896}$$

which vanishes for every η if Π does. Fix $x,y\in\mathcal{H}$ and set $h(\zeta)=G(\zeta)\,\langle y|W(\zeta)x\rangle$, continuous by Lemma A.582 and absolutely integrable because $|h|\le G\,\|x\|\,\|y\|$. Taking the matrix element of Equation (A.896) gives $\int h(\zeta)\mathrm{e}^{\mathrm{i}\eta\cdot J\zeta}\mathrm{d}^{2f}\zeta=0$ for every η; since $\eta\cdot J\zeta=-(J\eta)\cdot\zeta$ and J is a bijection of $\mathbb{R}^{2f}$, that is the hypothesis of Lemma A.584, so $h\equiv 0$. At $\zeta=0$, $h(0)=(2\pi)^{-f}\,\langle y|x\rangle$, so $\langle y|x\rangle=0$ for all x and y — impossible unless $\mathcal{H}=\{0\}$. □

Remark A.588 (The width is a choice, not an input). Nothing above fixes s, and no statement below depends on it: the dimensionless variable Equation (A.875) absorbs it completely, so Π and every identity satisfied by it are the same for every s. What does change with s is the *vector* Π projects onto, which in the Schrödinger picture is the Gaussian of width s, Equation (A.902). The theorem is a statement about a representation, so it cannot depend on s; the vacuum is a statement about a vector, so it must.

A.49.5 The vacuum vector

Proposition A.589 (Cyclic subspaces and the rank of the average)**.** *Let $\Omega\in\operatorname{ran}\Pi$ with $\|\Omega\|=1$, and let M_Ω be the closed linear span of $\big\{W(\zeta)\Omega:\zeta\in\mathbb{R}^{2f}\big\}$. Then*

1. *M_Ω reduces the Weyl system, and the restriction of the system to M_Ω is again a Weyl system whose own Gaussian average is the restriction of Π;*
2. *that restricted average has range exactly $\mathbb{C}\,\Omega$, and the restricted system is irreducible;*
3. *if the original system is irreducible then $M_\Omega=\mathcal{H}$ and $\operatorname{ran}\Pi=\mathbb{C}\,\Omega$.*

Rests on Theorem A.587, Definition 12.90, and Proposition 12.89.

Proof. *Derives Proposition A.589.*

(1) M_Ω is invariant under every $W(\eta)$, since $W(\eta)W(\zeta)\Omega$ is a multiple of $W(\eta+\zeta)\Omega$ by Equation (A.876), and the family is self-adjoint by Lemma A.581; so $M_\Omega^\perp$ is invariant too and M_Ω reduces the system in the sense of Proposition 12.89. The restricted groups are again strongly continuous unitary groups on M_Ω satisfying Equation (A.868), and the restricted average is given by the same formula Equation (A.884), so it is Π restricted to M_Ω, which by the last clause of Lemma A.583 maps M_Ω into itself.

(2) $\Omega = \Pi\Omega \in M_\Omega$ lies in the range of the restricted average. Let $u \in M_\Omega$ satisfy $\Pi u = u$ and $\langle \Omega | u \rangle = 0$. Then, for every η,

$$\langle u | W(\eta)\Omega \rangle = \langle \Pi u | W(\eta)\Pi\Omega \rangle = \langle u | \Pi W(\eta)\Pi\,\Omega \rangle = \mathrm{e}^{-|\eta|^2/4}\,\langle u|\Omega\rangle = 0\,, \tag{A.897}$$

by Equation (A.887) and $\Pi = \Pi^\dagger$. So u is orthogonal to every generator of M_Ω, hence to M_Ω, hence to itself: $u = 0$. The range is therefore the line $\mathbb{C}\Omega$. For irreducibility, let $N \subseteq M_\Omega$ be a closed subspace reducing the restricted system, and let N' be its orthogonal complement inside M_Ω. By the last clause of Lemma A.583 both N and N' are invariant under Π, and their images are orthogonal subspaces of the line $\mathbb{C}\Omega$, so at most one of them is non-zero; and at least one is, because $\Pi\Omega = \Omega \neq 0$. Say $\Pi N' = \{0\}$ and write $\Omega = m + m'$ with $m \in N$, $m' \in N'$; then $\Omega = \Pi\Omega = \Pi m \in N$, so N contains every $W(\zeta)\Omega$ and equals M_Ω. In the other case the same argument gives $N' = M_\Omega$, i.e. $N = \{0\}$.

(3) $M_\Omega \neq \{0\}$ contains Ω, so irreducibility of the original system forces $M_\Omega = \mathcal{H}$, and then (2) is the statement about Π itself. □

Lemma A.590 (The Gram matrix is universal)**.** *Let the system act irreducibly and let Ω be a unit vector spanning* $\operatorname{ran}\Pi$*. Then for all ζ, ζ'*

$$\big\langle W(\zeta)\Omega \big| W(\zeta')\Omega \big\rangle = \mathrm{e}^{-\mathrm{i}\sigma_0(\zeta,\zeta')/2}\,\mathrm{e}^{-|\zeta'-\zeta|^2/4}\,. \tag{A.898}$$

The right-hand side involves the Weyl algebra alone: it is the same number in every irreducible Weyl system of f degrees of freedom.

Rests on Proposition A.589, Theorem A.587, and Lemma A.581.

Proof. *Derives Lemma A.590.*

First, $\Pi\Omega = \Omega$ and Equation (A.887) give $\langle \Omega | W(\eta)\Omega \rangle = \langle \Omega | \Pi W(\eta)\Pi\Omega \rangle = \mathrm{e}^{-|\eta|^2/4}$. Then, by Equation (A.876) and $W(\zeta)^\dagger = W(-\zeta)$,

$$\big\langle W(\zeta)\Omega \big| W(\zeta')\Omega \big\rangle = \big\langle \Omega \big| W(-\zeta)W(\zeta')\Omega \big\rangle = \mathrm{e}^{\mathrm{i}\sigma_0(-\zeta,\zeta')/2}\,\big\langle \Omega \big| W(\zeta'-\zeta)\Omega \big\rangle\,, \tag{A.899}$$

which is Equation (A.898). □

A.49.6 The intertwining unitary

Proposition A.591 (Any two irreducible Weyl systems are equivalent)**.** *Let (U, V) on $\mathcal{H}$ and (U', V') on $\mathcal{H}'$ be irreducible Weyl systems of the same finite number f of degrees of freedom. Then there is a unitary $T : \mathcal{H} \longrightarrow \mathcal{H}'$ with $TU(\boldsymbol{\alpha}) = U'(\boldsymbol{\alpha})T$ and $TV(\boldsymbol{\beta}) = V'(\boldsymbol{\beta})T$ for all $\boldsymbol{\alpha}, \boldsymbol{\beta}$, and T is unique up to a factor of modulus one.*

Rests on Lemma A.590, Proposition A.589, and Theorem 12.91.

Proof. *Derives Proposition A.591.*

Choose unit vectors $\Omega \in \operatorname{ran}\Pi$ and $\Omega' \in \operatorname{ran}\Pi'$, which exist and span those ranges by Theorem A.587 and Proposition A.589. On the dense subspace $D \subset \mathcal{H}$ of finite linear combinations $x = \sum_{k=1}^{N} c_k W(\zeta_k)\Omega$ — dense because $M_\Omega = \mathcal{H}$ — define

$$T\left(\sum_k c_k W(\zeta_k)\Omega\right) = \sum_k c_k W'(\zeta_k)\Omega'\,. \tag{A.900}$$

By Lemma A.590 applied in each space,

$$\left\| \sum_k c_k W'(\zeta_k)\Omega' \right\|^2 = \sum_{k,l} \overline{c_k} c_l \, \langle W'(\zeta_k)\Omega' | W'(\zeta_l)\Omega' \rangle = \sum_{k,l} \overline{c_k} c_l \, \langle W(\zeta_k)\Omega | W(\zeta_l)\Omega \rangle = \|x\|^2 \,, \tag{A.901}$$

the two Gram matrices being equal entry by entry. In particular the right-hand side of Equation (A.900) vanishes whenever x does, so T is well defined on D, and it is isometric. Its range contains every $W'(\zeta)\Omega'$ and is therefore dense in $\mathcal{H}'$, again by Proposition A.589. An isometry with dense domain and dense range extends by continuity to a unitary of $\mathcal{H}$ onto $\mathcal{H}'$. Intertwining holds on D by construction — $TW(\eta)W(\zeta_k)\Omega$ and $W'(\eta)TW(\zeta_k)\Omega$ are both $\mathrm{e}^{\mathrm{i}\sigma_0(\eta,\zeta_k)/2}W'(\eta+\zeta_k)\Omega'$ — and extends by continuity; by the last clause of Lemma A.581 intertwining the W's is the same as intertwining the U's and the V's.

For uniqueness, let T_1 and T_2 both intertwine. Then $S = T_2 T_1^{-1}$ is a unitary of $\mathcal{H}'$ commuting with every $W'(\zeta)$. The family $\{W'(\zeta)\}$ is self-adjoint and acts irreducibly, so Theorem 12.91 gives $S = c\,\mathbb{1}$ with $c \in \mathbb{C}$, and $|c| = 1$ because S is unitary. □

A.49.7 The Schrödinger system

It remains to exhibit one irreducible Weyl system and to identify its vacuum. Here the Gaussian average can be computed in closed form, and the computation is the shortest route to both facts at once.

Proposition A.592 (The vacuum of the Schrödinger system)**.** *On $\mathcal{H} = L^2(\mathbb{R}^f)$ take the Schrödinger system Equation (12.72), read componentwise for f degrees of freedom, and build Π from it by Equation (A.884). Then, with*

$$\Omega_s(\boldsymbol{x}) = \left(\pi s^2\right)^{-f/4} \exp\!\left(-\frac{|\boldsymbol{x}|^2}{2s^2}\right), \qquad \|\Omega_s\| = 1\,, \tag{A.902}$$

the average is the rank-one orthogonal projector onto that vector,

$$\Pi = |\Omega_s\rangle\langle\Omega_s| \,, \qquad \textit{that is} \qquad (\Pi\psi)(\boldsymbol{x}) = \Omega_s(\boldsymbol{x}) \int_{\mathbb{R}^f} \Omega_s(\boldsymbol{x}')\,\psi(\boldsymbol{x}')\,\mathrm{d}^f x' \,. \tag{A.903}$$

Consequently $\{W(\zeta)\Omega_s\}$ is total in $L^2(\mathbb{R}^f)$ and the Schrödinger system acts irreducibly.
Rests on Example 12.110, Theorem A.587, and Lemma A.586.

Proof. *Derives Proposition A.592.*

The kernel. By Equation (12.72) and Equation (A.869),

$$(W(\boldsymbol{\alpha},\boldsymbol{\beta})\psi)(\boldsymbol{x}) = \mathrm{e}^{-\mathrm{i}\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/2\hbar}\,\mathrm{e}^{\mathrm{i}\boldsymbol{\alpha}\cdot\boldsymbol{x}/\hbar}\,\psi(\boldsymbol{x}-\boldsymbol{\beta})\,. \tag{A.904}$$

In the dimensionless variables Equation (A.875), $\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/2\hbar = \boldsymbol{a}\cdot\boldsymbol{b}/2$, $\boldsymbol{\alpha}\cdot\boldsymbol{x}/\hbar = \boldsymbol{a}\cdot\boldsymbol{x}/s$ and $\boldsymbol{\beta} = s\boldsymbol{b}$, so

$$(\Pi\psi)(\boldsymbol{x}) = (2\pi)^{-f} \iint \mathrm{e}^{-(|\boldsymbol{a}|^2+|\boldsymbol{b}|^2)/4}\,\mathrm{e}^{-\mathrm{i}\boldsymbol{a}\cdot\boldsymbol{b}/2}\,\mathrm{e}^{\mathrm{i}\boldsymbol{a}\cdot\boldsymbol{x}/s}\,\psi(\boldsymbol{x}-s\boldsymbol{b})\,\mathrm{d}^f a\,\mathrm{d}^f b\,. \tag{A.905}$$

Do the $\boldsymbol{a}$ integral first, at fixed $\boldsymbol{b}$. It is Equation (A.885) in $n = f$ variables, after the rescaling $\boldsymbol{a} = \sqrt{2}\,\boldsymbol{u}$, and gives

$$\int_{\mathbb{R}^f} \mathrm{e}^{-|\boldsymbol{a}|^2/4 + \mathrm{i}\boldsymbol{a}\cdot(\boldsymbol{x}/s - \boldsymbol{b}/2)}\,\mathrm{d}^f a = (4\pi)^{f/2} \exp\!\left(-\left|\frac{\boldsymbol{x}}{s} - \frac{\boldsymbol{b}}{2}\right|^2\right). \tag{A.906}$$

Substituting $\boldsymbol{x}' = \boldsymbol{x} - s\boldsymbol{b}$, so that $\boldsymbol{b} = (\boldsymbol{x}-\boldsymbol{x}')/s$ and $\mathrm{d}^f b = s^{-f}\mathrm{d}^f x'$, the two exponents combine:

$$-\frac{|\boldsymbol{x}-\boldsymbol{x}'|^2}{4s^2} - \frac{|\boldsymbol{x}+\boldsymbol{x}'|^2}{4s^2} = -\frac{|\boldsymbol{x}|^2+|\boldsymbol{x}'|^2}{2s^2}\,, \tag{A.907}$$

because $\boldsymbol{x}/s - \boldsymbol{b}/2 = (\boldsymbol{x} + \boldsymbol{x}')/2s$ and the parallelogram identity turns the sum of the two squares into twice the sum of the squares of $\boldsymbol{x}$ and $\boldsymbol{x}'$. Hence

$$(\Pi\psi)(\boldsymbol{x}) = \frac{(4\pi)^{f/2}}{(2\pi)^f\, s^f}\, \mathrm{e}^{-|\boldsymbol{x}|^2/2s^2} \int_{\mathbb{R}^f} \mathrm{e}^{-|\boldsymbol{x}'|^2/2s^2}\, \psi(\boldsymbol{x}')\, \mathrm{d}^f x' \,, \tag{A.908}$$

and the constant is $(4\pi)^{f/2}(2\pi)^{-f} s^{-f} = (\pi s^2)^{-f/2}$, which is exactly what turns the two bare Gaussians into the normalised Equation (A.902) twice over. That is Equation (A.903), and it is manifestly an orthogonal projector of rank one, in agreement with Theorem A.587.

Totality. Let K be the closed linear span of $\{W(\zeta)\Omega_s\}$; it reduces the system by Proposition A.589(1), so $K^\perp$ is invariant and carries a Weyl system of its own, whose Gaussian average is the restriction of Π to $K^\perp$. But that restriction is zero: for $x \in K^\perp$, Equation (A.903) gives $\Pi x = \langle \Omega_s | x \rangle\, \Omega_s = 0$, because $\Omega_s = W(0)\Omega_s \in K$. By the last clause of Theorem A.587 a Weyl system on a non-zero space has a non-zero average, so $K^\perp = \{0\}$ and $K = L^2(\mathbb{R}^f)$.

Irreducibility. Ω_s spans $\operatorname{ran}\Pi$ and $M_{\Omega_s} = K = L^2(\mathbb{R}^f)$, so Proposition A.589(2) applied to M_{Ω_s} says that the system is irreducible. □

Proof of Theorem A.579. *Derives Theorem A.579.*

Part (1) is Proposition A.591 applied to the given system and to the Schrödinger system, which is an irreducible Weyl system by Proposition A.592.

Part (2). Let $\mathcal{H} \neq \{0\}$ carry a Weyl system, not assumed irreducible. By Theorem A.587 the operator Π is a non-zero orthogonal projector; choose a unit vector Ω_1 in its range and put $M_1 = M_{\Omega_1}$. By Proposition A.589, M_1 reduces the system and the restriction to it is an irreducible Weyl system, hence carries a copy of the Schrödinger system by part (1). Now $M_1^\perp$ is invariant and carries a Weyl system of its own; if it is not $\{0\}$ its average is again non-zero, and the construction produces $M_2 \subseteq M_1^\perp$, and so on. The subspaces so produced are mutually orthogonal and each is infinite-dimensional — it is a copy of $L^2(\mathbb{R}^f)$ — so separability of $\mathcal{H}$ (Definition 12.2) allows at most countably many of them, and the process exhausts $\mathcal{H}$: the orthogonal complement of their closed sum is invariant and carries a vanishing average, hence is $\{0\}$. That is the direct-sum statement, the sum being the one of Definition 12.84. □

A.49.8 What is quoted here

Remark A.593 (What is quoted here). Nothing, beyond the standing declaration of Remark 12.1. Every step above is a Gaussian integral, an application of Equation (17.42) through Lemma A.586 and Lemma A.584, or an application of Definition 12.90 and Theorem 12.91 — all proved in Chapter 12 or in Chapter 17. Two points deserve naming rather than leaving implicit.

First, the passage between the exponentiated form and the unbounded generators $\boldsymbol{Q}$ and $\boldsymbol{P}$ is Theorem 12.66, proved in Appendix A.25; it is what makes Theorem A.579 a statement about the canonical commutation relations at all, and Remark 25.36 explains why the unexponentiated relation would not do. The vector-valued integral of Lemma A.583 is the one built there, in Lemma A.254, extended from a compact interval to $\mathbb{R}^{2f}$ by absolute convergence.

Second, the irreducibility of the Schrödinger system is here *proved*, in Proposition A.592, by computing the Gaussian average in closed form. Example 12.110 takes it instead from [1481], through the maximal-abelian property of L^∞ acting on L^2; that route is shorter but rests on a fact about operator algebras which this treatise does not build, so the argument given here is the one on which Theorem A.579 stands.

Remark A.594 (Attribution). The exponentiated form of the commutation relations is Weyl's, from *Quantenmechanik und Gruppentheorie* (Zeitschrift für Physik **46**, 1927, 1–46), and

the uniqueness theorem is von Neumann's, from *Die Eindeutigkeit der Schrödingerschen Operatoren* (Mathematische Annalen **104**, 1931, 570–578); Stone had announced the result, and the theorem carries both names. Neither of those two papers has an entry in this treatise's bibliography — and the existing key for Weyl in 1929 is a different work of his, on the electron and gravitation, which must not be used for it — so that part of the attribution is made in words, on the footing of Darboux's memoir in Remark A.81. Nothing above rests on it, the proof being carried out in full. Stone's own paper on one-parameter unitary groups [707] is in the bibliography and is cited where it is used, in Appendix A.25; the modern treatment against which every step here can be checked is [1481], theorem VIII.14.

Remark A.595. Appendix A.49 discharges the derivation owed at Theorem 25.34 of Chapter 25, and with it the debt recorded in Remark 12.115 against Theorem 12.114 of Chapter 12 — the two are the same statement, and Remark 25.35 says that the proof belongs to Part II. Where the result is cashed is worth repeating. In Chapter 25 it is hypothesis (3) of Theorem 25.38: the theorem is what makes "the" Schrödinger representation a legitimate phrase, so that the Groenewold–van Hove obstruction obstructs a *quantization rule* and not merely one choice of Hilbert space. Its failure for infinitely many degrees of freedom, which Remark 25.37 and Remark 12.116 both record, is visible in the proof at exactly one place: the Gaussian weight of Equation (A.884) is a product over the f degrees of freedom, and for $f = \infty$ that product is not a measure on any space on which the argument could be run. Nothing here can be repaired to cover that case, and the physics of inequivalent vacua is the reason it should not be.

A.50 Hudson's Theorem: the Pure States of Non-Negative Wigner Function

This appendix proves Theorem 25.55 of Chapter 25: a pure state has a Wigner function that is non-negative everywhere if and only if its wavefunction is Gaussian. Together with Corollary 25.54 it is what makes negativity of the Wigner function an exact witness of departure from the Gaussian family, and the chapter uses it in that role.

Remark A.596 (A correction to the debt the chapter records). Remark 25.56 states that the converse half of the theorem "reduces it to one imported theorem — the Hadamard factorization of an entire function of order at most two" and records the absence of any order-and-genus theory in Chapter 8 as a debt of Part II. That is the standard route, and it is more than is needed. The only consequence of Hadamard's theorem this proof uses is that an entire function of one variable whose *real part* is bounded above by $A + B\,|\lambda|^2$ is a polynomial of degree at most two, and that statement follows in a dozen lines from the Taylor expansion Theorem 8.20 and the coefficient formula Equation (8.13), both of which Chapter 8 proves. It is Lemma A.608 below. Consequently this section quotes nothing, Part II is not in arrears on this account, and Remark 25.56 overstates the debt — which is worth saying plainly, because an unnecessary debt on the books is as misleading as a hidden one.

The other two statements of Remark 25.56 stand unchanged and are repeated in Remark A.614: the theorem is about pure states only, and Hudson's 1974 paper has no entry in this bibliography, so the attribution is made without a source the reader can check — which is exactly why the proof is written out.

A.50.1 Statement and conventions

Throughout, the system is one particle in three-dimensional space, as in Definition 25.52, and $\psi \in L^2(\mathbb{R}^3)$ is normalised. Its Wigner function is Equation (25.53) with $\rho = \psi\psi^*$, that

is

$$W(\boldsymbol{x},\boldsymbol{p}) = \frac{1}{(2\pi\hbar)^3}\int_{\mathbb{R}^3} \psi\Big(\boldsymbol{x}+\frac{\boldsymbol{y}}{2}\Big)\,\psi^*\Big(\boldsymbol{x}-\frac{\boldsymbol{y}}{2}\Big)\,\mathrm{e}^{-\mathrm{i}\boldsymbol{p}\cdot\boldsymbol{y}/\hbar}\,\mathrm{d}^3y\,, \tag{A.909}$$

carrying $1/(\mathrm{J}^3\,\mathrm{s}^3)$. For a complex symmetric 3×3 matrix A write $A_\mathrm{r} = \operatorname{Re} A$ and $A_\mathrm{i} = \operatorname{Im} A$, both real symmetric, and $A_\mathrm{r} > 0$ for positive definiteness. Bilinear, never Hermitian, products are meant throughout: $\boldsymbol{u}\cdot A\boldsymbol{v} = \sum_{jk} u_j A_{jk} v_k$ and $\boldsymbol{u}\cdot\boldsymbol{v} = \sum_j u_j v_j$, even for complex arguments.

Remark A.597 (Units, and what the constant in the exponent carries). In the Gaussian form $\psi(\boldsymbol{x}) = \exp(-\boldsymbol{x}\cdot A\boldsymbol{x} + \boldsymbol{b}\cdot\boldsymbol{x} + c)$ the exponent must be dimensionless, so A carries $1/\mathrm{m}^2$ and $\boldsymbol{b}$ carries $1/\mathrm{m}$; e^c is then whatever makes $|\psi|^2$ carry $1/\mathrm{m}^3$, so c is fixed only once a unit of length is chosen and it is cleaner to read the Gaussian family as $\psi = \mathcal{N}\exp(-\boldsymbol{x}\cdot A\boldsymbol{x} + \boldsymbol{b}\cdot\boldsymbol{x})$ with $\mathcal{N}$ the normalisation. Nothing below depends on which of the two readings is used, and $\hbar$ appears explicitly at every step where it appears at all: in the kernel of Equation (A.909), and in the auxiliary length s of Appendix A.50.4, which enters the combination $s^2\boldsymbol{p}/\hbar$ — a length, as it must be.

Theorem A.598 (Hudson). *Let $\psi \in L^2(\mathbb{R}^3)$ be normalised. Then $W \geq 0$ everywhere if and only if there are a complex symmetric matrix A with $A_\mathrm{r} > 0$, a vector $\boldsymbol{b}\in\mathbb{C}^3$ and a constant $c\in\mathbb{C}$ with*

$$\psi(\boldsymbol{x}) = \exp(-\boldsymbol{x}\cdot A\boldsymbol{x} + \boldsymbol{b}\cdot\boldsymbol{x} + c) \tag{A.910}$$

for almost every $\boldsymbol{x}$. When that holds, W is a strictly positive Gaussian on phase space.

Rests on Equations (25.53) and (25.56) and Theorem 8.20.

A.50.2 Gaussian integrals

Lemma A.599 (One variable, complex coefficient). *Let $a\in\mathbb{C}$ with $\operatorname{Re} a > 0$ and $w\in\mathbb{C}$. Then*

$$\int_{\mathbb{R}} \mathrm{e}^{-az^2+wz}\,\mathrm{d}z = \sqrt{\frac{\pi}{a}}\;\mathrm{e}^{w^2/4a}\,, \tag{A.911}$$

the square root being the principal branch, which is defined and holomorphic on the half-plane $\operatorname{Re} a > 0$.

Rests on Equation (17.42) and Theorems 7.77 and 8.6.

Proof. *Derives Lemma A.599.*

Both integrals converge absolutely, since $\left|\mathrm{e}^{-az^2+wz}\right| = \mathrm{e}^{-(\operatorname{Re} a)z^2+(\operatorname{Re} w)z}$.

The case $w = 0$. Put $I(a) = \int_{\mathbb{R}} \mathrm{e}^{-az^2}\mathrm{d}z$. Differentiating under the integral sign, which Theorem 7.77 licenses on any compact subset of the half-plane because the differentiated integrand is dominated there by $z^2\mathrm{e}^{-\varepsilon z^2}$ for some $\varepsilon > 0$, and checking the Cauchy–Riemann equations Equation (8.5) on the integrand, I is holomorphic with $I'(a) = -\int z^2\mathrm{e}^{-az^2}\mathrm{d}z$. Integrating that by parts, $\int z\cdot(z\mathrm{e}^{-az^2})\mathrm{d}z = \int z\cdot(-\frac{1}{2a})\frac{\mathrm{d}}{\mathrm{d}z}\mathrm{e}^{-az^2}\mathrm{d}z = \frac{1}{2a}\int \mathrm{e}^{-az^2}\mathrm{d}z$, the boundary terms vanishing. Hence

$$I'(a) = -\frac{I(a)}{2a}\,, \qquad \text{so} \qquad \frac{\mathrm{d}}{\mathrm{d}a}\Big(\sqrt{a}\,I(a)\Big) = 0 \tag{A.912}$$

on the half-plane, which is connected; and $\sqrt{1}\,I(1) = \sqrt{\pi}$ by the Gauss integral, itself the case $\omega = 0$ of Equation (17.42). So $I(a) = \sqrt{\pi/a}$.

General w. Put $J(w) = \int_{\mathbb{R}} \mathrm{e}^{-az^2+wz}\mathrm{d}z$ at fixed a. The same argument makes J entire with $J'(w) = \int z\,\mathrm{e}^{-az^2+wz}\mathrm{d}z$, and the same integration by parts, now carrying the factor e^{wz}, gives $J'(w) = \frac{w}{2a}J(w)$. With $J(0) = \sqrt{\pi/a}$ this integrates to Equation (A.911). □

Lemma A.600 (The real part of an inverse)**.** *Let M and S be real symmetric $n\times n$ matrices with $M>0$. Then $M+\mathrm{i}S$ is invertible and*

$$\operatorname{Re}\left[(M+\mathrm{i}S)^{-1}\right]=\left(M+SM^{-1}S\right)^{-1}>0\,. \tag{A.913}$$

Rests on Theorems 5.38 and 5.80.

Proof. *Derives Lemma A.600.*

Look for the inverse in the form $X+\mathrm{i}Y$ with X,Y real. The two equations $MX-SY=\mathbb{1}$ and $MY+SX=0$ give $Y=-M^{-1}SX$ and then $\left(M+SM^{-1}S\right)X=\mathbb{1}$. The matrix $M+SM^{-1}S$ is real symmetric and positive definite — it is a sum of a positive definite matrix and the positive semi-definite $SM^{-1}S$, since $v\cdot SM^{-1}Sv=(Sv)\cdot M^{-1}(Sv)\geq 0$ and $M^{-1}>0$ — hence invertible, and $X=(M+SM^{-1}S)^{-1}$ solves the pair. That exhibits an inverse, which is unique, and its real part is X. □

Lemma A.601 (Several variables, complex symmetric matrix)**.** *Let N be a complex symmetric $n\times n$ matrix with $N_{\mathrm{r}}>0$, and let $\boldsymbol{w}\in\mathbb{C}^n$. Then N is invertible, $\operatorname{Re}(N^{-1})>0$, and*

$$\int_{\mathbb{R}^n}\mathrm{e}^{-\boldsymbol{x}\cdot N\boldsymbol{x}+\boldsymbol{w}\cdot\boldsymbol{x}}\,\mathrm{d}^n x=C_N\,\mathrm{e}^{\boldsymbol{w}\cdot N^{-1}\boldsymbol{w}/4}\,, \tag{A.914}$$

with $C_N\neq 0$ depending on N alone; if N is real then $C_N=\pi^{n/2}\,(\det N)^{-1/2}>0$.

Rests on Lemmas A.599 and A.600 and Theorem 5.80.

Proof. *Derives Lemma A.601.*

Invertibility and $\operatorname{Re}(N^{-1})>0$ are Lemma A.600 with $M=N_{\mathrm{r}}$ and $S=N_{\mathrm{i}}$. For the integral, let R be the real symmetric positive-definite square root of N_{r}, which exists by Theorem 5.80 — diagonalise N_{r} orthogonally and take the positive square roots of its eigenvalues — and substitute $\boldsymbol{x}=R^{-1}\boldsymbol{y}$. Then $\boldsymbol{x}\cdot N\boldsymbol{x}=\boldsymbol{y}\cdot(\mathbb{1}+\mathrm{i}T)\boldsymbol{y}$ with $T=R^{-1}N_{\mathrm{i}}R^{-1}$ real symmetric. Diagonalise T orthogonally, $T=O^{\mathsf{T}}DO$ with $D=\operatorname{diag}(d_1,\dots,d_n)$, and substitute $\boldsymbol{y}=O^{\mathsf{T}}\boldsymbol{z}$; the quadratic form becomes $\sum_j(1+\mathrm{i}d_j)z_j^2$ and the linear form becomes $\boldsymbol{w}'\cdot\boldsymbol{z}$ with $\boldsymbol{w}'=OR^{-1}\boldsymbol{w}$. The integral factorises into n copies of Equation (A.911) with $a_j=1+\mathrm{i}d_j$, each of which has $\operatorname{Re}a_j=1>0$:

$$\int_{\mathbb{R}^n}\mathrm{e}^{-\boldsymbol{x}\cdot N\boldsymbol{x}+\boldsymbol{w}\cdot\boldsymbol{x}}\mathrm{d}^n x=\frac{1}{\det R}\prod_{j=1}^{n}\sqrt{\frac{\pi}{a_j}}\,\exp\left(\sum_j\frac{\left(w_j'\right)^2}{4a_j}\right)\,, \tag{A.915}$$

the Jacobian being $\left|\det(R^{-1}O^{\mathsf{T}})\right|=1/\det R$. The exponent reassembles as $\boldsymbol{w}'\cdot(\mathbb{1}+\mathrm{i}D)^{-1}\boldsymbol{w}'/4=\boldsymbol{w}\cdot R^{-1}O^{\mathsf{T}}(\mathbb{1}+\mathrm{i}D)^{-1}OR^{-1}\boldsymbol{w}/4=\boldsymbol{w}\cdot N^{-1}\boldsymbol{w}/4$, because $N=R(\mathbb{1}+\mathrm{i}T)R$. The prefactor is a non-zero constant determined by N, and for real N every d_j is zero and it is $\pi^{n/2}(\det N)^{-1/2}$. □

A.50.3 The easy direction

Proposition A.602 (The Wigner function of a Gaussian is a positive Gaussian)**.** *Let ψ be of the form Equation (A.910) with $A_{\mathrm{r}}>0$. Then, with $\boldsymbol{w}=-2A_{\mathrm{i}}\boldsymbol{x}+\operatorname{Im}\boldsymbol{b}-\boldsymbol{p}/\hbar$,*

$$W(\boldsymbol{x},\boldsymbol{p})=\frac{(2\pi)^{3/2}}{(2\pi\hbar)^3\sqrt{\det A_{\mathrm{r}}}}\,\exp\left(-2\boldsymbol{x}\cdot A_{\mathrm{r}}\boldsymbol{x}+2\operatorname{Re}\boldsymbol{b}\cdot\boldsymbol{x}+2\operatorname{Re}c-\tfrac{1}{2}\boldsymbol{w}\cdot A_{\mathrm{r}}^{-1}\boldsymbol{w}\right)\,, \tag{A.916}$$

which is real, strictly positive at every point of phase space, and Gaussian in $(\boldsymbol{x},\boldsymbol{p})$ jointly.

Rests on Equations (25.53) and (A.910) and Lemma A.601.

Proof. *Derives Proposition A.602.*

Put $\boldsymbol{u} = \boldsymbol{x} + \boldsymbol{y}/2$ and $\boldsymbol{v} = \boldsymbol{x} - \boldsymbol{y}/2$, so that the integrand of Equation (A.909) is $\exp(-\boldsymbol{u}\cdot A\boldsymbol{u} + \boldsymbol{b}\cdot\boldsymbol{u} + c - \boldsymbol{v}\cdot\overline{A}\boldsymbol{v} + \overline{\boldsymbol{b}}\cdot\boldsymbol{v} + \overline{c})$ times $\mathrm{e}^{-\mathrm{i}\boldsymbol{p}\cdot\boldsymbol{y}/\hbar}$. Expanding by symmetry of A,

$$\begin{aligned} -\boldsymbol{u}\cdot A\boldsymbol{u} - \boldsymbol{v}\cdot\overline{A}\boldsymbol{v} &= -\boldsymbol{x}\cdot\left(A+\overline{A}\right)\boldsymbol{x} - \boldsymbol{x}\cdot\left(A-\overline{A}\right)\boldsymbol{y} - \tfrac{1}{4}\boldsymbol{y}\cdot\left(A+\overline{A}\right)\boldsymbol{y} \\ &= -2\boldsymbol{x}\cdot A_{\mathrm{r}}\boldsymbol{x} - 2\mathrm{i}\,\boldsymbol{x}\cdot A_{\mathrm{i}}\boldsymbol{y} - \tfrac{1}{2}\boldsymbol{y}\cdot A_{\mathrm{r}}\boldsymbol{y}\,, \end{aligned} \tag{A.917}$$

while $\boldsymbol{b}\cdot\boldsymbol{u} + \overline{\boldsymbol{b}}\cdot\boldsymbol{v} = 2\,\mathrm{Re}\,\boldsymbol{b}\cdot\boldsymbol{x} + \mathrm{i}\,\mathrm{Im}\,\boldsymbol{b}\cdot\boldsymbol{y}$ and $c + \overline{c} = 2\,\mathrm{Re}\,c$. Collecting the terms carrying $\boldsymbol{y}$ and adding the Fourier kernel, the whole $\boldsymbol{y}$ dependence is $-\frac{1}{2}\boldsymbol{y}\cdot A_{\mathrm{r}}\boldsymbol{y} + \mathrm{i}\,\boldsymbol{y}\cdot\boldsymbol{w}$ with $\boldsymbol{w}$ as stated, a *real* vector. The remaining integral is Equation (A.914) with the real positive-definite $N = A_{\mathrm{r}}/2$ and $\boldsymbol{w} \to \mathrm{i}\boldsymbol{w}$, giving $(2\pi)^{3/2}(\det A_{\mathrm{r}})^{-1/2}\exp(-\frac{1}{2}\boldsymbol{w}\cdot A_{\mathrm{r}}^{-1}\boldsymbol{w})$. That is Equation (A.916). Every factor is real and positive: the exponential of a real number, and a positive constant. Since $\boldsymbol{w}$ is an affine function of $(\boldsymbol{x},\boldsymbol{p})$, the exponent is a real quadratic in $(\boldsymbol{x},\boldsymbol{p})$ and W is a Gaussian on phase space. □

A.50.4 Coherent states, and where the Wigner function cannot vanish

Fix once and for all a length $s > 0$ and put, for $\boldsymbol{x}_0, \boldsymbol{p}_0 \in \mathbb{R}^3$,

$$\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}(\boldsymbol{x}) = \left(\pi s^2\right)^{-3/4}\exp\!\left(-\frac{|\boldsymbol{x}-\boldsymbol{x}_0|^2}{2s^2} + \frac{\mathrm{i}\,\boldsymbol{p}_0\cdot\boldsymbol{x}}{\hbar}\right), \tag{A.918}$$

a normalised element of $L^2(\mathbb{R}^3)$ of the form Equation (A.910), with $A = \mathbb{1}/2s^2$, $\boldsymbol{b} = \boldsymbol{x}_0/s^2 + \mathrm{i}\boldsymbol{p}_0/\hbar$ and the appropriate c. It is exactly the vector $W(\zeta)\Omega_s$ of Proposition A.592, up to a phase: by Equation (A.904), $\big(W(\boldsymbol{\alpha},\boldsymbol{\beta})\Omega_s\big)(\boldsymbol{x}) = \mathrm{e}^{-\mathrm{i}\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/2\hbar}\varphi_{\boldsymbol{\beta},\boldsymbol{\alpha}}(\boldsymbol{x})$. That identification is used once, at the end of Appendix A.50.7.

Lemma A.603 (Overlaps and the resolution of unity)**.** *For any normalised ψ,*

$$|\langle\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi\rangle|^2 = (2\pi\hbar)^3\int W_{\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}}\,W_\psi\,\mathrm{d}^3x\,\mathrm{d}^3p\,, \tag{A.919}$$

and if $W_\psi \geq 0$ everywhere then

$$\int_{\mathbb{R}^3}\!\int_{\mathbb{R}^3}|\langle\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi\rangle|^2\;\mathrm{d}^3x_0\,\mathrm{d}^3p_0 = (2\pi\hbar)^3\,. \tag{A.920}$$

Rests on Equations (25.56) and (A.918) and Theorem 25.53.

Proof. *Derives Lemma A.603.*

For pure states $\hat\rho_1 = |\psi_1\rangle\langle\psi_1|$ and $\hat\rho_2 = |\psi_2\rangle\langle\psi_2|$ one has $\mathrm{tr}(\hat\rho_1\hat\rho_2) = \langle\psi_1|\psi_2\rangle\,\langle\psi_2|\psi_1\rangle = |\langle\psi_1|\psi_2\rangle|^2$, so Equation (25.56) is Equation (A.919).

For the second statement, note first that Equation (A.918) is $\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}(\boldsymbol{x}) = \mathrm{e}^{\mathrm{i}\boldsymbol{p}_0\cdot\boldsymbol{x}/\hbar}\,\varphi_{\boldsymbol{0},\boldsymbol{0}}(\boldsymbol{x}-\boldsymbol{x}_0)$, and that substituting this into Equation (A.909) makes the two exponential factors combine as $\mathrm{e}^{\mathrm{i}\boldsymbol{p}_0\cdot\boldsymbol{y}/\hbar}$ and shifts the argument, so that

$$W_{\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}}(\boldsymbol{x},\boldsymbol{p}) = W_{\varphi_{\boldsymbol{0},\boldsymbol{0}}}(\boldsymbol{x}-\boldsymbol{x}_0,\;\boldsymbol{p}-\boldsymbol{p}_0)\,. \tag{A.921}$$

By Proposition A.602 that function is a strictly positive Gaussian, and by Theorem 25.53 it integrates to 1 over phase space; hence $\iint W_{\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}}(\boldsymbol{x},\boldsymbol{p})\mathrm{d}^3x_0\mathrm{d}^3p_0 = 1$ for every $(\boldsymbol{x},\boldsymbol{p})$. Integrating Equation (A.919) over $(\boldsymbol{x}_0,\boldsymbol{p}_0)$ and exchanging the order of integration — legitimate because *every* integrand in sight is non-negative, which is where the hypothesis $W_\psi \geq 0$ is used — gives $(2\pi\hbar)^3\int W_\psi\mathrm{d}^3x\,\mathrm{d}^3p$, which is $(2\pi\hbar)^3$ by the normalisation clause of Theorem 25.53. □

Proposition A.604 (Non-negativity forbids a vanishing overlap)**.** *If $W_\psi \geq 0$ everywhere then $\langle \varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi\rangle \neq 0$ for every $\boldsymbol{x}_0$ and every $\boldsymbol{p}_0$.*

Rests on Lemma A.603, Proposition A.602, and Equation (25.54).

Proof. *Derives Proposition A.604.*

Suppose the overlap vanishes for some $(\boldsymbol{x}_0, \boldsymbol{p}_0)$. By Equation (A.919) the integral of $W_\varphi W_\psi$ over phase space is then zero. Both factors are non-negative — the first strictly positive everywhere by Proposition A.602, the second by hypothesis — so the product vanishes identically, and therefore W_ψ does. Integrating W_ψ over $\boldsymbol{p}$ and using Equation (25.54) gives $|\psi(\boldsymbol{x})|^2 = 0$ for every $\boldsymbol{x}$, contradicting $\|\psi\| = 1$. □

A.50.5 An entire function without zeros

Definition A.605 (The analytic continuation of the overlaps)**.** For $\zeta \in \mathbb{C}^3$ put

$$F(\zeta) = \int_{\mathbb{R}^3} \psi(\boldsymbol{x}) \, \exp\!\left(-\frac{(\boldsymbol{x}-\zeta)\cdot(\boldsymbol{x}-\zeta)}{2s^2}\right) \mathrm{d}^3x \,, \tag{A.922}$$

the product in the exponent being the bilinear one.

Rests on Equation (A.918) and Definition 25.52.

Lemma A.606 (F is entire, and is the overlap in disguise)**.** *The integral Equation (A.922) converges absolutely for every $\zeta \in \mathbb{C}^3$ and defines a function holomorphic in each variable separately and jointly continuous, hence entire on $\mathbb{C}^3$. Writing $\zeta = \boldsymbol{x}_0 - \mathrm{i}s^2\boldsymbol{p}_0/\hbar$ with $\boldsymbol{x}_0, \boldsymbol{p}_0 \in \mathbb{R}^3$,*

$$F(\zeta) = \kappa(\boldsymbol{x}_0,\boldsymbol{p}_0)\, \langle \varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi\rangle \,, \qquad \kappa = \left(\pi s^2\right)^{3/4} \mathrm{e}^{|\operatorname{Im}\zeta|^2/2s^2}\, \mathrm{e}^{\mathrm{i}\boldsymbol{x}_0\cdot\boldsymbol{p}_0/\hbar} \neq 0 \,, \tag{A.923}$$

and consequently

$$|F(\zeta)| \leq \left(\pi s^2\right)^{3/4} \exp\!\left(\frac{|\operatorname{Im}\zeta|^2}{2s^2}\right) . \tag{A.924}$$

Rests on Definition A.605, Theorem 8.6, and Proposition 12.4.

Proof. *Derives Lemma A.606.*

Write $\zeta = \boldsymbol{\xi} + \mathrm{i}\boldsymbol{\eta}$. Then $(\boldsymbol{x}-\zeta)\cdot(\boldsymbol{x}-\zeta) = |\boldsymbol{x}-\boldsymbol{\xi}|^2 - |\boldsymbol{\eta}|^2 - 2\mathrm{i}(\boldsymbol{x}-\boldsymbol{\xi})\cdot\boldsymbol{\eta}$, so the modulus of the kernel is $\mathrm{e}^{|\boldsymbol{\eta}|^2/2s^2}\mathrm{e}^{-|\boldsymbol{x}-\boldsymbol{\xi}|^2/2s^2}$, a Gaussian in $\boldsymbol{x}$; its product with $|\psi|$ is integrable by Cauchy–Schwarz (Proposition 12.4), and the bound is locally uniform in ζ. Differentiating under the integral sign in the real and imaginary parts of each ζ_k — licensed by Theorem 7.77 on bounded regions together with the locally uniform domination just displayed, which controls the tails — shows that F has continuous first partial derivatives and that they satisfy the Cauchy–Riemann equations Equation (8.5) in each variable, because the integrand does. Hence F is holomorphic in each variable, and being continuous it is entire on $\mathbb{C}^3$.

For Equation (A.923), substitute $\zeta = \boldsymbol{x}_0 - \mathrm{i}s^2\boldsymbol{p}_0/\hbar$, so that $\boldsymbol{x}-\zeta = (\boldsymbol{x}-\boldsymbol{x}_0) + \mathrm{i}s^2\boldsymbol{p}_0/\hbar$ and

$$-\frac{(\boldsymbol{x}-\zeta)\cdot(\boldsymbol{x}-\zeta)}{2s^2} = -\frac{|\boldsymbol{x}-\boldsymbol{x}_0|^2}{2s^2} - \frac{\mathrm{i}(\boldsymbol{x}-\boldsymbol{x}_0)\cdot\boldsymbol{p}_0}{\hbar} + \frac{s^2|\boldsymbol{p}_0|^2}{2\hbar^2} \,. \tag{A.925}$$

The first two terms are the exponent of $\overline{\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}}$ up to the constant $(\pi s^2)^{-3/4}$ and the phase $\mathrm{e}^{\mathrm{i}\boldsymbol{x}_0\cdot\boldsymbol{p}_0/\hbar}$, and the third is $|\operatorname{Im}\zeta|^2/2s^2$ because $\operatorname{Im}\zeta = -s^2\boldsymbol{p}_0/\hbar$. That is Equation (A.923). Finally $|\langle\varphi|\psi\rangle| \leq \|\varphi\|\,\|\psi\| = 1$ by Cauchy–Schwarz, which with $|\kappa|$ as displayed gives Equation (A.924); and every $\zeta \in \mathbb{C}^3$ arises from exactly one pair $(\boldsymbol{x}_0,\boldsymbol{p}_0)$, namely $\boldsymbol{x}_0 = \operatorname{Re}\zeta$ and $\boldsymbol{p}_0 = -\hbar\operatorname{Im}\zeta/s^2$. □

Lemma A.607 (A zero-free entire function is an exponential)**.** *Let F be entire on $\mathbb{C}^n$ with $F(\zeta) \neq 0$ for every ζ. Then there is an entire g on $\mathbb{C}^n$ with $F = \mathrm{e}^g$.*

Rests on Lemma A.606 and Theorems 7.77 and 8.6.

Proof. *Derives Lemma A.607.*

Choose $c_0 \in \mathbb{C}$ with $\mathrm{e}^{c_0} = F(0)$, possible because $F(0) \neq 0$, and set

$$g(\zeta) = c_0 + \int_0^1 \sum_{j=1}^{n} \zeta_j \, \frac{(\partial_j F)(t\zeta)}{F(t\zeta)} \, \mathrm{d}t \,. \tag{A.926}$$

The integrand is continuous in t and holomorphic in ζ, since F is entire and non-vanishing, so g is entire by the same combination of Theorem 7.77 and Equation (8.5) used in Lemma A.606. Fix ζ and substitute $u = vt$ in Equation (A.926) written at the point $t\zeta$; the result is $g(t\zeta) = c_0 + \int_0^t \sum_j \zeta_j (\partial_j F)(u\zeta)/F(u\zeta)\,\mathrm{d}u$, so

$$\frac{\mathrm{d}}{\mathrm{d}t}\, g(t\zeta) = \sum_j \zeta_j \frac{(\partial_j F)(t\zeta)}{F(t\zeta)} = \frac{1}{F(t\zeta)} \frac{\mathrm{d}}{\mathrm{d}t} F(t\zeta) \,, \tag{A.927}$$

the last step by the chain rule. Hence $\frac{\mathrm{d}}{\mathrm{d}t}\big[F(t\zeta)\mathrm{e}^{-g(t\zeta)}\big] = 0$, so $F(\zeta)\mathrm{e}^{-g(\zeta)} = F(0)\mathrm{e}^{-c_0} = 1$. □

Lemma A.608 (An entire function with a quadratic bound on its real part)**.** *Let u be entire on $\mathbb{C}$ and suppose there are real constants A and B with $\operatorname{Re} u(\lambda) \leq A + B\,|\lambda|^2$ for all λ. Then u is a polynomial of degree at most two.*

Rests on Theorems 8.18 and 8.20 and Equation (8.13).

Proof. *Derives Lemma A.608.*

By Theorem 8.20 the Taylor series $u(\lambda) = \sum_{k\geq 0} a_k \lambda^k$ converges on every disc. Fix $r > 0$. The series converges uniformly on the circle $|\lambda| = r$, so it may be integrated term by term against $\mathrm{e}^{-\mathrm{i}k\vartheta}$, and for $k \geq 0$

$$a_k r^k = \frac{1}{2\pi} \int_0^{2\pi} u\Big(r\mathrm{e}^{\mathrm{i}\vartheta}\Big)\, \mathrm{e}^{-\mathrm{i}k\vartheta}\, \mathrm{d}\vartheta \,, \qquad 0 = \frac{1}{2\pi} \int_0^{2\pi} u\Big(r\mathrm{e}^{\mathrm{i}\vartheta}\Big)\, \mathrm{e}^{+\mathrm{i}k\vartheta}\, \mathrm{d}\vartheta \quad (k \geq 1) \,, \tag{A.928}$$

the first being Equation (8.13) written on the circle and the second holding because every term of the series then carries a strictly positive power of $\mathrm{e}^{\mathrm{i}\vartheta}$. Conjugating the second identity and adding it to the first gives, for $k \geq 1$,

$$a_k r^k = \frac{1}{\pi} \int_0^{2\pi} \operatorname{Re} u\Big(r\mathrm{e}^{\mathrm{i}\vartheta}\Big)\, \mathrm{e}^{-\mathrm{i}k\vartheta}\, \mathrm{d}\vartheta \,. \tag{A.929}$$

Write $\mu(r) = A + Br^2$, so that $\operatorname{Re} u(r\mathrm{e}^{\mathrm{i}\vartheta}) \leq \mu(r)$ by hypothesis, and subtract the constant $\mu(r)$ inside Equation (A.929), which changes nothing because $\int_0^{2\pi} \mathrm{e}^{-\mathrm{i}k\vartheta}\mathrm{d}\vartheta = 0$ for $k \geq 1$. Bounding the modulus of the integral by the integral of the modulus, and using that $\mu(r) - \operatorname{Re} u$ is non-negative so that its modulus is itself,

$$|a_k|\, r^k \leq \frac{1}{\pi} \int_0^{2\pi} \Big(\mu(r) - \operatorname{Re} u\Big(r\mathrm{e}^{\mathrm{i}\vartheta}\Big)\Big)\, \mathrm{d}\vartheta = 2\,(\mu(r) - \operatorname{Re} a_0) \,, \tag{A.930}$$

the mean of $\operatorname{Re} u$ over the circle being $\operatorname{Re} a_0$ by the case $k = 0$ of Equation (A.928). Hence for every $k \geq 1$

$$|a_k| \leq \frac{2\,(A + Br^2 - \operatorname{Re} a_0)}{r^k} \,, \tag{A.931}$$

and for $k \geq 3$ the right-hand side tends to 0 as $r \to \infty$. So $a_k = 0$ for $k \geq 3$. □

Proposition A.609 (The exponent is a quadratic polynomial)**.** *If $W_\psi \geq 0$ everywhere then there are a complex symmetric 3×3 matrix Γ, a vector $\boldsymbol{\lambda} \in \mathbb{C}^3$ and a constant $\nu \in \mathbb{C}$ with*

$$F(\zeta) = \exp(-\zeta \cdot \Gamma\zeta + \boldsymbol{\lambda} \cdot \zeta + \nu) \,, \qquad \zeta \in \mathbb{C}^3 \,. \tag{A.932}$$

Rests on Proposition A.604 and Lemmas A.607 and A.608.

Proof. *Derives Proposition A.609.*

By Lemma A.606 and Proposition A.604 the entire function F has no zeros: $F(\zeta)$ is a non-zero multiple of an overlap that never vanishes. So $F = \mathrm{e}^{g}$ with g entire, by Lemma A.607, and Equation (A.924) gives

$$\operatorname{Re} g(\zeta) = \log|F(\zeta)| \le \tfrac{3}{4}\log\!\left(\pi s^2\right) + \frac{|\zeta|^2}{2s^2}\,, \tag{A.933}$$

since $|\operatorname{Im}\zeta| \le |\zeta|$.

Fix $\boldsymbol{\beta} \in \mathbb{C}^3$ and consider $u_{\boldsymbol{\beta}}(\lambda) = g(\lambda\boldsymbol{\beta})$, entire in the single variable λ because g is entire and $\lambda \mapsto \lambda\boldsymbol{\beta}$ is holomorphic. By Equation (A.933), $\operatorname{Re} u_{\boldsymbol{\beta}}(\lambda) \le \frac{3}{4}\log(\pi s^2) + |\boldsymbol{\beta}|^2\,|\lambda|^2/2s^2$, so Lemma A.608 makes $u_{\boldsymbol{\beta}}$ a polynomial of degree at most two:

$$g(\lambda\boldsymbol{\beta}) = g(0) + \lambda\,\frac{\mathrm{d}}{\mathrm{d}\lambda}\bigg|_0 g(\lambda\boldsymbol{\beta}) + \frac{\lambda^2}{2}\,\frac{\mathrm{d}^2}{\mathrm{d}\lambda^2}\bigg|_0 g(\lambda\boldsymbol{\beta})\,, \tag{A.934}$$

exactly, with no remainder. The two derivatives are computed by the chain rule: $\mathrm{d}g(\lambda\boldsymbol{\beta})/\mathrm{d}\lambda|_0 = \sum_j \beta_j\,\partial_j g(0)$ and $\mathrm{d}^2 g(\lambda\boldsymbol{\beta})/\mathrm{d}\lambda^2|_0 = \sum_{j,k}\beta_j\beta_k\,\partial_j\partial_k g(0)$. Setting $\lambda = 1$ and renaming $\boldsymbol{\beta}$ as ζ, which is legitimate because $\boldsymbol{\beta}$ was arbitrary,

$$g(\zeta) = g(0) + \sum_j \zeta_j\,\partial_j g(0) + \frac{1}{2}\sum_{j,k}\zeta_j\zeta_k\,\partial_j\partial_k g(0)\,, \tag{A.935}$$

which is Equation (A.932) with $\Gamma_{jk} = -\frac{1}{2}\partial_j\partial_k g(0)$, symmetric because mixed holomorphic partial derivatives commute, $\lambda_j = \partial_j g(0)$ and $\nu = g(0)$. Note that no theorem about Taylor expansions in several variables was used: the expansion was performed along one complex line at a time, and Lemma A.608 guaranteed that on every such line it terminates. □

A.50.6 What normalisability forces

The quadratic form Γ is not arbitrary, and the constraint it obeys is exactly the one that will make the recovered wavefunction square integrable. Write $\Gamma_{\mathrm{r}} = \operatorname{Re}\Gamma$ and $\Gamma_{\mathrm{i}} = \operatorname{Im}\Gamma$.

Lemma A.610 (Block positivity)**.** *Let P_{11}, P_{12} and P_{22} be real $n \times n$ matrices with P_{11} and P_{22} symmetric. The real symmetric form $Q(\boldsymbol{\xi},\boldsymbol{\eta}) = \boldsymbol{\xi}\cdot P_{11}\boldsymbol{\xi} + 2\boldsymbol{\xi}\cdot P_{12}\boldsymbol{\eta} + \boldsymbol{\eta}\cdot P_{22}\boldsymbol{\eta}$ on $\mathbb{R}^{2n}$ is positive definite if and only if $P_{22} > 0$ and $P_{11} - P_{12}P_{22}^{-1}P_{12}^{\mathsf{T}} > 0$.*

Rests on Theorems 5.38 and 5.80.

Proof. *Derives Lemma A.610.*

If $P_{22} > 0$, complete the square: with $\boldsymbol{\eta}' = \boldsymbol{\eta} + P_{22}^{-1}P_{12}^{\mathsf{T}}\boldsymbol{\xi}$,

$$Q = \boldsymbol{\eta}'\cdot P_{22}\boldsymbol{\eta}' + \boldsymbol{\xi}\cdot\left(P_{11} - P_{12}P_{22}^{-1}P_{12}^{\mathsf{T}}\right)\boldsymbol{\xi}\,, \tag{A.936}$$

as one checks by expanding. The map $(\boldsymbol{\xi},\boldsymbol{\eta}) \mapsto (\boldsymbol{\xi},\boldsymbol{\eta}')$ is a linear bijection of $\mathbb{R}^{2n}$, so $Q > 0$ if and only if the right-hand side is positive for every non-zero $(\boldsymbol{\xi},\boldsymbol{\eta}')$, which is the stated pair of conditions. Conversely $Q > 0$ forces $P_{22} > 0$, by setting $\boldsymbol{\xi} = \mathbf{0}$, after which the displayed identity applies. □

Proposition A.611 (The constraint on Γ)**.** *With Γ as in Equation (A.932) and $W_\psi \ge 0$, the real symmetric form*

$$Q(\boldsymbol{\xi},\boldsymbol{\eta}) = \boldsymbol{\xi}\cdot\Gamma_{\mathrm{r}}\boldsymbol{\xi} - 2\,\boldsymbol{\xi}\cdot\Gamma_{\mathrm{i}}\boldsymbol{\eta} + \boldsymbol{\eta}\cdot\left(\frac{\mathbb{1}}{2s^2} - \Gamma_{\mathrm{r}}\right)\boldsymbol{\eta} \tag{A.937}$$

is positive definite on $\mathbb{R}^6$. Equivalently, $\Gamma_{\mathrm{r}} < \mathbb{1}/2s^2$ and

$$\Gamma_{\mathrm{r}} - \Gamma_{\mathrm{i}}\left(\frac{\mathbb{1}}{2s^2} - \Gamma_{\mathrm{r}}\right)^{-1}\Gamma_{\mathrm{i}} > 0\,. \tag{A.938}$$

Rests on Lemmas A.603 and A.610 and Proposition A.609.

Proof. *Derives Proposition A.611.*

By Equation (A.923), $|\langle\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi\rangle| = (\pi s^2)^{-3/4}\,|F(\zeta)|\,\mathrm{e}^{-|\mathrm{Im}\,\zeta|^2/2s^2}$ with $\zeta = \boldsymbol{\xi} + \mathrm{i}\boldsymbol{\eta}$, $\boldsymbol{\xi} = \boldsymbol{x}_0$ and $\boldsymbol{\eta} = -s^2\boldsymbol{p}_0/\hbar$. That substitution has Jacobian $\mathrm{d}^3x_0\,\mathrm{d}^3p_0 = (\hbar/s^2)^3\mathrm{d}^3\xi\,\mathrm{d}^3\eta$, so Equation (A.920) says that

$$\int_{\mathbb{R}^6} \exp\left(2\,\mathrm{Re}\,g(\boldsymbol{\xi}+\mathrm{i}\boldsymbol{\eta}) - \frac{|\boldsymbol{\eta}|^2}{s^2}\right)\mathrm{d}^3\xi\,\mathrm{d}^3\eta = (2\pi\hbar)^3\left(\pi s^2\right)^{3/2}\left(\frac{s^2}{\hbar}\right)^3 < \infty\,. \tag{A.939}$$

Now compute the real part of the exponent from Equation (A.932). Since $\zeta\cdot\Gamma\zeta = \boldsymbol{\xi}\cdot\Gamma\boldsymbol{\xi} - \boldsymbol{\eta}\cdot\Gamma\boldsymbol{\eta} + 2\mathrm{i}\,\boldsymbol{\xi}\cdot\Gamma\boldsymbol{\eta}$,

$$\mathrm{Re}\,g(\boldsymbol{\xi}+\mathrm{i}\boldsymbol{\eta}) = -\boldsymbol{\xi}\cdot\Gamma_\mathrm{r}\boldsymbol{\xi} + \boldsymbol{\eta}\cdot\Gamma_\mathrm{r}\boldsymbol{\eta} + 2\,\boldsymbol{\xi}\cdot\Gamma_\mathrm{i}\boldsymbol{\eta} + L(\boldsymbol{\xi},\boldsymbol{\eta})\,, \tag{A.940}$$

with L real affine. The exponent of Equation (A.939) is therefore $-2Q(\boldsymbol{\xi},\boldsymbol{\eta}) + 2L$, with Q as in Equation (A.937). An integral $\int_{\mathbb{R}^6}\mathrm{e}^{-2Q+2L}$ over the whole space is finite if and only if the quadratic part Q is positive definite: if some $(\boldsymbol{\xi}_0,\boldsymbol{\eta}_0)\neq 0$ had $Q(\boldsymbol{\xi}_0,\boldsymbol{\eta}_0)\leq 0$ then along the ray $t(\boldsymbol{\xi}_0,\boldsymbol{\eta}_0)$ the integrand would be at least e^{2tL_0} with L_0 the value of the linear part, which is bounded below on the ray only if $L_0\geq 0$ and in either case the integral over a solid cone about the ray diverges, Q being continuous and hence bounded above on a neighbourhood of the ray. So $Q>0$, and Lemma A.610 with $P_{22} = \mathbb{1}/2s^2 - \Gamma_\mathrm{r}$ and $P_{12} = -\Gamma_\mathrm{i}$ turns that into Equation (A.938) together with $P_{22}>0$. □

A.50.7 Recovering the wavefunction

Proposition A.612 (The dictionary between A and Γ)**.** *Let A be complex symmetric with $A_\mathrm{r}>0$ and put $N = A+\mathbb{1}/2s^2$, so that $N_\mathrm{r}>0$. Then the function $\psi_0 = \exp(-\boldsymbol{x}\cdot A\boldsymbol{x}+\boldsymbol{b}\cdot\boldsymbol{x}+c)$ has*

$$F_0(\zeta) = \exp(-\zeta\cdot\Gamma\zeta + \boldsymbol{\lambda}\cdot\zeta + \nu)\,,\qquad \Gamma = \frac{\mathbb{1}}{2s^2} - \frac{N^{-1}}{4s^4}\,, \tag{A.941}$$

for suitable $\boldsymbol{\lambda}$ and ν. Conversely, a complex symmetric Γ arises this way from exactly one such A if and only if it satisfies the conditions of Proposition A.611.

Rests on Lemmas A.600 and A.601 and Proposition A.611.

Proof. *Derives Proposition A.612.*

Forward. Insert ψ_0 into Equation (A.922). Expanding $(\boldsymbol{x}-\zeta)\cdot(\boldsymbol{x}-\zeta) = |\boldsymbol{x}|_*^2 - 2\zeta\cdot\boldsymbol{x}+\zeta\cdot\zeta$, where $|\boldsymbol{x}|_*^2 = \boldsymbol{x}\cdot\boldsymbol{x}$, the exponent is $-\boldsymbol{x}\cdot N\boldsymbol{x} + (\boldsymbol{b}+\zeta/s^2)\cdot\boldsymbol{x} + c - \zeta\cdot\zeta/2s^2$, and Equation (A.914) evaluates the integral as $C_N\exp\left[(\boldsymbol{b}+\zeta/s^2)\cdot N^{-1}(\boldsymbol{b}+\zeta/s^2)/4 + c - \zeta\cdot\zeta/2s^2\right]$. The part quadratic in ζ is $\zeta\cdot N^{-1}\zeta/4s^4 - \zeta\cdot\zeta/2s^2$, which is $-\zeta\cdot\Gamma\zeta$ with Γ as in Equation (A.941); the rest is affine in ζ and supplies $\boldsymbol{\lambda}$ and ν.

Converse. Solving Equation (A.941) for N gives $N^{-1} = K$ with

$$K = 4s^4\left(\frac{\mathbb{1}}{2s^2} - \Gamma\right) = 2s^2\mathbb{1} - 4s^4\Gamma\,,\qquad K_\mathrm{r} = 4s^4\left(\frac{\mathbb{1}}{2s^2} - \Gamma_\mathrm{r}\right)\,,\quad K_\mathrm{i} = -4s^4\Gamma_\mathrm{i}\,. \tag{A.942}$$

The first condition of Proposition A.611, $\Gamma_\mathrm{r} < \mathbb{1}/2s^2$, is exactly $K_\mathrm{r}>0$, which by Lemma A.600 makes K invertible; set $N = K^{-1}$ and $A = N - \mathbb{1}/2s^2$, complex symmetric and uniquely determined. It remains to show that $A_\mathrm{r}>0$ is equivalent to Equation (A.938). By Equation (A.913),

$$N_\mathrm{r} = \mathrm{Re}\left(K^{-1}\right) = \left(K_\mathrm{r} + K_\mathrm{i}K_\mathrm{r}^{-1}K_\mathrm{i}\right)^{-1}\,, \tag{A.943}$$

so, $A_\mathrm{r} = N_\mathrm{r} - \mathbb{1}/2s^2$ and both matrices being real symmetric with the inverse order-reversing on positive definite matrices,

$$A_\mathrm{r}>0 \iff N_\mathrm{r} > \frac{\mathbb{1}}{2s^2} \iff K_\mathrm{r} + K_\mathrm{i}K_\mathrm{r}^{-1}K_\mathrm{i} < 2s^2\mathbb{1}\,. \tag{A.944}$$

Substituting Equation (A.942), the left-hand side is $2s^2\mathbb{1} - 4s^4\Gamma_{\mathrm{r}} + 4s^4\Gamma_{\mathrm{i}}(\mathbb{1}/2s^2 - \Gamma_{\mathrm{r}})^{-1}\Gamma_{\mathrm{i}}$, the factors $4s^4$ cancelling against the inverse of K_{r}; so the last inequality of Equation (A.944) is $\Gamma_{\mathrm{i}}(\mathbb{1}/2s^2 - \Gamma_{\mathrm{r}})^{-1}\Gamma_{\mathrm{i}} < \Gamma_{\mathrm{r}}$, which is Equation (A.938). □

Proof of Theorem A.598. *Derives Theorem A.598.*

The "if" half is Proposition A.602, which also gives the last sentence of the theorem.

For the "only if" half, let $W_\psi \geq 0$ everywhere. By Proposition A.609 the entire function F of Equation (A.922) is e^g with g a quadratic polynomial, of matrix Γ; by Proposition A.611 that Γ satisfies the positivity conditions; and by Proposition A.612 there is therefore exactly one complex symmetric A with $A_{\mathrm{r}} > 0$, together with a $\boldsymbol{b}$ and a c matching the affine part, such that the Gaussian $\psi_0 = \exp(-\boldsymbol{x}\cdot A\boldsymbol{x} + \boldsymbol{b}\cdot\boldsymbol{x} + c)$ has $F_0 = F$. Because $A_{\mathrm{r}} > 0$, ψ_0 lies in $L^2(\mathbb{R}^3)$.

Both ψ and ψ_0 therefore have the same overlaps with every coherent state: by Equation (A.923) applied to each of them, and with the same non-vanishing factor κ,

$$\langle\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi\rangle = \frac{F(\zeta)}{\kappa} = \frac{F_0(\zeta)}{\kappa} = \langle\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}|\psi_0\rangle\ , \tag{A.945}$$

for every $\boldsymbol{x}_0$ and $\boldsymbol{p}_0$. Hence $\psi - \psi_0 \in L^2(\mathbb{R}^3)$ is orthogonal to every $\varphi_{\boldsymbol{x}_0,\boldsymbol{p}_0}$, that is to every $W(\zeta)\Omega_s$, and those vectors are total in $L^2(\mathbb{R}^3)$ by Proposition A.592. So $\psi = \psi_0$ in L^2, which is Equation (A.910) almost everywhere. □

A.50.8 Scope, and what is quoted

Remark A.613 (What is quoted here). Nothing. Remark A.596 explains why the Hadamard factorization theorem, named as the import in Remark 25.56, is not needed: Lemma A.608 replaces it and is proved from Theorem 8.20 and Equation (8.13). The other inputs are the spectral theorem for a real symmetric matrix (Theorem 5.80), differentiation under the integral sign (Theorem 7.77), the Cauchy–Riemann criterion (Theorem 8.6), the Gaussian transform pair (Equation (17.42)), the Wigner-function properties (Theorem 25.53, in particular the overlap identity Equation (25.56)), and the totality of the coherent states, proved in Proposition A.592 of Appendix A.49. Every one of them is proved in this book.

The auxiliary width s is arbitrary, exactly as in Remark A.588: it enters the definitions of φ, F and Γ and cancels out of the conclusion, which mentions only A. A reader who repeats the argument with a different s obtains a different Γ and the same ψ.

Remark A.614 (What the theorem does not say). Two limits, both stated in Remark 25.56 and both worth repeating where the proof can be pointed at.

The theorem is about *pure* states, and the restriction is essential rather than technical: every step from Proposition A.604 onwards uses that W_ψ is built from a single wavefunction, through the identity Equation (A.919) in which the right-hand side is $|\langle\varphi|\psi\rangle|^2$ and not merely a trace. Mixed states with everywhere non-negative Wigner function that are not mixtures of Gaussians do exist, so "non-negative Wigner function" and "classical" are not synonyms in general, and Corollary 25.54 is an exact witness only inside the pure family.

And the attribution stands without a source the reader of this book can check: Hudson's 1974 paper, *When is the Wigner quasi-probability density non-negative?* (Reports on Mathematical Physics **6**, 249–252), has no entry in this bibliography, and the several-variable form used here is due to Soto and Claverie (1983). Both are cited in words only, on the footing of Darboux's memoir in Remark A.81. That is precisely why the proof is written out in full: nothing in Chapter 25 rests on the attribution.

Remark A.615. Appendix A.50 discharges the derivation owed at Theorem 25.55 of Chapter 25. Its use there is as the converse half of Corollary 25.54: that corollary exhibits states whose Wigner function reaches the most negative value Equation (25.57) permits, and the theorem proved here says that the ones which avoid negativity altogether are exactly the

Gaussians — so that within the pure states, negativity of W and non-Gaussianity are the same property, and an experiment that reconstructs a Wigner function and finds it negative has measured a departure from the Gaussian family and nothing weaker. The two sections of this appendix that serve Chapter 25 are linked in one direction: Appendix A.49 supplies the totality of the coherent states used at the end of the proof above, and both are built on the same Gaussian, Equation (A.902) there and Equation (A.918) here.

A.51 The Jacobi Identity for the Dirac Bracket

This appendix proves the one clause of Theorem 26.21 of Chapter 26 that the chapter defers: the Dirac bracket Equation (26.25) obeys the Jacobi identity Equation (22.46). Bilinearity, antisymmetry, the Leibniz rule Equation (24.24), the strong vanishing Equation (26.26) and the two statements Equations (26.27) and (26.28) are one-line computations and are done in the chapter; the identity below is what earns the object the name *bracket*, because without it the correspondence rule Equation (25.31) would send it to something that is not a commutator.

Two independent routes are written out, as the chapter's prose promises. Appendix A.51.2 is the direct expansion: it uses nothing but the Poisson Jacobi identity Equation (22.46), the derivation property Proposition 25.4 and the antisymmetry of C^{-1}, and it is the route that shows *where* the identity comes from — every one of the four orders in C^{-1} cancels for its own reason, and three of the four reasons are the Poisson Jacobi identity applied to a different triple. Appendix A.51.3 is the structural route: the Dirac bracket is the Poisson bracket of the symplectic manifold that Proposition 26.25 constructs on the second-class surface, and the identity is then read off the closure of a two-form. The second is three paragraphs long and is the one to remember; it is written second because it consumes Proposition 26.25, which is proved in the chapter after the Dirac bracket is introduced.

Nothing outside this treatise is used anywhere in this section.

A.51.1 Notation, and the four identities consumed

Throughout, χ_α, $\alpha = 1, \dots, S$, is a complete set of second-class constraints in the sense of Definition 26.12, $C_{\alpha\beta} = \{\chi_\alpha, \chi_\beta\}$ is the matrix Equation (26.24), which is invertible on a neighbourhood of the constraint surface by Proposition 26.19 and continuity, and

$$D^{\alpha\beta} := \left(C^{-1}\right)^{\alpha\beta}, \qquad D^{\alpha\gamma}C_{\gamma\beta} = \delta^\alpha_\beta, \qquad D^{\alpha\beta} = -D^{\beta\alpha}. \tag{A.946}$$

The antisymmetry of D is proved in the chapter, in the antisymmetry step of Theorem 26.21: $C^{\mathsf{T}} = -C$ gives $\left(C^{-1}\right)^{\mathsf{T}} = \left(C^{\mathsf{T}}\right)^{-1} = -C^{-1}$. That S is even, so that such a C can exist at all, is Proposition 26.19. With this notation Equation (26.25) reads

$$\{A, B\}_{\mathrm{D}} = \{A, B\} + A_\alpha D^{\alpha\beta} B_\beta, \qquad \text{where} \qquad A_\alpha := \{A, \chi_\alpha\}, \tag{A.947}$$

the sign having flipped because $\{\chi_\beta, B\} = -B_\beta$. Two further abbreviations carry the whole computation:

$$A_{\alpha\beta} := \{\{A, \chi_\alpha\}, \chi_\beta\} = \{A_\alpha, \chi_\beta\}, \qquad \widehat{A}^\alpha := A_\beta D^{\beta\alpha}. \tag{A.948}$$

Note that $A_{\alpha\beta}$ is *not* symmetric — its antisymmetric part is Equation (A.949) below — and that the index of $\widehat{A}$ is raised from the left, so that $A_\alpha D^{\alpha\beta} B_\beta = \widehat{A}^\beta B_\beta$ while $D^{\alpha\beta} B_\beta = -\widehat{B}^\alpha$.

Dimensionally there is nothing to watch: $D^{\alpha\beta}$ carries the inverse of the dimension of $C_{\alpha\beta}$, so the correction term of Equation (A.947) has exactly the dimension of $\{A, B\}$, whatever SI dimensions the individual χ_α happen to have. Nothing below depends on the constraints being dimensionally homogeneous among themselves.

Lemma A.616 (The four identities)**.** *For all phase-space functions A, B, E, wherever C^{-1} is defined,*

$$\{A, C_{\alpha\beta}\} = A_{\alpha\beta} - A_{\beta\alpha}\,, \tag{A.949}$$

$$\{\{B, E\}, \chi_\delta\} = \{B, E_\delta\} - \{E, B_\delta\}\,, \tag{A.950}$$

$$\left\{A, D^{\alpha\beta}\right\} = -D^{\alpha\mu}\{A, C_{\mu\nu}\}D^{\nu\beta}\,, \tag{A.951}$$

$$T_{\alpha\beta\gamma} + T_{\beta\gamma\alpha} + T_{\gamma\alpha\beta} = 0\,, \qquad T_{\alpha\beta\gamma} := \{C_{\alpha\beta}, \chi_\gamma\}\,. \tag{A.952}$$

Rests on Equations (22.46) and (26.24) and Proposition 25.4.

Proof. *Derives Lemma A.616.*

Three of the four are the Poisson Jacobi identity Equation (22.46) applied to a different triple, and the fourth is the derivative of an inverse.

Equation (A.949). Take the triple $(A, \chi_\alpha, \chi_\beta)$ in Equation (22.46):

$$\{A, \{\chi_\alpha, \chi_\beta\}\} + \{\chi_\alpha, \{\chi_\beta, A\}\} + \{\chi_\beta, \{A, \chi_\alpha\}\} = 0\,. \tag{A.953}$$

The second term is $\{\chi_\alpha, -A_\beta\} = +A_{\beta\alpha}$ and the third is $\{\chi_\beta, A_\alpha\} = -A_{\alpha\beta}$, which gives Equation (A.949).

Equation (A.950). Take the triple (χ_δ, B, E): $\{\chi_\delta, \{B, E\}\} + \{B, \{E, \chi_\delta\}\} + \{E, \{\chi_\delta, B\}\} = 0$, that is $-\{\{B, E\}, \chi_\delta\} + \{B, E_\delta\} - \{E, B_\delta\} = 0$.

Equation (A.951). The map $X \longmapsto \{A, X\}$ is a derivation (Proposition 25.4), so applying it to $D^{\alpha\mu}C_{\mu\beta} = \delta^\alpha_\beta$ gives $\{A, D^{\alpha\mu}\}C_{\mu\beta} + D^{\alpha\mu}\{A, C_{\mu\beta}\} = 0$; contracting with $D^{\beta\nu}$ isolates $\{A, D^{\alpha\nu}\}$. This is the *only* fact about the inverse matrix that the computation needs, and it is why D may be kept as an unexpanded symbol throughout.

Equation (A.952). Take the triple $(\chi_\gamma, \chi_\alpha, \chi_\beta)$: each of the three terms of Equation (22.46) is minus one of the T's, in the cyclic order stated. □

A.51.2 Route A: the direct expansion

Theorem A.617 (Jacobi identity for the Dirac bracket)**.** *Wherever $C_{\alpha\beta}$ is invertible, and for all phase-space functions A, B, E,*

$$\{A, \{B, E\}_D\}_D + \{B, \{E, A\}_D\}_D + \{E, \{A, B\}_D\}_D = 0\,, \tag{A.954}$$

strongly — *as an identity of functions, not merely on the constraint surface.*

Rests on Definition 26.20, Equation (22.46), and Lemma A.616.

Proof. *Derives Theorem A.617.*

Write $\mathfrak{S}$ for the sum over the three cyclic images $(A, B, E) \to (B, E, A) \to (E, A, B)$, so that the left-hand side of Equation (A.954) is $\mathfrak{S}\,\{A, \{B, E\}_{\mathrm{D}}\}_{\mathrm{D}}$.

Step 1: expand once and sort by the number of D factors. Put $F := \{B, E\}_{\mathrm{D}} = \{B, E\} + B_\alpha D^{\alpha\beta} E_\beta$. By Equation (A.947) applied a second time, $\{A, F\}_{\mathrm{D}} = \{A, F\} + A_\gamma D^{\gamma\delta} F_\delta$ with $F_\delta = \{F, \chi_\delta\}$. Expanding both pieces by the Leibniz rule (Proposition 25.4) and using Equation (A.950) on $\{\{B, E\}, \chi_\delta\}$,

$$\{A, F\} = \{A, \{B, E\}\} + \{A, B_\alpha\} D^{\alpha\beta} E_\beta + B_\alpha D^{\alpha\beta}\{A, E_\beta\} + B_\alpha \left\{A, D^{\alpha\beta}\right\} E_\beta\,, \tag{A.955}$$

$$F_\delta = \{B, E_\delta\} - \{E, B_\delta\} + B_{\alpha\delta} D^{\alpha\beta} E_\beta + B_\alpha D^{\alpha\beta} E_{\beta\delta} + B_\alpha \left\{D^{\alpha\beta}, \chi_\delta\right\} E_\beta\,. \tag{A.956}$$

Assembling, and using Equation (A.951) on $\left\{A, D^{\alpha\beta}\right\}$ and on $\left\{D^{\alpha\beta}, \chi_\delta\right\}$, the eight surviving terms sort by the number of factors of D they carry:

$$\begin{aligned}\{A, \{B, E\}_{\mathrm{D}}\}_{\mathrm{D}} = {} & \underbrace{\{A, \{B, E\}\}}_{\text{order 0}} + \underbrace{\{A, B_\alpha\} D^{\alpha\beta} E_\beta + B_\alpha D^{\alpha\beta}\{A, E_\beta\} + A_\gamma D^{\gamma\delta}\left(\{B, E_\delta\} - \{E, B_\delta\}\right)}_{\text{order 1}} \\ & + \underbrace{\widehat{B}^\mu \widehat{E}^\nu \{A, C_{\mu\nu}\} - \widehat{A}^\delta \widehat{E}^\alpha B_{\alpha\delta} + \widehat{A}^\delta \widehat{B}^\beta E_{\beta\delta}}_{\text{order 2}} + \underbrace{\widehat{A}^\delta \widehat{B}^\mu \widehat{E}^\nu T_{\mu\nu\delta}}_{\text{order 3}}\,.\end{aligned} \tag{A.957}$$

The three order-two terms and the order-three term are obtained by substituting Equation (A.951) and then absorbing each $A_\gamma D^{\gamma\delta}$ and $B_\alpha D^{\alpha\mu}$ into the hatted abbreviation of Equation (A.948), remembering from it that $D^{\nu\beta}E_\beta = -\widehat{E}^\nu$, which is where the sign of the first order-two term and of the order-three term comes from.

Step 2: order zero. $\mathfrak{S}\,\{A,\{B,E\}\} = 0$ is the Poisson Jacobi identity Equation (22.46) itself.

Step 3: order one. Introduce the trilinear object

$$G(U,V,W) := \{U, V_\alpha\}\, D^{\alpha\beta} W_\beta\,. \tag{A.958}$$

The first order-one term is $G(A,B,E)$. For the second, relabel $\alpha \leftrightarrow \beta$ and use $D^{\beta\alpha} = -D^{\alpha\beta}$: $B_\alpha D^{\alpha\beta}\,\{A, E_\beta\} = -G(A,E,B)$. For the third, the same manoeuvre on each of the two pieces gives $A_\gamma D^{\gamma\delta}\,\{B, E_\delta\} = -G(B,E,A)$ and $-A_\gamma D^{\gamma\delta}\,\{E, B_\delta\} = +G(E,B,A)$. The order-one part of Equation (A.957) is therefore

$$G(A,B,E) - G(A,E,B) - G(B,E,A) + G(E,B,A)\,. \tag{A.959}$$

Now apply $\mathfrak{S}$. A cyclic sum of G is a sum of three terms that depends only on which of the two *orientations* of the triple its arguments carry, so $\mathfrak{S}G(B,E,A) = \mathfrak{S}G(A,B,E)$ and $\mathfrak{S}G(E,B,A) = \mathfrak{S}G(A,E,B)$: in each case the three summands are the same three terms in a different order. Hence the first term of Equation (A.959) cancels the third and the second cancels the fourth, and the cyclic sum vanishes. Concretely, the summand $G(A,B,E)$ produced by the first term of the (A,B,E) copy is cancelled by the summand $-G(A,B,E)$ produced by the third term of the (E,A,B) copy; the pairing of the second and fourth terms is the same one cycle over. This is the step that a reader cannot reconstruct without being told which term meets which, and it is the reason Equation (A.950) had to be used in Step 1: without it the third order-one term is a bracket of a bracket and does not have the shape Equation (A.958) at all.

Step 4: order two. Replace $\{A, C_{\mu\nu}\}$ by $A_{\mu\nu} - A_{\nu\mu}$, which is Equation (A.949), and relabel so that every term carries the free index pair in the order (p,q):

$$X(A,B,E) = \widehat{B}^p\widehat{E}^q A_{pq} - \widehat{B}^q\widehat{E}^p A_{pq} - \widehat{A}^q\widehat{E}^p B_{pq} + \widehat{A}^q\widehat{B}^p E_{pq}\,, \tag{A.960}$$

the second term coming from $-\widehat{B}^p\widehat{E}^q A_{qp}$ by the interchange $p \leftrightarrow q$. Now collect the cyclic sum by which of A_{pq}, B_{pq}, E_{pq} each term carries. The coefficient of A_{pq} receives $\widehat{B}^p\widehat{E}^q - \widehat{B}^q\widehat{E}^p$ from $X(A,B,E)$, $+\widehat{B}^q\widehat{E}^p$ from the fourth term of $X(B,E,A)$ and $-\widehat{E}^q\widehat{B}^p$ from the third term of $X(E,A,B)$; the four contributions cancel in pairs. The coefficients of B_{pq} and of E_{pq} are the same computation read one and two cycles on, so $\mathfrak{S}X = 0$.

Step 5: order three. By Equation (A.952) the totally contracted coefficient is a cyclic sum of T. Writing the order-three term of Equation (A.957) as $\widehat{A}^p\widehat{B}^q\widehat{E}^r T_{qrp}$ and applying $\mathfrak{S}$, which permutes $\widehat{A},\widehat{B},\widehat{E}$ cyclically, the three summands are $\widehat{A}^p\widehat{B}^q\widehat{E}^r$ times, in turn, T_{qrp}, T_{rpq} and T_{pqr}. Their sum vanishes by Equation (A.952).

All four orders vanish separately, so Equation (A.954) holds. No constraint was set to zero anywhere in the argument, so the identity is strong, as claimed. □

Remark A.618 (What each order used). It is worth recording the audit, because the four cancellations look alike and are not. Order zero is the Poisson Jacobi identity on the triple (A,B,E). Order one is the Poisson Jacobi identity on (χ_δ,B,E), which turns a bracket of a bracket into two terms of the shape Equation (A.958), plus the antisymmetry of D. Order two is the Poisson Jacobi identity on $(A,\chi_\alpha,\chi_\beta)$, which is what makes the derivative of the inverse matrix collapse onto the second brackets $A_{\alpha\beta}$ already present in the sum, plus the antisymmetry of D. Order three is the Poisson Jacobi identity on three constraints $(\chi_\gamma,\chi_\alpha,\chi_\beta)$. The antisymmetry of D enters at orders one, two and three, and never on its

own: at every order it does no more than allow the terms to be written with their indices in a common order, and the vanishing is always supplied by Equation (22.46). So the Dirac bracket inherits its Jacobi identity from the Poisson bracket four times over, once for each way of feeding a constraint into the triple.

A.51.3 Route B: the bracket of the induced symplectic form

The second proof is shorter, gives the reason rather than the verification, and is the one worth remembering. Its input is Proposition 26.25, proved in the chapter: with $C_{\alpha\beta}$ invertible at x, the tangent space splits as $T_xM = W \oplus T_x\Sigma_\chi$ along the projector Equation (26.42), the two summands are ω-orthogonal, and the restriction ω_Σ of the symplectic form to $T_x\Sigma_\chi$ is non-degenerate, so that $(\Sigma_\chi, \omega_\Sigma)$ is a symplectic manifold.

Proposition A.619 (The Dirac bracket is a projected Hamiltonian flow)**.** *Let X_A be the Hamiltonian vector field of A in the ambient space, Equation (24.5), and let P be the projector Equation (26.42). Then, for all A and B,*

$$\{B, A\}_D = \mathrm{d}B\left(P\left(X_A\right)\right) . \tag{A.961}$$

On Σ_χ the vector field $P(X_A)$ is the Hamiltonian vector field of the restriction $A|_{\Sigma_\chi}$ with respect to ω_Σ, and consequently

$$\{A, B\}_D\Big|_{\Sigma_\chi} = \{A|_{\Sigma_\chi}, B|_{\Sigma_\chi}\}_{\omega_\Sigma} . \tag{A.962}$$

Rests on Proposition 26.25 and Equations (24.7) and (26.42).

Proof. *Derives Proposition A.619.*

By Equation (24.7), $\{u, v\} = \mathrm{d}u\left(X_v\right)$ for every pair of functions. Hence $\{B, A\} = \mathrm{d}B\left(X_A\right)$, $\{B, \chi_\alpha\} = \mathrm{d}B\left(X_{\chi_\alpha}\right)$ and $\{\chi_\beta, A\} = \mathrm{d}\chi_\beta\left(X_A\right)$, so that Equation (26.25) reads

$$\{B, A\}_{\mathrm{D}} = \mathrm{d}B\left(X_A\right) - \mathrm{d}B\left(X_{\chi_\alpha}\right)\left(C^{-1}\right)^{\alpha\beta}\mathrm{d}\chi_\beta\left(X_A\right) = \mathrm{d}B\Big(X_A - X_{\chi_\alpha}\left(C^{-1}\right)^{\alpha\beta}\mathrm{d}\chi_\beta\left(X_A\right)\Big) , \tag{A.963}$$

and the argument of $\mathrm{d}B$ is exactly $P\left(X_A\right)$ of Equation (26.42). That is the whole of Equation (A.961), and it is the whole point: the Dirac bracket differs from the Poisson bracket only in that the Hamiltonian vector field is projected onto the constraint surface before it is used.

For the second statement, let $v \in T_x\Sigma_\chi$. The ω-orthogonality of the splitting gives $\omega(X_{\chi_\alpha}, v) = \mathrm{d}\chi_\alpha(v) = 0$, so

$$\omega_\Sigma(P\left(X_A\right), v) = \omega(X_A, v) - \left(C^{-1}\right)^{\alpha\beta}\mathrm{d}\chi_\beta\left(X_A\right)\omega(X_{\chi_\alpha}, v) = \mathrm{d}A(v) . \tag{A.964}$$

Since $P\left(X_A\right)$ is tangent to Σ_χ and $\mathrm{d}A(v)$ for tangent v depends on A only through $A|_{\Sigma_\chi}$, this says precisely that $P\left(X_A\right)$ is the ω_Σ-Hamiltonian vector field of $A|_{\Sigma_\chi}$. Feeding that back into Equation (A.961) with the roles of A and B exchanged, and using antisymmetry of both brackets, gives Equation (A.962). □

Second derivation of the Jacobi identity. *Derives Theorem A.617.*

This is a second, independent proof of Theorem A.617. Fix a point x at which $C_{\alpha\beta}$ is invertible, and let $c_\alpha := \chi_\alpha(x)$. The shifted functions $\chi_\alpha - c_\alpha$ have the same brackets as the χ_α, hence the same invertible matrix $C_{\alpha\beta}$, and they define the level surface Σ_c through x. Everything in Proposition 26.25 and in Proposition A.619 therefore applies verbatim to Σ_c, and the Dirac bracket built from $\chi_\alpha - c_\alpha$ is, term by term in Equation (26.25), the Dirac bracket built from the χ_α: constants drop out of every bracket. So the level surfaces

of the constraints foliate a neighbourhood of Σ_χ by symplectic manifolds (Σ_c, ω_c), and by Equation (A.962) the Dirac bracket of two functions restricted to Σ_c is the Poisson bracket of (Σ_c, ω_c) applied to their restrictions.

Now ω_c is the pullback $i_c^*\omega$ of the ambient symplectic form along the inclusion, so $\mathrm{d}\omega_c = i_c^*\mathrm{d}\omega = 0$: it is closed because ω is, and non-degenerate by Proposition 26.25. A symplectic manifold's Poisson bracket satisfies the Jacobi identity — that is Equation (22.46) on (Σ_c, ω_c), which by Theorem 24.12 may be computed in canonical coordinates, where it is the same computation as in the ambient space. Hence the cyclic sum Equation (A.954), restricted to Σ_c, vanishes.

Finally, the value of the cyclic sum at x is determined by its restriction to the leaf through x: by Equation (A.962) each of its three terms is, at x, the corresponding double bracket of (Σ_c, ω_c) applied to restrictions. Since x was an arbitrary point of the neighbourhood on which C^{-1} exists, Equation (A.954) holds there identically. □

Remark A.620 (Why the leaves, and not the surface alone). The last paragraph is the step at which a shorter-looking argument fails, and the failure is worth naming. It is tempting to say that Equation (26.26) lets one add any multiple of a constraint to either argument without changing the Dirac bracket, so that an identity holding on Σ_χ holds everywhere. It does not: by the Leibniz rule, $\{A, c^\alpha\chi_\alpha\}_{\mathrm{D}} = \chi_\alpha \{A, c^\alpha\}_{\mathrm{D}}$, which vanishes *on* Σ_χ and not off it. What Equation (26.26) does say — and this is the right reading — is that every χ_α is a Casimir of the Dirac bracket, so its level sets are unions of symplectic leaves, and the foliation used above is not an artifice but the canonical structure the bracket itself defines. The Dirac bracket makes a neighbourhood of Σ_χ a Poisson manifold in the sense of Definition 24.36, whose symplectic leaves are the Σ_c; Theorem A.617 is the assertion that it is a Poisson bracket at all.

Remark A.621 (What is quoted here). Nothing. Both routes are carried out from material proved in this treatise: the Poisson Jacobi identity Equation (22.46), the derivation property Proposition 25.4, the relation between the bracket and the symplectic form Equation (24.7), Darboux's theorem Theorem 24.12 in the form proved in Appendix A.12, and the splitting of Proposition 26.25. The one hypothesis that is not proved but assumed is the regularity of the constraint set (Remark 26.7), which is what makes Σ_χ a submanifold in the first place; it is an assumption about the system under study and is stated as such in the chapter.

Remark A.622. Appendix A.51 discharges the derivation owed at Theorem 26.21 of Chapter 26, whose proof establishes every other property of the Dirac bracket and defers this one. With it the object of Definition 26.20 is a bracket in the full sense, so that Postulate 26.47 may send it to a commutator, and the three facts the chapter draws together are seen to be one fact in three costumes: the Jacobi identity proved here, the degree-of-freedom count of Theorem 26.17, and the reduced Liouville measure of Proposition 26.25 are the tangential, the dimensional and the volumetric readings of the single statement that $(\Sigma_\chi, \omega_\Sigma)$ is a symplectic manifold. Remark 26.26 makes the same point from the measure side; Example 26.22 is the worked instance, where the leaves are the tangent bundles of a surface in $\mathbb{R}^3$ and the reduced bracket is the one Chapter 21 obtains by eliminating a coordinate.

A.52 The Gauss–Codazzi Form of the Einstein–Hilbert Lagrangian

This appendix proves Proposition 26.41 of Chapter 26: that the $3+1$ decomposition Equation (26.78) gives $\sqrt{|g|} = N\sqrt{h}$, that the four-dimensional curvature scalar splits into the intrinsic curvature of the leaf, a quadratic in the extrinsic curvature and two divergences, and — the conclusion the chapter actually consumes — that no time derivative of the lapse or of the shift survives anywhere in the Einstein–Hilbert Lagrangian.

The mathematics is the Gauss–Codazzi decomposition of the Riemann tensor of an ambient manifold along a hypersurface. The difficulty is not the decomposition, which is four projections of one identity; it is the *signature bookkeeping*, and this treatise sits in exactly the place where that bookkeeping is worst. The metric of Chapter 39 is mostly minus, so the unit normal to a spacelike leaf satisfies $n \cdot n = +1$; the curvature conventions of Theorem 13.152 and Definition 13.153 are the ones for which the round two-sphere has $R > 0$; and Definition 26.40 takes h_{ij} to be the *positive-definite* Riemannian metric of the leaf, so that the metric g_{ij} actually induced on the leaf by Equation (26.78) is $-h_{ij}$. Three sign conventions, and every formula in the literature is written with a different combination of them. Nothing below is inherited from a mostly-plus source. The discipline used instead is this. Write

$$\epsilon := n^\mu n_\mu \in \{+1, -1\} \,, \tag{A.965}$$

carry ϵ as a symbol through every step, do the whole computation with the *induced* metric $\gamma_{\mu\nu} = g_{\mu\nu} - \epsilon n_\mu n_\nu$ — whatever its sign — and only at the very end substitute $\epsilon = +1$ and $\gamma_{ij} = -h_{ij}$. A reader checking against a mostly-plus text sets $\epsilon = -1$ and $\gamma_{ij} = +h_{ij}$ and compares line by line; Remark A.633 records what happens when the substitution is made, which is the one place where the answer differs from the printed statement of Proposition 26.41 and the reason the chapter's prose insists that the sign be settled here rather than assumed.

Throughout, the ambient connection ∇ is the Levi-Civita connection of $g_{\mu\nu}$ (Theorem 13.150 with vanishing torsion), ${R^\lambda}_{\rho\mu\nu}$ is Equation (13.306), and $R_{\mu\nu}$, R are the contractions Equation (13.307). Indices $\mu, \nu, \ldots$ run over $0, 1, 2, 3$ and $i, j, k, \ldots$ over $1, 2, 3$; $x^0 = ct$, as in Notation 26.28. Since h_{ij} and N, N^i are dimensionless and the x^i carry metres, every term of Equation (26.80) has the SI dimension $1/\mathrm{m}^2$, and the identity is dimensionally homogeneous as it stands; no factor of c or G enters until the Lagrangian is multiplied by $1/2\kappa$.

A.52.1 The kit: normal, inverse metric, projector, determinant

Lemma A.623 (The adapted frame of the $3+1$ split)**.** *Write Equation (26.78) in terms of the coframe*

$$\theta^0 = \mathrm{d}x^0 \,, \qquad \theta^i = \mathrm{d}x^i + N^i \,\mathrm{d}x^0 \,, \qquad \textit{so that} \qquad \mathrm{d}s^2 = N^2 \theta^0 \theta^0 - h_{ij} \theta^i \theta^j \,. \tag{A.966}$$

Then, with $N > 0$:

1. *the dual frame is $e_0 = \partial_0 - N^i \partial_i$, $e_i = \partial_i$, and the inverse metric is*

$$g^{00} = \frac{1}{N^2} \,, \qquad g^{0i} = -\frac{N^i}{N^2} \,, \qquad g^{ij} = \frac{N^i N^j}{N^2} - h^{ij} \,, \tag{A.967}$$

   with h^{ij} the inverse of h_{ij};

2. *the future-directed unit normal to the leaves $x^0 = \text{const}$ is*

$$n_\mu = N \delta^0_\mu \,, \qquad n^\mu = \left(\frac{1}{N}, -\frac{N^i}{N} \right) = \frac{1}{N} e_0 \,, \qquad \epsilon = n^\mu n_\mu = +1 \,, \tag{A.968}$$

   so the normal is timelike and the leaves are spacelike;

3. $\det g = -N^2 h$ *with* $h = \det h_{ij} > 0$*, hence*

$$\sqrt{|g|} = N \sqrt{h} \,. \tag{A.969}$$

Rests on Definitions 13.117 and 26.40 and Equation (26.78).

Proof. *Derives Lemma A.623.*

(i). That Equation (A.966) reproduces Equation (26.78) is the definition of θ^i. For the dual frame, $\theta^0(e_0) = 1$, $\theta^i(e_0) = -N^i + N^i = 0$, $\theta^0(e_i) = 0$ and $\theta^j(e_i) = \delta^j_i$, so $\{e_0, e_i\}$ is indeed dual to $\{\theta^0, \theta^i\}$. In that basis the metric is the block array $\operatorname{diag}(N^2, -h_{ij})$, whose inverse is the block array $\operatorname{diag}(N^{-2}, -h^{ij})$; hence

$$g^{-1} = \frac{1}{N^2}\, e_0 \otimes e_0 - h^{ij}\, e_i \otimes e_j \,, \tag{A.970}$$

and expanding $e_0 = \partial_0 - N^k \partial_k$ in coordinates gives Equation (A.967).

(ii). A covector annihilating every vector tangent to a leaf — that is, every ∂_i — is proportional to δ^0_μ. Normalizing, $g^{\mu\nu}\left(N\delta^0_\mu\right)\left(N\delta^0_\nu\right) = N^2 g^{00} = 1$ by Equation (A.967), so Equation (A.968) is a unit covector and $\epsilon = +1$. Raising with Equation (A.967), $n^\mu = N g^{\mu 0}$ gives the components stated, and $n^0 = 1/N > 0$ makes it future directed.

(iii). This is the step Proposition 26.41 asserts and does not prove. The change of coframe Equation (A.966) has the matrix $\theta^a = \Lambda^a{}_\mu \mathrm{d}x^\mu$ with $\Lambda^0{}_0 = 1$, $\Lambda^0{}_i = 0$, $\Lambda^i{}_0 = N^i$, $\Lambda^i{}_j = \delta^i_j$: it is lower triangular with unit diagonal, so $\det \Lambda = 1$. Since $g_{\mu\nu} = \Lambda^a{}_\mu \hat{g}_{ab} \Lambda^b{}_\nu$ with $\hat{g} = \operatorname{diag}(N^2, -h_{ij})$,

$$\det g = (\det \Lambda)^2 \det \hat{g} = N^2\,(-1)^3 \det h_{ij} = -N^2 h \,, \tag{A.971}$$

the factor $(-1)^3$ being the three minus signs the signature puts on the spatial block. Completing the square in $\mathrm{d}x^i + N^i \mathrm{d}x^0$ is thus exactly the statement that the shift can be removed from the determinant by a unimodular change of coframe. □

Definition A.624 (Projector and induced metric)**.** The *projector* onto a leaf and the *induced metric* are

$$\gamma^\mu{}_\nu := \delta^\mu_\nu - \epsilon\, n^\mu n_\nu \,, \qquad \gamma_{\mu\nu} := g_{\mu\nu} - \epsilon\, n_\mu n_\nu \,. \tag{A.972}$$

A tensor is *tangential* if every index is annihilated by contraction with n, equivalently if projecting every index returns it. For a tangential tensor T the *intrinsic* covariant derivative is

$$D_\mu T_{\nu\ldots} := \gamma^\alpha{}_\mu \gamma^\beta{}_\nu \cdots \nabla_\alpha T_{\beta\ldots} \,. \tag{A.973}$$

Rests on Equation (A.968) and Definition 13.145.

Three facts about Equation (A.972) are used without further comment. First, $\gamma^\mu{}_\nu n^\nu = n^\mu - \epsilon^2 n^\mu = 0$ and $\gamma^\mu{}_\nu v^\nu = v^\mu$ for v tangent to a leaf, since such a v has $n_\nu v^\nu = 0$; so γ is the projection along n, and $\gamma^\mu{}_\alpha \gamma^\alpha{}_\nu = \gamma^\mu{}_\nu$. Second, D is the Levi-Civita connection of γ on the leaf: it is torsion free, and $D_\mu \gamma_{\nu\rho} = \gamma\gamma\gamma\nabla\,(g - \epsilon nn) = 0$, the first term because $\nabla g = 0$ and the second because each projector annihilates the n it meets. Third — and this is the sign that will have to be paid for at the end — in the coordinates of Lemma A.623 one has $n_i = 0$, so

$$\gamma_{ij} = g_{ij} = -h_{ij} \,, \qquad \gamma^{ij} = -h^{ij} \,, \tag{A.974}$$

where γ^{ij} means the inverse of γ_{ij} *as a three-by-three matrix*, which is also $\gamma^{\mu\nu}$ restricted to spatial indices. The induced metric of Equation (26.78) is negative definite; the positive-definite h_{ij} of Definition 26.40 is its negative.

A.52.2 The extrinsic curvature, and the dictionary

Definition A.625 (Four-dimensional extrinsic curvature)**.** Put

$$\mathcal{K}_{\mu\nu} := \gamma^\alpha{}_\mu \gamma^\beta{}_\nu \nabla_\alpha n_\beta \,, \qquad \mathcal{K} := \gamma^{\mu\nu}\mathcal{K}_{\mu\nu} \,, \qquad a_\mu := n^\lambda \nabla_\lambda n_\mu \,. \tag{A.975}$$

Rests on Equation (A.972) and Definition 13.145.

Lemma A.626 (Decomposition of ∇n, and the acceleration)**.** *$\mathcal{K}_{\mu\nu}$ and a_μ are tangential, $\mathcal{K}$ is symmetric, and*

$$\nabla_\mu n_\nu = \mathcal{K}_{\mu\nu} + \epsilon\, n_\mu a_\nu \,, \tag{A.976}$$

$$\nabla_\mu n^\mu = \mathcal{K} \,, \tag{A.977}$$

$$(\nabla_\mu n^\nu)\,(\nabla_\nu n^\mu) = \mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} \,, \tag{A.978}$$

$$a_\mu = -\epsilon\, D_\mu \ln N \,. \tag{A.979}$$

Rests on Definition A.625, Lemma A.623, and Equation (13.295).

Proof. *Derives Lemma A.626.*

Tangentiality of $\mathcal{K}$ is built into Equation (A.975). For a, differentiate $n^\nu n_\nu = \epsilon$: $n^\nu \nabla_\mu n_\nu = 0$, and contracting with n^μ gives $n^\nu a_\nu = 0$.

Equation (A.976). Insert $\delta^\alpha_\mu = \gamma^\alpha{}_\mu + \epsilon n^\alpha n_\mu$ in both slots of $\nabla_\mu n_\nu$. The $\gamma\gamma$ term is $\mathcal{K}_{\mu\nu}$. Any term carrying n^β in the second slot vanishes, because $n^\beta \nabla_\alpha n_\beta = 0$. The remaining term is $\epsilon n^\alpha n_\mu \gamma^\beta{}_\nu \nabla_\alpha n_\beta = \epsilon n_\mu \gamma^\beta{}_\nu a_\beta = \epsilon n_\mu a_\nu$, since a is tangential.

Symmetry of $\mathcal{K}$ follows: the leaves are level sets of the coordinate x^0, so $n_\mu/N = \partial_\mu x^0$ is a gradient and $\nabla_{[\mu}\left(n_{\nu]}/N\right) = 0$, whence

$$\nabla_\mu n_\nu - \nabla_\nu n_\mu = n_\nu \partial_\mu \ln N - n_\mu \partial_\nu \ln N \,. \tag{A.980}$$

Projecting both slots kills the right-hand side, so $\mathcal{K}_{\mu\nu} = \mathcal{K}_{\nu\mu}$.

Equations (A.977) and (A.978). Trace Equation (A.976) with $g^{\mu\nu}$: the second term gives $\epsilon n^\nu a_\nu = 0$ and the first gives $g^{\mu\nu}\mathcal{K}_{\mu\nu} = \gamma^{\mu\nu}\mathcal{K}_{\mu\nu} = \mathcal{K}$, because $\mathcal{K}$ is tangential and g and γ agree on tangential tensors. Squaring Equation (A.976),

$$(\mathcal{K}_\mu{}^\nu + \epsilon n_\mu a^\nu)\,(\mathcal{K}_\nu{}^\mu + \epsilon n_\nu a^\mu) = \mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} \,, \tag{A.981}$$

each cross term carrying an n contracted with a tangential index and the last term carrying $a^\nu n_\nu = 0$.

Equation (A.979). Compare Equation (A.980) with the antisymmetric part of Equation (A.976), which is $\epsilon\,(n_\mu a_\nu - n_\nu a_\mu)$, and contract with n^μ. The left-hand side gives $\epsilon\,(\epsilon a_\nu - 0) = a_\nu$ and the right-hand side gives $n_\nu\,(n^\mu \partial_\mu \ln N) - \epsilon \partial_\nu \ln N$. Projecting with γ, which fixes the tangential a_ν and kills n_ν, leaves Equation (A.979). □

Lemma A.627 (The dictionary between $\mathcal{K}, \gamma$ and K, h)**.** *In the coordinates of Lemma A.623, with K_{ij} the extrinsic curvature Equation (26.79) of Definition 26.40, $K = h^{ij}K_{ij}$, $K^{ij} = h^{ik}h^{jl}K_{kl}$ and ${}^{(3)}R$ the Ricci scalar of h_{ij}:*

$$\mathcal{K}_{ij} = -K_{ij} \,, \qquad \mathcal{K} = K \,, \qquad \mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} = K_{ij}K^{ij} \,, \qquad R[\gamma] = -{}^{(3)}R \,, \tag{A.982}$$

$R[\gamma]$ denoting the curvature scalar Equation (13.307) of the induced metric γ_{ij} of Equation (A.974). The Levi-Civita connections of γ_{ij} and of h_{ij} coincide, so D_i of Equation (A.973) is the D_i of Definition 26.40.

Rests on Equations (26.79) and (A.974) and Definition 13.153.

Proof. *Derives Lemma A.627.*

Connections and Riemann tensors. $\gamma_{ij} = -h_{ij}$ differs from h_{ij} by a constant factor, and the Christoffel symbols Equation (13.299) are homogeneous of degree zero in the metric — one inverse metric against one derivative of the metric — so they are the same for γ and for h. By Equation (13.306) the Riemann tensors $R^i{}_{jkl}$ and hence the Ricci tensors R_{jl} agree. The scalars do not: $R[\gamma] = \gamma^{jl}R_{jl} = -h^{jl}R_{jl} = -{}^{(3)}R$, which is the fourth relation.

Extrinsic curvature. Since $n_i = 0$, ${\gamma^\alpha}_i = \delta^\alpha_i$, so $\mathcal{K}_{ij} = \nabla_i n_j = \partial_i \left(N\delta^0_j\right) - {\Gamma^\lambda}_{ij} n_\lambda = -N{\Gamma^0}_{ij}$. Compute ${\Gamma^0}_{ij}$ from Equation (13.299) with $g_{0i} = -N_i$, $g_{ij} = -h_{ij}$ and Equation (A.967):

$$\begin{aligned} {\Gamma^0}_{ij} &= \tfrac{1}{2} g^{00} \left(\partial_i g_{0j} + \partial_j g_{0i} - \partial_0 g_{ij}\right) + \tfrac{1}{2} g^{0k} \left(\partial_i g_{kj} + \partial_j g_{ki} - \partial_k g_{ij}\right) \\ &= \frac{1}{2N^2} \left[\partial_0 h_{ij} - \partial_i N_j - \partial_j N_i + N^k \left(\partial_i h_{kj} + \partial_j h_{ki} - \partial_k h_{ij}\right)\right] , \end{aligned} \tag{A.983}$$

every term having picked up one overall minus from $g_{ij} = -h_{ij}$, $g_{0i} = -N_i$ and, in the second group, a further minus from $g^{0k} = -N^k/N^2$. Now the Christoffel symbols of h_{ij} give $D_i N_j + D_j N_i = \partial_i N_j + \partial_j N_i - 2{\Gamma^{(3)k}}_{ij} N_k$ and $2{\Gamma^{(3)k}}_{ij} N_k = N^l \left(\partial_i h_{lj} + \partial_j h_{li} - \partial_l h_{ij}\right)$, so the bracket of Equation (A.983) is $\partial_0 h_{ij} - D_i N_j - D_j N_i$ and

$${\Gamma^0}_{ij} = \frac{1}{2N^2} \left(\partial_0 h_{ij} - D_i N_j - D_j N_i\right) = \frac{K_{ij}}{N} , \tag{A.984}$$

by Equation (26.79). Hence $\mathcal{K}_{ij} = -K_{ij}$, the first relation. This is not a choice: it is forced, because $\mathcal{K}$ is one half the Lie derivative of γ along n while K is one half the Lie derivative of h, and $\gamma = -h$.

Trace and square. $\mathcal{K} = \gamma^{ij}\mathcal{K}_{ij} = \left(-h^{ij}\right)\left(-K_{ij}\right) = K$: the two minus signs cancel, so the traces agree even though the tensors differ in sign. Likewise $\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} = \gamma^{ik}\gamma^{jl}\mathcal{K}_{ij}\mathcal{K}_{kl} = h^{ik}h^{jl}K_{ij}K_{kl} = K_{ij}K^{ij}$, four minus signs cancelling in pairs. Only the curvature scalar, which carries one inverse metric rather than an even number, survives the substitution with its sign changed — and it is exactly that asymmetry which Remark A.633 is about. □

A.52.3 The Gauss equation

Lemma A.628 (Gauss equation, arbitrary signature)**.** *For a hypersurface with unit normal n, $\epsilon = n \cdot n$,*

$$R[\gamma]^\kappa{}_{\nu\rho\mu} = {\gamma^\kappa}_\alpha {\gamma^\tau}_\nu {\gamma^\lambda}_\rho {\gamma^\sigma}_\mu \, R^\alpha{}_{\tau\lambda\sigma} - \epsilon \left(\mathcal{K}_{\rho\nu}\mathcal{K}_\mu{}^\kappa - \mathcal{K}_{\mu\nu}\mathcal{K}_\rho{}^\kappa\right) , \tag{A.985}$$

$R[\gamma]$ being the Riemann tensor of the induced metric.
Rests on Equations (13.305) and (A.973) and Definition A.625.

Proof. *Derives Lemma A.628.*

Let ω_μ be a tangential covector field. By Equation (A.973), $(D\omega)_{\alpha\beta} = {\gamma^\sigma}_\alpha {\gamma^\tau}_\beta \nabla_\sigma \omega_\tau$, and applying D once more,

$$D_\rho D_\mu \omega_\nu = {\gamma^\lambda}_\rho {\gamma^\alpha}_\mu {\gamma^\beta}_\nu \nabla_\lambda \left[{\gamma^\sigma}_\alpha {\gamma^\tau}_\beta \nabla_\sigma \omega_\tau\right] . \tag{A.986}$$

Expand the derivative by the Leibniz rule. Because $\nabla_\lambda {\gamma^\sigma}_\alpha = -\epsilon \left(n^\sigma \nabla_\lambda n_\alpha + n_\alpha \nabla_\lambda n^\sigma\right)$, and because every n_α or n_β meets a projector and dies, the two terms in which ∇ falls on a projector are

$$-\epsilon \, \mathcal{K}_{\rho\mu} \, n^\sigma {\gamma^\tau}_\nu \nabla_\sigma \omega_\tau - \epsilon \, \mathcal{K}_{\rho\nu} \, {\gamma^\sigma}_\mu n^\tau \nabla_\sigma \omega_\tau \, . \tag{A.987}$$

The first is symmetric in $\rho \leftrightarrow \mu$ and therefore drops out of the commutator $D_\rho D_\mu - D_\mu D_\rho$. In the second, differentiate $\omega_\tau n^\tau = 0$ to get $n^\tau \nabla_\sigma \omega_\tau = -\omega_\tau \nabla_\sigma n^\tau$, and then ${\gamma^\sigma}_\mu \omega_\tau \nabla_\sigma n^\tau = \omega_\tau \mathcal{K}_\mu{}^\tau$ because ω is tangential; so the second term equals $+\epsilon \, \mathcal{K}_{\rho\nu}\mathcal{K}_\mu{}^\tau \omega_\tau$.

The remaining term of Equation (A.986) is ${\gamma^\lambda}_\rho {\gamma^\sigma}_\mu {\gamma^\tau}_\nu \nabla_\lambda \nabla_\sigma \omega_\tau$. Antisymmetrizing in $\rho \leftrightarrow \mu$ and using the Ricci identity Equation (13.305) in its covector form, $[\nabla_\lambda, \nabla_\sigma]\,\omega_\tau = -R^\kappa{}_{\tau\lambda\sigma}\omega_\kappa$ (which follows from Equation (13.305) by applying the commutator to the scalar $\omega_\lambda V^\lambda$), and the same identity on the leaf for D,

$$-R[\gamma]^\kappa{}_{\nu\rho\mu}\omega_\kappa = \epsilon \left(\mathcal{K}_{\rho\nu}\mathcal{K}_\mu{}^\tau - \mathcal{K}_{\mu\nu}\mathcal{K}_\rho{}^\tau\right)\omega_\tau - {\gamma^\lambda}_\rho {\gamma^\sigma}_\mu {\gamma^\tau}_\nu R^\kappa{}_{\tau\lambda\sigma}\omega_\kappa \, . \tag{A.988}$$

Both sides are tangential in the free index κ and ω was an arbitrary tangential covector, so the coefficients agree after projecting κ, which is Equation (A.985). □

Remark A.629 (A check at $\epsilon = +1$ that uses no relativity). The sign of the quadratic term in Equation (A.985) can be checked on the one case every reader already knows, and in the signature that matters here. Take the sphere of radius r in Euclidean $\mathbb{R}^3$: the ambient is flat, $\epsilon = +1$ because the normal is a unit vector of a positive-definite metric, and $\mathcal{K}_{ij} = \nabla_i n_j = \gamma_{ij}/r$ for the outward normal. Then Equation (A.985), with indices lowered, gives $R[\gamma]_{\kappa\nu\rho\mu} = r^{-2}\left(\gamma_{\mu\nu}\gamma_{\rho\kappa} - \gamma_{\rho\nu}\gamma_{\mu\kappa}\right)$, whose double contraction is $R[\gamma] = 2/r^2$. That is 2 times the Gaussian curvature, which is what Definition 13.153 says a two-dimensional curvature scalar must be, and it is Gauss's *theorema egregium*: the sphere's intrinsic curvature is fixed by its second fundamental form alone. A sign error in Equation (A.985) would make the sphere intrinsically hyperbolic.

A.52.4 The Codazzi equation

Lemma A.630 (Codazzi equation)**.** *With the same notation,*

$$D_\mu \mathcal{K}_{\nu\rho} - D_\nu \mathcal{K}_{\mu\rho} = -\gamma^\alpha{}_\mu \gamma^\beta{}_\nu \gamma^\lambda{}_\rho \, n_\kappa R^\kappa{}_{\lambda\alpha\beta} \,, \tag{A.989}$$

and contracting ν with ρ,

$$D_\nu \left(\mathcal{K}^\nu{}_\mu - \mathcal{K}\gamma^\nu{}_\mu\right) = \gamma^\alpha{}_\mu R_{\alpha\kappa} n^\kappa \,. \tag{A.990}$$

No factor of ϵ appears in either.

Rests on Lemma A.626, Equation (13.305), and Definition A.625.

Proof. *Derives Lemma A.630.*

By Equation (A.976), $\mathcal{K}_{\beta\lambda} = \nabla_\beta n_\lambda - \epsilon n_\beta a_\lambda$, so

$$D_\mu \mathcal{K}_{\nu\rho} = \gamma^\alpha{}_\mu \gamma^\beta{}_\nu \gamma^\lambda{}_\rho \nabla_\alpha \nabla_\beta n_\lambda - \epsilon \, a_\rho \mathcal{K}_{\mu\nu} \,, \tag{A.991}$$

the second term because $\gamma^\beta{}_\nu \nabla_\alpha \left(n_\beta a_\lambda\right) = a_\lambda \gamma^\beta{}_\nu \nabla_\alpha n_\beta$, the other piece dying on $\gamma^\beta{}_\nu n_\beta = 0$. Antisymmetrizing in $\mu \leftrightarrow \nu$, the term $a_\rho \mathcal{K}_{\mu\nu}$ is symmetric and drops, and the Ricci identity in covector form leaves Equation (A.989).

For the contraction, apply $\gamma^{\nu\rho}$. On the left it gives $D_\mu \mathcal{K} - D_\nu \mathcal{K}^\nu{}_\mu$, which is minus the left-hand side of Equation (A.990). On the right, $\gamma^{\beta\lambda} = g^{\beta\lambda} - \epsilon n^\beta n^\lambda$; the $g^{\beta\lambda}$ piece contracts the second and fourth slots of $R_{\kappa\lambda\alpha\beta}$, which by the antisymmetry within each index pair (Proposition 13.154) is the same as contracting the first and third, that is again the Ricci tensor, giving $n^\kappa R_{\kappa\alpha}$, while the $n^\beta n^\lambda$ piece vanishes because $R_{\kappa\lambda\alpha\beta} n^\kappa n^\lambda = 0$ by antisymmetry in the first pair. Rearranging gives Equation (A.990). □

Equation (A.990) is worth reading before it is used. Under the dictionary Equation (A.982) the mixed-index extrinsic curvature carries two inverse metrics' worth of sign and is unchanged, $\mathcal{K}^j{}_i = \gamma^{jk}\mathcal{K}_{ki} = \left(-h^{jk}\right)\left(-K_{ki}\right) = K^j{}_i$, so the left-hand side is $D_j K^j{}_i - D_i K$. By Equation (26.82) that is $2\kappa h^{-1/2} D_j \pi^j{}_i = -\kappa h^{-1/2} \mathcal{H}_i$ with $\mathcal{H}_i$ the momentum constraint Equation (26.85); and the right-hand side is a projection of the Ricci tensor onto one normal and one tangential index. So the momentum constraint of Theorem 26.42 is the contracted Codazzi equation, which is the precise content of the first paragraph of Remark 26.44: the constraints are the $G^0{}_\mu$ components of the field equations, and they are conditions on data laid down on one leaf because Codazzi's equation contains no derivative off the leaf.

A.52.5 The twice-normal contraction

The double contraction of Equation (A.985) will leave behind the term $R_{\mu\nu} n^\mu n^\nu$, which is neither intrinsic nor a projection of anything on the leaf. Converting it is the step that produces the total derivatives, and it is the one usually passed over. It is not passed over here.

Lemma A.631 (The normal–normal Ricci contraction)**.** *For any unit normal field,*

$$R_{\mu\nu}n^\mu n^\nu = \nabla_\mu\left(a^\mu - \mathcal{K}n^\mu\right) - \left(\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2\right) . \tag{A.992}$$

Rests on Equation (13.305), Lemma A.626, and Definition 13.153.

Proof. *Derives Lemma A.631.*

Apply the Ricci identity Equation (13.305) to n^λ, set $\lambda = \mu$ and contract: since $R^\mu{}_{\rho\mu\nu} = R_{\rho\nu}$ by Equation (13.307),

$$\nabla_\mu\nabla_\nu n^\mu - \nabla_\nu\nabla_\mu n^\mu = R_{\rho\nu}n^\rho . \tag{A.993}$$

Contract with n^ν and rewrite each side as a divergence minus the term the Leibniz rule left over:

$$n^\nu\nabla_\mu\nabla_\nu n^\mu = \nabla_\mu\left(n^\nu\nabla_\nu n^\mu\right) - \left(\nabla_\mu n^\nu\right)\left(\nabla_\nu n^\mu\right) , \tag{A.994}$$

$$n^\nu\nabla_\nu\left(\nabla_\mu n^\mu\right) = \nabla_\nu\left(n^\nu\nabla_\mu n^\mu\right) - \left(\nabla_\nu n^\nu\right)\left(\nabla_\mu n^\mu\right) . \tag{A.995}$$

Subtracting, and inserting Equations (A.977) and (A.978) for the two quadratic terms and $a^\mu = n^\nu\nabla_\nu n^\mu$ for the first divergence, gives Equation (A.992). □

Equation (A.992) is the trace of what is called the Ricci, or Mainardi, equation — the twice-normal projection of the Riemann tensor. Only the trace is needed below, and only the trace is proved: the untraced equation would be an identity for $\gamma^\alpha{}_\mu\gamma^\beta{}_\nu n^\lambda n^\sigma R_{\alpha\lambda\beta\sigma}$ in terms of the Lie derivative of $\mathcal{K}$ along n, and nothing in this appendix or in Chapter 26 consumes it.

A.52.6 Assembling the Lagrangian

Theorem A.632 (The 3+1 identity for the curvature scalar)**.** *For a foliation by hypersurfaces with unit normal n and $\epsilon = n\cdot n$,*

$$R = R[\gamma] - \epsilon\left(\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2\right) + 2\epsilon\,\nabla_\mu\left(a^\mu - \mathcal{K}n^\mu\right) . \tag{A.996}$$

Specialized to Equation (26.78) by Lemmas A.623 and A.627, that is $\epsilon = +1$, $\gamma_{ij} = -h_{ij}$,

$$\sqrt{|g|}\,R = -N\sqrt{h}\left({}^{(3)}R + K_{ij}K^{ij} - K^2\right) + 2\,\partial_\mu\left[\sqrt{|g|}\left(a^\mu - Kn^\mu\right)\right] , \tag{A.997}$$

with $\sqrt{|g|} = N\sqrt{h}$. In particular ${}^{(3)}R$ contains h_{ij} and its spatial derivatives only, and K_{ij} contains $\partial_0 h_{ij}$ linearly and no other time derivative, so neither $\partial_0 N$ nor $\partial_0 N^i$ occurs anywhere on the right.

Rests on Lemmas A.627, A.628 and A.631.

Proof. *Derives Theorem A.632.*

Step 1: contract the Gauss equation once. Put $\rho = \kappa$ in Equation (A.985) and sum. On the right, $\gamma^\kappa{}_\alpha\gamma^\lambda{}_\kappa = \gamma^\lambda{}_\alpha$, so, lowering the free index,

$$R[\gamma]_{\nu\mu} = \gamma^{\lambda\alpha}\gamma^\tau{}_\nu\gamma^\sigma{}_\mu R_{\alpha\tau\lambda\sigma} - \epsilon\left(\mathcal{K}_\mu{}^\rho\mathcal{K}_{\rho\nu} - \mathcal{K}\mathcal{K}_{\mu\nu}\right) . \tag{A.998}$$

Writing $\gamma^{\lambda\alpha} = g^{\lambda\alpha} - \epsilon n^\lambda n^\alpha$ and using $g^{\lambda\alpha}R_{\alpha\tau\lambda\sigma} = R_{\tau\sigma}$ from Equation (13.307),

$$R[\gamma]_{\nu\mu} = \gamma^\tau{}_\nu\gamma^\sigma{}_\mu\left[R_{\tau\sigma} - \epsilon\, n^\alpha n^\lambda R_{\alpha\tau\lambda\sigma}\right] - \epsilon\left(\mathcal{K}_\mu{}^\rho\mathcal{K}_{\rho\nu} - \mathcal{K}\mathcal{K}_{\mu\nu}\right) . \tag{A.999}$$

Step 2: contract again. Apply $\gamma^{\nu\mu}$. The first bracket gives $\gamma^{\tau\sigma}R_{\tau\sigma} = R - \epsilon R_{\tau\sigma}n^\tau n^\sigma$. The second gives $\gamma^{\tau\sigma}n^\alpha n^\lambda R_{\alpha\tau\lambda\sigma} = R_{\alpha\lambda}n^\alpha n^\lambda$: the $g^{\tau\sigma}$ part is again a Ricci contraction on

the second and fourth slots, and the $n^\tau n^\sigma$ part vanishes because $R_{\alpha\tau\lambda\sigma}n^\alpha n^\tau = 0$. The quadratic terms give $\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2$. Hence

$$R[\gamma] = R - 2\epsilon\, R_{\mu\nu}n^\mu n^\nu - \epsilon\left(\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2\right) . \tag{A.1000}$$

Step 3: eliminate the normal–normal Ricci term. Substitute Equation (A.992) into Equation (A.1000) and solve for R:

$$\begin{aligned} R &= R[\gamma] + \epsilon\left(\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2\right) + 2\epsilon\, R_{\mu\nu}n^\mu n^\nu \\ &= R[\gamma] + \epsilon\left(\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2\right) + 2\epsilon\left[\nabla_\mu\left(a^\mu - \mathcal{K}n^\mu\right) - \left(\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} - \mathcal{K}^2\right)\right] , \end{aligned} \tag{A.1001}$$

which is Equation (A.996): the quadratic term appears twice with opposite weight and what survives is $-\epsilon\left(\mathcal{K}\mathcal{K} - \mathcal{K}^2\right)$. It is worth noticing that the sign of the quadratic term in the final answer is opposite to the sign it carries in the Gauss equation, and that the flip is entirely the work of Lemma A.631; this is the step at which a derivation that quotes the Ricci equation instead of proving it can go wrong without leaving a trace.

Step 4: substitute. By Lemma A.623, $\epsilon = +1$; by Lemma A.627, $R[\gamma] = -{}^{(3)}R$, $\mathcal{K}_{\mu\nu}\mathcal{K}^{\mu\nu} = K_{ij}K^{ij}$ and $\mathcal{K} = K$. So

$$R = -{}^{(3)}R - \left(K_{ij}K^{ij} - K^2\right) + 2\nabla_\mu\left(a^\mu - Kn^\mu\right) . \tag{A.1002}$$

Multiplying by $\sqrt{|g|} = N\sqrt{h}$ and using the standard identity $\sqrt{|g|}\,\nabla_\mu V^\mu = \partial_\mu\left(\sqrt{|g|}V^\mu\right)$ for the divergence of a vector field — which follows from $\Gamma^\mu{}_{\mu\nu} = \partial_\nu \ln\sqrt{|g|}$, itself a contraction of Equation (13.299) — gives Equation (A.997).

Step 5: the velocities. ${}^{(3)}R$ is built from h_{ij} and its spatial derivatives alone. K_{ij} is given by Equation (26.79), in which ∂_0 acts on h_{ij} and on nothing else: N and N^i enter algebraically and through *spatial* derivatives D_iN_j only. The divergence term contains ∂_0 of $\sqrt{|g|}\left(a^0 - Kn^0\right)$, hence of N, N^i and h_{ij}; but it is a total derivative and is removed by the boundary term of Appendix A.52.7, so no time derivative of the lapse or the shift survives in the bulk Lagrangian. □

Remark A.633 (The overall sign, settled). Equation (A.997) carries an overall minus sign that Equation (26.80) does not display, and it is worth saying plainly where it comes from and what it costs, because this is exactly the bookkeeping the chapter's prose defers to this appendix.

The source is isolated in Lemma A.627 and is a single asymmetry: of the four quantities in the dictionary, three are built with an even number of inverse metrics and are blind to $\gamma_{ij} = -h_{ij}$, while the curvature *scalar* carries exactly one and changes sign. So with the curvature conventions of Theorem 13.152 and Definition 13.153 — the conventions for which the round two-sphere has $R = 2/r^2$, checked in Remark A.629 — and the mostly-minus signature of Chapter 39, the four-scalar that equals $N\sqrt{h}\left({}^{(3)}R + K_{ij}K^{ij} - K^2\right)$ up to divergences is $-\sqrt{|g|}\,R$, and not $+\sqrt{|g|}\,R$.

Nothing physical turns on this, and three things should be said about it. First, the gravitational Lagrangian density in this signature is therefore $-\sqrt{|g|}\,R/2\kappa$; that is the sign carried, for precisely this reason, by every mostly-minus treatment of general relativity, and it is the combination whose ADM form is $+N\sqrt{h}\left({}^{(3)}R + K_{ij}K^{ij} - K^2\right)/2\kappa$. Second, that is exactly the Lagrangian L used in the proof of Theorem 26.42 — read the first display of that proof — so the momentum Equation (26.82), the constraint densities Equations (26.84) and (26.85) and the degree-of-freedom count all stand unchanged. Third, and this is why Proposition 26.41 can be used as it is written, neither of the two facts the chapter draws from it is touched: $\sqrt{|g|} = N\sqrt{h}$ is Equation (A.969), and the absence of $\partial_0 N$ and $\partial_0 N^i$

is Step 5 above, and both are independent of the overall sign. A reader working in a mostly-plus convention sets $\epsilon = -1$ and $\gamma_{ij} = +h_{ij}$ in Equation (A.996) and recovers the familiar $R = {}^{(3)}\!R + K_{ij}K^{ij} - K^2 - 2\nabla_\mu\left(a^\mu - Kn^\mu\right)$ with no minus sign in front, which is the form printed in the standard references [1221, 1509, 1746] and the reason the sign is so easy to import unexamined.

A.52.7 The boundary term

The divergence in Equation (A.997) is a genuine coordinate divergence, so over a region $\mathcal{R}$ bounded by two leaves it contributes only a surface integral. Evaluate it. The acceleration is tangential, so $n_\mu a^\mu = Na^0 = 0$ and $a^0 = 0$: the acceleration has no flux through a leaf. And $\sqrt{|g|}\,n^0 = N\sqrt{h}\cdot N^{-1} = \sqrt{h}$ by Equations (A.968) and (A.969). Hence the $\mu = 0$ component of the divergence's argument is

$$\sqrt{|g|}\left(a^0 - Kn^0\right) = -\sqrt{h}\,K\,, \tag{A.1003}$$

and, integrating Equation (A.997) over $\mathcal{R}$,

$$\int_{\mathcal{R}} \mathrm{d}^4x\left(-\sqrt{|g|}\,R\right) = \int_{\mathcal{R}} \mathrm{d}^4x\,N\sqrt{h}\left({}^{(3)}\!R + K_{ij}K^{ij} - K^2\right) + 2\oint_{\partial\mathcal{R}} \mathrm{d}^3x\,\sqrt{h}\,K\,, \tag{A.1004}$$

the sign of the last term following the outward orientation of $\partial\mathcal{R}$ once that orientation is fixed. Dividing by 2κ, the surface term is $\kappa^{-1}\oint\sqrt{h}\,K$, which is the Gibbons–Hawking–York boundary action [1490, 1596].

Two statements are made about it here and only the first is proved. The first is Equation (A.1004) itself: the bulk ADM Lagrangian and the gravitational action differ by exactly that surface integral, which is why Proposition 26.41 may write "plus total derivatives" and Theorem 26.42 may drop them. The second is quoted: adding the Gibbons–Hawking–York term to the action makes the variational problem well posed with h_{ij} — and only h_{ij} — held fixed on $\partial\mathcal{R}$, because the unwanted normal derivatives of the metric variation that $\sqrt{|g|}\,R$ produces on the boundary are precisely what it cancels. That is proved in [1596] and not here; the constrained-dynamics consequence of the same term, that the numerical value of the Hamiltonian of an isolated system is carried entirely by a surface integral, is Remark 26.45.

Remark A.634 (What is quoted here). Two imports, and one debt of Chapter 13.

Quoted. That the Gibbons–Hawking–York term makes the variational problem well posed, as stated in the paragraph above; it is used nowhere in Chapter 26 except as the justification for discarding total derivatives, which Equation (A.1004) establishes independently.

Owed by Chapter 13. A general-signature Gauss–Codazzi theory of hypersurfaces. That chapter carries the classical version Equation (13.92), but it is the theory of a surface in *flat Euclidean* $\mathbb{R}^3$, built from a position vector $\boldsymbol{x}$ and its derivatives, and it is not usable for a spacelike leaf of a Lorentzian spacetime: there is no position vector, the ambient is curved, and the normal's square is ϵ rather than $+1$. The chapter's later treatment of a quadric in a flat ambient of signature (p, q) carries the right sign structure but is again an embedding into a *flat* space given by an explicit position vector. Lemmas A.628, A.630 and A.631 are therefore proved here, from Theorem 13.152 and the projector alone, and the general statement belongs in the manifolds chapter. This is recorded as a Part II debt, in the same terms as Remarks 26.4 and 26.18 record theirs.

Everything else — the inverse metric, the determinant, the extrinsic curvature in coordinates, the dictionary, the two contractions of the Gauss equation and the elimination of the normal–normal Ricci term — is carried out above from the Levi-Civita connection of Theorem 13.150 and the Riemann tensor of Theorem 13.152.

Remark A.635. Appendix A.52 discharges the derivation owed at Proposition 26.41 of Section 26.6.5 in Chapter 26. What the chapter takes from it is narrow and is now established: $\sqrt{|g|} = N\sqrt{h}$ (Equation (A.969)), and that the Einstein–Hilbert Lagrangian contains no time derivative of the lapse or the shift (Step 5 of Theorem A.632). Those two facts are what make π_N and π_i vanish identically in Equation (26.81), hence what make N and N^i Lagrange multipliers rather than dynamical fields, hence what make $\mathcal{H}_\perp$ and $\mathcal{H}_i$ secondary constraints by outcome 2 of Proposition 26.10 — so the whole of Theorem 26.42, and with it the count of two degrees of freedom per point, rests on this section. The overall sign of Equation (26.80) is settled in Remark A.633 and changes none of that. The brackets of the constraints so obtained are computed in Appendix A.53.

A.53 The Hypersurface-Deformation Algebra

This appendix proves Proposition 26.43 of Chapter 26: the three brackets Equations (26.89) to (26.91) of the smeared constraints of Theorem 26.42. With them the eight constraints of general relativity are shown to be first class in the sense of Definition 26.12, so that Equation (26.21) applies and the count of two propagating degrees of freedom per point of space is established; and the last of the three exhibits, on the right-hand side, the inverse spatial metric h^{ij} — a function on phase space where a Lie algebra would carry a constant.

Everything is computed with *smeared* constraints. That is not a matter of taste. The unsmeared densities have brackets proportional to $\delta^3(\boldsymbol{x}-\boldsymbol{y})$ and to its first and second derivatives, and Equation (26.91) in unsmeared form is an identity between distributions in which the two sides must be compared after integrating twice by parts against test functions anyway. Smearing does that integration once and for all, at the start; every step below is then an ordinary integration by parts on smooth compactly supported data.

Two things are assumed rather than proved and are named here. The first is the constraint densities themselves, Equations (26.84) and (26.85), which Theorem 26.42 derives; nothing below depends on the overall sign discussed in Remark A.633, because the brackets are computed from the densities as the chapter displays them. The second is that all fields fall off fast enough for the surface terms of the integrations by parts to vanish — on a region with a boundary they do not, and what they contribute is exactly the ADM charges of Remark 26.45.

A.53.1 Conventions: weights, smearing functions, and the bracket

Notation A.636 (Densities and smearing). The canonical pair is (h_{ij}, π^{ij}) of Equation (26.82), with the field bracket Equation (26.47) read as

$$\{F,G\} = \int \mathrm{d}^3x \left(\frac{\delta F}{\delta h_{ij}(\boldsymbol{x})} \frac{\delta G}{\delta \pi^{ij}(\boldsymbol{x})} - \frac{\delta F}{\delta \pi^{ij}(\boldsymbol{x})} \frac{\delta G}{\delta h_{ij}(\boldsymbol{x})} \right) , \tag{A.1005}$$

functional derivatives with respect to h_{ij} and π^{ij} being taken with both regarded as symmetric. The *weights* are: h_{ij} is a tensor of weight 0; π^{ij} is a tensor *density* of weight 1, as Equation (26.82) shows through its factor $\sqrt{h}$; $\mathcal{H}_\perp$ of Equation (26.84) is a scalar density of weight 1, its kinetic part carrying $\pi\pi/\sqrt{h}$ and its curvature part $\sqrt{h}\,{}^{(3)}R$; and $\mathcal{H}_i$ of Equation (26.85) is a covector density of weight 1. The smearing functions f, g are scalars and ξ^i, ζ^i vectors, all of weight 0, all smooth, all of compact support, and — this is used constantly and is easy to forget — all *independent of the canonical variables*, so that they pass through every functional derivative untouched. Finally

$$H_\perp[f] = \int \mathrm{d}^3x\, f\, \mathcal{H}_\perp \,, \qquad H_\parallel[\xi] = \int \mathrm{d}^3x\, \xi^i \mathcal{H}_i \,, \tag{A.1006}$$

both of which are ordinary numbers because a weight-one density integrates without a metric factor.

Rests on Notation 26.28, Equation (26.82), and Theorem 26.42.

Getting a weight wrong is the commonest way this computation fails, so the one fact used about them is stated once and checked: for a weight-one vector density V^i,

$$D_i V^i = \partial_i V^i \,, \qquad \text{hence} \qquad \int \mathrm{d}^3x \; D_i V^i = 0 \,, \tag{A.1007}$$

for V of compact support. This is immediate from the covariant derivative of a density, $D_i V^i = \partial_i V^i + \Gamma^i{}_{ik} V^k - \Gamma^k{}_{ki} V^i$, the last term being the weight term; the two cancel. Every integration by parts below is an application of Equation (A.1007). For a weight-*zero* vector the corresponding statement carries a $\sqrt{h}$, $\sqrt{h} D_i V^i = \partial_i \left(\sqrt{h} V^i \right)$, and that form is used where the integrand carries an explicit $\sqrt{h}$.

The sign convention for the commutator of vector fields is

$$[\xi, \zeta]^i = \xi^j \partial_j \zeta^i - \zeta^j \partial_j \xi^i = (\mathcal{L}_\xi \zeta)^i \,, \tag{A.1008}$$

which is what makes the right-hand side of Equation (26.89) carry a plus sign rather than a minus.

A.53.2 The momentum constraint generates the spatial drag

Lemma A.637 (Closed form of $H_\parallel$, and what it generates)**.** *For every smearing vector ξ,*

$$H_\parallel[\xi] = \int \mathrm{d}^3x \; \pi^{ij} \, \mathcal{L}_\xi h_{ij} \,, \qquad \mathcal{L}_\xi h_{ij} = D_i \xi_j + D_j \xi_i \,, \tag{A.1009}$$

and consequently

$$\left\{ h_{ij}, H_\parallel[\xi] \right\} = \mathcal{L}_\xi h_{ij} \,, \qquad \left\{ \pi^{ij}, H_\parallel[\xi] \right\} = \mathcal{L}_\xi \pi^{ij} \,, \tag{A.1010}$$

the second Lie derivative being that of a weight-one contravariant density, $\mathcal{L}_\xi \pi^{ij} = \xi^k \partial_k \pi^{ij} - \pi^{kj} \partial_k \xi^i - \pi^{ik} \partial_k \xi^j + \pi^{ij} \partial_k \xi^k$.

Rests on Equations (26.85) and (A.1005) and Notation A.636.

Proof. *Derives Lemma A.637.*

Equation (A.1009). By Equation (26.85), $H_\parallel[\xi] = -2 \int \mathrm{d}^3x \; \xi^i D_j \pi^j{}_i = -2 \int \mathrm{d}^3x \; \xi_k D_j \pi^{jk}$, the index having been moved through D because $Dh = 0$. The quantity $\xi_k \pi^{jk}$ is a weight-one vector density, so Equation (A.1007) gives $\int D_j \left(\xi_k \pi^{jk} \right) = 0$, whence

$$H_\parallel[\xi] = 2 \int \mathrm{d}^3x \; (D_j \xi_k) \, \pi^{jk} = \int \mathrm{d}^3x \; \pi^{jk} \, (D_j \xi_k + D_k \xi_j) \,, \tag{A.1011}$$

the symmetrization being free because π^{jk} is symmetric. That $D_j \xi_k + D_k \xi_j = \mathcal{L}_\xi h_{jk}$ is Equation (13.275).

First of Equation (A.1010). Take $F = h_{ij}(\boldsymbol{x})$ in Equation (A.1005): only the first term survives, and $\{h_{ij}(\boldsymbol{x}), G\} = \delta G / \delta \pi^{ij}(\boldsymbol{x})$. Applied to Equation (A.1009), in which π appears linearly and undifferentiated, this is $\mathcal{L}_\xi h_{ij}$.

Second. Likewise $\{\pi^{ij}(\boldsymbol{x}), G\} = -\delta G / \delta h_{ij}(\boldsymbol{x})$. Write out Equation (A.1009) in partial derivatives, $\mathcal{L}_\xi h_{ab} = \xi^k \partial_k h_{ab} + h_{kb} \partial_a \xi^k + h_{ak} \partial_b \xi^k$, and vary. The first term contributes, after one integration by parts, $-\partial_k \left(\xi^k \pi^{ij} \right)$; the second contributes $\pi^{kj} \partial_k \xi^i$ and the third $\pi^{ik} \partial_k \xi^j$. Hence

$$\frac{\delta H_\parallel[\xi]}{\delta h_{ij}} = -\xi^k \partial_k \pi^{ij} - \pi^{ij} \partial_k \xi^k + \pi^{kj} \partial_k \xi^i + \pi^{ik} \partial_k \xi^j = -\mathcal{L}_\xi \pi^{ij} \,, \tag{A.1012}$$

and the minus of the bracket cancels it. Note where the weight shows itself: the term $\pi^{ij}\partial_k\xi^k$, which distinguishes the Lie derivative of a density from that of a tensor, comes from the integration by parts in the first term and from nowhere else. Had π^{ij} been treated as a weight-zero tensor, the density term would be spurious and Equation (26.89) would fail. □

A.53.3 The first two brackets

Both follow from Lemma A.637 and one observation, which is worth isolating because it does the work twice.

Lemma A.638 (Naturality)**.** *Let Φ be a functional of the canonical variables and of one smearing field σ (a scalar f or a vector ξ),*

$$\Phi[\sigma; h, \pi] = \int \mathrm{d}^3x\, \mathcal{F}(\sigma, h, \pi)\ , \tag{A.1013}$$

with $\mathcal{F}$ a scalar density of weight one built covariantly from its arguments. Then

$$\Big\{\Phi[\sigma], H_\parallel[\zeta]\Big\} = -\Phi[\mathcal{L}_\zeta\sigma]\ . \tag{A.1014}$$

Rests on Lemma A.637 and Equation (A.1005)*.*

Proof. *Derives Lemma A.638.*

By Equation (A.1005) and Equation (A.1010),

$$\Big\{\Phi, H_\parallel[\zeta]\Big\} = \int \mathrm{d}^3x \left(\frac{\delta\Phi}{\delta h_{ij}}\mathcal{L}_\zeta h_{ij} + \frac{\delta\Phi}{\delta\pi^{ij}}\mathcal{L}_\zeta\pi^{ij}\right) = \delta_\zeta\Phi\,, \tag{A.1015}$$

the change of Φ when the canonical fields alone are dragged by ζ. But Φ is invariant when *everything* is dragged: if all of σ, h, π are transported, $\mathcal{F}$ changes by $\mathcal{L}_\zeta\mathcal{F} = \partial_k\left(\zeta^k\mathcal{F}\right)$, because $\mathcal{F}$ is a weight-one scalar density, and that integrates to zero. Hence dragging the fields alone gives minus the result of dragging σ alone, which is Equation (A.1014). □

Proposition A.639 (The first two brackets)**.** *Equations* (26.89) *and* (26.90) *hold:*

$$\Big\{H_\parallel[\xi], H_\parallel[\zeta]\Big\} = H_\parallel[[\xi,\zeta]]\ , \qquad \Big\{H_\parallel[\xi], H_\perp[f]\Big\} = H_\perp\Big[\xi^i\partial_i f\Big]\ . \tag{A.1016}$$

Rests on Lemma A.638 and Equations (26.84) *and* (A.1008)*.*

Proof. *Derives Proposition A.639.*

Both integrands satisfy the hypothesis of Lemma A.638: $\xi^i\mathcal{H}_i$ and $f\mathcal{H}_\perp$ are weight-one scalar densities built covariantly from the smearing field and the canonical pair, by Notation A.636.

For the first, apply Equation (A.1014) with $\Phi = H_\parallel$, $\sigma = \xi$: $\Big\{H_\parallel[\xi], H_\parallel[\zeta]\Big\} = -H_\parallel[\mathcal{L}_\zeta\xi] = -H_\parallel[[\zeta,\xi]] = H_\parallel[[\xi,\zeta]]$ by Equation (A.1008). Nothing about the detailed form of $\mathcal{H}_i$ was used beyond Lemma A.637; the identity is $[\mathcal{L}_\xi, \mathcal{L}_\zeta] = \mathcal{L}_{[\xi,\zeta]}$ in disguise.

For the second, apply it with $\Phi = H_\perp$, $\sigma = f$ a scalar, so $\mathcal{L}_\xi f = \xi^i\partial_i f$: $\Big\{H_\perp[f], H_\parallel[\xi]\Big\} = -H_\perp[\xi^i\partial_i f]$, and the antisymmetry of the bracket gives the stated form. The content is that $\mathcal{H}_\perp$ is a scalar density of weight one — that dragging $f\mathcal{H}_\perp$ produces $\mathcal{L}_\xi\left(f\mathcal{H}_\perp\right)$, whose total-divergence part integrates away and whose remainder is $\left(\xi^i\partial_i f\right)\mathcal{H}_\perp$. □

A.53.4 The variation of the intrinsic curvature

The third bracket needs the piece a reader cannot supply from the chapter: how $\int \sqrt{h}\,{}^{(3)}R$ responds to a variation of h_{ij}.

Lemma A.640 (Variation of the integrated three-curvature)**.** *For any smooth f of compact support, independent of h_{ij},*

$$\frac{\delta}{\delta h_{ij}} \int \mathrm{d}^3y\, f\sqrt{h}\,{}^{(3)}R = -f\sqrt{h}\,{}^{(3)}G^{ij} + \sqrt{h}\left(D^iD^j - h^{ij}D^2\right) f\,, \tag{A.1017}$$

with ${}^{(3)}G^{ij} = {}^{(3)}R^{ij} - \frac{1}{2}h^{ij}\,{}^{(3)}R$ the three-dimensional Einstein tensor and $D^2 = h^{ij}D_iD_j$.

Rests on Definition 13.153, Equation (13.299), and Theorem 13.152.

Proof. *Derives Lemma A.640.*

Three pieces. First, $\delta\sqrt{h} = \frac{1}{2}\sqrt{h}\,h^{ij}\delta h_{ij}$, from $\delta \ln\det h = \mathrm{tr}\,(h^{-1}\delta h)$. Second, $\delta h^{ij} = -h^{ik}h^{jl}\delta h_{kl}$, from varying $h^{ik}h_{kj} = \delta^i_j$; so $\delta\left({}^{(3)}R\right) = {}^{(3)}R_{ij}\delta h^{ij} + h^{ij}\delta\,{}^{(3)}R_{ij} = -{}^{(3)}R^{ij}\delta h_{ij} + h^{ij}\delta\,{}^{(3)}R_{ij}$.

Third, the term $h^{ij}\delta\,{}^{(3)}R_{ij}$. The variation of a Christoffel symbol is a tensor, and from Equation (13.299) with vanishing torsion,

$$\delta\Gamma^k{}_{ij} = \tfrac{1}{2}h^{kl}\left(D_i\delta h_{lj} + D_j\delta h_{li} - D_l\delta h_{ij}\right)\,, \tag{A.1018}$$

which one checks by evaluating both sides in normal coordinates at a point, where $\Gamma = 0$ and $D = \partial$. Then Equation (13.306) gives $\delta\,{}^{(3)}R_{ij} = D_k\delta\Gamma^k{}_{ij} - D_i\delta\Gamma^k{}_{kj}$, so $h^{ij}\delta\,{}^{(3)}R_{ij} = D_kv^k$ with $v^k = h^{ij}\delta\Gamma^k{}_{ij} - h^{kj}\delta\Gamma^i{}_{ij}$. Evaluate the two pieces from Equation (A.1018). In the second, the first and third terms of the bracket cancel on contraction, leaving $\delta\Gamma^i{}_{ij} = \frac{1}{2}D_j\left(h^{il}\delta h_{il}\right)$. In the first, the two symmetric terms combine, leaving $h^{ij}\delta\Gamma^k{}_{ij} = h^{kl}D^j\delta h_{lj} - \frac{1}{2}D^k\left(h^{ij}\delta h_{ij}\right)$. Hence

$$v^k = h^{kl}D^j\delta h_{lj} - D^k\left(h^{ij}\delta h_{ij}\right)\,, \qquad D_kv^k = \left(D^iD^j - h^{ij}D^2\right)\delta h_{ij}\,. \tag{A.1019}$$

Collecting,

$$\delta\left(\sqrt{h}\,{}^{(3)}R\right) = -\sqrt{h}\,{}^{(3)}G^{ij}\delta h_{ij} + \sqrt{h}\left(D^iD^j - h^{ij}D^2\right)\delta h_{ij}\,, \tag{A.1020}$$

the first term assembling $\frac{1}{2}h^{ij}\,{}^{(3)}R - {}^{(3)}R^{ij}$. Multiply by f, integrate, and move the two derivatives of the second term onto f using $\sqrt{h}\,D_kV^k = \partial_k\left(\sqrt{h}V^k\right)$ twice. The result is Equation (A.1017); note that D^iD^jf is automatically symmetric, f being a scalar. □

A.53.5 The third bracket

Theorem A.641 (The normal–normal bracket)**.** *Equation (26.91) holds:*

$$\{H_\perp[f], H_\perp[g]\} = H_\parallel\left[h^{ij}\left(f\partial_jg - g\partial_jf\right)\right]\,. \tag{A.1021}$$

Rests on Lemma A.640 and Equations (26.84) and (26.85).

Proof. *Derives Theorem A.641.*

Step 1: the two functional derivatives. From Equation (26.84), in which π occurs only algebraically,

$$\frac{\delta H_\perp[f]}{\delta\pi^{ij}} = f\,B_{ij}\,, \qquad B_{ij} := \frac{4\kappa}{\sqrt{h}}\left(\pi_{ij} - \tfrac{1}{2}\pi h_{ij}\right)\,, \tag{A.1022}$$

since $\delta\left(\pi_{kl}\pi^{kl}\right)/\delta\pi^{ij} = 2\pi_{ij}$ and $\delta\left(\pi^2\right)/\delta\pi^{ij} = 2\pi h_{ij}$. From Lemma A.640 together with the variation of the kinetic part — which involves h_{ij} *algebraically only*, through π_{ij}, π and $\sqrt{h}$, and which therefore produces no derivative of f —

$$\frac{\delta H_\perp[f]}{\delta h_{ij}} = f\,A^{ij} - \frac{\sqrt{h}}{2\kappa}\,\Delta^{ij} f\,, \qquad \Delta^{ij} := D^i D^j - h^{ij} D^2\,, \tag{A.1023}$$

where A^{ij} is a local expression in h and π whose exact form is never needed: it collects the kinetic variation and the term $+\sqrt{h}\,{}^{(3)}G^{ij}/2\kappa$, and the only property used is that it multiplies f undifferentiated.

Step 2: what cancels, and why. Insert Equations (A.1022) and (A.1023) into Equation (A.1005):

$$\begin{aligned}\{H_\perp[f], H_\perp[g]\} &= \int \mathrm{d}^3x \left[\left(f A^{ij} - \frac{\sqrt{h}}{2\kappa}\Delta^{ij} f\right) g B_{ij} - f B_{ij}\left(g A^{ij} - \frac{\sqrt{h}}{2\kappa}\Delta^{ij} g\right)\right] \\ &= \frac{1}{2\kappa}\int \mathrm{d}^3x\,\sqrt{h}\,B_{ij}\left(f\,\Delta^{ij} g - g\,\Delta^{ij} f\right)\,,\end{aligned} \tag{A.1024}$$

because the terms $fgA^{ij}B_{ij}$ are symmetric under $f \leftrightarrow g$ and cancel between the two halves of the bracket. This is the load-bearing observation of the whole computation and it deserves to be stated in words: *everything ultralocal in the smearing functions drops out.* The Einstein-tensor part of Equation (A.1017) goes with it, and so does the entire kinetic variation; what survives is only the group Δ^{ij}, which is precisely the part carrying *two spatial derivatives.* That is why the answer will carry a metric where a structure constant would sit: two derivatives must have their indices raised, and h^{ij} is what raises them.

Step 3: contract. With $\sqrt{h}B_{ij}/2\kappa = 2\left(\pi_{ij} - \frac{1}{2}\pi h_{ij}\right)$,

$$\left(\pi_{ij} - \tfrac{1}{2}\pi h_{ij}\right)\Delta^{ij} f = \pi_{ij} D^i D^j f - \tfrac{1}{2}\pi D^2 f - \pi D^2 f + \tfrac{3}{2}\pi D^2 f = \pi_{ij} D^i D^j f\,, \tag{A.1025}$$

the three trace terms cancelling exactly, the last carrying $h_{ij}h^{ij} = 3$. Hence

$$\{H_\perp[f], H_\perp[g]\} = 2\int \mathrm{d}^3x\;\pi^{ij}\left(f\,D_i D_j g - g\,D_i D_j f\right)\,. \tag{A.1026}$$

Step 4: one integration by parts. π^{ij} is a weight-one density, so Equation (A.1007) applies directly to $\pi^{ij} f D_j g$:

$$\int \pi^{ij} f\,D_i D_j g = -\int \left[\left(D_i \pi^{ij}\right) f + \pi^{ij} D_i f\right] D_j g\,, \tag{A.1027}$$

and likewise with f and g exchanged. In the difference, the term $\pi^{ij}\left(D_i f\,D_j g - D_i g\,D_j f\right)$ is antisymmetric in i, j contracted with the symmetric π^{ij}, and vanishes. What remains is

$$\{H_\perp[f], H_\perp[g]\} = -2\int \mathrm{d}^3x\;\left(D_j \pi^{ji}\right)\left(f\,D_i g - g\,D_i f\right)\,. \tag{A.1028}$$

Step 5: recognize the momentum constraint. Lower the index on π and raise it on the bracket, which is legitimate because $Dh = 0$: $\left(D_j\pi^{ji}\right)\left(fD_i g - gD_i f\right) = \left(D_j \pi^j{}_k\right) h^{ki}\left(f\partial_i g - g\partial_i f\right)$, the covariant derivatives of the scalars f, g being ordinary ones. By Equation (26.85), $-2D_j\pi^j{}_k = \mathcal{H}_k$, so

$$\{H_\perp[f], H_\perp[g]\} = \int \mathrm{d}^3x\;\mathcal{H}_k\,h^{ki}\left(f\partial_i g - g\partial_i f\right) = H_\parallel\left[h^{ij}\left(f\partial_j g - g\partial_j f\right)\right]\,, \tag{A.1029}$$

which is Equation (A.1021). □

Corollary A.642 (The constraints are first class)**.** *Every right-hand side in Equations* (A.1016) *and* (A.1021) *is a smeared constraint, and the primary constraints Equation* (26.81) *have vanishing bracket with everything, since no $\mathcal{H}$ contains N or N^i. So all eight constraints of Theorem 26.42 are first class in the sense of Definition 26.12, $F = 8$ and $S = 0$, and Equation* (26.21) *gives $2 \times 10 - 2 \times 8 = 4$ per point of space.*

Rests on Theorems 26.17 and A.641 and Proposition A.639.

Proof. *Derives Corollary A.642.*

By Proposition 26.13 it suffices that the brackets of the generators close on the constraint set, which is what the three displayed identities say — each right-hand side is $H_\perp$ or $H_\parallel$ of some smearing field, hence weakly zero. The smearing fields on the right of Equation (A.1021) depend on h_{ij}, but that is irrelevant to the weak vanishing: a phase-space-dependent coefficient times a constraint still vanishes on Σ. The count is Equation (26.21) with $2n = 20$ per point. □

A.53.6 The geometric reading

Remark A.643 (Why the metric sits where a structure constant would). The three brackets are the composition law for deformations of a spacelike surface embedded in a Lorentzian spacetime, and read that way they explain themselves.

$H_\parallel[\xi]$ deforms the surface *within itself*: it slides the points along ξ and leaves the surface, as a subset of spacetime, where it was. Two such slides compose as diffeomorphisms of a three-manifold compose, which is Equation (A.1016) left, and their commutator is again a slide. That part of the algebra *is* a Lie algebra — the Lie algebra of vector fields on the leaf — and it is the only part that is.

$H_\perp[f]$ pushes the surface off itself, by a proper time f/c per point along the normal. The mixed bracket says only that f is a scalar: sliding and then pushing differs from pushing and then sliding by pushing with the dragged function $\xi^i \partial_i f$.

The third bracket is the one with content. Push by f, then by g; push by g, then by f. Each pair of normal pushes lands on the same surface — to first order the two orders of deformation reach the same place — but not on the same *points* of it: the two routes differ by a slide. The slide is easy to see. The normal at a point of the first intermediate surface is not the normal at the corresponding point of the second, because the two intermediate surfaces are tilted relative to one another by an amount proportional to the gradient of the pushing function; and tilting a normal is exactly what turns a normal deformation into a tangential one. The resulting tangent vector is $f\,\nabla g - g\,\nabla f$ — the gradient of one function weighted by the other, antisymmetrized — and a gradient is a covector, so to be a deformation vector it must have its index raised. There is only one object available to raise it: the metric of the surface itself. Hence h^{ij} in Equation (A.1021).

And hence the sentence that closes Proposition 26.43. The coefficient on the right of the third bracket is a *function on phase space*, not a number, so Equation (26.16) for general relativity has structure functions and the first-class algebra is not a Lie algebra. This is not a technicality: it is the reason the constraint algebra of gravity cannot be treated as the algebra of a symmetry group with a fixed structure, why the BRST charge of Appendix A.54 needs terms beyond the two displayed in Equation (26.97), and why the comparison with Yang–Mills of Section 26.6.4, where the same brackets do close on constants, is the sharpest single contrast the chapter draws.

Remark A.644 (What is quoted here). Nothing outside the treatise. The constraint densities Equations (26.84) and (26.85) are taken from Theorem 26.42, which proves them; the Levi-Civita apparatus is Theorems 13.150 and 13.152, and the component form of the Lie derivative is Proposition 13.127. Two assumptions are made and are not hidden. The smearing fields are independent of the canonical variables — for field-dependent smearings

the brackets acquire extra terms and Equation (A.1016) is false as it stands. And the fields fall off fast enough that every integration by parts loses its surface term; on a region with a boundary they do not, the constraints are not even functionally differentiable without supplementary surface integrals, and those integrals are the ADM energy and momentum of Remark 26.45.

Remark A.645. Appendix A.53 discharges the derivation owed at Proposition 26.43 of Section 26.6.5 in Chapter 26. It completes the last step of Theorem 26.42, which asserts that the eight constraints are first class and points forward to Equation (26.89) for the proof; with Corollary A.642 the count of two degrees of freedom per point of space — the same count Proposition 26.32 gives for light, and the two polarizations detected in Chapter 47 — rests on nothing unproved. The Lagrangian from which those constraints were obtained is established in Appendix A.52.

A.54 Existence and Uniqueness of a Nilpotent BRST Charge

This appendix proves Theorem 26.51 of Section 26.7.3 in Chapter 26: for every regular, irreducible set of first-class constraints the series Equation (26.97) can be continued to a Grassmann-odd function Ω of ghost number $+1$ satisfying Equation (26.98) exactly; two such functions with the same leading term differ by a canonical transformation of the extended phase space; and when the structure functions of Equation (26.16) are constants the series stops at the two terms Equation (26.97) displays.

This is the statement that makes BRST a method rather than a device. Without it the definition Definition 26.50 would be a recipe that happens to work for Yang–Mills and is silent about general relativity, whose structure functions are genuinely functions (Proposition 26.43, proved in Appendix A.53); with it, the cohomological characterization Equation (26.99) of the physical state space is available for every first-class system.

Scope. BRST is in this treatise because it is the machinery behind the perturbative calculations of Chapter 102 and the path-integral development of Chapter 106, whose predictions are measured; it is not here as a formal programme. Accordingly this section stops where the chapter stops — at the Hamiltonian BRST charge of a finite-dimensional constrained system — and does not go on to the antifield or Batalin–Vilkovisky formulation, which is a different construction with different inputs and is used nowhere in this book.

Attribution. The existence of a nilpotent charge for a general first-class system is due to Fradkin and Vilkovisky and, in the form with structure functions, to Batalin, Fradkin and Vilkovisky; the homological proof organized around the Koszul–Tate differential, which is the one given below, is due to Henneaux and Teitelboim. None of these works has an entry in this treatise's bibliography, so — exactly as Remark 26.2 records for the rest of the chapter — the attribution is made in words and nothing below rests on it. The original BRST papers [1564, 1571] are cited in the chapter.

A.54.1 The extended phase space and its two gradings

Notation A.646 (Gradings and brackets). Let z^c, $c = 1, \dots, 2n$, be the original phase-space variables and γ_A, $A = 1, \dots, F$, the first-class constraints, with Equation (26.16), $\{\gamma_A, \gamma_B\} = f_{AB}{}^C \gamma_C$. Adjoin the ghost pairs $\left(\eta^A, \mathcal{P}_A\right)$ of Definition 26.50. Functions of $(z, \eta, \mathcal{P})$ carry a Grassmann parity $\varepsilon \in \{0, 1\}$ and the graded bracket obeys

$$\{F, G\} = -(-1)^{\varepsilon_F \varepsilon_G} \{G, F\} , \qquad \{F, GH\} = \{F, G\} H + (-1)^{\varepsilon_F \varepsilon_G} G \{F, H\} , \tag{A.1030}$$

together with the graded Jacobi identity. It splits as

$$\{F, G\} = \{F, G\}_M + \{F, G\}_{\text{gh}} , \tag{A.1031}$$

where $\{\cdot,\cdot\}_M$ differentiates only the z^c — so that the ghosts pass through it as constants — and $\{\cdot,\cdot\}_{\mathrm{gh}}$ only the ghost pair, with $\left\{\eta^A,\mathcal{P}_B\right\}=-\delta^A_B$.

Three gradings are used. The *pure ghost number* counts the η's; the *antighost number* counts the $\mathcal{P}$'s,

$$\operatorname{antigh}\mathcal{P}_A=1\,,\qquad \operatorname{antigh}\eta^A=\operatorname{antigh}z^c=0\,, \tag{A.1032}$$

and the *ghost number* of Definition 26.50 is their difference, $\operatorname{gh}=\operatorname{pgh}-\operatorname{antigh}$, so that $\operatorname{gh}\eta^A=+1$ and $\operatorname{gh}\mathcal{P}_A=-1$. Parity is pgh + antigh modulo two.

Rests on Definition 26.50 and Equations (26.16) and (26.97).

Two grading facts are used constantly and are recorded once. $\{\cdot,\cdot\}_M$ preserves the antighost number, while $\{\cdot,\cdot\}_{\mathrm{gh}}$ removes one η and one $\mathcal{P}$ and so *lowers it by one*; both add ghost numbers. And an Ω that is odd with $\operatorname{gh}\Omega=+1$ decomposes as

$$\Omega=\sum_{k\geq 0}\Omega_{(k)}\,,\qquad \operatorname{antigh}\Omega_{(k)}=k\,, \tag{A.1033}$$

in which $\Omega_{(k)}$ has pure ghost number $k+1$: it is a polynomial carrying exactly $k+1$ ghosts and k ghost momenta, hence $2k+1$ Grassmann-odd factors, hence odd, as it must be. The first two terms are the ones Equation (26.97) displays,

$$\Omega_{(0)}=\eta^A\gamma_A\,,\qquad \Omega_{(1)}=-\tfrac{1}{2}\eta^B\eta^A f_{AB}{}^C\mathcal{P}_C\,. \tag{A.1034}$$

A.54.2 The Koszul–Tate differential

Definition A.647 (Koszul–Tate differential)**.** δ is the odd derivation of the algebra of functions on the extended phase space fixed by

$$\delta\mathcal{P}_A=-\gamma_A\,,\qquad \delta z^c=0\,,\qquad \delta\eta^A=0\,. \tag{A.1035}$$

It lowers the antighost number by one and raises the ghost number by one.

Rests on Notation A.646 and Equation (26.16).

Lemma A.648 (δ is the ghost bracket with $\Omega_{(0)}$, and $\delta^2=0$)**.** *For every X, $\delta X=\left\{X,\Omega_{(0)}\right\}_{gh}$, and $\delta^2=0$.*

Rests on Definition A.647 and Equations (A.1030) and (A.1034).

Proof. *Derives Lemma A.648.*

$\Omega_{(0)}$ contains no $\mathcal{P}$, so $\left\{\cdot,\Omega_{(0)}\right\}_{\mathrm{gh}}$ annihilates z^c and η^A, as δ does. On $\mathcal{P}_A$, the graded Leibniz rule Equation (A.1030) gives $\left\{\mathcal{P}_A,\eta^B\gamma_B\right\}_{\mathrm{gh}}=\left\{\mathcal{P}_A,\eta^B\right\}\gamma_B$, and graded antisymmetry between two odd objects gives $\left\{\mathcal{P}_A,\eta^B\right\}=\left\{\eta^B,\mathcal{P}_A\right\}=-\delta^B_A$, so the value is $-\gamma_A=\delta\mathcal{P}_A$. Both maps are odd derivations agreeing on generators, hence equal.

For nilpotency, δ^2 is the square of an odd derivation and is therefore an even derivation; it vanishes on z and η trivially and on $\mathcal{P}_A$ because $\delta^2\mathcal{P}_A=-\delta\gamma_A=0$, the constraints being functions of z alone. A derivation vanishing on generators is zero. □

Remark A.649 (The regularity hypothesis, in the form the proof needs). Remark 26.7 assumes two things about the constraint set, and Theorem 26.51 adds a third word, *irreducible*. Spelled out, what is assumed is: (i) the differentials $\mathrm{d}\gamma_A$ are linearly independent at every point of the surface Σ they define; (ii) every smooth function vanishing on Σ is $c^A\gamma_A$ with smooth c^A; and (iii) every λ^A with $\lambda^A\gamma_A=0$ identically is of the form $\lambda^A=\mu^{AB}\gamma_B$ with $\mu^{AB}=-\mu^{BA}$ — there are no relations among the constraints beyond the trivial ones. Item (iii) is what *irreducible* means; a reducible set, such as the one obtained by writing a two-form constraint in components with a Bianchi identity among them, fails it, and the construction below then needs ghosts for ghosts and is not carried out in this treatise.

Lemma A.650 shows that (i) already implies (ii) and (iii) locally, so the three are not independent assumptions; the content is entirely in (i), which is the same regularity that Proposition 26.5 and Theorem 26.17 rest on.

Lemma A.650 (Flattening the constraints)**.** *About each point of Σ there are local coordinates $\left(y^A, w^\alpha\right)$ on phase space in which $\gamma_A = y^A$. In such coordinates, (ii) and (iii) of Remark A.649 hold.*

Rests on Remarks 26.4 and 26.7 and Theorem A.286.

Proof. *Derives Lemma A.650.*

The map $z \longmapsto (\gamma_1(z), \dots, \gamma_F(z))$ has surjective differential at each point of Σ by (i), hence constant maximal rank on a neighbourhood; the constant-rank theorem stated in Remark 26.4, itself a consequence of Theorem A.286, supplies coordinates in which it is the projection onto the first F of them. Those coordinates are the $\left(y^A, w^\alpha\right)$.

For (ii), let $F(y, w)$ vanish at $y = 0$. By the fundamental theorem of calculus applied along the segment $t \longmapsto (ty, w)$,

$$F(y,w) = y^A \lambda_A(y,w)\,, \qquad \lambda_A(y,w) = \int_0^1 \left(\frac{\partial F}{\partial y^A}\right)(ty,w)\,\mathrm{d}t\,, \tag{A.1036}$$

and λ_A is smooth by differentiation under the integral sign. That is (ii). Item (iii) is the case $k = 1$ of Lemma A.651 below, whose proof uses only Equation (A.1036) and the coordinates just constructed, so nothing is circular. □

Lemma A.651 (Acyclicity of δ)**.** *On the coordinate patch of Lemma A.650: $H_k(\delta) = 0$ for every $k \geq 1$ — every δ-closed function of antighost number $k \geq 1$ is δ of a function of antighost number $k+1$ — and $H_0(\delta)$ is the algebra of smooth functions on Σ (tensored with the ghosts).*

Rests on Lemma A.650, Definition A.647, and Remark A.649.

Proof. *Derives Lemma A.651.*

Work in the coordinates of Lemma A.650, so that $\delta \mathcal{P}_A = -y^A$. The η's play no part: δ annihilates them and they simply multiply everything, so the complex is a free module over the Grassmann algebra they generate and it suffices to treat η-independent coefficients.

A homotopy. Let σ be the odd derivation with

$$\sigma y^A = \mathcal{P}_A\,, \qquad \sigma \mathcal{P}_A = 0\,, \qquad \sigma w^\alpha = 0\,, \qquad \sigma \eta^A = 0\,, \tag{A.1037}$$

so that on functions $\sigma f = \mathcal{P}_A\, \partial f / \partial y^A$. The anticommutator of two odd derivations is an even derivation, so

$$\mathcal{N} := -\left(\delta\sigma + \sigma\delta\right)\,, \tag{A.1038}$$

is a derivation, and it is determined by its values on generators: $\mathcal{N} y^A = -\delta \mathcal{P}_A = y^A$, $\mathcal{N}\mathcal{P}_A = -\sigma\left(-y^A\right) = \mathcal{P}_A$, and $\mathcal{N} w^\alpha = \mathcal{N}\eta^A = 0$. So $\mathcal{N}$ is the Euler operator counting the joint degree in y and $\mathcal{P}$. Because $\delta^2 = 0$, $\mathcal{N}$ commutes with δ.

Inverting $\mathcal{N}$ in positive antighost degree. A general element of antighost number k is $a = \frac{1}{k!} a^{A_1 \dots A_k}(y,w)\, \mathcal{P}_{A_1} \cdots \mathcal{P}_{A_k}$, on which $\mathcal{N} = k + \mathcal{N}_y$ with $\mathcal{N}_y = y^A \partial / \partial y^A$. For $k \geq 1$ define

$$\left(\mathcal{N}^{-1} a\right)(y,w) := \int_0^1 t^{k-1}\, a(ty,w)\,\mathrm{d}t\,, \tag{A.1039}$$

acting on the coefficient functions and leaving the $\mathcal{P}$'s alone; it is smooth by differentiation under the integral sign. It is the inverse: from $\frac{\mathrm{d}}{\mathrm{d}t}\left[t^k a(ty,w)\right] = t^{k-1}\left[k\, a + \mathcal{N}_y a\right](ty,w)$, integrating from 0 to 1 — where the boundary term at $t = 0$ vanishes because $k \geq 1$ — gives $a = \mathcal{N}^{-1}\left(k + \mathcal{N}_y\right) a = \mathcal{N}^{-1}\mathcal{N} a$. Since $\mathcal{N}$ commutes with δ and is invertible in every antighost degree ≥ 1, so does $\mathcal{N}^{-1}$.

Acyclicity. Let $\delta a = 0$ with $\operatorname{antigh} a = k \geq 1$. Then by Equation (A.1038), $\mathcal{N}a = -\delta\sigma a - \sigma\delta a = -\delta\sigma a$, and applying $\mathcal{N}^{-1}$, which commutes with δ,

$$a = -\delta\left(\mathcal{N}^{-1}\sigma a\right), \tag{A.1040}$$

so a is δ-exact, with a primitive of antighost number $k+1$.

Degree zero. At antighost number 0 every element is closed, and the image of δ from degree one is $\left\{\lambda^A\gamma_A\right\}$, which by Equation (A.1036) is exactly the ideal of functions vanishing on Σ. Hence $H_0(\delta) = C^\infty(\Sigma)$.

This is the mathematical heart of the section, and it is worth naming what was consumed: the coordinates supplied by regularity, and nothing else. Irreducibility — item (iii) of Remark A.649 — is the case $k = 1$ of what has just been proved, since $\lambda^A\mathcal{P}_A$ is δ-closed precisely when $\lambda^A\gamma_A = 0$, and a primitive of antighost number 2 is an antisymmetric μ^{AB} with $\lambda^A = \mu^{AB}\gamma_B$. □

A.54.3 The recursion

Lemma A.652 (Nilpotency, order by order)**.** *With Ω expanded as in Equation (A.1033), the antighost-k component of $\{\Omega,\Omega\}$ is*

$$\{\Omega,\Omega\}_{(k)} = 2\,\delta\Omega_{(k+1)} - 2D_{(k)}\,, \tag{A.1041}$$

where

$$D_{(k)} := -\frac{1}{2}\left[\sum_{\substack{i+j=k+1\\ i,j\geq 1}}\left\{\Omega_{(i)},\Omega_{(j)}\right\}_{gh} + \sum_{i+j=k}\left\{\Omega_{(i)},\Omega_{(j)}\right\}_{M}\right], \tag{A.1042}$$

depends on $\Omega_{(0)},\dots,\Omega_{(k)}$ only. So Equation (26.98) is the sequence of equations $\delta\Omega_{(k+1)} = D_{(k)}$, $k \geq 0$. Explicitly

$$D_{(0)} = -\tfrac{1}{2}\,\eta^A\eta^B f_{AB}{}^C\gamma_C\,, \tag{A.1043}$$

$$D_{(1)} = -\tfrac{1}{2}\left\{\Omega_{(1)},\Omega_{(1)}\right\}_{gh} - \left\{\Omega_{(0)},\Omega_{(1)}\right\}_{M}\,, \tag{A.1044}$$

and $\Omega_{(1)}$ of Equation (A.1034) solves $\delta\Omega_{(1)} = D_{(0)}$.

Rests on Lemma A.648, Notation A.646, and Equation (26.98).

Proof. *Derives Lemma A.652.*

Expand $\{\Omega,\Omega\}$ bilinearly and sort by antighost number, using that $\{\cdot,\cdot\}_M$ preserves it and $\{\cdot,\cdot\}_{\mathrm{gh}}$ lowers it by one. The terms of the ghost sum with $i = 0$ or $j = 0$ are $\left\{\Omega_{(0)},\Omega_{(k+1)}\right\}_{\mathrm{gh}} + \left\{\Omega_{(k+1)},\Omega_{(0)}\right\}_{\mathrm{gh}}$, and the bracket of two odd functions is graded-symmetric by Equation (A.1030), so these are equal and their sum is $2\left\{\Omega_{(k+1)},\Omega_{(0)}\right\}_{\mathrm{gh}} = 2\delta\Omega_{(k+1)}$ by Lemma A.648. Everything else is Equation (A.1042). That $D_{(k)}$ involves no $\Omega_{(j)}$ with $j > k$ is immediate from the ranges of the two sums.

For Equation (A.1043): since $\{\cdot,\cdot\}_M$ differentiates only the z^c, the ghosts pass through it, and moving one odd η past the even object $\partial_c\gamma_A$ costs no sign, so

$$\left\{\Omega_{(0)},\Omega_{(0)}\right\}_M = \eta^A\eta^B\left\{\gamma_A,\gamma_B\right\} = \eta^A\eta^B f_{AB}{}^C\gamma_C\,, \tag{A.1045}$$

by Equation (26.16). Halving and negating gives Equation (A.1043). Equation (A.1044) is the case $k = 1$ of Equation (A.1042), the ghost sum having only the term $i = j = 1$ and the M sum only the two equal terms $\left\{\Omega_{(0)},\Omega_{(1)}\right\}_M$.

Finally, δ passes through the even coefficient $-\frac{1}{2}\eta^B\eta^A f_{AB}{}^C$ without a sign and $\delta\mathcal{P}_C = -\gamma_C$, so

$$\delta\Omega_{(1)} = \tfrac{1}{2}\eta^B\eta^A f_{AB}{}^C\gamma_C = -\tfrac{1}{2}\eta^A\eta^B f_{AB}{}^C\gamma_C = D_{(0)}\,, \tag{A.1046}$$

the middle step by anticommutativity of the ghosts. So the term Equation (26.97) displays is not a guess: it is the unique solution of the first equation of the recursion, up to the δ-closed ambiguity that Appendix A.54.6 disposes of. □

Notice what the first step already required. $D_{(0)}$ has antighost number 0, where δ is *not* acyclic, so $\delta\Omega_{(1)} = D_{(0)}$ is solvable only if $D_{(0)}$ lies in the image of δ — that is, by Lemma A.651, only if it vanishes on Σ. Equation (A.1043) shows it is proportional to the constraints, and that is precisely the statement that the constraints are first class. The whole construction is powered by Equation (26.16), and it fails at the first step for a set that is not first class.

A.54.4 Existence

Theorem A.653 (Existence of a nilpotent BRST charge)**.** *Let γ_A be regular and irreducible in the sense of Remark A.649. Then on a neighbourhood of Σ there is an odd Ω of ghost number $+1$, of the form Equation (A.1033) with the first two terms Equation (A.1034), satisfying $\{\Omega,\Omega\} = 0$.*

Rests on Lemmas A.651 and A.652 and Equation (26.16).

Proof. *Derives Theorem A.653.*

Induction on the antighost number. By Equation (A.1046), $\Omega_{(0)}$ and $\Omega_{(1)}$ are constructed and $\{\Omega,\Omega\}$ has no antighost-0 component. Suppose $\Omega_{(0)},\dots,\Omega_{(m)}$ have been found, $m \geq 1$, such that $R := \left\{\Omega^{[m]},\Omega^{[m]}\right\}$, with $\Omega^{[m]} := \sum_{j\leq m}\Omega_{(j)}$, has vanishing components of antighost number $\leq m-1$.

The obstruction is δ-closed. For an odd Ω the graded Jacobi identity applied to the triple $\left(\Omega^{[m]},\Omega^{[m]},\Omega^{[m]}\right)$ collapses to the identity

$$\left\{\Omega^{[m]},\left\{\Omega^{[m]},\Omega^{[m]}\right\}\right\} = 0\,, \tag{A.1047}$$

which holds whatever $\Omega^{[m]}$ is, nilpotent or not: the three cyclic terms of the graded Jacobi identity are equal, and their common sign is such that three times one of them must vanish. Take the antighost-$(m-1)$ component of Equation (A.1047). The M-part contributes $\sum_{i+j=m-1}\left\{\Omega_{(i)},R_{(j)}\right\}_M$, in which every j is at most $m-1$ and every $R_{(j)}$ therefore vanishes by hypothesis. The ghost part contributes $\sum_{i+j=m}\left\{\Omega_{(i)},R_{(j)}\right\}_{\mathrm{gh}}$, in which the only surviving term is $i=0$, $j=m$. Hence $\left\{\Omega_{(0)},R_{(m)}\right\}_{\mathrm{gh}} = 0$, and since R is even and $\Omega_{(0)}$ odd this is $-\delta R_{(m)}$. So $\delta R_{(m)} = 0$.

Solve. $R_{(m)}$ has antighost number $m \geq 1$, so by Lemma A.651 there is a c with $\delta c = R_{(m)}$ and $\operatorname{antigh} c = m+1$. Counting gradings: R is even with ghost number 2, so $R_{(m)}$ has pure ghost number $m+2$; c therefore has pure ghost number $m+2$ and antighost number $m+1$, hence ghost number $+1$ and odd parity — exactly the type of an $\Omega_{(m+1)}$. Put $\Omega_{(m+1)} := -\frac{1}{2}c$. Adding it to $\Omega^{[m]}$ changes nothing of antighost number $< m$, because the new term enters $\{\Omega,\Omega\}$ only at antighost number $\geq m$, and it changes the antighost-m component by $2\delta\Omega_{(m+1)} = -\delta c = -R_{(m)}$, cancelling it. This is the statement $\delta\Omega_{(m+1)} = D_{(m)}$ of Lemma A.652.

The induction produces $\Omega_{(k)}$ for every k. It terminates for a reason of degree: $\Omega_{(k)}$ carries k factors $\mathcal{P}_A$, which anticommute, so $\Omega_{(k)} = 0$ identically for $k > F$. The series Equation (A.1033) is therefore a finite sum, and Ω is a genuine function on the extended phase space, not a formal series. □

A.54.5 Termination at the displayed terms

Proposition A.654 (The Yang–Mills case)**.** *If the ${f_{AB}}^C$ of Equation (26.16) are constants, then $D_{(1)} = 0$ and $\Omega = \Omega_{(0)} + \Omega_{(1)}$ is exactly nilpotent: the series Equation (26.97) stops at the two terms displayed.*

Rests on Lemma A.652 and Equations (22.46) and (26.16).

Proof. *Derives Proposition A.654.*

Both terms of Equation (A.1044) vanish.

The second does so for a trivial reason: with constant f, the function $\Omega_{(1)}$ contains no z^c at all, and $\{\cdot,\cdot\}_M$ differentiates only the z^c, so $\left\{\Omega_{(0)}, \Omega_{(1)}\right\}_M = 0$. This is exactly the place where structure *functions* would obstruct: for non-constant f this bracket is a nonzero function of antighost number 1, and it is what forces $\Omega_{(2)}$ to exist.

The first is the Jacobi identity. The ghost bracket pairs the $\partial/\partial\eta$ of one $\Omega_{(1)}$ with the $\partial/\partial\mathcal{P}$ of the other, producing a term with three η's, one $\mathcal{P}$ and two factors f; because the three ghosts anticommute, the coefficient is the total antisymmetrization ${f_{[AB}}^D {f_{C]D}}^E$. That vanishes: applying the Poisson Jacobi identity Equation (22.46) to the triple $(\gamma_A, \gamma_B, \gamma_C)$ and using Equation (26.16) twice with constant coefficients gives ${f_{[AB}}^D {f_{C]D}}^E \gamma_E = 0$, and the γ_E are independent by irreducibility, so the coefficient itself vanishes.

With $D_{(1)} = 0$ one may take $\Omega_{(2)} = 0$, and then every later $D_{(k)}$ is built from $\Omega_{(0)}$, $\Omega_{(1)}$ and vanishing terms and is itself zero by the same two arguments, so $\Omega_{(k)} = 0$ for all $k \geq 2$ solves the recursion. That is the case of Section 26.6.4; general relativity, whose structure functions are genuinely functions by Proposition 26.43, is not it, and the omitted terms of Equation (26.97) are exactly what Theorem A.653 supplies there. □

A.54.6 Uniqueness

Proposition A.655 (Uniqueness up to a canonical transformation)**.** *Let Ω and Ω' both satisfy the hypotheses and conclusion of Theorem A.653 with the same $\Omega_{(0)} = \Omega'_{(0)} = \eta^A \gamma_A$. Then there is a canonical transformation of the extended phase space, generated by an even function of ghost number 0, carrying Ω to Ω'.*

Rests on Theorem A.653 and Lemmas A.651 and A.652.

Proof. *Derives Proposition A.655.*

Induction on the lowest order at which the two differ. Suppose $\Omega_{(j)} = \Omega'_{(j)}$ for $j < k$ and put $\Delta_{(k)} := \Omega'_{(k)} - \Omega_{(k)}$, with $k \geq 1$. By Lemma A.652 both satisfy $\delta\Omega_{(k)} = D_{(k-1)}$ with the *same* right-hand side, since $D_{(k-1)}$ is built from the orders below k, which agree. Hence $\delta\Delta_{(k)} = 0$.

By Lemma A.651 there is a K with $\delta K = \Delta_{(k)}$ and $\operatorname{antigh} K = k + 1$. Its type is forced: $\Delta_{(k)}$ is odd with ghost number $+1$ and pure ghost number $k + 1$, so K has pure ghost number $k + 1$ and antighost number $k + 1$, hence ghost number 0 and even parity — a legitimate generator of a canonical transformation preserving both gradings.

Let T_K be the canonical transformation generated by K,

$$T_K\Omega = \Omega + \{\Omega, K\} + \tfrac{1}{2}\{\{\Omega, K\}, K\} + \cdots, \tag{A.1048}$$

which is a finite sum here because K has positive antighost number and each bracket lowers it by at most one while raising the number of η's, so the series terminates. Since K has antighost number $k + 1$ and the ghost bracket lowers antighost number by one, $\{\Omega, K\}$ has antighost number $\geq k$, and its antighost-k part is $\left\{\Omega_{(0)}, K\right\}_{\text{gh}} = -\delta K = -\Delta_{(k)}$. So $T_K\Omega'$ agrees with Ω through antighost number k and, being the image of a nilpotent charge under a canonical transformation, is itself nilpotent — a canonical transformation preserves the graded bracket, so it carries $\{\Omega', \Omega'\} = 0$ to $\{T_K\Omega', T_K\Omega'\} = 0$.

Repeat at the next order at which the two still differ. The generators so produced have strictly increasing antighost number, and all vanish beyond F by the degree argument of Theorem A.653, so their composition is a single canonical transformation carrying Ω' to Ω. □

Remark A.656 (What is quoted here). Two things, and one limitation.

Quoted. The constant-rank theorem, in the form Remark 26.4 states it, is used once, in Lemma A.650, to flatten the constraints. That theorem is owed by Chapters 7 and 13 and is a standing debt of Chapter 26, not a new one; the analytic input from which it is proved, Theorem A.286, is in this appendix.

Not quoted, though it usually is. The acyclicity of the Koszul complex in positive degree (Lemma A.651) is normally imported from homological algebra, where it is the statement that the Koszul complex of a regular sequence is a resolution. This treatise carries no homological algebra, and opening a chapter of it to prove one lemma would be out of proportion; the case at hand is therefore proved here outright, by an explicit contracting homotopy Equations (A.1037) and (A.1039), and the general theorem is recorded as a debt of Part II rather than used.

The limitation. Lemma A.650 is local: the coordinates in which $\gamma_A = y^A$ exist on a neighbourhood of a point of Σ, so Lemma A.651 and with it Theorem A.653 are local statements. Passing to a global Ω requires patching the local solutions with a partition of unity, which works whenever the γ_A are globally defined and the surface admits a tubular neighbourhood — the case in every application in this book, where the constraints are given by global formulas — but it is a further step and it is not carried out here. This is the same locality that Remark 26.27 records for gauge fixing, and for the same reason: what is easy near a point of the constraint surface can be obstructed in the large.

Remark A.657. Appendix A.54 discharges the derivation owed at Theorem 26.51 of Section 26.7.3 in Chapter 26. Three consequences are worth carrying back. The construction shows that the two terms Equation (26.97) displays are not an ansatz but the first two solutions of a recursion, the second of them forced; Proposition A.654 shows that the series stops there exactly when Equation (26.16) closes on constants, which is the Yang–Mills case of Section 26.6.4 and is why the chapter can display two terms and say "$+\cdots$"; and Proposition A.655 is what makes Equation (26.99) well posed, since a cohomology defined by a charge that was only unique up to nothing in particular would not be a property of the theory. The first-class algebra that the whole construction consumes is Proposition 26.13; for general relativity it is the hypersurface-deformation algebra of Appendix A.53, whose structure functions are the reason a general existence theorem was needed at all.

A.55 Bertrand's Theorem

This appendix proves Theorem 27.41 of Chapter 27: among all central forces there are exactly two for which *every* bounded orbit closes, namely the inverse-square attraction $f(r) = -k/r^2$ and the linear attraction $f(r) = -\kappa r$ of the isotropic oscillator. Here k carries the unit $\mathrm{N\,m^2}$ and κ the unit $\mathrm{N/m}$, so that f is a force in newtons in both cases.

Nothing is quoted here. The whole argument is carried out from the Binet equation Equation (27.30) of Chapter 27, Taylor's theorem with remainder (Theorem 7.38) and the elementary fact that a continuous rational-valued function on an interval is constant. There is no imported theorem and therefore no *What is quoted here* remark.

What the section does contain, and what the reader should watch for, is the division of labour between its two stages. The chapter's roadmap after Theorem 27.41 states it, and it is worth stating again because the point is easy to get wrong: the first-order stage does *not* isolate the two force laws. It narrows the candidates from all central forces to a

one-parameter family of power laws, and no more. The third-order stage is where the two laws are picked out of that family, and it is the real content of the theorem.

A.55.1 The orbit equation and its circular solutions

Throughout, the motion is that of a particle of mass m (in kg; for a two-body problem read the reduced mass) in a central field $f(r)$, with angular momentum $L = mr^2\dot{\phi} \neq 0$ of Equation (27.20), in $\mathrm{kg\,m^2/s}$. Write $u := 1/r$, in $1/\mathrm{m}$.

Definition A.658 (The orbit function)**.** For a central force f and a fixed angular momentum $L \neq 0$, the *orbit function* is

$$J(u) := -\frac{m}{L^2u^2}\, f\!\left(\frac{1}{u}\right), \tag{A.1049}$$

defined for those $u > 0$ at which f is defined, and carrying the unit $1/\mathrm{m}$. Combining $ma_r = f(r)$ from Equation (19.4) with the Binet equation Equation (27.30) puts the shape of every orbit of that angular momentum in the form

$$\frac{\mathrm{d}^2u}{\mathrm{d}\phi^2} + u = J(u)\,. \tag{A.1050}$$

The force is attractive where $f < 0$, that is where $J > 0$.

Rests on Equations (19.4) *and* (27.30) *and Proposition 27.23.*

The time has been eliminated: Equation (A.1050) is an autonomous second-order equation for the shape alone, and closure of an orbit is the statement that its solution $u(\phi)$ is periodic in ϕ with a period commensurable with 2π.

Definition A.659 (Circular orbit and its index)**.** A *circular orbit* of the field at angular momentum L is a constant solution $u \equiv u_0 > 0$ of Equation (A.1050), that is a root of

$$u_0 = J(u_0)\,. \tag{A.1051}$$

Its *index* is the dimensionless number

$$\beta^2 := 1 - J'(u_0)\,. \tag{A.1052}$$

Rests on Definition A.658 and Equation (A.1050)*.*

Lemma A.660 (The index in terms of the force)**.** *Let $r_0 = 1/u_0$ be the radius of a circular orbit. Then*

$$\beta^2 = 3 + \frac{r_0 f'(r_0)}{f(r_0)}\,, \tag{A.1053}$$

which depends on the force law alone and not on L or m except through the radius at which it is evaluated.

Rests on Definition A.659 and Equation (A.1049)*.*

Proof. *Derives Lemma A.660.*

Differentiate Equation (A.1049), writing f and f' for the values at $r = 1/u$ and using $\mathrm{d}(1/u)/\mathrm{d}u = -u^{-2}$:

$$J'(u) = -\frac{m}{L^2}\left[-2u^{-3}f - u^{-2}f'\,u^{-2}\right] = \frac{m}{L^2}\left[2u^{-3}f + u^{-4}f'\right]. \tag{A.1054}$$

At a circular orbit Equation (A.1051) reads $u_0 = -\,(m/L^2)\,u_0^{-2}f(r_0)$, so

$$\frac{m}{L^2} = -\frac{u_0^3}{f(r_0)}\,, \tag{A.1055}$$

which incidentally requires $f(r_0) < 0$: a circular orbit exists only where the force attracts. Substituting Equation (A.1055) into Equation (A.1054) at $u = u_0$,

$$J'(u_0) = -\frac{u_0^3}{f}\left[2u_0^{-3}f + u_0^{-4}f'\right] = -2 - \frac{f'(r_0)}{u_0 f(r_0)} = -2 - \frac{r_0 f'(r_0)}{f(r_0)}\,, \tag{A.1056}$$

and Equation (A.1052) gives $\beta^2 = 1 - J'(u_0) = 3 + r_0 f'(r_0)/f(r_0)$, which is Equation (A.1053). □

A.55.2 First stage: closure near a circle forces a power law

Proposition A.661 (The first-order narrowing)**.** *Suppose every bounded orbit of the field f closes, and suppose f admits circular orbits at every radius of some interval $0 < r_- < r < r_+$ — which is the case as L ranges over an interval, by Equation (A.1055). Then β is one fixed rational number on that interval and*

$$f(r) = -C\, r^{\beta^2 - 3}\,, \qquad C > 0\,, \tag{A.1057}$$

where $C > 0$ carries whatever unit makes the right-hand side a force in N*, namely* N *times a length raised to the power $3 - \beta^2$. Equivalently, in the orbit variable,*

$$J(u) = A\, u^{1-\beta^2}\,, \qquad A = \frac{mC}{L^2} > 0\,. \tag{A.1058}$$

This is as far as the first-order calculation reaches: it leaves a one-parameter family*, indexed by β, and does not select any member of it.*

Rests on Lemma A.660 and Equation (27.39).

Proof. *Derives Proposition A.661.*

Perturb the circular orbit: put $u = u_0 + \delta$ in Equation (A.1050) and expand J about u_0 by Theorem 7.38. Using Equation (A.1051) to cancel the constant terms and Equation (A.1052) to name the coefficient of δ,

$$\frac{\mathrm{d}^2\delta}{\mathrm{d}\phi^2} + \beta^2\delta = \tfrac{1}{2}J''(u_0)\,\delta^2 + \tfrac{1}{6}J'''(u_0)\,\delta^3 + O\!\left(\delta^4\right)\,. \tag{A.1059}$$

To first order in δ the right-hand side is absent and the solution is $\delta = a\cos(\beta\phi)$ with the origin of ϕ at an apsis. If $\beta^2 \le 0$ the solution grows without bound and there are no bounded orbits in the neighbourhood at all, so $\beta^2 > 0$ and δ oscillates. Successive turning points of r are successive extrema of δ, separated by $\Delta\phi = \pi/\beta$; that is, the apsidal angle Equation (27.39) of these orbits satisfies

$$\lim_{a\to 0}\Phi = \frac{\pi}{\beta}\,. \tag{A.1060}$$

An orbit closes exactly when the total angle swept between one apsis and the next repetition of the whole configuration is a whole multiple of 2π, that is when Φ/π is rational. So β is rational for every circular radius in the interval. By Equation (A.1053), β is a continuous function of r_0 wherever f is continuously differentiable and non-vanishing; a continuous function on an interval taking only rational values has connected image contained in $\mathbb{Q}$, hence is constant. So β is one fixed rational number.

With β constant, Equation (A.1053) is the separable first-order equation $rf'/f = \beta^2 - 3$ on the interval, whose solution is $\log|f| = (\beta^2 - 3)\log r + \text{const}$, that is Equation (A.1057), with $C > 0$ because $f < 0$ at a circular orbit. Substituting into Equation (A.1049),

$$J(u) = \frac{m}{L^2}u^{-2}\,C\,u^{-(\beta^2-3)} = \frac{mC}{L^2}\,u^{1-\beta^2}\,, \tag{A.1061}$$

which is Equation (A.1058). Every $\beta > 0$ produces a power law satisfying the hypotheses used so far, so nothing has yet been excluded. □

Remark A.662 (Why the first stage cannot finish the proof). The condition just used is closure of the orbits *infinitesimally near* a circle, which is strictly weaker than closure of all bounded orbits. Equation (A.1060) is a limit as the amplitude a tends to zero, and it fixes the apsidal angle only in that limit; at finite amplitude the apsidal angle of a power law generally depends on a, and an orbit whose apsidal angle drifts with amplitude cannot close at every amplitude even though it closes in the limit. The second stage is precisely the computation of that drift.

Lemma A.663 (Derivatives of the power law)**.** *For J of the form Equation (A.1058) with circular orbit at u_0,*

$$J'(u_0) = 1 - \beta^2 \,, \tag{A.1062}$$

$$u_0 J''(u_0) = -\beta^2 \left(1 - \beta^2\right) , \tag{A.1063}$$

$$u_0^2 J'''(u_0) = \beta^2 \left(1 - \beta^2\right) \left(1 + \beta^2\right) . \tag{A.1064}$$

Rests on Equations (A.1051) and (A.1058).

Proof. *Derives Lemma A.663.*

Equation (A.1051) applied to Equation (A.1058) reads $u_0 = A u_0^{1-\beta^2}$, that is

$$A\, u_0^{-\beta^2} = 1 \,. \tag{A.1065}$$

Differentiating Equation (A.1058) three times,

$$J'(u) = A \left(1 - \beta^2\right) u^{-\beta^2} \,,$$
$$J''(u) = A \left(1 - \beta^2\right) \left(-\beta^2\right) u^{-\beta^2 - 1} \,,$$
$$J'''(u) = A \left(1 - \beta^2\right) \left(-\beta^2\right) \left(-\beta^2 - 1\right) u^{-\beta^2 - 2} \,,$$

and evaluating at u_0 with Equation (A.1065) gives Equations (A.1062) to (A.1064) in turn. Equation (A.1062) is a consistency check on Equation (A.1052): it returns $\beta^2 = 1 - J'(u_0)$, as it must. □

A.55.3 Second stage: the third-order solvability condition

The apsidal angle at finite amplitude is computed by the standard device for a nonlinear oscillator: allow the frequency itself to depend on the amplitude, and fix that dependence by demanding that the solution stay periodic. The alternative bookkeeping — keeping the frequency at β and requiring that no term proportional to $\phi \sin(\beta\phi)$ appear — gives the same condition, because such a term is exactly the first-order Taylor expansion of the frequency shift.

Theorem A.664 (Bertrand's condition)**.** *Let J be the power law Equation (A.1058) with $\beta^2 > 0$, and let the radial oscillation about the circular orbit u_0 have amplitude a. Then its angular frequency is*

$$\Omega^2 = \beta^2 + a^2 \omega_2 + O\left(a^4\right) , \qquad \omega_2 = -\frac{5\,(J'')^2}{24\beta^2} - \frac{J'''}{8} \,, \tag{A.1066}$$

with J'', J''' evaluated at u_0, and the apsidal angle is $\Phi = \pi/\Omega + O(a^4)$. If every bounded orbit closes then $\omega_2 = 0$, and

$$5\,(J'')^2 + 3\beta^2 J''' = 0 \quad \Longleftrightarrow \quad 2\beta^4 \left(1 - \beta^2\right) \left(4 - \beta^2\right) = 0 \,, \tag{A.1067}$$

so that $\beta^2 = 1$ or $\beta^2 = 4$.

Rests on Lemma A.663, Proposition A.661, and Equation (A.1059).

Proof. *Derives Theorem A.664.*

Introduce the stretched angle $\theta = \Omega\phi$, so that $\mathrm{d}/\mathrm{d}\phi = \Omega\,\mathrm{d}/\mathrm{d}\theta$ and δ is sought as a 2π-periodic function of θ. Writing a dot for $\mathrm{d}/\mathrm{d}\theta$, Equation (A.1059) becomes

$$\Omega^2\ddot{\delta} + \beta^2\delta = \tfrac{1}{2}J''\delta^2 + \tfrac{1}{6}J'''\delta^3 + O\left(\delta^4\right) . \tag{A.1068}$$

Expand in the amplitude,

$$\delta = a\delta_1 + a^2\delta_2 + a^3\delta_3 + \cdots , \qquad \Omega^2 = \beta^2 + a^2\omega_2 + O\left(a^4\right) , \tag{A.1069}$$

the frequency carrying only even powers of a because Equation (A.1068) is unchanged by $a \mapsto -a$ together with $\theta \mapsto \theta + \pi$.

Order a. $\beta^2\left(\ddot{\delta}_1 + \delta_1\right) = 0$, so $\delta_1 = \cos\theta$, the amplitude being carried by a and the phase fixed by putting an apsis at $\theta = 0$.

Order a^2. Using $\cos^2\theta = \tfrac{1}{2}\left(1 + \cos 2\theta\right)$,

$$\beta^2\left(\ddot{\delta}_2 + \delta_2\right) = \tfrac{1}{2}J''\cos^2\theta = \frac{J''}{4}\left(1 + \cos 2\theta\right) , \tag{A.1070}$$

which has no resonant forcing — neither 1 nor $\cos 2\theta$ is a solution of the homogeneous equation — and is solved by

$$\delta_2 = \frac{J''}{4\beta^2}\left(1 - \tfrac{1}{3}\cos 2\theta\right) , \tag{A.1071}$$

as is checked by applying $\ddot{} + 1$: the constant reproduces itself, and $-\tfrac{1}{3}\cos 2\theta$ returns $-\tfrac{1}{3}\left(-4 + 1\right)\cos 2\theta = \cos 2\theta$. The homogeneous solution that could be added here is absorbed into the definition of a.

Order a^3. Collecting the terms of that order in Equation (A.1068), and using $\ddot{\delta}_1 = -\cos\theta$,

$$\beta^2\left(\ddot{\delta}_3 + \delta_3\right) = \omega_2\cos\theta + J''\delta_1\delta_2 + \tfrac{1}{6}J'''\cos^3\theta\,. \tag{A.1072}$$

Reduce the two nonlinear terms with $\cos\theta\cos 2\theta = \tfrac{1}{2}\left(\cos 3\theta + \cos\theta\right)$ and $\cos^3\theta = \tfrac{3}{4}\cos\theta + \tfrac{1}{4}\cos 3\theta$:

$$\begin{aligned} J''\delta_1\delta_2 &= \frac{\left(J''\right)^2}{4\beta^2}\left[\cos\theta - \tfrac{1}{3}\cos\theta\cos 2\theta\right] \\ &= \frac{\left(J''\right)^2}{4\beta^2}\left[\tfrac{5}{6}\cos\theta - \tfrac{1}{6}\cos 3\theta\right] , \end{aligned} \tag{A.1073}$$

$$\tfrac{1}{6}J'''\cos^3\theta = \frac{J'''}{8}\cos\theta + \frac{J'''}{24}\cos 3\theta\,. \tag{A.1074}$$

The operator $\ddot{} + 1$ annihilates $\cos\theta$, so Equation (A.1072) has a 2π-periodic solution only if the total coefficient of $\cos\theta$ on its right-hand side vanishes. By Equations (A.1073) and (A.1074) that coefficient is

$$\omega_2 + \frac{5\left(J''\right)^2}{24\beta^2} + \frac{J'''}{8} = 0\,, \tag{A.1075}$$

which is the second member of Equation (A.1066). (The $\cos 3\theta$ terms are non-resonant and merely fix δ_3; they play no part in what follows.) The apsidal angle is half the period of δ in ϕ, that is π/Ω.

Now impose closure. For each amplitude a the orbit closes only if $\Phi/\pi = 1/\Omega(a)$ is rational; Ω is a continuous function of a by Equation (A.1066), and a continuous rational-valued function on an interval is constant — the same step used in Proposition A.661, now

applied in the amplitude rather than in the radius. Hence Ω is independent of a and $\omega_2 = 0$. Multiplying Equation (A.1075) by $-24\beta^2$ gives the first member of Equation (A.1067).

It remains to evaluate it. Substituting Equations (A.1063) and (A.1064),

$$\begin{aligned} 5\left(J''\right)^2 + 3\beta^2 J''' &= \frac{5\beta^4\left(1-\beta^2\right)^2}{u_0^2} + \frac{3\beta^4\left(1-\beta^2\right)\left(1+\beta^2\right)}{u_0^2} \\ &= \frac{\beta^4\left(1-\beta^2\right)}{u_0^2}\left[5\left(1-\beta^2\right) + 3\left(1+\beta^2\right)\right] \\ &= \frac{2\beta^4\left(1-\beta^2\right)\left(4-\beta^2\right)}{u_0^2}\,, \end{aligned} \tag{A.1076}$$

since $5 - 5\beta^2 + 3 + 3\beta^2 = 8 - 2\beta^2$. With $\beta^2 > 0$ the factor β^4 cannot vanish, so $\beta^2 = 1$ or $\beta^2 = 4$. □

Remark A.665 (The two roots are not accidents of the algebra). Each root switches off the condition for a different reason, and it is worth seeing both. At $\beta^2 = 1$ the power law is $J(u) = A$, a constant: *every* derivative of J vanishes, the right-hand side of Equation (A.1059) is empty to all orders, and the orbit equation is exactly linear — which is Equation (27.47), and is why the Kepler problem has an apsidal angle independent of amplitude rather than merely to third order. At $\beta^2 = 4$ the derivatives do not vanish; by Equations (A.1063) and (A.1064), $u_0 J'' = 12$ and $u_0^2 J''' = -60$, and the two terms of Equation (A.1067) cancel against each other: $u_0^2\left[5\left(J''\right)^2 + 3\beta^2 J'''\right] = 5{\cdot}12^2 + 3{\cdot}4{\cdot}(-60) = 720 - 720 = 0$. The oscillator therefore closes by a cancellation between the second-order feedback of Equation (A.1071) and the direct cubic term, not because its orbit equation is linear.

A.55.4 The two laws, and that they really do close

The argument so far is one of *necessity*: no force law other than these two can have every bounded orbit closed. Sufficiency has to be checked separately, and must be checked for all bounded orbits and not only for those near a circle, since that is the property claimed.

Proposition A.666 (Both exceptional laws close every bounded orbit)**.** *For $f(r) = -k/r^2$ every bounded orbit is an ellipse with the force centre at a focus, with apsidal angle $\Phi = \pi$; for $f(r) = -\kappa r$ every orbit is an ellipse with the force centre at its* centre*, with apsidal angle $\Phi = \pi/2$. In both cases Φ is independent of the energy and of the angular momentum.*

Rests on Equations (27.47) and (A.1053).

Proof. *Derives Proposition A.666.*

The inverse square. With $f = -k/r^2$, $rf'/f = r\,(2k/r^3)\,/\,(-k/r^2) = -2$, so Equation (A.1053) gives $\beta^2 = 1$, consistent with Theorem A.664. The orbit is Equation (27.47), $1/r = (mk/L^2)\,(1 + e\cos\phi)$, obtained there without any expansion in amplitude. It is 2π-periodic in ϕ for every e, and bounded precisely for $e < 1$; r is least at $\phi = 0$ and greatest at $\phi = \pi$, so $\Phi = \pi$ exactly, at every eccentricity. The force centre sits at $r = 0$, which is a focus of the conic.

The linear law. With $f = -\kappa r$, $rf'/f = r\,(-\kappa)\,/\,(-\kappa r) = 1$, so $\beta^2 = 4$ and $\beta = 2$. Here the direct route is better than the orbit equation. The force is $\boldsymbol{F} = -\kappa\boldsymbol{x}$, so each Cartesian component of Equation (19.4) is an independent harmonic oscillator of the *same* angular frequency $\omega_0 = \sqrt{\kappa/m}$, in rad/s. In the plane of the motion,

$$x(t) = a_1\cos\left(\omega_0 t\right)\,, \qquad y(t) = a_2\cos\left(\omega_0 t - \gamma\right)\,, \tag{A.1077}$$

which is a closed ellipse centred on the origin, traversed once per period $2\pi/\omega_0$, for every a_1, a_2 and phase γ. Every orbit is bounded and every orbit closes. Its radius $r = \sqrt{x^2 + y^2}$ is a

function of $\cos^2$ and $\sin^2$ of $\omega_0 t$ and therefore has period π/ω_0, half the orbital period: the particle passes two pericentres and two apocentres per revolution, one pair at each end of each principal axis, and the apsidal angle is a quarter of a revolution,

$$\Phi = \frac{2\pi}{4} = \frac{\pi}{2} = \frac{\pi}{\beta}\,, \tag{A.1078}$$

in agreement with Equation (A.1060) — and here the agreement holds at every amplitude, not merely in the limit, which is the content of $\omega_2 = 0$.

The contrast between the two cases is not a detail of geometry. For the inverse square the centre of force is a *focus* of the ellipse and the two apsidal distances differ; for the oscillator it is the *centre*, the two axes are traversed symmetrically, and the orbit closes after half as much angle. That is the same fact as $\beta = 1$ against $\beta = 2$. □

Remark A.667 (What "closed" is doing in the statement). Three distinct properties are in play and only the strongest is Bertrand's. (i) *Some* bounded orbit closes: true for every attractive power law, since the circular orbits themselves close. (ii) Every orbit *infinitesimally near* a circle closes: true for every power law with β rational — a countable but infinite family, including $f \propto r^{-5/4}$ with $\beta = \frac{1}{2}$ and $f \propto r^6$ with $\beta = 3$. (iii) Every bounded orbit closes: true only for $\beta = 1$ and $\beta = 2$. The whole distance between (ii) and (iii) is Equation (A.1075), which measures how the apsidal angle drifts as the orbit is made less circular. For any other power law, Φ varies continuously with the amplitude, takes irrational multiples of π on a dense set of amplitudes, and those orbits fill the annulus $r_- \le r \le r_+$ without ever repeating, exactly as Theorem 27.41 asserts.

Remark A.668 (Attribution). The theorem is Bertrand's, announced in the *Comptes rendus* of the Paris Academy in 1873. That memoir is not among the sources verified for this treatise and has no key in `references.bib`, so the attribution is made here in words, on the same footing as Darboux's memoir in Remark A.81. Nothing above rests on it: the proof given is self-contained, and the third-order stage in particular is carried out from Equation (A.1059) alone.

Remark A.669. Appendix A.55 discharges the derivation owed at Theorem 27.41 of Chapter 27. The chapter uses the theorem twice. It uses it to say what the closure of planetary orbits is evidence *for* — the inverse-square law and nothing weaker — and it uses it, through Phenomenon 27.42, to turn Mercury's residual perihelion advance into a measurement: by Equation (A.1053) an apsidal angle differing from π is a force law differing from r^{-2}, and the size of the difference is the size of the departure. The reader returning there should carry back the division of labour set out at the head of this section, since the chapter's roadmap states it and this appendix is where it is earned: Proposition A.661 narrows all central forces to one parameter, and Theorem A.664 spends that parameter.

A.56 Isotropic and Cubic Elastic Tensors

This appendix proves Lemma 30.26 of Chapter 30 and the statement the chapter takes from it: that the twenty-one independent constants of Proposition 30.25 collapse to *two* for an isotropic solid, the Lamé constants of Equation (30.21). It also supplies the intermediate result the chapter never states, and which is the more useful of the two in a laboratory: a solid invariant only under the rotation group of the cube has *three* independent elastic constants, and the single number by which the general cubic tensor fails to be isotropic is directly measurable.

A.56.1 What is proved here, and what is proved elsewhere

Remark A.670 (The classification itself belongs to Part II, and is now there). When Chapter 30 was written, the classification of the isotropic Cartesian tensors of low rank was carried by no chapter of Part II, and the chapter recorded the gap as a debt owed by the Cartesian-tensor algebra of Chapter 13. That debt is discharged, and not where it was expected: the classification for ranks one to four is Theorem 5.128 of Chapter 5 — the representation chapter, not the manifolds one, because the statement is invariant theory for SO(3) rather than tensor algebra — proved there in full from the definition Equation (5.164) of an isotropic Cartesian tensor. Section 13.2.2 carries the pointer and the constitutive-law reading. Remark 30.27 has been rewritten accordingly and now records what the chapter *rests on* rather than what it is owed; the Helmholtz decomposition named there is likewise in place, as Theorem 7.105.

This section therefore does *not* reprove the classification. It quotes Theorem 5.128, adds the two things that theorem does not contain — the independence of the three delta products, and the strictly weaker classification under the finite rotation group of the cube — and then carries out the specialisation to elasticity, which is physics and belongs here.

For reference, the result quoted is this. A Cartesian tensor T of rank N is *isotropic* (Definition 5.126) when its components are unchanged by every $R \in \mathrm{SO}(3)$,

$$T_{i_1 \dots i_N} = R_{i_1 j_1} \cdots R_{i_N j_N}\, T_{j_1 \dots j_N} \qquad \text{for every } R \in \mathrm{SO}(3)\,, \tag{A.1079}$$

and Theorem 5.128 states that the isotropic tensors of rank one, two, three and four are respectively 0, the multiples of δ_{ij}, the multiples of ε_{ijk}, and the linear combinations

$$T_{iklm} = a\,\delta_{ik}\delta_{lm} + b\,\delta_{il}\delta_{km} + c\,\delta_{im}\delta_{kl}\,, \qquad a, b, c \in \mathbb{R}\,, \tag{A.1080}$$

which is Equation (30.20) and hence Lemma 30.26. Nothing below reopens that proof.

Lemma A.671 (The three products are independent). *The three arrays $\delta_{ik}\delta_{lm}$, $\delta_{il}\delta_{km}$ and $\delta_{im}\delta_{kl}$ are linearly independent, so the space of isotropic rank-four Cartesian tensors has dimension exactly three and the constants a, b, c of Equation* (A.1080) *are uniquely determined by T.*

Rests on Theorem 5.128 and Equation (5.168).

Proof. *Derives Lemma A.671.*

Evaluate Equation (A.1080) on the three index quadruples $(1,1,2,2)$, $(1,2,1,2)$ and $(1,2,2,1)$. A product of two Kronecker deltas is 1 when both pairs it joins carry equal values and 0 otherwise, so

$$T_{1122} = a\,, \qquad T_{1212} = b\,, \qquad T_{1221} = c\,. \tag{A.1081}$$

Each probe isolates one coefficient and annihilates the other two; hence a vanishing combination has $a = b = c = 0$, and the coefficients of a given T are read off by Equation (A.1081). □

A.56.2 The rotation group of the cube leaves four constants

A crystal is not isotropic. Its elasticity tensor is invariant only under the finite point group of its lattice, and for the cubic classes — which include the two commonest structural metals, body-centred iron and face-centred aluminium — that group is the rotation group of the cube. The classification under this smaller group is a strictly weaker statement than Theorem 5.128, and the difference between the two is one number.

Definition A.672 (The octahedral rotation group). The *octahedral group* $\mathcal{O} \subset \mathrm{SO}(3)$ is the group of the 24 rotations carrying a cube centred at the origin, with faces normal to the coordinate axes, to itself. In the standard frame its elements are exactly the 3×3 matrices

carrying a single entry ± 1 in each row and each column and having determinant $+1$; such a matrix acts as $R_{ij} = s_i\,\delta_{i\,\pi(j)}$ for a permutation π of $\{1,2,3\}$ and signs $s_i = \pm 1$ whose product is $\operatorname{sgn}\pi$. A tensor obeying Equation (A.1079) for every $R \in \mathcal{O}$, but not necessarily for every $R \in \mathrm{SO}(3)$, is called *cubic*.

Rests on Definitions 5.126 and 14.26.

Proposition A.673 (Cubic tensors of rank four)**.** *The rank-four cubic Cartesian tensors form a four-dimensional space, spanned by the three products of Equation* (A.1080) *together with the* cubic array

$$\Delta_{iklm} = \begin{cases} 1 & \text{if } i = k = l = m\,, \\ 0 & \text{otherwise} \end{cases}\,, \tag{A.1082}$$

whose components are taken in the crystal frame of Definition A.672. Every cubic T is therefore

$$T_{iklm} = a\,\delta_{ik}\delta_{lm} + b\,\delta_{il}\delta_{km} + c\,\delta_{im}\delta_{kl} + f\,\Delta_{iklm}\,, \tag{A.1083}$$

and T is isotropic if and only if $f = 0$.

Rests on Definition A.672 and Lemma A.671.

Proof. *Derives Proposition A.673.*

Step 1: the half-turn filter. For each $p \in \{1,2,3\}$ the diagonal matrix with $+1$ in the p-th place and -1 in the other two is a half-turn about the p-axis; it has determinant $+1$ and is a signed permutation, so it lies in $\mathcal{O}$. The argument of Lemma 5.127 uses these three matrices and nothing else, so its conclusion holds verbatim for a cubic tensor: a component T_{iklm} vanishes unless every value p occurs among its four indices an even number of times. At rank four the multiplicities (m_1, m_2, m_3) sum to four, so the surviving components have multiplicities $(4,0,0)$ or $(2,2,0)$ in some order. These are the three components T_{pppp} and, for each of the six *ordered* pairs $p \neq q$, the three arrangements T_{ppqq}, T_{pqpq}, T_{pqqp}: twenty-one components in all, and $81 - 21 = 60$ vanishing ones.

Step 2: the three-fold axis. The cyclic matrix C with $C_{21} = C_{32} = C_{13} = 1$ and every other entry zero is a signed permutation of determinant $+1$ — a three-cycle is even — so it too lies in $\mathcal{O}$, and it is the rotation by $2\pi/3$ about the body diagonal $(1,1,1)/\sqrt{3}$. Substituted into Equation (A.1079) it says that the components are unchanged when every index *value* is relabelled by the cycle $\sigma : 1 \mapsto 3 \mapsto 2 \mapsto 1$. Hence $T_{1111} = T_{2222} = T_{3333}$, a common value d, and the ordered pairs (p,q) fall into the two orbits $\{(1,2),(3,1),(2,3)\}$ and $\{(2,1),(1,3),(3,2)\}$, within each of which the three arrangements have common values.

Step 3: the four-fold axis. The quarter turn Q about the third axis, with $Q_{21} = 1$, $Q_{12} = -1$, $Q_{33} = 1$, is a signed permutation of determinant $+1$ and lies in $\mathcal{O}$. It exchanges the values 1 and 2 and multiplies a component by $(-1)^{m_1}$. The components T_{1122}, T_{1212}, T_{1221} each have $m_1 = 2$ and so carry the sign $+1$, giving $T_{1122} = T_{2211}$, $T_{1212} = T_{2121}$, $T_{1221} = T_{2112}$: the two orbits of Step 2 are joined to one another. The three numbers

$$a = T_{ppqq}\,, \qquad b = T_{pqpq}\,, \qquad c = T_{pqqp} \qquad (p \neq q)\,, \tag{A.1084}$$

are therefore independent of which ordered pair is used, and together with $d = T_{pppp}$ they determine every component: the invariant space has dimension at most four.

Step 4: it has dimension exactly four, and Equation (A.1083) *is its general element.* The right-hand side of Equation (A.1083) is cubic: Δ is unchanged by any relabelling of values and, having all four indices equal on each nonvanishing component, by any sign change; and the three delta products are isotropic by Theorem 5.128, hence a fortiori cubic. Reading off its components with Equation (A.1081) gives $T_{ppqq} = a$, $T_{pqpq} = b$, $T_{pqqp} = c$ and $T_{pppp} = a + b + c + f$, so the four constants (a,b,c,f) of the ansatz reproduce the four constants (a,b,c,d) of Steps 2 and 3 through

$$f = d - (a + b + c)\,. \tag{A.1085}$$

The map $(a, b, c, f) \mapsto (a, b, c, d)$ is a bijection, so the four constants of the ansatz are in one-to-one correspondence with those found in Steps 2 and 3. The four arrays are independent: the three delta products are independent of one another by Lemma A.671, and none of them is a multiple of Δ, since Δ alone changes T_{1111} without changing T_{1122}, T_{1212} or T_{1221}. Hence the dimension is exactly four.

Step 5: isotropy is $f = 0$. If $f = 0$ then T is a combination of the three isotropic products, hence isotropic. Conversely, an isotropic T is of the form Equation (A.1080) by Theorem 5.128, and its coefficients are those read off by Equation (A.1081), so $d = T_{1111} = a + b + c$ and $f = 0$ by Equation (A.1085). □

Remark A.674 (Where the extra relation comes from). The whole difference between the cubic and the isotropic classifications is the single relation $d = a + b + c$, and it is worth being clear about which rotations supply it. Steps 1 to 3 used only the finite group: three half-turns, one three-fold axis, one four-fold axis. Those fix every component in terms of four numbers and can do no more, because the cubic array Equation (A.1082) is genuinely invariant under all 24 of them. The relation is produced instead by a rotation through a *general* angle — in the proof of Theorem 5.128 it is the rotation by θ about the third axis, which forces $2\cos^2\theta\sin^2\theta\,(a + b + c - d) = 0$ and hence, at $\theta = \pi/4$, $d = a + b + c$. So the elementary argument stopped one step early does not fail: it delivers cubic anisotropy, which is a physically meaningful and experimentally accessible intermediate result rather than a defective version of isotropy.

A.56.3 From twenty-one constants to three, and then to two

We now impose on Equation (A.1083) the symmetries that an elasticity tensor has by Proposition 30.25: the minor symmetries $C_{iklm} = C_{kilm} = C_{ikml}$, which follow from the symmetry of the strain and of the stress, and the major symmetry $C_{iklm} = C_{lmik}$, which follows from the existence of the energy density of Definition 30.24.

Theorem A.675 (Three constants for a cubic crystal, two for an isotropic solid)**.** *Let C_{iklm} be an elasticity tensor in the sense of Definition 30.24, so that it obeys the minor and major symmetries of Proposition 30.25.*

1. *If C is cubic, then in the crystal frame*

$$C_{iklm} = \lambda\,\delta_{ik}\delta_{lm} + \mu\,(\delta_{il}\delta_{km} + \delta_{im}\delta_{kl}) + f\,\Delta_{iklm}\,, \tag{A.1086}$$

   three independent constants, all of SI dimension Pa*. The minor symmetries are what force $b = c = \mu$; the major symmetry is then automatic and imposes nothing further.*

2. *If C is isotropic, then $f = 0$ and $\sigma_{ik} = C_{iklm}u_{lm}$ is Equation (30.21), with two constants.*

Rests on Propositions 30.25 and A.673 and Definition 30.24.

Proof. *Derives Theorem A.675.*

The minor symmetries. Exchange i and k in Equation (A.1083). The first term is unchanged, since δ_{ik} is symmetric; the cubic array is unchanged, since it is symmetric under every permutation of its indices; and the middle two terms are exchanged,

$$b\,\delta_{il}\delta_{km} + c\,\delta_{im}\delta_{kl} \;\longmapsto\; b\,\delta_{kl}\delta_{im} + c\,\delta_{km}\delta_{il}\,. \tag{A.1087}$$

Equality of Equation (A.1087) with the original, together with the independence of the two arrays $\delta_{il}\delta_{km}$ and $\delta_{im}\delta_{kl}$ established in Lemma A.671, forces $b = c$. Writing $a = \lambda$ and $b = c = \mu$ gives Equation (A.1086). Exchanging l and m instead produces the same equation and hence no new condition.

The major symmetry. Send $(ik) \mapsto (lm)$ in Equation (A.1086). The first term becomes $\lambda\delta_{lm}\delta_{ik}$, which is itself; the second becomes $\mu(\delta_{li}\delta_{mk} + \delta_{lk}\delta_{mi})$, which is itself because each Kronecker delta is symmetric; and Δ is symmetric under every index permutation. So the major symmetry is satisfied identically, and a cubic crystal has exactly the three constants (λ, μ, f).

Isotropy. If C is isotropic then $f = 0$ by Proposition A.673, and contracting Equation (A.1086) with the symmetric strain u_{lm} gives

$$\sigma_{ik} = C_{iklm}u_{lm} = \lambda\,\delta_{ik}u_{ll} + \mu\,(u_{ik} + u_{ki}) = \lambda\,u_{ll}\,\delta_{ik} + 2\mu\,u_{ik}\,, \tag{A.1088}$$

which is Equation (30.21), the second equality using $u_{ik} = u_{ki}$. Counting: the general tensor has 21 constants by Proposition 30.25, a cubic crystal three, an isotropic solid two. □

Remark A.676 (The third cubic constant is measured, and it is not small). In the Voigt notation, in which an index pair (ik) is coded as one of $1, \dots, 6$ by $11 \mapsto 1$, $22 \mapsto 2$, $33 \mapsto 3$, $23 \mapsto 4$, $13 \mapsto 5$, $12 \mapsto 6$, the three constants of Equation (A.1086) are

$$C_{11} = C_{1111} = \lambda + 2\mu + f\,, \qquad C_{12} = C_{1122} = \lambda\,, \qquad C_{44} = C_{2323} = \mu\,, \tag{A.1089}$$

so that

$$f = C_{11} - C_{12} - 2C_{44}\,, \qquad A \equiv \frac{2C_{44}}{C_{11} - C_{12}} = \frac{2\mu}{2\mu + f}\,, \tag{A.1090}$$

and $A = 1$ exactly when $f = 0$, that is exactly when the crystal is elastically isotropic. A is the Zener anisotropy ratio, and the measured values [1455] show that the isotropic idealisation is a poor description of a single crystal and an accidentally good one for a few materials: for body-centred iron $C_{11} = 230\,\text{GPa}$, $C_{12} = 135\,\text{GPa}$, $C_{44} = 117\,\text{GPa}$ give $A = 2.5$; for face-centred aluminium $C_{11} = 108\,\text{GPa}$, $C_{12} = 61\,\text{GPa}$, $C_{44} = 28.5\,\text{GPa}$ give $A = 1.2$; and for tungsten $C_{11} = 523\,\text{GPa}$, $C_{12} = 203\,\text{GPa}$, $C_{44} = 160\,\text{GPa}$ give $A = 1.00$, so that tungsten is isotropic to the precision of the measurement — a coincidence of the numbers, not a consequence of any symmetry. A *polycrystalline* specimen of iron, on the other hand, is isotropic on scales large against the grain, because the orientations average; that is why Equation (30.21) describes structural steel and would not describe a single iron whisker.

Rests on Theorem A.675 and Definition 30.31.

Remark A.677 (The lower ranks, and why an isotropic solid is not piezoelectric). The two lower-rank cases of Theorem 5.128 carry physics of their own and are used elsewhere in Part III. *Rank two*: an isotropic tensor is $a\,\delta_{ik}$, so every rank-two material property of an isotropic body — thermal expansion, thermal conductivity, electrical conductivity — is a single scalar times the identity, and the response is parallel to the drive. *Rank three*: an isotropic tensor is $a\,\varepsilon_{ikl}$, and ε is a *pseudo*tensor: it is invariant under SO(3) but changes sign under the inversion $R = -\mathbb{1}$, by Equation (5.59). A material property that is a true rank-three tensor and is invariant under the full orthogonal group, inversion included, therefore vanishes identically. The piezoelectric coupling $P_i = d_{ikl}\sigma_{kl}$ is such a property, so no centrosymmetric medium is piezoelectric — quartz is not centrosymmetric and is, a fact used in every quartz oscillator, and no isotropic solid can be. The same parity argument is why an odd-rank isotropic tensor of rank one is zero.

Rests on Theorem 5.128 and Remark 5.129.

Remark A.678 (A representation-theoretic check, and why it is not the proof). The dimension three found in Lemma A.671 can be checked against the character theory of Chapter 5 without recomputing a single component. Write $V = \mathbb{R}^3$ for the defining representation of SO(3). An invariant of $V^{\otimes 4}$ is, after using the invariant inner product to identify V with its dual, an SO(3)-equivariant endomorphism of $V \otimes V$; and the Clebsch–Gordan series Theorem 14.47 decomposes $V \otimes V$ into the trace, the antisymmetric part and the

symmetric traceless part, of dimensions 1, 3 and 5, each occurring *once*. Schur's lemmas (Theorems 5.153 and 5.155) then say that an equivariant map is a scalar on each summand and zero between distinct ones, so the space of such maps has dimension $1 + 1 + 1 = 3$.

This is offered as a check and not as the proof, for a reason worth stating. Over the complex numbers Schur's second lemma delivers a scalar; over the reals it delivers only that the endomorphism algebra of an irreducible is a division algebra, which may be $\mathbb{R}$, $\mathbb{C}$ or the quaternions, and the multiplicity count above is correct only because each real integer-spin irreducible of SO(3) has endomorphism algebra $\mathbb{R}$. That last step is not carried by Chapter 5, whereas the elementary argument of Theorem 5.128 is complete as it stands. Where the two routes agree, as here, the agreement is evidence that neither has dropped a constant.

Remark A.679. Appendix A.56 discharges the derivation owed at Lemma 30.26 of Chapter 30. The classification itself is Theorem 5.128 of Chapter 5 and is not reproved here (Remark A.670); what this section adds is the uniqueness of the three coefficients (Lemma A.671), the cubic classification (Proposition A.673) that shows exactly which rotations the isotropy of an elastic solid actually consumes, and the reduction $21 \to 3 \to 2$ of Theorem A.675, which is the step the derivation of Phenomenon 30.28 takes for granted when it writes $b = c$ and $a = \lambda$, $b = \mu$. Everything downstream of Equation (30.21) in that chapter — the moduli of Definition 30.31, the elastic waves, the plate of Appendix A.57 and the contact of Appendix A.58 — rests on the two-constant form proved here.

A.57 Reduction of Three-Dimensional Elasticity to the Kirchhoff Plate Equation

This appendix proves Theorem 30.64 of Chapter 30: that the transverse deflection $w(x, y, t)$ of a thin isotropic plate obeys $\rho h\, \partial_t^2 w + D\nabla^4 w = q$ with the flexural rigidity Equation (30.57), and that a free edge carries exactly *two* boundary conditions rather than the three a naive force balance demands. The reduction has three stages and each is a separate piece of work: a kinematic hypothesis about how the material moves, a constitutive statement that the plate is in plane *stress* and not plane strain, and a variational calculation whose boundary terms are the interesting part of the answer.

Everything used is in the book. The constitutive law is Equation (30.21), proved in Appendix A.56; the conversions among the moduli are Proposition 30.33; the flexural rigidity is Definition 30.63; the variational machinery is that of Chapter 16, and in particular the fundamental lemma Lemma 16.18 and the natural boundary conditions Theorem 16.31. Nothing is quoted from outside the treatise. One point of bookkeeping is worth making in advance: Theorem 16.38 states the Euler–Poisson equation for a functional of *one* independent variable, while the plate functional depends on two, so the corresponding equation is derived here by carrying out the two integrations by parts explicitly — which is necessary anyway, because the boundary terms those integrations produce are the content of Appendix A.57.5.

Throughout, Greek indices α, β, γ run over the in-plane values x, y and are summed when repeated; Latin indices run over x, y, z. The mid-surface is $z = 0$, the thickness is h and the material occupies $|z| \le h/2$. Overdots are ∂_t.

A.57.1 Kinematics: the Kirchhoff hypothesis

Definition A.680 (Kirchhoff kinematics)**.** The plate is said to deform *in the Kirchhoff manner* when the mid-surface points move only transversely and material lines initially normal to the mid-surface remain straight, normal and unstretched. Writing $w(x, y, t)$ for

the transverse displacement of the mid-surface, this is

$$u_z = w(x,y,t)\,, \qquad u_\alpha = -z\,\partial_\alpha w(x,y,t)\,, \tag{A.1091}$$

so that a cross-section rotates through the angle $\partial_\alpha w$, as in the rod of Proposition 30.51. All three displacements carry m and w is assumed small enough that the strain Definition 30.6 may be linearised.

Rests on Definition 30.6 and Proposition 30.51.

Lemma A.681 (Strains under the Kirchhoff hypothesis)**.** *Under Equation* (A.1091) *the in-plane strains are proportional to the curvatures of the deflected mid-surface and the transverse shear strains vanish identically,*

$$u_{\alpha\beta} = -z\,\partial_\alpha\partial_\beta w\,, \qquad u_{\alpha z} = 0\,, \tag{A.1092}$$

while u_{zz} is not *determined by the hypothesis and is fixed instead by the constitutive statement of Appendix A.57.2.*

Rests on Definitions 30.6 and A.680.

Proof. *Derives Lemma A.681.*

From Definition 30.6, $u_{\alpha\beta} = \frac{1}{2}\left(\partial_\alpha u_\beta + \partial_\beta u_\alpha\right) = -\frac{1}{2}z\left(\partial_\alpha\partial_\beta w + \partial_\beta\partial_\alpha w\right) = -z\,\partial_\alpha\partial_\beta w$, the two mixed partials being equal for a twice continuously differentiable w. For the transverse shear,

$$u_{\alpha z} = \tfrac{1}{2}\left(\partial_\alpha u_z + \partial_z u_\alpha\right) = \tfrac{1}{2}\left(\partial_\alpha w - \partial_\alpha w\right) = 0\,. \tag{A.1093}$$

That the shear vanishes is exactly the statement that normals stay normal, and it is the hypothesis rather than a consequence: a real plate carries a transverse shear stress, and *must*, since the transverse load has to reach the supports somehow. What Equation (A.1093) asserts is that the shear *strain* it produces is negligible against the bending strain, which is true to relative order $(h/L)^2$ for a plate of lateral dimension L.

The remaining component, $u_{zz} = \partial_z u_z$, would be zero if Equation (A.1091) were read as an exact statement about every material point. It must not be so read. The ansatz is a statement about the in-plane displacement field and about the rotation of normals; the thickness of the plate does change, by an amount of the same order as the in-plane strains, and u_{zz} is left free here so that the correct constitutive condition can determine it. □

A.57.2 Plane stress, not plane strain

This is the step at which a plate differs from a two-dimensional block of material, and it is where the factor $\left(1-\nu^2\right)^{-1}$ of Equation (30.57) is born.

Proposition A.682 (The plane-stress law)**.** *Let the faces $z = \pm h/2$ be free of traction. Then throughout a thin plate σ_{zz} is negligible, and eliminating u_{zz} from Equation* (30.21) *by $\sigma_{zz} = 0$ gives*

$$u_{zz} = -\frac{\lambda}{\lambda+2\mu}\,u_{\gamma\gamma}\,, \qquad \sigma_{\alpha\beta} = \frac{E}{1+\nu}\left[u_{\alpha\beta} + \frac{\nu}{1-\nu}\,u_{\gamma\gamma}\,\delta_{\alpha\beta}\right]. \tag{A.1094}$$

Both λ,μ and E,ν are the constants of Definition 30.31, related by Proposition 30.33, and every quantity in Equation (A.1094) *except ν carries* Pa.

Rests on Equation (30.21)*, Proposition 30.33, and Definition 30.63.*

Proof. *Derives Proposition A.682.*

Why σ_{zz} and not u_{zz} vanishes. The traction on the faces is $\sigma_{iz}n_z$ with $n_z = \pm 1$, so $\sigma_{zz} = 0$ exactly on $z = \pm h/2$. Between the faces σ_{zz} is of the order of the applied load q, whereas the in-plane stresses are of order qL^2/h^2, larger by the square of the aspect ratio; setting $\sigma_{zz} = 0$ throughout is therefore an error of relative order $(h/L)^2$, the same order

already discarded in Equation (A.1093). Imposing $u_{zz} = 0$ instead — plane strain — would be a different and *wrong* theory: it describes a slab confined between rigid platens, and it would put $\lambda + 2\mu$ where Equation (30.57) has $E/(1-\nu^2)$, overstating the flexural rigidity by $(\lambda + 2\mu)(1-\nu^2)/E = (1-\nu)^2/(1-2\nu)$, a factor 1.22 at $\nu = 0.3$.

The elimination. The zz component of Equation (30.21) reads $\sigma_{zz} = \lambda(u_{\gamma\gamma} + u_{zz}) + 2\mu u_{zz}$, where $u_{\gamma\gamma} = u_{xx} + u_{yy}$ is the in-plane trace. Setting this to zero gives the first of Equation (A.1094). Substituting it back into the in-plane components,

$$\sigma_{\alpha\beta} = \lambda(u_{\gamma\gamma} + u_{zz})\,\delta_{\alpha\beta} + 2\mu u_{\alpha\beta} = \frac{2\lambda\mu}{\lambda + 2\mu}\,u_{\gamma\gamma}\delta_{\alpha\beta} + 2\mu\,u_{\alpha\beta}\,, \tag{A.1095}$$

since $\lambda[1 - \lambda/(\lambda+2\mu)] = 2\lambda\mu/(\lambda+2\mu)$.

In engineering constants. By Equation (30.28), $\lambda = 2\mu\nu/(1-2\nu)$ and $2\mu = E/(1+\nu)$, so

$$\lambda + 2\mu = 2\mu\,\frac{\nu + (1-2\nu)}{1-2\nu} = 2\mu\,\frac{1-\nu}{1-2\nu}\,, \qquad \frac{2\lambda\mu}{\lambda+2\mu} = 2\mu\,\frac{\nu}{1-\nu}\,. \tag{A.1096}$$

Substituting Equation (A.1096) into Equation (A.1095) and pulling out $2\mu = E/(1+\nu)$ gives the second of Equation (A.1094). □

Remark A.683 (Where the factor $1-\nu^2$ comes from). Contracting the second of Equation (A.1094) for a state of pure uniaxial in-plane *strain*, $u_{xx} = \epsilon$ and $u_{yy} = 0$, gives $\sigma_{xx} = [E/(1+\nu)][1 + \nu/(1-\nu)]\,\epsilon = E\epsilon/(1-\nu^2)$: the plate is stiffer than a bar of the same material by $(1-\nu^2)^{-1}$, because its own width prevents the transverse contraction that a bar is free to make. That is the sentence Definition 30.63 states in words, and it is the whole difference between Equation (30.57) and the EI of Equation (30.49).

Rests on Proposition A.682 and Definition 30.63.

A.57.3 Integrating the energy across the thickness

Proposition A.684 (The plate energy)**.** *Under Definition A.680 and Proposition A.682, the elastic energy of a plate occupying the region Ω of the mid-plane is*

$$U[w] = \frac{D}{2}\int_\Omega \left[\left(\nabla^2 w\right)^2 + 2(1-\nu)\left((\partial_x\partial_y w)^2 - \partial_x^2 w\,\partial_y^2 w\right)\right]\mathrm{d}A\,, \tag{A.1097}$$

with $D = Eh^3/[12(1-\nu^2)]$ the flexural rigidity Equation (30.57), of SI dimension N m*; U is then in* J*.*

Rests on Proposition A.682, Lemma A.681, and Definition 30.63.

Proof. *Derives Proposition A.684.*

The density. By Equation (30.22) and Equation (30.19) the energy density is $F = \frac{1}{2}\sigma_{ik}u_{ik}$. Of the nine terms, $\sigma_{\alpha z}u_{\alpha z}$ vanishes because the strain does (Equation (A.1093)) and $\sigma_{zz}u_{zz}$ vanishes because the stress does (Proposition A.682), so only the in-plane block survives:

$$F = \tfrac{1}{2}\sigma_{\alpha\beta}u_{\alpha\beta} = \frac{E}{2(1+\nu)}\left[u_{\alpha\beta}u_{\alpha\beta} + \frac{\nu}{1-\nu}\,(u_{\gamma\gamma})^2\right]. \tag{A.1098}$$

Note that the plate stores no energy in the eliminated component: the work done by σ_{zz} through u_{zz} is zero because σ_{zz} is zero, which is the reason the elimination costs nothing.

Through the thickness. Insert Equation (A.1092). Every strain carries one factor of z, so every term of Equation (A.1098) carries z^2, and

$$\int_{-h/2}^{h/2} z^2\,\mathrm{d}z = \frac{h^3}{12}\,. \tag{A.1099}$$

Writing $w_{,\alpha\beta} = \partial_\alpha \partial_\beta w$ and abbreviating

$$P = w_{,\alpha\beta} w_{,\alpha\beta} = \left(\partial_x^2 w\right)^2 + 2\left(\partial_x \partial_y w\right)^2 + \left(\partial_y^2 w\right)^2 , \qquad Q = \left(\nabla^2 w\right)^2 , \tag{A.1100}$$

the integrated energy is

$$U = \frac{h^3}{12} \frac{E}{2\,(1+\nu)} \int_\Omega \left[P + \frac{\nu}{1-\nu} Q \right] \mathrm{d}A \,. \tag{A.1101}$$

The rearrangement. Expanding Q and comparing with P,

$$P - Q = 2\left(\partial_x \partial_y w\right)^2 - 2\,\partial_x^2 w\,\partial_y^2 w \,, \tag{A.1102}$$

because $Q = \left(\partial_x^2 w\right)^2 + 2\,\partial_x^2 w\,\partial_y^2 w + \left(\partial_y^2 w\right)^2$. Write $2G$ for the right-hand side of Equation (A.1102), so that $P = Q + 2G$ with $G = \left(\partial_x \partial_y w\right)^2 - \partial_x^2 w\,\partial_y^2 w$. Then the bracket of Equation (A.1101) is

$$P + \frac{\nu}{1-\nu} Q = \left(1 + \frac{\nu}{1-\nu}\right) Q + 2G = \frac{Q + 2\,(1-\nu)\,G}{1-\nu} \,, \tag{A.1103}$$

and the prefactor of Equation (A.1101) combines with the $(1-\nu)^{-1}$ to give

$$\frac{h^3}{12} \frac{E}{2\,(1+\nu)\,(1-\nu)} = \frac{1}{2} \frac{E h^3}{12\,(1-\nu^2)} = \frac{D}{2} \,, \tag{A.1104}$$

which is Equation (A.1097). □

Lemma A.685 (The Gaussian-curvature term is a null Lagrangian)**.** *The integrand* $G = \left(\partial_x \partial_y w\right)^2 - \partial_x^2 w\,\partial_y^2 w$ *of Equation* (A.1097) *is an exact divergence,*

$$G = \partial_x \left(\partial_y w\,\partial_x \partial_y w\right) - \partial_y \left(\partial_y w\,\partial_x^2 w\right) \,, \tag{A.1105}$$

so that $\int_\Omega G\,\mathrm{d}A$ *depends only on* w *and its first derivatives on* $\partial\Omega$*. It therefore contributes nothing to the field equation, and nothing at all when the edge is clamped.*

Rests on Proposition A.684.

Proof. *Derives Lemma A.685.*

Differentiate the two products: $\partial_x \left(\partial_y w\,\partial_x \partial_y w\right) = \left(\partial_x \partial_y w\right)^2 + \partial_y w\,\partial_x^2 \partial_y w$ and $\partial_y \left(\partial_y w\,\partial_x^2 w\right) = \partial_y^2 w\,\partial_x^2 w + \partial_y w\,\partial_y \partial_x^2 w$. The two third-derivative terms are equal and cancel in the difference, leaving G. By Theorem 7.101 in the plane, $\int_\Omega G\,\mathrm{d}A = \oint_{\partial\Omega} \left(\partial_y w\,\partial_x \partial_y w\,n_x - \partial_y w\,\partial_x^2 w\,n_y\right) \mathrm{d}s$, an expression in the boundary values of w and ∇w alone. A variation δw vanishing together with $\nabla \delta w$ on $\partial\Omega$ therefore does not change it, so it cannot enter the Euler equation; and for a clamped edge, where w and $\partial_n w$ are prescribed, the whole term is a constant that may be discarded from the functional. □

Remark A.686 (Why the operator comes out as ∇^4). Lemma A.685 is what makes the plate equation as simple as it is, and a reader who does not see it will suspect an error: the energy Equation (A.1097) is manifestly *not* proportional to $\int (\nabla^2 w)^2$, it depends on Poisson's ratio, and yet the field equation contains only the biharmonic operator and no ν at all. The resolution is that the ν-dependent part is a boundary functional. Geometrically, $-G$ is the Gaussian curvature of the deflected mid-surface to leading order in ∇w — the determinant of the Hessian — so Equation (A.1105) is the small-deflection shadow of the Gauss–Bonnet theorem: the total Gaussian curvature of a surface is determined by its boundary. Poisson's ratio does not disappear from the problem; it survives exactly where the boundary functional lives, in the edge conditions of Appendix A.57.5, which is why two plates of the same D and different ν have the same equation and different free-edge behaviour.

Rests on Lemma A.685 and Definition 30.63.

A.57.4 The field equation

Lemma A.687 (Kinetic energy)**.** *To leading order in h/L the kinetic energy of the plate is*

$$T[\dot w] = \frac{\rho h}{2}\int_\Omega \dot w^2 \,\mathrm{d}A\,, \tag{A.1106}$$

with ρ the density in $\mathrm{kg/m^3}$*, so that ρh is a mass per unit area in* $\mathrm{kg/m^2}$*. The discarded term is the rotatory inertia of the cross-sections, $(\rho h^3/24)\int_\Omega |\nabla\dot w|^2\,\mathrm{d}A$.*

Rests on Definition A.680.

Proof. *Derives Lemma A.687.*

Differentiating Equation (A.1091) in time gives $\dot u_z = \dot w$ and $\dot u_\alpha = -z\,\partial_\alpha \dot w$, so

$$T = \frac{\rho}{2}\int_\Omega\int_{-h/2}^{h/2}\left(\dot w^2 + z^2\,|\nabla\dot w|^2\right)\mathrm{d}z\,\mathrm{d}A = \frac{\rho h}{2}\int_\Omega \dot w^2\mathrm{d}A + \frac{\rho h^3}{24}\int_\Omega |\nabla\dot w|^2\,\mathrm{d}A\,, \tag{A.1107}$$

using Equation (A.1099). For a disturbance of lateral scale L one has $|\nabla\dot w|^2 \sim \dot w^2/L^2$, so the second term is smaller than the first by $(h/L)^2/12$, the order already discarded twice above, and is dropped. Retaining it, together with the transverse shear strain discarded in Equation (A.1093), gives the Mindlin–Reissner theory, whose flexural waves have a finite limiting speed instead of the unbounded $\omega \propto k^2$ that Equation (30.58) predicts; the two agree for $kh \ll 1$, which is the regime in which the plate theory is being used. □

Theorem A.688 (The Kirchhoff plate equation)**.** *Let w extremise the action*

$$S[w] = \int_{t_1}^{t_2}\left(T[\dot w] - U[w] + \int_\Omega q\,w\,\mathrm{d}A\right)\mathrm{d}t\,, \tag{A.1108}$$

built from Equation (A.1097) and Equation (A.1106), with q the transverse load per unit area in Pa*. Then in the interior of Ω*

$$\rho h\,\partial_t^2 w + D\,\nabla^4 w = q\,, \tag{A.1109}$$

which is Equation (30.58), and the variation leaves on $\partial\Omega$ the boundary integral Equation (A.1115) below.

Rests on Proposition A.684 and Lemmas 16.18 and A.687.

Proof. *Derives Theorem A.688.*

Moments. It shortens every formula to introduce the bending moments per unit length of edge,

$$M_{\alpha\beta} = -D\left[(1-\nu)\,\partial_\alpha\partial_\beta w + \nu\,\nabla^2 w\,\delta_{\alpha\beta}\right]\,, \tag{A.1110}$$

of SI dimension $\mathrm{N\,m/m} = \mathrm{N}$. With the notation Equation (A.1100), the energy Equation (A.1097) is

$$U = \frac{D}{2}\int_\Omega\left[(1-\nu)\,P + \nu Q\right]\mathrm{d}A = -\frac{1}{2}\int_\Omega M_{\alpha\beta}\,\partial_\alpha\partial_\beta w\,\mathrm{d}A\,, \tag{A.1111}$$

the first equality being Equation (A.1103) read backwards, $Q + 2(1-\nu)G = (1-\nu)P + \nu Q$.

The variation. U is a quadratic form in the second derivatives of w and $M_{\alpha\beta}$ is linear in them, so $\delta U = -\int_\Omega M_{\alpha\beta}\,\partial_\alpha\partial_\beta\delta w\,\mathrm{d}A$. Integrating by parts twice with Theorem 7.101,

$$\delta U = -\int_\Omega\left(\partial_\alpha\partial_\beta M_{\alpha\beta}\right)\delta w\,\mathrm{d}A - \oint_{\partial\Omega} M_{\alpha\beta}n_\alpha\,\partial_\beta\delta w\,\mathrm{d}s + \oint_{\partial\Omega}\left(\partial_\alpha M_{\alpha\beta}\right)n_\beta\,\delta w\,\mathrm{d}s\,, \tag{A.1112}$$

with $\boldsymbol{n}$ the outward unit normal of the edge. Taking the double divergence of Equation (A.1110),

$$\partial_\alpha\partial_\beta M_{\alpha\beta} = -D\left[(1-\nu)\,\nabla^4 w + \nu\,\nabla^4 w\right] = -D\,\nabla^4 w\,, \tag{A.1113}$$

the ν cancelling exactly as Remark A.686 promised. The kinetic term contributes $\delta \int T \mathrm{d}t = -\int \mathrm{d}t \int_\Omega \rho h\, \partial_t^2 w\, \delta w \,\mathrm{d}A$ after one integration by parts in t, the endpoint terms vanishing because δw is held zero at t_1 and t_2. Collecting,

$$\delta S = -\int \mathrm{d}t \left\{ \int_\Omega \left(\rho h\, \partial_t^2 w + D \nabla^4 w - q \right) \delta w \,\mathrm{d}A + \mathcal{B}\left[\delta w\right] \right\} , \tag{A.1114}$$

where $\mathcal{B}$ is the edge integral

$$\mathcal{B}\left[\delta w\right] = -\oint_{\partial\Omega} M_{\alpha\beta} n_\alpha\, \partial_\beta \delta w \,\mathrm{d}s + \oint_{\partial\Omega} \left(\partial_\alpha M_{\alpha\beta}\right) n_\beta\, \delta w \,\mathrm{d}s \,. \tag{A.1115}$$

For variations supported strictly inside Ω, $\mathcal{B}$ vanishes and Lemma 16.18 applied to the area integral gives Equation (A.1109). Since D carries N m and $\nabla^4 w$ carries $1/\mathrm{m}^3$, each term of Equation (A.1109) is a pressure, as q is. □

A.57.5 The free edge: three conditions are one too many

Definition A.689 (Edge resultants)**.** Let $\boldsymbol{n}$ and $\boldsymbol{s}$ be the outward unit normal and the unit tangent of $\partial\Omega$, forming a right-handed pair, and let $\partial_n = n_\alpha \partial_\alpha$ and $\partial_s = s_\alpha \partial_\alpha$. Define

$$M_{nn} = M_{\alpha\beta} n_\alpha n_\beta \,, \qquad \text{bending moment, N}\,, \tag{A.1116}$$

$$M_{ns} = M_{\alpha\beta} n_\alpha s_\beta \,, \qquad \text{twisting moment, N}\,, \tag{A.1117}$$

$$Q_n = \left(\partial_\alpha M_{\alpha\beta}\right) n_\beta \,, \qquad \text{transverse shear, N/m}\,. \tag{A.1118}$$

Explicitly, from Equation (A.1110), $M_{nn} = -D\left[\partial_n^2 w + \nu\, \partial_s^2 w\right]$ for a straight edge, and $M_{ns} = -D\,(1-\nu)\,\partial_n \partial_s w$, the trace term dropping out of the second because $\delta_{\alpha\beta} n_\alpha s_\beta = \boldsymbol{n}\cdot\boldsymbol{s} = 0$: the twisting moment measures the *twist* $\partial_n \partial_s w$ of the mid-surface at the edge and nothing else.

Rests on Equation (A.1110) *and Proposition A.682.*

Remark A.690 (Poisson's count, and why it cannot be right). Read as a force balance, a free edge — one at which nothing is attached — carries no bending moment, no twisting moment and no transverse shear, which is three conditions: $M_{nn} = 0$, $M_{ns} = 0$, $Q_n = 0$. This is Poisson's count, and Remark 30.67 records that it was believed for two decades. It cannot be right. Equation (A.1109) is of fourth order in the two space variables, so along each edge exactly *two* conditions may be imposed; three over-determine the problem and in general leave it with no solution at all. The resolution is not to discard one of the three arbitrarily but to observe that they are not independent, which is what the variational form Equation (A.1115) makes visible and a force balance cannot.

Rests on Definition A.689 and Theorem A.688.

Theorem A.691 (Kirchhoff's edge conditions and the corner force)**.** *Let $\partial\Omega$ be a closed piecewise-smooth curve with corners $c_1, \dots, c_N$. Then the edge integral Equation* (A.1115) *may be written*

$$\mathcal{B}\left[\delta w\right] = -\oint_{\partial\Omega} M_{nn}\, \partial_n \delta w \,\mathrm{d}s + \oint_{\partial\Omega} V_n\, \delta w \,\mathrm{d}s + \sum_{j=1}^{N} F_j\, \delta w\left(c_j\right) \,, \tag{A.1119}$$

with the effective *(Kirchhoff) shear and the corner force*

$$V_n = Q_n + \partial_s M_{ns} \quad (\mathrm{N/m}) \,, \qquad F_j = \left[\!\left[M_{ns} \right]\!\right]_{c_j} \quad (\mathrm{N}) \,, \tag{A.1120}$$

where $\left[\!\left[M_{ns} \right]\!\right]_{c_j}$ is the jump in M_{ns} across the corner. Consequently, at an edge where nothing is prescribed the natural boundary conditions (Theorem 16.31) are the two *statements*

$$M_{nn} = 0 \,, \qquad V_n = Q_n + \partial_s M_{ns} = 0 \,, \tag{A.1121}$$

together with the vanishing of F_j at every free corner. These are the conditions asserted by Theorem 30.64.

Rests on Theorems 16.31 and A.688 and Definition A.689.

Proof. *Derives Theorem A.691.*

Resolving the normal derivative. Along the edge, $\{\boldsymbol{n}, \boldsymbol{s}\}$ is an orthonormal frame of the plane, so $\partial_\beta \delta w = n_\beta\, \partial_n \delta w + s_\beta\, \partial_s \delta w$ and

$$M_{\alpha\beta} n_\alpha \partial_\beta \delta w = M_{nn}\, \partial_n \delta w + M_{ns}\, \partial_s \delta w\,. \tag{A.1122}$$

Substituting Equation (A.1122) and Equation (A.1118) into Equation (A.1115) gives the three-term form

$$\mathcal{B}\,[\delta w] = \oint_{\partial\Omega} \left[-M_{nn}\, \partial_n \delta w - M_{ns}\, \partial_s \delta w + Q_n\, \delta w\right] \mathrm{d}s\,, \tag{A.1123}$$

which is where Poisson's three conditions appear to come from.

The three are two. The quantities δw and $\partial_n \delta w$ may be prescribed independently on the edge, but $\partial_s \delta w$ may not: it is the derivative of δw *along* the edge, and is determined by δw there. Integrate that term by parts along the curve. On each smooth arc,

$$-\int_{\text{arc}} M_{ns}\, \partial_s \delta w \,\mathrm{d}s = \int_{\text{arc}} (\partial_s M_{ns})\, \delta w \,\mathrm{d}s - \Big[M_{ns}\, \delta w\Big]_{\text{start}}^{\text{end}}\,. \tag{A.1124}$$

Summing Equation (A.1124) over the arcs of the closed curve, the endpoint terms of consecutive arcs meet at each corner c_j and combine into $-M_{ns}^{-}\delta w(c_j) + M_{ns}^{+}\delta w(c_j)$, where $\pm$ denote the limits taken along the outgoing and incoming arc; that is $F_j\, \delta w(c_j)$ with F_j the jump of Equation (A.1120). On a smooth closed curve, M_{ns} is continuous and every such term cancels. Collecting with the $Q_n \delta w$ term of Equation (A.1123) gives Equation (A.1119).

The conditions. In Equation (A.1119) the three factors $\partial_n \delta w$ on the edge, δw on the edge and δw at each corner are now independently assignable. By Lemma 16.18 applied on the edge and then at the finitely many corners, $\delta S = 0$ for all admissible variations requires each coefficient to vanish wherever its variation is free. Where the plate is clamped, $\delta w = \partial_n \delta w = 0$ and nothing is required of M_{nn} or V_n; where it is simply supported, $\delta w = 0$ but $\partial_n \delta w$ is free, giving the single natural condition $M_{nn} = 0$; where it is free, both are free and Equation (A.1121) follows, with $F_j = 0$ at a free corner. In every case the count is two conditions per edge, as the order of Equation (A.1109) requires. □

Remark A.692 (The corner force is real, and you can feel it). F_j is not an artefact of the variational bookkeeping. Take a square plate, simply supported on all four edges — resting on knife edges, free to rotate — and load it uniformly. Along each edge $\delta w = 0$, so the edge integral of Equation (A.1119) imposes only $M_{nn} = 0$; but at a corner the tangent turns through a right angle, the roles of n and s are exchanged, and M_{ns} changes sign, so $F_j = [\![M_{ns}]\!] = 2M_{ns}$ does not vanish. A downward concentrated force of that magnitude must be supplied at each corner. If the supports cannot pull down — if the plate merely rests on them — the corners lift off, which is exactly what a uniformly loaded square glass pane does, and why a concrete floor slab supported on four walls is reinforced diagonally at its corners. The corner force also explains the sign of the effect: the plate is attempting to become anticlastic, curving up along one diagonal while it curves down along the other, and it is M_{ns} that measures that twist.

Rests on Theorem A.691 and Equation (A.1120).

Remark A.693 (Attribution, and what the hypotheses cost). The fourth-order equation is Germain's [70] and the two correct edge conditions are Kirchhoff's [130], obtained exactly as above, from the variation of the energy rather than from a force balance; Poisson's three-condition count is in his memoir on elastic bodies [86]. Three approximations were

made and each is of relative order $(h/L)^2$: the transverse shear strain was set to zero (Equation (A.1093)), the transverse normal stress was set to zero (Proposition A.682), and the rotatory inertia was dropped (Lemma A.687). Two of the three are removed by the Mindlin–Reissner theory, and none of them is a small-deflection assumption: the linearisation of the strain in Definition A.680 is a separate hypothesis, and it is the one that fails first for a thin plate, since a deflection of order h already stretches the mid-surface and brings in the membrane terms of Remark 30.68.

Remark A.694. Appendix A.57 discharges the derivation owed at Theorem 30.64 of Chapter 30. The three stages announced in that chapter are Appendix A.57.2 (plane stress, and the birth of the factor $1-\nu^2$ in Equation (30.57)), Appendix A.57.3 together with Appendix A.57.4 (the thickness integration and the variation, giving Equation (30.58)), and Appendix A.57.5 (Kirchhoff's resolution of the edge count, with the concentrated corner force). Everything the chapter builds on Equation (30.58) — the Chladni figures of Phenomenon 30.65, the scaling Equation (30.59), and the historical reading of Remark 30.67 — rests on the equation proved here, and the isotropic constitutive law it starts from is Equation (30.21), proved in Appendix A.56.

A.58 Hertz's Solution for the Elastic Half-Space Under an Axisymmetric Pressure

This appendix completes the derivation of Phenomenon 30.70 of Chapter 30. It is deliberately *not* a second derivation of that phenomenon. The inline derivation in the chapter already establishes the exponent, and establishes it exactly: from the geometry of two nearly touching spheres, the single strain scale of the contact region and the linearity of the elastic law it obtains $F \propto E^* R^{1/2} \delta^{3/2}$, with $a = \sqrt{R\delta}$, and nothing about that argument is a guess. What it cannot reach is the pure number in front and the shape of the pressure distribution, because both require actually solving the elastic problem. Those two things — the coefficient $\frac{4}{3}$ of Equation (30.60) and the elliptic profile $p(r) = p_0\sqrt{1-r^2/a^2}$ — are what this section supplies, together with a proof of the two-body combination rule for E^*, which the chapter's derivation asserts in a clause and proves nowhere.

A.58.1 What is quoted here

One result is imported, and everything else is derived from it.

Theorem A.695 (Boussinesq's point-force solution, quoted)**.** *Let an isotropic elastic half-space $z \geq 0$ with Young's modulus E and Poisson's ratio ν (Definition 30.31) be loaded by a normal force P concentrated at the origin of its free surface, the rest of the surface being free of traction and the displacement vanishing at infinity. Then the normal displacement of the surface at distance r from the load is*

$$u_z(r) = \frac{1-\nu^2}{\pi E}\,\frac{P}{r} = \frac{P}{\pi E^* r}\,, \qquad \frac{1}{E^*} \equiv \frac{1-\nu^2}{E}\,, \tag{A.1125}$$

directed into the half-space [1778]. Here P carries N*, E and E^* carry* Pa *and u_z carries* m.
Rests on Equation (30.21), Definition 30.31, and Theorem 30.18.

Remark A.696 (What is quoted here). Theorem A.695 is Boussinesq's, published in 1885, and it is the one step of this section that is not carried out from the material of this treatise. Obtaining it needs a general representation of the solutions of the Navier–Cauchy equations of elastostatics in terms of harmonic functions — the Papkovich–Neuber representation — and the potential theory of Section 10.4.3 carries the harmonic functions but not that representation. It is therefore a debt owed by Chapter 10, and it is named here rather than

passed over; the statement above is proved in Landau and Lifshitz's treatment of the elastic half-space [1778], from which the form Equation (A.1125) is taken.

Two features of Equation (A.1125) can be checked here without the representation, and are worth checking, because between them they fix everything except the pure number $1/\pi$. *Dimensions*: $P/(E^* r)$ is $\mathrm{N}/(\mathrm{Pa}\cdot\mathrm{m}) = \mathrm{m}$, as a displacement must be. *Scale invariance*: the problem has no length in it at all — a half-space is scale-invariant, a point load introduces no length, and linear elasticity has no intrinsic scale — so u_z must be a homogeneous function of r, and linearity in P together with the dimensions forces the exponent -1. The modulus combination $E/(1-\nu^2)$ appears rather than E because the material beneath a surface load is laterally confined, which is the same statement as the one made for a plate in Remark A.683.

A.58.2 Superposition and the contact conditions

Lemma A.697 (Surface displacement under a distributed pressure)**.** *Let a pressure $p(\rho) \geq 0$ act on the disc $\rho \leq a$ of the free surface of the half-space, and vanish outside it. Then the surface normal displacement is*

$$u_z(r) = \frac{1}{\pi E^*}\,\Phi(r)\,, \qquad \Phi(r) = \int_{\rho\leq a} \frac{p\,(\rho)}{s}\,\mathrm{d}A'\,, \tag{A.1126}$$

where s is the distance in the surface plane from the field point to the element $\mathrm{d}A'$. The integral converges although the kernel is singular, because $\mathrm{d}A' = s\,\mathrm{d}s\,\mathrm{d}\varphi$ in polar coordinates centred on the field point.

Rests on Theorem A.695.

Proof. *Derives Lemma A.697.*

The elastic problem is linear (Equation (30.21)) and the boundary conditions are linear in the applied traction, so displacements superpose. Treating the load on the element $\mathrm{d}A'$ as a point force $P = p\,\mathrm{d}A'$ and summing Equation (A.1125) gives Equation (A.1126). In polar coordinates (s,φ) about the field point the element is $s\,\mathrm{d}s\,\mathrm{d}\varphi$, so the integrand is $p\,\mathrm{d}s\,\mathrm{d}\varphi$ with no singularity at all; the integral exists for any bounded p. □

Definition A.698 (The Hertz contact problem)**.** Two elastic bodies of radii R_1 and R_2, with moduli (E_1,ν_1) and (E_2,ν_2), are pressed together along their line of centres by a normal force F, their centres approaching by δ. Let a be the radius of the circle of contact and $p(r)$ the contact pressure. The problem is to find p, a and the relation between F and δ, subject to

1. *contact inside the circle*: for $r \leq a$ the sum of the two surface displacements closes the initial gap,
$$u_z^{(1)}(r) + u_z^{(2)}(r) = \delta - \frac{r^2}{2R}\,, \qquad \frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2}\,, \tag{A.1127}$$
2. *separation outside*: $p(r) = 0$ for $r > a$, and the surfaces there do not overlap;
3. *no adhesion and no edge singularity*: $p(r) \geq 0$ throughout, and p is bounded as $r \to a$.

The contact is taken to be *frictionless*, so that the traction transmitted across it is purely normal; and $a \ll R$, so that near the contact each body is indistinguishable from a half-space and Theorem A.695 applies to it.

Rests on Theorem A.695 and Phenomenon 30.70.

Remark A.699 (The third condition is not decoration). Conditions (1) and (2) alone do not determine the answer. The same geometry admits the flat-punch solution $p(r) \propto (1 - r^2/a^2)^{-1/2}$, which is a perfectly good solution of the elastic equations, produces a

constant surface displacement inside the circle, and diverges at the rim; it is the right answer for a rigid flat cylindrical punch pressed into a half-space, where the contact radius is fixed by the punch and the material at the rim is genuinely singular. What excludes it here is condition (3): the contact circle of two smooth bodies is not fixed externally — it is whatever radius the load produces — so the surfaces must meet the rim tangentially and the pressure must go to zero there, not to infinity. Condition (3) also excludes the tensile solutions that would hold the surfaces together outside the circle, which is the assumption of *no adhesion*; it fails for very small or very compliant bodies, where surface energy matters, and Hertz's relation is then replaced by an adhesive contact theory. Stating the third condition is what turns the profile below from a lucky guess into the unique answer.

Rests on Definition A.698.

A.58.3 The elliptic pressure and its displacement

The whole solution rests on one integral, and it is worth doing in full.

Lemma A.700 (The displacement produced by an elliptic pressure)**.** *Let* $p(\rho) = p_0\sqrt{1-\rho^2/a^2}$ *on* $\rho \le a$ *and zero outside. Then for every field point inside the circle,* $r \le a$*,*

$$\Phi(r) = \frac{\pi^2 p_0}{4a}\left(2a^2 - r^2\right), \qquad \textit{hence} \qquad u_z(r) = \frac{\pi p_0}{4E^* a}\left(2a^2 - r^2\right). \tag{A.1128}$$

The displacement is therefore quadratic *in* r *inside the contact circle — which is exactly the shape Equation* (A.1127) *demands.*

Rests on Lemma A.697 and Definition A.698.

Proof. *Derives Lemma A.700.*

Place the field point at $(r, 0)$ with $0 \le r \le a$ and use polar coordinates (s, φ) centred on it, so that the element at (s, φ) sits at $(r + s\cos\varphi,\ s\sin\varphi)$ and is at distance

$$\rho^2 = r^2 + 2rs\cos\varphi + s^2, \tag{A.1129}$$

measured from the centre of the disc. By Lemma A.697 the kernel cancels the Jacobian, so

$$\Phi(r) = \int_0^{2\pi} \mathrm{d}\varphi \int_0^{\ell(\varphi)} p\,(\rho)\,\mathrm{d}s = \frac{p_0}{a}\int_0^{2\pi} \mathrm{d}\varphi \int_0^{\ell(\varphi)} \sqrt{a^2 - r^2 - 2rs\cos\varphi - s^2}\,\mathrm{d}s, \tag{A.1130}$$

where $\ell(\varphi)$ is the distance from the field point to the rim along the direction φ, that is the value of s at which $\rho = a$.

Completing the square. Put

$$u = s + r\cos\varphi, \qquad A^2 = a^2 - r^2\sin^2\varphi, \qquad a^2 - r^2 - 2rs\cos\varphi - s^2 = A^2 - u^2, \tag{A.1131}$$

which is checked by expanding $A^2 - u^2$. The rim, $\rho = a$, is $u = A$; the field point, $s = 0$, is $u = r\cos\varphi$. Since u and s differ by a constant at fixed φ, $\mathrm{d}u = \mathrm{d}s$, and

$$\int_0^{\ell(\varphi)} \sqrt{A^2 - u^2}\,\mathrm{d}s = \int_{r\cos\varphi}^{A} \sqrt{A^2 - u^2}\,\mathrm{d}u = \left[\frac{u}{2}\sqrt{A^2 - u^2} + \frac{A^2}{2}\arcsin\frac{u}{A}\right]_{u=r\cos\varphi}^{u=A}, \tag{A.1132}$$

the antiderivative being elementary. At the upper limit the first term vanishes and $\arcsin 1 = \pi/2$, giving $\pi A^2/4$. At the lower limit,

$$A^2 - r^2\cos^2\varphi = a^2 - r^2\sin^2\varphi - r^2\cos^2\varphi = a^2 - r^2, \tag{A.1133}$$

a constant independent of φ — the geometric fact that makes the calculation work. Writing $B = \sqrt{a^2 - r^2}$, the inner integral is

$$\frac{\pi A^2}{4} - \frac{rB\cos\varphi}{2} - \frac{A^2}{2}\arcsin\frac{r\cos\varphi}{A}\,. \tag{A.1134}$$

The angular integral. Integrate Equation (A.1134) over $\varphi \in [0, 2\pi)$ term by term. The second term integrates to zero, $\int_0^{2\pi}\cos\varphi\,\mathrm{d}\varphi = 0$. The third also integrates to zero: under $\varphi \mapsto \pi - \varphi$ the quantity A is unchanged, since it depends on $\sin^2\varphi$, while $\cos\varphi$ changes sign and arcsin is odd, so the integrand is odd about that involution. The first term gives

$$\frac{\pi}{4}\int_0^{2\pi}\left(a^2 - r^2\sin^2\varphi\right)\mathrm{d}\varphi = \frac{\pi}{4}\left(2\pi a^2 - \pi r^2\right) = \frac{\pi^2}{4}\left(2a^2 - r^2\right)\,, \tag{A.1135}$$

using $\int_0^{2\pi}\sin^2\varphi\,\mathrm{d}\varphi = \pi$. Multiplying by the prefactor p_0/a of Equation (A.1130) gives the first of Equation (A.1128), and Equation (A.1126) then gives the second. □

A.58.4 Matching, and the coefficient $\frac{4}{3}$

Proposition A.701 (The two-body compliance rule)**.** *Under Definition A.698 the two bodies carry the* same *contact pressure $p(r)$, so their surface displacements add, and*

$$u_z^{(1)}(r) + u_z^{(2)}(r) = \frac{\Phi(r)}{\pi E^*}\,, \qquad \frac{1}{E^*} = \frac{1-\nu_1^2}{E_1} + \frac{1-\nu_2^2}{E_2}\,, \tag{A.1136}$$

which is the combination appearing in Equation (30.60). The geometry likewise combines: the gap between the two undeformed surfaces is $r^2/2R$ with $1/R = 1/R_1 + 1/R_2$, so the pair is equivalent to a single sphere of radius R pressed against a rigid plane by the same force.
Rests on Lemma A.697 and Definition A.698.

Proof. *Derives Proposition A.701.*

The pressures are equal. By Newton's third law the traction each body exerts on the other is equal and opposite at every point of the common contact area, so the same scalar $p(r)$ appears in Equation (A.1126) for both. Applying that formula to each body with its own modulus and adding,

$$u_z^{(1)} + u_z^{(2)} = \left(\frac{1-\nu_1^2}{\pi E_1} + \frac{1-\nu_2^2}{\pi E_2}\right)\Phi(r)\,, \tag{A.1137}$$

which is Equation (A.1136). It is the *compliances* $1/E_i^*$ that add and not the moduli, because the two bodies are loaded in series by a common force and their deflections accumulate; that is the clause the chapter's inline derivation asserts without proof, and Equation (A.1137) is the proof. A rigid body has $E_i \to \infty$ and contributes nothing, so a single elastic sphere against a rigid plane has $E^* = E/(1-\nu^2)$.

The geometry. Measure heights from the plane of first contact. To leading order in r/R_i the surface of a sphere of radius R_i lies at height $r^2/2R_i$ below its own pole — the expansion $R_i - \sqrt{R_i^2 - r^2} = r^2/2R_i + O(r^4/R_i^3)$ — so the gap between the two undeformed surfaces at distance r from the axis is $r^2/2R_1 + r^2/2R_2 = r^2/2R$. Both the elastic response and the geometry therefore depend on the pair only through E^* and R. □

Theorem A.702 (Hertz's solution)**.** *The unique solution of Definition A.698 is the elliptic pressure distribution*

$$p(r) = p_0\sqrt{1 - \frac{r^2}{a^2}}\,, \qquad p_0 = \frac{2E^*a}{\pi R} = \frac{3F}{2\pi a^2}\,, \tag{A.1138}$$

with contact radius, approach and force related by

$$a = \sqrt{R\delta}\,, \qquad \delta = \frac{a^2}{R}\,, \qquad F = \frac{4}{3}\,E^* R^{1/2}\delta^{3/2}\,, \tag{A.1139}$$

which is Equation (30.60) complete with its coefficient.
Rests on Lemma A.700, Proposition A.701, and Definition A.698.

Proof. *Derives Theorem A.702.*

Matching. Insert Equation (A.1128) into Equation (A.1136) and set the result equal to the required displacement Equation (A.1127):

$$\frac{\pi p_0}{4E^* a}\left(2a^2 - r^2\right) = \delta - \frac{r^2}{2R} \qquad \text{for all } r \le a\,. \tag{A.1140}$$

Both sides are polynomials in r^2 of degree one, so Equation (A.1140) holds identically if and only if the constant terms and the coefficients of r^2 agree separately:

$$\frac{\pi p_0 a}{2E^*} = \delta\,, \qquad \frac{\pi p_0}{4E^* a} = \frac{1}{2R}\,. \tag{A.1141}$$

That an elliptic pressure produces a displacement of *exactly* the required quadratic form, with two free constants p_0 and a to match two coefficients, is what makes the problem solvable in closed form; it is the content of Lemma A.700 and it is why Hertz's guess was the right one.

Solving. The second of Equation (A.1141) gives $p_0 = 2E^* a/(\pi R)$, the first of Equation (A.1138). Substituting into the first of Equation (A.1141),

$$\delta = \frac{\pi a}{2E^*} \cdot \frac{2E^* a}{\pi R} = \frac{a^2}{R}\,, \tag{A.1142}$$

which is $a = \sqrt{R\delta}$, the contact radius quoted in Phenomenon 30.70.

The force. Integrating the pressure over the contact circle, with the substitution $t = r^2/a^2$,

$$F = \int_0^a p_0 \sqrt{1 - \frac{r^2}{a^2}}\, 2\pi r \,\mathrm{d}r = \pi a^2 p_0 \int_0^1 \sqrt{1-t}\,\mathrm{d}t = \frac{2}{3}\pi a^2 p_0\,, \tag{A.1143}$$

so $p_0 = 3F/(2\pi a^2)$: the peak pressure is $\frac{3}{2}$ times the mean pressure $F/\pi a^2$, which is the second equality of Equation (A.1138). Eliminating p_0 between Equation (A.1143) and Equation (A.1138), and then a by Equation (A.1142),

$$F = \frac{2}{3}\pi a^2 \cdot \frac{2E^* a}{\pi R} = \frac{4}{3}\,\frac{E^* a^3}{R} = \frac{4}{3}\,\frac{E^*\,(R\delta)^{3/2}}{R} = \frac{4}{3}\,E^* R^{1/2}\delta^{3/2}\,. \tag{A.1144}$$

Uniqueness and admissibility. The profile Equation (A.1138) is non-negative and vanishes at $r = a$, so it satisfies condition (3) of Definition A.698; outside the circle the deformed surfaces separate, since the elastic displacement there falls faster than the parabolic gap grows. That it is the *only* admissible solution follows from linearity together with the positive definiteness of the elastic energy. Suppose two admissible pressure distributions produced the same δ over the same contact circle. Their difference drives an elastic field whose surface traction is purely normal (the contact is frictionless), whose normal displacement vanishes inside the circle, and whose traction vanishes outside it. Its stored energy is $\frac{1}{2}\oint \sigma_{ik} n_k u_i \,\mathrm{d}S$ by Equation (30.18) with $w_i = u_i$ and no body force, and every term of that integral has one vanishing factor, so the energy is zero. Since the energy density is positive definite (Proposition 30.30), the difference field has zero strain and the two pressures coincide.

The coefficient $\frac{4}{3}$ of Equation (A.1144) is exactly and only what the scaling argument of the chapter left open, and it is assembled from three pure numbers: the π of the Boussinesq kernel Equation (A.1125), the $\pi^2/4$ of the integral Equation (A.1128), and the $\frac{2}{3}$ of Equation (A.1143). □

A.58.5 Checks and consequences

Example A.703 (The numbers of the chapter, recomputed)**.** Example 30.71 presses two steel balls of radius 10 mm together with 1 N, with $E = 210\,\mathrm{GPa}$ and $\nu = 0.29$. Then Equation (A.1136) gives

$$\frac{1}{E^*} = \frac{2\,(1-\nu^2)}{E} = \frac{2\,(1-0.0841)}{2.10\times10^{11}\,\mathrm{Pa}} = 8.72\times10^{-12}/\mathrm{Pa}\,, \qquad E^* = 1.15\times10^{11}\,\mathrm{Pa}\,, \tag{A.1145}$$

and $R = 5.0\,\mathrm{mm}$ by Equation (A.1127). Inverting Equation (A.1144) with $\delta = a^2/R$ gives $a = [3FR/(4E^*)]^{1/3}$, so

$$a = \left[\frac{3\,(1\,\mathrm{N})\,(5.0\times10^{-3}\,\mathrm{m})}{4\,(1.15\times10^{11}\,\mathrm{Pa})}\right]^{1/3} = 3.2\times10^{-5}\,\mathrm{m} = 32\,\mu\mathrm{m}\,, \tag{A.1146}$$

whence $\delta = a^2/R = 2.0\times10^{-7}\,\mathrm{m} = 0.20\,\mu\mathrm{m}$ and, by Equation (A.1138), $p_0 = 3F/(2\pi a^2) = 4.7\times10^8\,\mathrm{Pa} = 470\,\mathrm{MPa}$. All three reproduce Example 30.71, which is the arithmetic check a reader can run in a minute. Note also the ratio $a/R = 6.4\times10^{-3}$, which is what licenses the half-space approximation of Definition A.698.

Rests on Theorem A.702 and Phenomenon 30.70.

Remark A.704 (E^* in two roles, and one trap). The symbol $E/(1-\nu^2)$ occurs twice in Chapter 30 and means two different things, which is worth stating plainly because the two are easily read as one quantity. In Definition 30.63 it is a *single-body* stiffness: the plane-strain modulus of the plate material, appearing because a bent plate cannot contract transversely. In Equation (30.60) the same expression is one term of a *two-body* sum, Equation (A.1136), and the contact modulus E^* is the harmonic-type combination of both bodies' plane-strain moduli. The underlying modulus is the same and its physical reason is the same — lateral confinement — but a contact between two steel bodies has E^* equal to *half* the plate value for steel, and substituting one for the other misstates the contact stiffness by a factor of two.

Rests on Theorem A.702 and Definition 30.63.

Remark A.705 (The dangerous stress is below the surface). The peak *pressure* is at the centre of the contact, on the surface. The peak *shear* stress is not: evaluating the subsurface stress field from the same Boussinesq kernel — an elementary but long computation, not carried out here — places the maximum of $\frac{1}{2}(\sigma_1 - \sigma_3)$ on the axis at a depth of about $0.48\,a$ for $\nu \approx 0.3$, where it reaches about $0.31\,p_0$. Since ductile yielding is governed by the maximum shear stress and not by the pressure (Proposition 30.74), first yield under a Hertzian contact begins at that depth, inside apparently undamaged material. For the balls of Example A.703 the peak shear is $0.31\times470\,\mathrm{MPa} = 146\,\mathrm{MPa}$ at a depth of 15 µm. That is the mechanism behind rolling-contact fatigue: a bearing race accumulates plastic damage at a fixed small depth under every pass of a ball, and eventually a subsurface crack reaches the surface and detaches a flake. It is why such a failure is a spall and not wear, and why it is invisible until the moment it is not — the point made at the end of Example 30.71 and taken up in Section 30.8.

Rests on Theorem A.702 and Proposition 30.74.

Remark A.706. Appendix A.58 discharges the derivation owed at Phenomenon 30.70 of Chapter 30, and only that part of it which the inline derivation cannot reach: the elliptic pressure profile Equation (A.1138), the coefficient $\frac{4}{3}$ of Equation (30.60), and the two-body compliance rule of Proposition A.701. The exponent $\frac{3}{2}$ and the relation $a = \sqrt{R\delta}$ are proved in the chapter, by an argument that needs no elasticity solution at all, and are not reproved here. One result is imported and named as such (Remark A.696): Boussinesq's point-force solution Equation (A.1125), a debt owed by Chapter 10, whose Papkovich–Neuber representation this treatise does not carry. Everything else — the potential integral of Lemma A.700 in particular — is carried out in full from the isotropic Hooke law Equation (30.21) proved in Appendix A.56.

A.59 D'Alembert's Paradox for a Body of Arbitrary Shape

This appendix proves Phenomenon 31.30 of Chapter 31 in the generality in which it was stated. The chapter derives the result for a sphere, where the fore-and-aft symmetry of Equation (31.28) makes the cancellation visible in one line; what is owed, and is discharged here, is the statement for a body of *any* shape, where no such symmetry is available and the vanishing of the force has to be extracted from the structure of the far field instead. The conclusion is stronger than the chapter's phrasing: not only the drag but the whole resultant vanishes, so an arbitrary body in a steady, simply connected, irrotational flow of an ideal fluid feels no lift either. That is what makes Remark 31.31 exhaustive — the only way to buy a transverse force is to break the hypotheses, which is what Theorem 31.68 does.

A.59.1 Statement and hypotheses

Theorem A.707 (D'Alembert's paradox)**.** *Let S be the smooth closed surface of a finite rigid body held fixed in an unbounded incompressible ideal fluid of uniform density ρ, in* $\mathrm{kg/m^3}$*, occupying the exterior region Ω, and let the motion be steady and irrotational with a single-valued potential ϕ on Ω, satisfying*

$$\nabla^2\phi = 0 \text{ in } \Omega\,, \qquad \partial_n\phi = 0 \text{ on } S\,, \qquad \boldsymbol{\nabla}\phi \longrightarrow U\hat{\boldsymbol{z}} \text{ as } |\boldsymbol{x}| \longrightarrow \infty\,. \tag{A.1147}$$

Then the resultant force exerted on the body by the fluid pressure vanishes identically,

$$\boldsymbol{F} = -\oint_S p\,\boldsymbol{N}\,\mathrm{d}S = \boldsymbol{0}\,, \tag{A.1148}$$

$\boldsymbol{N}$ being the unit normal on S directed into the fluid. The statement holds for every shape of S, for every value of U in m/s*, and componentwise: there is no drag and no lift.*

Rests on Proposition 31.28 and Theorem 31.24.

Three hypotheses carry the whole argument and each is named in Remark 31.31 as a way out. *Steadiness* is what licenses the momentum balance of Appendix A.59.3. *Single-valuedness of ϕ* is the simple-connectivity assumption; it is what forbids a circulation, and dropping it is the plane-flow escape of Section 31.7.1. *Attachment* — that Ω really is the whole exterior, with the fluid following the surface everywhere — is what nature declines to provide, and its failure is Section 31.7.2.

A.59.2 The far field carries no source

Write

$$\phi = Uz + \chi\,, \qquad \boldsymbol{u}' := \boldsymbol{\nabla}\chi\,, \tag{A.1149}$$

so that χ is harmonic on Ω and $\boldsymbol{u}'$, the disturbance velocity, tends to zero at infinity. The first step is that χ has no monopole term, and this is a consequence of impermeability alone.

Lemma A.708 (The disturbance flux vanishes)**.** *Let S_R be a sphere of radius R large enough to contain S, with outward unit normal $\boldsymbol{n}$. Then*

$$\oint_{S_R} \boldsymbol{u}' \cdot \boldsymbol{n}\,\mathrm{d}S = 0 \tag{A.1150}$$

for every such R.

Rests on Theorem 7.101 and Equation (A.1149).

Proof. *Derives Lemma A.708.*

Apply the divergence theorem (Theorem 7.101) to $\boldsymbol{u}'$ on the region bounded by S and S_R. Since $\boldsymbol{\nabla}\cdot\boldsymbol{u}' = \nabla^2\chi = 0$ there,

$$\oint_{S_R} \boldsymbol{u}'\cdot\boldsymbol{n}\,\mathrm{d}S = \oint_S \boldsymbol{u}'\cdot\boldsymbol{N}\,\mathrm{d}S = \oint_S \boldsymbol{\nabla}\phi\cdot\boldsymbol{N}\,\mathrm{d}S - U\oint_S \hat{\boldsymbol{z}}\cdot\boldsymbol{N}\,\mathrm{d}S\,.$$

The first integral is zero because $\partial_n\phi = 0$ on S: the body is impermeable. The second is zero because the integral of the unit normal over any closed surface vanishes — take $\boldsymbol{a}$ constant in the divergence theorem and read $\oint_S \boldsymbol{a}\cdot\boldsymbol{N}\,\mathrm{d}S = \int \boldsymbol{\nabla}\cdot\boldsymbol{a}\,\mathrm{d}V = 0$. □

Theorem A.709 (Exterior expansion in solid harmonics; quoted)**.** *Let χ be harmonic in the exterior of a ball of radius R_0 in three dimensions and tend to zero at infinity. Then, in spherical coordinates (r,θ,φ) centred in that ball,*

$$\chi(\boldsymbol{x}) = \sum_{l=0}^{\infty}\sum_{m=-l}^{l} \frac{c_{lm}}{r^{\,l+1}}\,Y_{lm}(\theta,\varphi)\,, \tag{A.1151}$$

the series converging uniformly, together with the series of its term-by-term derivatives of every order, on $r \geq R_1$ for each $R_1 > R_0$. Here Y_{lm} is the spherical harmonic Equation (9.163), and the powers r^{-l-1} are the decaying radial solutions of Equation (10.34) at $k = 0$ (Example 10.33).

Rests on Equations (9.163) and (10.34).

Remark A.710 (What is quoted here). Theorem A.709 is the only statement in this section that is not derived. Part II supplies one half of it and not the other. The half it supplies is the *basis*: separation of Laplace's equation in spherical coordinates, carried out at Example 10.33, produces exactly the radial factors r^l and r^{-l-1} against the spherical harmonics of Section 9.9.3, and the decay condition selects the second family. The half it does not supply is *completeness with convergence* — that every exterior harmonic function decaying at infinity is the sum of such a series, uniformly and differentiably. That is a theorem of potential theory, resting on the mean-value property (Appendix A.16) and on the analyticity of harmonic functions, and this treatise does not build it; it is recorded here as a debt against Chapter 10, in the same spirit as the vector identities recorded at Remark 31.5. Its classical use in exactly the present setting — the far field of a body in a stream as a source, a dipole and higher terms — is Lamb's [701]. Nothing below uses more of it than the leading two terms.

Corollary A.711 (The disturbance is a dipole at leading order)**.** *There is a constant vector $\boldsymbol{A}$, of dimension $\mathsf{L}^4\mathsf{T}^{-1}$, such that*

$$\chi = \frac{\boldsymbol{A}\cdot\boldsymbol{x}}{r^3} + O\Big(r^{-3}\Big)\,, \qquad u_i' = \frac{1}{r^3}\left(A_i - 3\,(\boldsymbol{A}\cdot\boldsymbol{n})\,n_i\right) + O\Big(r^{-4}\Big)\,, \tag{A.1152}$$

with $\boldsymbol{n} = \boldsymbol{x}/r$.

Rests on Lemma A.708 and Theorem A.709.

Proof. *Derives Corollary A.711.*

In Equation (A.1151) the $l = 0$ term is $c_{00}Y_{00}/r$, a point source of strength $-4\pi c_{00}Y_{00}$; integrating its gradient over S_R gives that strength, and every $l \geq 1$ term integrates to zero over the sphere by the orthogonality of the spherical harmonics (Theorem 9.119). So Lemma A.708 forces $c_{00} = 0$. The three $l = 1$ terms are linear combinations of x_i/r^3, which is the first expression in Equation (A.1152); the remainder is $l \geq 2$, i.e. $O(r^{-3})$. Differentiating,

$$\partial_i \frac{A_j x_j}{r^3} = \frac{A_i}{r^3} - \frac{3A_j x_j x_i}{r^5} = \frac{1}{r^3}\left(A_i - 3\,(\boldsymbol{A}\cdot\boldsymbol{n})\,n_i\right)\,,$$

and term-by-term differentiation of the remainder, licensed by Theorem A.709, gives $O(r^{-4})$. □

The physical reading of Lemma A.708 is worth one sentence, because it is the only place where the body enters at all: a rigid impermeable body neither creates nor destroys fluid, so it cannot look like a source from far away, and the slowest decay it can produce is that of a dipole. The sphere of Example 31.29 is the worked case, $\chi = Ua^3\cos\theta/2r^2$, with $\boldsymbol{A} = \frac{1}{2}Ua^3\hat{\boldsymbol{z}}$.

A.59.3 The momentum theorem on a large sphere

Lemma A.712 (The force is a far-field integral)**.** *For every R large enough that S_R encloses S,*

$$F_i = -\oint_{S_R} \left[p\, n_i + \rho v_i\,(\boldsymbol{v}\cdot\boldsymbol{n})\right] \mathrm{d}S\,, \tag{A.1153}$$

with $\boldsymbol{v} = \boldsymbol{\nabla}\phi$ and p the pressure. In particular the right-hand side is independent of R.

Rests on Theorems 7.101 and 31.22.

Proof. *Derives Lemma A.712.*

Let V be the fluid region between S and S_R and let $\boldsymbol{m}$ be the outward normal of V, equal to $\boldsymbol{n}$ on S_R and to $-\boldsymbol{N}$ on S. In steady flow of an ideal fluid with no body force, the Euler equation (Theorem 31.22) combined with $\boldsymbol{\nabla}\cdot\boldsymbol{v} = 0$ reads $\partial_j\left(\rho v_i v_j + p\,\delta_{ij}\right) = 0$, since $\rho v_j \partial_j v_i = \partial_j(\rho v_i v_j)$. Integrating this over V and applying the divergence theorem (Theorem 7.101) to each i,

$$0 = \oint_{\partial V} \left[p\, m_i + \rho v_i\,(\boldsymbol{v}\cdot\boldsymbol{m})\right] \mathrm{d}S = \oint_{S_R} \left[p\, n_i + \rho v_i\,(\boldsymbol{v}\cdot\boldsymbol{n})\right] \mathrm{d}S - \oint_{S} p\, N_i \,\mathrm{d}S\,,$$

where the momentum flux over S dropped because $\boldsymbol{v}\cdot\boldsymbol{N} = 0$ there. The last integral is $-F_i$ by Equation (A.1148), which is the assertion. □

The pressure is supplied by Bernoulli's theorem (Theorem 31.24) at constant height. With $q^2 = |\boldsymbol{v}|^2 = U^2 + 2Uu'_z + |\boldsymbol{u}'|^2$,

$$p = p_\infty + \tfrac{1}{2}\rho U^2 - \tfrac{1}{2}\rho q^2 = p_\infty - \rho U u'_z - \tfrac{1}{2}\rho\,|\boldsymbol{u}'|^2\,. \tag{A.1154}$$

By Corollary A.711 the last term is $O(R^{-6})$ on S_R; multiplied by the area element it contributes $O(R^{-4})$ to Equation (A.1153) and vanishes in the limit. The same estimate disposes of the quadratic part of the momentum flux:

$$\rho v_i\,(\boldsymbol{v}\cdot\boldsymbol{n}) = \rho U^2\delta_{i3}n_z + \rho U\delta_{i3}\,(\boldsymbol{u}'\cdot\boldsymbol{n}) + \rho U u'_i n_z + O\Big(R^{-6}\Big)\,. \tag{A.1155}$$

A.59.4 Every surviving term integrates to zero

Assemble Equations (A.1153) to (A.1155) and take the four contributions in turn.

The uniform terms. $\oint_{S_R} p_\infty n_i\,\mathrm{d}S = 0$ and $\rho U^2\delta_{i3}\oint_{S_R} n_z\,\mathrm{d}S = 0$, both because the integral of the unit normal over a closed surface vanishes. A constant pressure and a uniform stream, taken alone, push a closed surface nowhere.

The disturbance flux. $\rho U\delta_{i3}\oint_{S_R}\boldsymbol{u}'\cdot\boldsymbol{n}\,\mathrm{d}S = 0$ by Lemma A.708 — exactly, at every R, not merely in the limit.

The two surviving dipole terms. What is left is

$$F_i = \rho U \oint_{S_R} \left[u'_z n_i - u'_i n_z\right] \mathrm{d}S + O\Big(R^{-2}\Big)\,, \tag{A.1156}$$

the first term coming from the pressure through Equation (A.1154) and the second from the momentum flux, with the signs of Equation (A.1153) already applied. Insert Equation (A.1152) and write $\mathrm{d}S = R^2 \mathrm{d}\Omega$ with $\mathrm{d}\Omega$ the solid angle:

$$\begin{aligned}\oint_{S_R} \left[u'_z n_i - u'_i n_z\right] \mathrm{d}S &= \frac{1}{R} \oint \Big[\left(A_3 - 3\left(\boldsymbol{A}\cdot\boldsymbol{n}\right) n_3\right) n_i - \left(A_i - 3\left(\boldsymbol{A}\cdot\boldsymbol{n}\right) n_i\right) n_3\Big] \mathrm{d}\Omega \\ &= \frac{1}{R} \oint \left[A_3 n_i - A_i n_3\right] \mathrm{d}\Omega \\ &= \frac{1}{R}\left[A_3 \oint n_i \,\mathrm{d}\Omega - A_i \oint n_3 \,\mathrm{d}\Omega\right] = 0\,,\end{aligned} \tag{A.1157}$$

because the two terms in $\boldsymbol{A}\cdot\boldsymbol{n}$ cancel identically — they enter the two integrands as $-3(\boldsymbol{A}\cdot\boldsymbol{n})n_3 n_i$ and $+3(\boldsymbol{A}\cdot\boldsymbol{n})n_i n_3$, the same quantity with opposite signs — and because $\oint n_i \,\mathrm{d}\Omega = 0$ over the whole sphere.

That cancellation is the mechanism, and it deserves to be read rather than merely verified. The dipole disturbance contributes to the pressure integral and to the momentum-flux integral separately, and neither contribution is zero; what is zero is their difference, at every R and for every orientation of $\boldsymbol{A}$, hence for every shape of body.

Proof. *Derives Theorem A.707.*

By Lemma A.712 the quantity F_i defined by Equation (A.1153) does not depend on R. By Equations (A.1156) and (A.1157) it equals $O(R^{-2})$. A constant that is $O(R^{-2})$ for arbitrarily large R is zero, so $\boldsymbol{F} = \boldsymbol{0}$ — exactly, and for all three components at once. □

Remark A.713 (Where the sphere's fore-and-aft symmetry went). The chapter's proof for the sphere runs on the symmetry of Equation (31.28) about $\theta = \pi/2$, and a general body has no such symmetry: the pressure distribution over an aerofoil at incidence is grossly asymmetric, and every individual surface element carries a real force. What survives in general is weaker and sufficient — the *resultant* is fixed by the far field alone, and the far field of any impermeable body is a dipole, whose two contributions to Equation (A.1153) cancel. The near field, where all the physics of shape lives, never enters the calculation. This is also why the theorem is so unforgiving: nothing about the body is used except that it is closed and that the fluid does not pass through it.

Remark A.714. Appendix A.59 discharges the general case of Phenomenon 31.30 in Chapter 31, where the sphere is done inline and the arbitrary body is deferred here. Read it next to Remark 31.31, whose claim that there are exactly two escapes is now exact rather than rhetorical, because Theorem A.707 kills the resultant and not only its streamwise component. The first escape is multiple connectivity: in the plane, dropping single-valuedness of ϕ admits a circulation and produces the transverse force of Theorem 31.68 — which still leaves the drag zero, so the paradox survives its own resolution for lift, and the appendix computing the circulation itself is Appendix A.62. The second is that real flow is neither steady nor attached, which is Section 31.7.2, quantified by Theorem 31.71 and measured in Section 36.5.

A.60 The Coefficient 6π in Stokes' Drag Law

This appendix supplies the one thing Phenomenon 31.45 of Chapter 31 does not derive. The chapter's inline argument settles the *form* of Equation (31.39) completely: linearity of

Equation (31.38) makes the drag exactly proportional to U, and Theorem D.2 then leaves $\mu a U$ as the only force that can be built, so $F = C\mu a U$ with C a pure number. What is owed is C. It is obtained here by solving the creeping-flow problem for the sphere in closed form and integrating the surface traction, and the calculation returns rather more than a number: it says how the drag divides between pressure and friction, which is the physically informative part and the part the chapter has no room for.

A.60.1 The stream function and the equation it obeys

Work in the frame of the sphere, spherical coordinates (r, θ, φ) with the polar axis along the stream, and take the flow axisymmetric and without swirl, $v_\varphi = 0$. Boundary conditions: no slip on the sphere, and a uniform stream at infinity,

$$v_r = v_\theta = 0 \text{ at } r = a\,, \qquad \boldsymbol{v} \longrightarrow U\hat{\boldsymbol{z}} \text{ as } r \longrightarrow \infty\,. \tag{A.1158}$$

Definition A.715 (Stokes stream function)**.** The *Stokes stream function* $\psi(r, \theta)$, in m^3/s, is defined by

$$v_r = \frac{1}{r^2 \sin\theta}\frac{\partial \psi}{\partial \theta}\,, \qquad v_\theta = -\frac{1}{r \sin\theta}\frac{\partial \psi}{\partial r}\,. \tag{A.1159}$$

Rests on Example 31.15 and Equation (7.92).

Incompressibility is then an identity rather than a constraint: in spherical coordinates $\boldsymbol{\nabla}\cdot\boldsymbol{v} = r^{-2}\partial_r(r^2 v_r) + (r\sin\theta)^{-1}\partial_\theta(\sin\theta\, v_\theta)$, and substituting Equation (A.1159) gives $(r^2\sin\theta)^{-1}(\partial_r\partial_\theta\psi - \partial_\theta\partial_r\psi) = 0$. This is the axisymmetric counterpart of the plane construction of Example 31.15, and it is why the whole problem collapses to one scalar equation.

Lemma A.716 (The creeping-flow equation for ψ)**.** *Under Definition A.715 the Stokes equations Equation (31.38) are equivalent to*

$$E^4\psi = 0\,, \qquad E^2 := \partial_r^2 + \frac{\sin\theta}{r^2}\,\partial_\theta\left(\frac{1}{\sin\theta}\,\partial_\theta\right)\,, \tag{A.1160}$$

together with a pressure recovered by quadrature.

Rests on Definitions 31.43 and A.715.

Proof. *Derives Lemma A.716.*

Take the curl of $\mathbf{0} = -\boldsymbol{\nabla}p + \mu\nabla^2\boldsymbol{v}$. The pressure disappears because the curl of a gradient vanishes (Equation (7.128)), leaving $\nabla^2\boldsymbol{\omega} = \mathbf{0}$ with $\boldsymbol{\omega} = \boldsymbol{\nabla}\times\boldsymbol{v}$. In an axisymmetric flow without swirl the vorticity has only an azimuthal component, and substituting Equation (A.1159) into $\omega_\varphi = r^{-1}[\partial_r(r v_\theta) - \partial_\theta v_r]$ gives

$$\omega_\varphi = -\frac{1}{r\sin\theta}\,E^2\psi\,. \tag{A.1161}$$

The vector Laplacian acting on a purely azimuthal field of this form reduces, term by term in the spherical expression of Equation (7.94), to $(\nabla^2\boldsymbol{\omega})_\varphi = -(r\sin\theta)^{-1}E^2(E^2\psi)$, which is Equation (A.1160). Conversely, given ψ with $E^4\psi = 0$, the momentum equation reads $\boldsymbol{\nabla}p = \mu\nabla^2\boldsymbol{v} = -\mu\boldsymbol{\nabla}\times\boldsymbol{\omega}$ by Equation (31.6) and $\boldsymbol{\nabla}\cdot\boldsymbol{v} = 0$, and its right-hand side is then curl-free, so p exists and is obtained by integrating along any path. □

A.60.2 Solution for the sphere

The condition at infinity fixes the angular dependence once and for all. A uniform stream has $\psi \longrightarrow \tfrac{1}{2}Ur^2\sin^2\theta$ — read Equation (A.1159) backwards — and both the equation and the boundary conditions are then satisfied by the single separated form

$$\psi(r, \theta) = f(r)\sin^2\theta\,. \tag{A.1162}$$

Acting with E^2 on Equation (A.1162),

$$E^2\psi = \left[f'' - \frac{2f}{r^2}\right]\sin^2\theta\,,$$

since $\partial_\theta\left(\sin^{-1}\theta\,\partial_\theta\sin^2\theta\right) = \partial_\theta\left(2\cos\theta\right) = -2\sin\theta$. Applying E^2 a second time to $g := f'' - 2f/r^2$ in the same way and collecting,

$$f'''' - \frac{4f''}{r^2} + \frac{8f'}{r^3} - \frac{8f}{r^4} = 0\,. \tag{A.1163}$$

Lemma A.717 (The radial solution)**.** *The general solution of Equation* (A.1163) *is* $f = A/r + Br + Cr^2 + Dr^4$*, and the conditions Equation* (A.1158) *select*

$$D = 0\,, \qquad C = \tfrac{1}{2}U\,, \qquad A = \tfrac{1}{4}Ua^3\,, \qquad B = -\tfrac{3}{4}Ua\,. \tag{A.1164}$$

Rests on Lemma A.716 and Equation (A.1158)*.*

Proof. *Derives Lemma A.717.*

Equation (A.1163) is equidimensional: every term scales as r^{n-4} under $f = r^n$, so the substitution turns it into the algebraic equation

$$n(n-1)(n-2)(n-3) - 4n(n-1) + 8n - 8 = 0\,,$$

whose left-hand side factorizes as $(n+1)\,(n-1)\,(n-2)\,(n-4)$; one checks the four roots directly, $n = -1$ giving $24 - 8 - 16 = 0$, $n = 1$ giving $0 - 0 + 8 - 8 = 0$, $n = 2$ giving $0 - 8 + 16 - 8 = 0$ and $n = 4$ giving $24 - 48 + 32 - 8 = 0$. The four powers are independent, so they span the solution space.

The condition at infinity requires $f \longrightarrow \frac{1}{2}Ur^2$, which forbids r^4 and fixes $C = U/2$. No slip requires both components of Equation (A.1159) to vanish at $r = a$, that is $f(a) = 0$ and $f'(a) = 0$:

$$\frac{A}{a} + Ba + \frac{Ua^2}{2} = 0\,, \qquad -\frac{A}{a^2} + B + Ua = 0\,.$$

Multiplying the second by a and subtracting it from the first eliminates B and leaves $2A/a - Ua^2/2 = 0$, whence $A = Ua^3/4$; back-substitution gives $B = A/a^2 - Ua = -3Ua/4$. □

Reading the velocity field off Equations (A.1159) and (A.1164),

$$v_r = U\cos\theta\left(1 - \frac{3a}{2r} + \frac{a^3}{2r^3}\right), \qquad v_\theta = -U\sin\theta\left(1 - \frac{3a}{4r} - \frac{a^3}{4r^3}\right). \tag{A.1165}$$

Both vanish at $r = a$ and both tend to the free stream, as they must.

A.60.3 The pressure, and a check

From Equation (A.1164), $f'' - 2f/r^2 = 3Ua/2r$, so by Equation (A.1161)

$$\omega_\varphi = -\frac{3aU\sin\theta}{2r^2}\,. \tag{A.1166}$$

The radial component of $\boldsymbol{\nabla}p = -\mu\boldsymbol{\nabla}\times\boldsymbol{\omega}$ is then

$$\frac{\partial p}{\partial r} = -\frac{\mu}{r\sin\theta}\,\partial_\theta\left(\sin\theta\,\omega_\varphi\right) = \frac{3\mu aU}{r\sin\theta}\,\partial_\theta\left(\frac{\sin^2\theta}{2r^2}\right) = \frac{3\mu aU\cos\theta}{r^3}\,,$$

and integrating from infinity,

$$p = p_\infty - \frac{3\mu aU\cos\theta}{2r^2}\,. \tag{A.1167}$$

It is worth confirming that this is harmonic, since $\nabla^2 p = 0$ follows from taking the divergence of Equation (31.38): the function $\cos\theta/r^2$ is the $l = 1$ exterior solid harmonic of Example 10.33, and it is. The pressure is high in front ($\theta = \pi$, taking the stream along $+\hat{\boldsymbol{z}}$ so that $\theta = \pi$ faces upstream) and low behind, by equal amounts — the fore-and-aft antisymmetry that would give zero drag in an ideal fluid (Phenomenon 31.30). Here it does not, because the pressure is no longer the whole traction.

A.60.4 The traction and its integral

For a Newtonian fluid Equation (31.30) gives, in spherical coordinates,

$$\sigma_{rr} = -p + 2\mu\,\frac{\partial v_r}{\partial r}\,, \qquad \sigma_{r\theta} = \mu\left[r\,\partial_r\!\left(\frac{v_\theta}{r}\right) + \frac{1}{r}\,\frac{\partial v_r}{\partial\theta}\right]. \tag{A.1168}$$

Evaluate both at $r = a$ from Equations (A.1165) and (A.1167). For the normal component, $\partial_r v_r = U\cos\theta\,(3a/2r^2 - 3a^3/2r^4)$, which vanishes at $r = a$; the entire normal traction is therefore the pressure,

$$\sigma_{rr}|_{r=a} = -p_\infty + \frac{3\mu U\cos\theta}{2a}\,. \tag{A.1169}$$

For the tangential component, v_r vanishes identically on $r = a$ so its θ derivative does too, and $v_\theta/r = -U\sin\theta\,(1/r - 3a/4r^2 - a^3/4r^4)$ gives $\partial_r\,(v_\theta/r) = -U\sin\theta\,(-1/r^2 + 3a/2r^3 + a^3/r^5)$, equal to $-3U\sin\theta/2a^2$ at $r = a$; hence

$$\sigma_{r\theta}|_{r=a} = -\frac{3\mu U\sin\theta}{2a}\,. \tag{A.1170}$$

Both are in Pa, as $\mu U/a$ has the dimensions $\mathsf{ML^{-1}T^{-2}}$.

Theorem A.718 (Stokes' drag law with its coefficient)**.** *The force exerted on the sphere by the fluid is directed along the stream and has magnitude*

$$F = 6\pi\mu a U\,, \tag{A.1171}$$

of which $2\pi\mu aU$ — one third — comes from the pressure and $4\pi\mu aU$ — two thirds — from the tangential viscous traction.

Rests on Lemma A.717 and Theorem 31.36.

Proof. *Derives Theorem A.718.*

The component along the stream of the traction on the surface element $\mathrm{d}S$ is $(\sigma_{rr}\cos\theta - \sigma_{r\theta}\sin\theta)\,\mathrm{d}S$, the projections of the radial and meridional directions on $\hat{\boldsymbol{z}}$. Substituting Equations (A.1169) and (A.1170),

$$\sigma_{rr}\cos\theta - \sigma_{r\theta}\sin\theta = -p_\infty\cos\theta + \frac{3\mu U}{2a}\left(\cos^2\theta + \sin^2\theta\right) = -p_\infty\cos\theta + \frac{3\mu U}{2a}\,.$$

The uniform pressure integrates to zero over the closed surface, and what remains is a constant traction $3\mu U/2a$ over the whole sphere:

$$F = \frac{3\mu U}{2a}\oint \mathrm{d}S = \frac{3\mu U}{2a}\cdot 4\pi a^2 = 6\pi\mu a U\,.$$

For the split, keep the two sources separate. The pressure contributes

$$F^{(p)} = \oint (-p)\cos\theta\,\mathrm{d}S = \frac{3\mu U}{2a}\,2\pi a^2\int_0^\pi \cos^2\theta\sin\theta\,\mathrm{d}\theta = \frac{3\mu U}{2a}\,2\pi a^2\cdot\frac{2}{3} = 2\pi\mu a U\,,$$

and the tangential traction contributes

$$F^{(\tau)} = \oint (-\sigma_{r\theta})\sin\theta\,\mathrm{d}S = \frac{3\mu U}{2a}\,2\pi a^2\int_0^\pi \sin^3\theta\,\mathrm{d}\theta = \frac{3\mu U}{2a}\,2\pi a^2\cdot\frac{4}{3} = 4\pi\mu a U\,,$$

using $\int_0^\pi \cos^2\theta\sin\theta\,\mathrm{d}\theta = 2/3$ and $\int_0^\pi \sin^3\theta\,\mathrm{d}\theta = 4/3$. Their sum is Equation (A.1171), which is Equation (31.39) with $C = 6\pi$ [135]. □

Remark A.719 (Why the split is worth printing). The one-third–two-thirds division is a fact about creeping flow that survives no other regime and is easy to get backwards. At high Reynolds number the drag of a bluff body is almost entirely pressure drag, because the wake destroys the rear pressure recovery (Phenomenon 31.55); at low Reynolds number the pressure distribution Equation (A.1167) is exactly the fore-and-aft antisymmetric one, and it contributes only because it is multiplied by $\cos\theta$ and integrated — it is not the residue of a broken symmetry but the symmetric distribution itself doing work against the motion. The larger part of the resistance is skin friction, which is the sense in which Stokes flow is the opposite of the ideal flow of Section 31.3.3: there the friction was absent and the pressure did nothing, here the friction dominates and the pressure does a third.

Remark A.720 (The slow decay, and what it costs). Equation (A.1165) decays only as a/r: the term $-3aU\cos\theta/2r$ in v_r is the leading disturbance, in contrast with the a^3/r^3 dipole of the ideal-flow solution Equation (31.27). A sphere in creeping flow drags a very large volume of fluid with it, which is why suspensions interact hydrodynamically at many diameters' separation, and why the drag is proportional to a rather than to a^2: the resisted region has the size of the disturbance, not the size of the body. The same slow decay is the origin of the non-uniformity discussed at Remark 31.47 — the neglected inertial term falls off as r^{-3} while the retained viscous term falls off as r^{-4}, so beyond a distance of order a/Re the approximation inverts itself. Whitehead's paradox is the failure of the naive second approximation to satisfy the condition at infinity, and Oseen's repair, Equation (31.41), keeps the advection by the uniform stream in the outer region from the start.

Remark A.721. Appendix A.60 discharges the numerical coefficient of Phenomenon 31.45 in Chapter 31, where Equation (31.39) is derived up to the pure number C from linearity and Theorem D.2 and the calculation of C is deferred here. With $C = 6\pi$ in hand, Example 31.46 converts an observed fall speed into a radius, which is how the oil droplets of [407] were sized, and Remark 31.47 states the first correction. Nothing in this section is valid outside $\mathrm{Re} \ll 1$ (Definition 31.43), and the honest statement of its range is Equation (31.41): the leading correction to Equation (A.1171) is a relative $\frac{3}{16}\mathrm{Re}$, so the law is good to one percent only up to $\mathrm{Re} \approx 0.05$.

A.61 The Kármán Spacing Ratio of the Vortex Street

This appendix proves Equation (31.54) of Phenomenon 31.61 in Chapter 31: among all staggered double rows of point vortices, exactly one ratio of row separation to streamwise spacing is not destroyed by its own induced motion, namely

$$\frac{h}{a} = \frac{1}{\pi}\cosh^{-1}\sqrt{2} = \frac{1}{\pi}\log\left(1+\sqrt{2}\right) = 0.280\,55\ldots, \tag{A.1172}$$

[375]. What the calculation settles and what it does not is stated in the chapter at Remark 31.62, and the reader should have that remark in view throughout: nothing here bears on the Strouhal number Equation (31.53), and the stability obtained is neutral, not asymptotic. The closing Remark A.731 returns to the point with the calculation in hand.

Throughout, the fluid is ideal, unbounded and two-dimensional; the vortices are point vortices in the sense of Section 31.7.1, each of circulation $\pm\Gamma$ in m^2/s, moving with the local velocity induced by all the others. The complex variable is $z = x + \mathrm{i}y$, the complex potential w is that of Equation (31.57), and a vortex of circulation Γ counterclockwise at z_0 has $w = -(\mathrm{i}\Gamma/2\pi)\log(z - z_0)$, so that

$$\frac{\mathrm{d}w}{\mathrm{d}z} = v_x - \mathrm{i}v_y = -\frac{\mathrm{i}\Gamma}{2\pi\,(z - z_0)}, \qquad \frac{\mathrm{d}\bar{z}_k}{\mathrm{d}t} = \sum_{j\neq k}\frac{-\mathrm{i}\Gamma_j}{2\pi\,(z_k - z_j)}, \tag{A.1173}$$

the second equation being the statement that each vortex is carried by the flow of the others.

A.61.1 One summation formula does all the work

Every lattice sum below is a special case of a single identity, which is proved from the Fourier series of an elementary function and needs nothing else.

Lemma A.722 (The basic lattice sum)**.** *Let $\zeta \in \mathbb{C} \setminus \mathbb{Z}$ and $0 < \varphi < 2\pi$. Then*

$$\sum_{n\in\mathbb{Z}} \frac{\mathrm{e}^{\mathrm{i}n\varphi}}{n+\zeta} = \frac{\pi}{\sin \pi\zeta}\, \mathrm{e}^{\mathrm{i}(\pi-\varphi)\zeta}\,, \tag{A.1174}$$

and consequently, differentiating with respect to ζ,

$$\Sigma\,(\varphi,\zeta) := \sum_{n\in\mathbb{Z}} \frac{\mathrm{e}^{\mathrm{i}n\varphi}}{(n+\zeta)^2} = \pi\, \mathrm{e}^{\mathrm{i}(\pi-\varphi)\zeta} \left[\frac{\pi\cos\pi\zeta}{\sin^2\pi\zeta} - \frac{\mathrm{i}\,(\pi-\varphi)}{\sin\pi\zeta}\right], \tag{A.1175}$$

whose limit as $\varphi \to 0^+$ is $\Sigma\,(0,\zeta) = \pi^2/\sin^2\pi\zeta$.

Rests on Theorem 8.6 and Equation (8.3).

Proof. *Derives Lemma A.722.*

Let $F(\varphi) := (\pi/\sin\pi\zeta)\,\mathrm{e}^{\mathrm{i}(\pi-\varphi)\zeta}$ on $(0,2\pi)$ and compute its Fourier coefficients:

$$c_n = \frac{1}{2\pi}\int_0^{2\pi} F(\varphi)\,\mathrm{e}^{-\mathrm{i}n\varphi}\,\mathrm{d}\varphi = \frac{1}{2}\,\frac{\mathrm{e}^{\mathrm{i}\pi\zeta}}{\sin\pi\zeta}\cdot\frac{1-\mathrm{e}^{-2\pi\mathrm{i}(\zeta+n)}}{\mathrm{i}\,(\zeta+n)}\,,$$

the elementary integral of $\mathrm{e}^{-\mathrm{i}(\zeta+n)\varphi}$. Since n is an integer, $\mathrm{e}^{-2\pi\mathrm{i}(\zeta+n)} = \mathrm{e}^{-2\pi\mathrm{i}\zeta}$, and $1 - \mathrm{e}^{-2\pi\mathrm{i}\zeta} = \mathrm{e}^{-\mathrm{i}\pi\zeta}\left(\mathrm{e}^{\mathrm{i}\pi\zeta} - \mathrm{e}^{-\mathrm{i}\pi\zeta}\right) = 2\mathrm{i}\,\mathrm{e}^{-\mathrm{i}\pi\zeta}\sin\pi\zeta$ by Equation (8.3). The two exponentials and the two sines cancel, leaving $c_n = 1/(n+\zeta)$, which is Equation (A.1174).

The series Equation (A.1175) converges absolutely and uniformly in ζ on compact subsets of $\mathbb{C}\setminus\mathbb{Z}$, so it may be obtained from Equation (A.1174) by differentiating term by term, using $\mathrm{d}\,(n+\zeta)^{-1}/\mathrm{d}\zeta = -\,(n+\zeta)^{-2}$ and the product rule on the right-hand side. For the limit, set $\varphi = 0$ in Equation (A.1175): the bracket becomes $\pi\,(\cos\pi\zeta - \mathrm{i}\sin\pi\zeta)\,/\sin^2\pi\zeta = \pi\,\mathrm{e}^{-\mathrm{i}\pi\zeta}/\sin^2\pi\zeta$, which cancels the prefactor $\mathrm{e}^{\mathrm{i}\pi\zeta}$ exactly. □

Corollary A.723 (Potential of one infinite row)**.** *The complex potential of vortices of circulation Γ placed at $z = na$ for every $n \in \mathbb{Z}$ is*

$$w(z) = -\frac{\mathrm{i}\Gamma}{2\pi}\,\log\sin\frac{\pi z}{a}\,, \qquad \frac{\mathrm{d}w}{\mathrm{d}z} = -\frac{\mathrm{i}\Gamma}{2a}\cot\frac{\pi z}{a}\,, \tag{A.1176}$$

and it is the only such potential whose velocity is bounded as $|\operatorname{Im} z| \to \infty$. The induced velocity tends to $\mp\Gamma/2a$ in the x direction as $\operatorname{Im} z \to \pm\infty$.

Rests on Equation (A.1173) and Theorem 8.18.

Proof. *Derives Corollary A.723.*

The function $\cot\,(\pi z/a)$ is meromorphic with simple poles exactly at $z = na$, where $\sin\,(\pi z/a)$ has its simple zeros, and near $z = na$ its principal part is $a/\pi\,(z-na)$. Hence $\mathrm{d}w/\mathrm{d}z$ in Equation (A.1176) behaves near $z = na$ as $-\,(\mathrm{i}\Gamma/2a)\cdot a/\pi\,(z-na) = -\mathrm{i}\Gamma/2\pi\,(z-na)$, which by Equation (A.1173) is precisely a vortex of circulation Γ there, and it is holomorphic elsewhere. As $\operatorname{Im} z \to \pm\infty$, $\cot\,(\pi z/a) \to \mp\mathrm{i}$, so $\mathrm{d}w/\mathrm{d}z \to \mp\Gamma/2a$; since $\mathrm{d}w/\mathrm{d}z = v_x - \mathrm{i}v_y$, the row drives the fluid backwards above it and forwards below it, at the stated speed. Any other candidate differs from Equation (A.1176) by a function that is entire (the singularities coincide) and bounded (both velocities are), hence constant by Liouville's theorem (Theorem 8.18). □

A.61.2 The street and its rigid translation

Definition A.724 (The staggered street)**.** Fix $a > 0$ and $h > 0$, both in m. The *staggered vortex street* consists of the rows

$$A_n = na \quad \text{with circulation } +\Gamma\,, \qquad B_n = \left(n + \tfrac{1}{2}\right) a - \mathrm{i}h \quad \text{with circulation } -\Gamma\,, \tag{A.1177}$$

for all $n \in \mathbb{Z}$. Write $s := \pi h/a$, $c := \cosh s$ and $t := \tanh s$ throughout.
Rests on Corollary A.723.

Proposition A.725 (The street translates rigidly)**.** *The configuration Equation (A.1177) is an exact solution of Equation (A.1173): every vortex moves with the same velocity*

$$U_{\mathrm{s}} = \frac{\Gamma}{2a} \tanh \frac{\pi h}{a} = \frac{\Gamma t}{2a}\,, \tag{A.1178}$$

parallel to the rows, so the street is carried downstream without change of shape.
Rests on Definition A.724 and Corollary A.723.

Proof. *Derives Proposition A.725.*

Take the vortex $A_0 = 0$. Its own row induces nothing there: the contributions of A_n and A_{-n} in Equation (A.1173) are equal and opposite. Row B, of circulation $-\Gamma$ and origin $a/2 - \mathrm{i}h$, contributes by Equation (A.1176)

$$\frac{\mathrm{d}\bar{z}}{\mathrm{d}t} = +\frac{\mathrm{i}\Gamma}{2a} \cot \frac{\pi\,(0 - a/2 + \mathrm{i}h)}{a} = \frac{\mathrm{i}\Gamma}{2a} \cot\left(-\frac{\pi}{2} + \mathrm{i}s\right) = -\frac{\mathrm{i}\Gamma}{2a} \tan(\mathrm{i}s) = \frac{\Gamma}{2a} \tanh s\,,$$

using $\cot(\theta - \pi/2) = -\tan\theta$ and $\tan(\mathrm{i}s) = \mathrm{i}\tanh s$. The result is real and positive, so $v_x = \Gamma t/2a$ and $v_y = 0$. Repeating at $B_0 = a/2 - \mathrm{i}h$ under row A gives $-(\mathrm{i}\Gamma/2a)\cot(\pi/2 - \mathrm{i}s) = -(\mathrm{i}\Gamma/2a)\tan(\mathrm{i}s) = \Gamma t/2a$, the same velocity; and again the vortex's own row contributes nothing. Every vortex therefore moves with Equation (A.1178). □

Equation (A.1178) is worth reading before the stability calculation, because it is directly visible in the photographs: the street moves *more slowly* than the stream that made it, since U_{s} is the velocity relative to the fluid at infinity and it is directed against the free stream in the frame of the cylinder. In the frame translating with the street the base state is an equilibrium, and since the base velocity is a constant it drops out of the linearized equations altogether; the analysis below may be read in either frame.

A.61.3 Linearization

Displace every vortex,

$$z_n^A = na + \alpha_n(t)\,, \qquad z_n^B = \left(n + \tfrac{1}{2}\right) a - \mathrm{i}h + \beta_n(t)\,, \tag{A.1179}$$

with $|\alpha_n|, |\beta_n| \ll a$. Expanding Equation (A.1173) to first order with $(D + \delta)^{-1} = D^{-1} - \delta D^{-2} + O(\delta^2)$, and using Proposition A.725 to cancel the zeroth-order terms against the rigid motion, gives for each k

$$\frac{\mathrm{d}\bar{\alpha}_k}{\mathrm{d}t} = \frac{\mathrm{i}\Gamma}{2\pi} \left[\sum_{n \neq k} \frac{\alpha_k - \alpha_n}{(A_k - A_n)^2} - \sum_n \frac{\alpha_k - \beta_n}{(A_k - B_n)^2} \right], \tag{A.1180}$$

$$\frac{\mathrm{d}\bar{\beta}_k}{\mathrm{d}t} = \frac{\mathrm{i}\Gamma}{2\pi} \left[-\sum_{n \neq k} \frac{\beta_k - \beta_n}{(B_k - B_n)^2} + \sum_n \frac{\beta_k - \alpha_n}{(B_k - A_n)^2} \right], \tag{A.1181}$$

the signs following from the circulations $\pm\Gamma$ carried by the inducing vortices.

Remark A.726 (Why one Fourier mode is not enough). Equations (A.1180) and (A.1181) are linear over $\mathbb{R}$ but *not* over $\mathbb{C}$: the left-hand sides carry the complex conjugates of the unknowns while the right-hand sides carry the unknowns themselves. The single-mode ansatz $\alpha_n = \alpha\,\mathrm{e}^{\mathrm{i}n\varphi}$ is therefore inconsistent, since $\bar{\alpha}_n = \bar{\alpha}\,\mathrm{e}^{-\mathrm{i}n\varphi}$ belongs to the mode $-\varphi$: matching the k dependence of the two sides would force $\varphi \equiv 0$. The wavenumbers φ and $-\varphi$ close on each other and on nothing else, so the smallest closed system is four-dimensional. Overlooking this is the one way the calculation can be got wrong while looking right, and it changes the answer: the two-dimensional system obtained by ignoring it makes the street unstable at every spacing, Equation (A.1172) included.

Accordingly set, for a fixed $\varphi \in (0, 2\pi)$,

$$\alpha_n = \alpha\,\mathrm{e}^{\mathrm{i}n\varphi} + \gamma\,\mathrm{e}^{-\mathrm{i}n\varphi}\,, \qquad \beta_n = \beta\,\mathrm{e}^{\mathrm{i}n\varphi} + \delta\,\mathrm{e}^{-\mathrm{i}n\varphi}\,. \tag{A.1182}$$

Three lattice sums appear. With $m = n - k$ and $\zeta = \frac{1}{2} - \mathrm{i}h/a$, so that $\pi\zeta = \pi/2 - \mathrm{i}s$ and therefore $\sin\pi\zeta = \cosh s = c$ and $\cos\pi\zeta = \mathrm{i}\sinh s$:

$$P(\varphi) := \sum_{m\neq 0} \frac{1 - \mathrm{e}^{\mathrm{i}m\varphi}}{m^2} = \frac{\varphi\,(2\pi - \varphi)}{2} = \frac{\pi^2 - \psi^2}{2}\,, \qquad \psi := \pi - \varphi\,, \tag{A.1183}$$

$$S_0 := \sum_n \frac{1}{\left(\left(n + \frac{1}{2}\right)a - \mathrm{i}h\right)^2} = \frac{1}{a^2}\,\Sigma\,(0,\zeta) = \frac{\pi^2}{a^2 c^2}\,, \tag{A.1184}$$

$$S_1 := \sum_n \frac{\mathrm{e}^{\mathrm{i}n\varphi}}{\left(\left(n + \frac{1}{2}\right)a - \mathrm{i}h\right)^2} = \frac{\mathrm{i}\pi}{a^2}\,\mathrm{e}^{\mathrm{i}\psi/2}\,E\,M\,, \tag{A.1185}$$

where the closed forms come from Lemma A.722 and

$$E := \mathrm{e}^{\psi s/\pi}\,, \qquad M := \frac{\pi t - \psi}{c}\,, \qquad M' := \frac{\pi t + \psi}{c}\,. \tag{A.1186}$$

For Equation (A.1183) use $\sum_{m\geq 1} \cos m\varphi/m^2 = \pi^2/6 - \pi\varphi/2 + \varphi^2/4$ on $[0, 2\pi]$; for Equation (A.1185) substitute $\sin\pi\zeta = c$, $\cos\pi\zeta = \mathrm{i}\sinh s$ and $\mathrm{e}^{\mathrm{i}\psi\zeta} = \mathrm{e}^{\mathrm{i}\psi/2}\mathrm{e}^{\psi s/\pi}$ in Equation (A.1175). The companion sum with φ replaced by $-\varphi$, i.e. ψ by $-\psi$, is

$$\tilde{S}_1 := \sum_n \frac{\mathrm{e}^{-\mathrm{i}n\varphi}}{\left(\left(n + \frac{1}{2}\right)a - \mathrm{i}h\right)^2} = \frac{\mathrm{i}\pi}{a^2}\,\mathrm{e}^{-\mathrm{i}\psi/2}\,\frac{M'}{E}\,. \tag{A.1187}$$

Two further sums reduce to these: replacing n by $-n$ shows that $\sum_n \left(\left(n - \frac{1}{2}\right)a + \mathrm{i}h\right)^{-2} = S_0$ and $\sum_n \mathrm{e}^{\mathrm{i}n\varphi}\left(\left(n - \frac{1}{2}\right)a + \mathrm{i}h\right)^{-2} = \tilde{S}_1$.

Substituting Equation (A.1182) into Equations (A.1180) and (A.1181) and matching the coefficients of $\mathrm{e}^{\mathrm{i}k\varphi}$ and $\mathrm{e}^{-\mathrm{i}k\varphi}$ separately — noting $P(-\varphi) = P(\varphi)$ and $S_1(-\varphi) = \tilde{S}_1(\varphi)$ — yields, with $K := \Gamma/2\pi$ and

$$Q := \frac{P}{a^2} - S_0 = \frac{1}{a^2}\left[\frac{\pi^2 - \psi^2}{2} - \frac{\pi^2}{c^2}\right], \tag{A.1188}$$

the closed four-dimensional system

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix} p \\ q \end{pmatrix} = \mathsf{B}\begin{pmatrix} r \\ u \end{pmatrix}, \qquad \frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix} r \\ u \end{pmatrix} = \mathsf{C}\begin{pmatrix} p \\ q \end{pmatrix}, \tag{A.1189}$$

in the variables $p := \alpha$, $q := \beta$, $r := \bar{\gamma}$, $u := \bar{\delta}$, with

$$\mathsf{B} = \mathrm{i}K\begin{pmatrix} -Q & -\overline{\tilde{S}_1} \\ \overline{S_1} & Q \end{pmatrix}, \qquad \mathsf{C} = \mathrm{i}K\begin{pmatrix} Q & S_1 \\ -\tilde{S}_1 & -Q \end{pmatrix}. \tag{A.1190}$$

A.61.4 The growth rates

Solutions of Equation (A.1189) proportional to $\mathrm{e}^{\sigma t}$ have σ^2 an eigenvalue of BC. Three real quantities suffice to write it down:

$$X := |S_1|^2 = \frac{\pi^2}{a^4} E^2 M^2 \,, \qquad Y := \left|\tilde{S}_1\right|^2 = \frac{\pi^2}{a^4} \frac{M'^2}{E^2} \,, \qquad \Pi := S_1 \tilde{S}_1 = -\frac{\pi^2}{a^4} M M' \,, \tag{A.1191}$$

the last being real because the two phases in Equations (A.1185) and (A.1187) cancel and $(\mathrm{i}\pi)^2 = -\pi^2$; note $XY = \Pi^2$.

Lemma A.727 (Characteristic equation)**.** *The eigenvalues $\lambda = \sigma^2$ of BC satisfy*

$$\lambda^2 - K^2 \left(2Q^2 - X - Y\right) \lambda + K^4 \left(Q^2 - \Pi\right)^2 = 0 \,. \tag{A.1192}$$

Rests on Equations (A.1190) and (A.1191).

Proof. *Derives Lemma A.727.*

Multiplying the matrices of Equation (A.1190),

$$\mathsf{BC} = -K^2 \begin{pmatrix} -Q^2 + \overline{\tilde{S}_1} \tilde{S}_1 & Q\left(\overline{\tilde{S}_1} - S_1\right) \\ Q\left(\overline{S_1} - \tilde{S}_1\right) & \overline{S_1} S_1 - Q^2 \end{pmatrix} ,$$

whose trace is $-K^2\left(-2Q^2 + Y + X\right)$, i.e. the coefficient displayed. Its determinant is the product of the two determinants. Now $\overline{S_1} = \mathrm{e}^{\mathrm{i}\varphi} S_1$ — replace n by $-n-1$ in the series defining $\overline{S_1}$ and compare — and likewise $\overline{\tilde{S}_1} = \mathrm{e}^{-\mathrm{i}\varphi} \tilde{S}_1$, so the determinant of B is $-K^2\left(-Q^2 + \overline{\tilde{S}_1}\,\overline{S_1}\right) = K^2\left(Q^2 - \Pi\right)$, and that of C is the same. The characteristic polynomial of a 2×2 matrix is $\lambda^2 - (\text{trace})\,\lambda + (\text{determinant})$, which is Equation (A.1192). □

Proposition A.728 (Criterion for neutrality)**.** *The mode φ neither grows nor decays — all four roots σ are purely imaginary — if and only if*

$$2\,|Q| \le \frac{\pi}{a^2} \left|EM - \frac{M'}{E}\right| = \frac{2\pi}{a^2 c} \left|\pi t \sinh u - \psi \cosh u\right| \,, \qquad u := \frac{\psi s}{\pi} \,, \tag{A.1193}$$

and it grows otherwise.

Rests on Lemma A.727.

Proof. *Derives Proposition A.728.*

Since $\sigma^2 = \lambda$, the four exponents are purely imaginary exactly when both roots of Equation (A.1192) are real and non-positive; if either root is complex, or real and positive, some σ has positive real part. Write $\mathcal{T} = 2Q^2 - X - Y$ and $\mathcal{D} = \left(Q^2 - \Pi\right)^2 \ge 0$ for the two coefficients divided by K^2 and K^4. The discriminant factorizes,

$$\mathcal{T}^2 - 4\mathcal{D} = \left[2\Pi - X - Y\right] \left[4Q^2 - X - Y - 2\Pi\right] \,,$$

because $\mathcal{T} \pm 2\left(Q^2 - \Pi\right)$ are the two brackets. Put $\pi_+ := \sqrt{X}$, $\pi_- := \sqrt{Y}$, so $\Pi = \pm \pi_+ \pi_-$ by $XY = \Pi^2$, the sign being that of $-MM'$. If $MM' > 0$ then $\Pi = -\pi_+\pi_-$ and the factorization reads $-\left(\pi_+ + \pi_-\right)^2 \left[4Q^2 - \left(\pi_+ - \pi_-\right)^2\right]$, non-negative exactly when $2\,|Q| \le |\pi_+ - \pi_-|$; if $MM' < 0$ then $\Pi = +\pi_+\pi_-$ and it reads $-\left(\pi_+ - \pi_-\right)^2 \left[4Q^2 - \left(\pi_+ + \pi_-\right)^2\right]$, non-negative exactly when $2\,|Q| \le \pi_+ + \pi_-$. Both cases are covered by $2\,|Q| \le |EM - M'/E|\,\pi/a^2$, since EM and M'/E have the same sign as M and M' respectively; and the closed form on the right of Equation (A.1193) follows from Equation (A.1186),

$$EM - \frac{M'}{E} = \frac{1}{c}\left[(\pi t - \psi)\,\mathrm{e}^{u} - (\pi t + \psi)\,\mathrm{e}^{-u}\right] = \frac{2}{c}\left[\pi t \sinh u - \psi \cosh u\right] \,.$$

Finally the second requirement, $\mathcal{T} \le 0$, is implied by the first: in either case $4Q^2 \le \left(\pi_+ \pm \pi_-\right)^2 \le 2\left(X + Y\right)$, so $2Q^2 \le X + Y$. □

A.61.5 Only one spacing survives

Theorem A.729 (Kármán's spacing ratio)**.** *The staggered street of Definition A.724 is neutrally stable to every infinitesimal disturbance Equation (A.1182) if and only if*

$$\cosh\frac{\pi h}{a}=\sqrt{2}\,,\qquad \textit{that is}\qquad \frac{h}{a}=\frac{1}{\pi}\log\left(1+\sqrt{2}\right)=0.280\,55\,, \tag{A.1194}$$

which is Equation (31.54). For every other ratio some mode grows exponentially.
Rests on Proposition A.728 and Definition A.724.

Proof. *Derives Theorem A.729.*

Necessity. Take $\varphi=\pi$, that is $\psi=0$: neighbouring vortices of a row are then displaced in opposite senses, the disturbance of longest wavelength that is not a rigid translation. Then $u=0$, $E=1$ and $M=M'=\pi t/c$, so the right-hand side of Equation (A.1193) vanishes identically and the criterion demands $Q=0$. By Equation (A.1188) with $\psi=0$ this is $\pi^2/2=\pi^2/c^2$, i.e. Equation (A.1194). Solving, $\sinh s=\sqrt{c^2-1}=1$ and $s=\log\left(c+\sinh s\right)=\log\left(1+\sqrt{2}\right)$, whence Equation (A.1172).

Sufficiency. Let $c=\sqrt{2}$, so $t=1/\sqrt{2}$, $\sinh s=1$ and $s=\log\left(1+\sqrt{2}\right)$. Then $Q=-\psi^2/2a^2$ by Equation (A.1188), and Equation (A.1193) becomes, after multiplying by a^2 and using $c=\sqrt{2}$,

$$\psi^2\le\pi\left|\pi\sinh u-\sqrt{2}\,\psi\cosh u\right|\,,\qquad u=\frac{\psi s}{\pi}\,. \tag{A.1195}$$

Both sides are even in ψ, so take $0\le\psi\le\pi$, where the bracket is negative and Equation (A.1195) is the assertion $G(u)\ge0$ for $0\le u\le s$, with $\psi=\pi u/s$ and

$$G(u):=\frac{\cosh s}{s}\,u\cosh u-\sinh u-\frac{u^2}{s^2}\,,$$

obtained by dividing Equation (A.1195) by π^2 and substituting $\sqrt{2}=\cosh s$, $1=\sinh s$. Now $G(0)=0$ and $G(s)=\cosh^2 s-\sinh s-1=2-1-1=0$; moreover

$$\begin{aligned}G'(u)&=\frac{\cosh s}{s}\left(\cosh u+u\sinh u\right)-\cosh u-\frac{2u}{s^2}\,,\\ G''(u)&=\left(\frac{2\cosh s}{s}-1\right)\sinh u+\frac{\cosh s}{s}\,u\cosh u-\frac{2}{s^2}\,.\end{aligned}$$

Since $2\cosh s/s>1$, every u-dependent term of G'' is strictly increasing on $[0,s]$, so G'' is; and $G''(0)=-2/s^2<0$ while $G''(s)=2\sqrt{2}/s+1-2/s^2>0$ numerically ($s=0.881\,37$ gives $3.209+1-2.575$). Hence G'' changes sign exactly once, so G' decreases and then increases. As $G'(0)=\cosh s/s-1>0$ and $G'(s)=\cosh^2 s/s+\cosh s\sinh s-\cosh s-2/s=0$ — the two terms $\cosh^2 s/s=2/s$ and $-2/s$ cancel, as do $\cosh s\sinh s=\sqrt{2}$ and $-\cosh s=-\sqrt{2}$ — the function G' is positive on $(0,u^*)$ and negative on (u^*,s) for a single u^*. Therefore G rises from $G(0)=0$ and falls back to $G(s)=0$ without crossing zero in between, so $G\ge0$ on $[0,s]$, which is Equation (A.1195). Equality holds only at $\psi=0$ and $\psi=\pi$, the mode of Equation (A.1194) and the rigid translation.

Instability elsewhere. If $c\ne\sqrt{2}$ then $Q\ne0$ at $\psi=0$, while $X=Y=-\Pi=\pi^4t^2/a^4c^2$ there, so the discriminant computed in Proposition A.728 equals $[4\Pi]\,[4Q^2]=16\Pi Q^2<0$: the roots λ are a complex conjugate pair, their square roots are not purely imaginary, and the mode $\varphi=\pi$ grows. □

Proposition A.730 (The unstaggered street is always unstable)**.** *If the second row is placed at $B_n=na-\mathrm{i}h$, directly beneath the first, the mode $\varphi=\pi$ grows for every $h>0$.*
Rests on Theorem A.729.

Proof. *Derives Proposition A.730.*

The only change is in the offset, so Lemma A.722 is applied at $\zeta = -\mathrm{i}h/a$ instead of $\frac{1}{2} - \mathrm{i}h/a$, giving $\sin\pi\zeta = -\mathrm{i}\sinh s$ and $\cos\pi\zeta = \cosh s$; hence $S_0 = -\pi^2/a^2\sinh^2 s$, and S_1, $\tilde{S}_1$ come out *real*. At $\psi = 0$ they are equal, with $\sqrt{X} = \pi^2\cosh s/a^2\sinh^2 s$ and $\Pi = +X$, so the second case of Proposition A.728 applies and neutrality would require $|Q| \le \sqrt{X}$. Here $Q = (\pi^2/a^2)\left(\frac{1}{2} + 1/\sinh^2 s\right)$, so the requirement reads $\frac{1}{2}\sinh^2 s + 1 \le \cosh s$, i.e. $(\cosh s - 1)^2 \le 0$ after using $\sinh^2 s = \cosh^2 s - 1$. That holds only at $s = 0$, where the two rows coincide. For every real separation the unstaggered arrangement therefore grows, and no spacing rescues it — which is why only the staggered pattern is ever photographed. □

Remark A.731 (What the calculation settles, and what it does not). Four limitations are built into the statement proved above and none of them is repaired by any refinement of the algebra.

First, the stability is *neutral*. Theorem A.729 says that at the critical ratio no linear mode grows; it does not say that any decays, and it says nothing at second order, where the street is in fact unstable. The observed consequence is that the photographed spacing drifts slowly downstream instead of locking to Equation (A.1172), and the agreement with the photographs — close to a few percent — is better than a neutral result has any right to expect.

Second, the vortices are points in an unbounded ideal fluid. Real vortices have cores of finite size, diffuse by Equation (31.52), and decay; the calculation has no viscosity in it anywhere.

Third, and most important, *the cylinder never appears*. The configuration Equation (A.1177) is postulated, not derived: nothing here explains why two boundary layers separating from a bluff body should roll up into two staggered rows, nor with what strength Γ, nor at what rate. In particular nothing here predicts the Strouhal number, and Remark 31.62 says so at length: Equation (31.53) is a measurement, disciplined by the similarity argument of Phenomenon 31.49 into the form $\mathrm{St} = \mathrm{St}(\mathrm{Re})$ and no further.

Fourth, the analysis is of a rigid infinite pattern already formed. The selection it performs is therefore of the same kind as the selection of a preferred wavelength in Section 31.8.1: it says which configurations can persist, not which one nature will build.

Remark A.732. Appendix A.61 discharges Equation (31.54) of Phenomenon 31.61 in Chapter 31, and only that equation: Equation (31.53), the Strouhal number that shares the phenomenon with it, is reported there as measurement and is not derived here or anywhere else in this treatise. The two halves of that phenomenon are of different epistemic kinds and Remark 31.62 is where the difference is set out; the reader who has followed the algebra above should return to it, because the calculation just performed makes concrete how much idealization purchased the one number that could be derived. The measured record for the cylinder wake is collected in Chapter 36.

A.62 The Joukowski Map, the Kutta Condition and the 2π Lift Slope

This appendix proves Proposition 31.70 of Chapter 31 — that the Kutta condition selects Equation (31.60) from the one-parameter family of irrotational flows past a thin profile, giving a lift-curve slope of exactly 2π per radian. The chapter proves Theorem 31.68, which converts a circulation into a force and says nothing about what the circulation is; Remark 31.69 names the physical selection principle and defers the computation here. Three things are established below: the flow past a circle with arbitrary circulation (Appendix A.62.1), the conformal transfer to the profile with the trailing edge as the distinguished point (Appendix A.62.2), and the value of Γ that the finiteness of the velocity there enforces (Appendix A.62.3).

The sign convention is the chapter's throughout: Γ is the circulation measured counterclockwise, Equation (31.55), and the transverse force per unit span is $Y = -\rho U\Gamma$, Equation (31.59). The complex velocity is Equation (31.57), $\mathrm{d}w/\mathrm{d}z = v_x - \mathrm{i}v_y$.

A.62.1 Flow past a circle with circulation

Lemma A.733 (The circle with incidence and circulation)**.** *Let $U > 0$ in* m/s*, $R > 0$ in* m*, $\alpha \in (-\pi/2, \pi/2)$ and $\Gamma \in \mathbb{R}$ in* m^2/s*. The function*

$$w(\zeta) = U\left(\zeta\,\mathrm{e}^{-\mathrm{i}\alpha} + \frac{R^2\mathrm{e}^{\mathrm{i}\alpha}}{\zeta}\right) - \frac{\mathrm{i}\Gamma}{2\pi}\log\zeta \tag{A.1196}$$

is holomorphic on $|\zeta| > R$ apart from the branch cut of the logarithm, has $|\zeta| = R$ as a streamline, tends to the uniform stream $U\mathrm{e}^{\mathrm{i}\alpha}$ at infinity, and carries circulation Γ around the circle. Its derivative on the circle is

$$\left.\frac{\mathrm{d}w}{\mathrm{d}\zeta}\right|_{\zeta=R\mathrm{e}^{\mathrm{i}\theta}} = \mathrm{i}\,\mathrm{e}^{-\mathrm{i}\theta}\left[2U\sin(\theta-\alpha) - \frac{\Gamma}{2\pi R}\right], \tag{A.1197}$$

so the stagnation points on the circle are at the angles θ with

$$\sin(\theta-\alpha) = \frac{\Gamma}{4\pi U R}. \tag{A.1198}$$

Rests on Proposition 31.28 and Equation (31.57).

Proof. *Derives Lemma A.733.*

On $\zeta = R\mathrm{e}^{\mathrm{i}\theta}$ the first bracket of Equation (A.1196) is $UR\left(\mathrm{e}^{\mathrm{i}(\theta-\alpha)} + \mathrm{e}^{-\mathrm{i}(\theta-\alpha)}\right) = 2UR\cos(\theta-\alpha)$, which is real, and $\log\zeta = \log R + \mathrm{i}\theta$, so $\operatorname{Im} w = -(\Gamma/2\pi)\log R$, a constant: the circle is a streamline. As $\zeta \to \infty$, $\mathrm{d}w/\mathrm{d}\zeta \to U\mathrm{e}^{-\mathrm{i}\alpha}$, which by Equation (31.57) is the stream $\boldsymbol{v} = U(\cos\alpha, \sin\alpha)$. The circulation is $\oint(\mathrm{d}w/\mathrm{d}\zeta)\,\mathrm{d}\zeta$ around the circle; the first bracket is single valued and contributes nothing, and $-(\mathrm{i}\Gamma/2\pi)\oint\mathrm{d}\zeta/\zeta = -(\mathrm{i}\Gamma/2\pi)\,2\pi\mathrm{i} = \Gamma$ by Theorem 8.24.

For Equation (A.1197), differentiate Equation (A.1196) and set $\zeta = R\mathrm{e}^{\mathrm{i}\theta}$:

$$\frac{\mathrm{d}w}{\mathrm{d}\zeta} = U\left(\mathrm{e}^{-\mathrm{i}\alpha} - \frac{R^2\mathrm{e}^{\mathrm{i}\alpha}}{\zeta^2}\right) - \frac{\mathrm{i}\Gamma}{2\pi\zeta} = U\mathrm{e}^{-\mathrm{i}\theta}\left(\mathrm{e}^{\mathrm{i}(\theta-\alpha)} - \mathrm{e}^{-\mathrm{i}(\theta-\alpha)}\right) - \frac{\mathrm{i}\Gamma\mathrm{e}^{-\mathrm{i}\theta}}{2\pi R},$$

and the bracket is $2\mathrm{i}\sin(\theta-\alpha)$ by Equation (8.3). Factoring out $\mathrm{i}\mathrm{e}^{-\mathrm{i}\theta}$ gives Equation (A.1197), which vanishes exactly at the angles Equation (A.1198).

Uniqueness among flows with the stated data is the Neumann uniqueness of Proposition 31.28: two such potentials differ by a function whose velocity vanishes at infinity, whose normal derivative vanishes on the circle, and around which the circulation is zero, hence by the maximum principle (Theorem 10.77) a constant. □

Note that Equation (A.1198) has a solution only for $|\Gamma| \le 4\pi UR$; larger circulations lift the stagnation points off the circle entirely. Nothing in the potential problem picks a value — every Γ gives a legitimate irrotational flow that does not penetrate the body, which is exactly the indeterminacy stated at Remark 31.69.

A.62.2 The Joukowski map and the cusped edge

Definition A.734 (The Joukowski map)**.** For $b > 0$ in m, the map

$$z = Z(\zeta) := \zeta + \frac{b^2}{\zeta} \tag{A.1199}$$

carries $|\zeta| > b$ bijectively onto the complement of the segment $[-2b, 2b]$ of the real axis, with inverse

$$\zeta = \tfrac{1}{2}\left(z + \sqrt{z^2 - 4b^2}\right), \tag{A.1200}$$

the branch of the square root behaving as z at infinity.

Rests on Theorem 8.6.

That Equation (A.1200) inverts Equation (A.1199) is the quadratic formula applied to $\zeta^2 - z\zeta + b^2 = 0$, whose two roots have product b^2; the branch named is the one of modulus greater than b, and it is holomorphic off the segment because $z^2 - 4b^2$ vanishes only at $z = \pm 2b$. The circle $|\zeta| = b$ itself maps two-to-one onto the segment: $\zeta = b\mathrm{e}^{\mathrm{i}\theta}$ gives $z = 2b\cos\theta$. The chord is therefore $c = 4b$, and the point $\zeta = b$ maps to the trailing edge $z = 2b$.

Lemma A.735 (Transfer of the flow)**.** *Let w be as in Equation (A.1196) with $R = b$, and put $W(z) := w(\zeta(z))$ with Equation (A.1200). Then W is a complex potential for the flow past the segment: it is holomorphic off the segment, the segment is a streamline, the free stream at infinity is $U\mathrm{e}^{\mathrm{i}\alpha}$, the circulation around the segment is Γ, and the physical velocity is*

$$\frac{\mathrm{d}W}{\mathrm{d}z} = \frac{\mathrm{d}w/\mathrm{d}\zeta}{\mathrm{d}z/\mathrm{d}\zeta} = \frac{\mathrm{d}w/\mathrm{d}\zeta}{1 - b^2/\zeta^2}\,. \tag{A.1201}$$

Rests on Definition A.734 and Lemma A.733.

Proof. *Derives Lemma A.735.*

A composition of holomorphic functions is holomorphic and its derivative is given by the chain rule; both statements follow from Theorem 8.6 and Definition 8.5 exactly as for real functions, and $\mathrm{d}z/\mathrm{d}\zeta = 1 - b^2/\zeta^2$ is non-zero on $|\zeta| > b$, which gives Equation (A.1201). Since W takes the same values as w, its imaginary part is constant on the image of the circle, i.e. on the segment, and its behaviour at infinity is that of w because $\zeta(z) = z + O\left(z^{-1}\right)$ there. The circulation is unchanged for the same reason: it is the real part of $\oint_{C_z} \mathrm{d}W$, and $\mathrm{d}W = \mathrm{d}w$ under the substitution $z \mapsto \zeta(z)$, which carries a circuit around the segment to a circuit around the circle. □

Remark A.736 (What conformal mapping buys, and what it is). The step just taken is the only one where a general theorem might have been invoked, and it has been avoided. What is usually quoted here is that a holomorphic bijection carries harmonic functions to harmonic functions and streamlines to streamlines, so a solved problem in one plane is a solved problem in the other; the general statement needs the holomorphic inverse function theorem, and beyond it, to know that a suitable map exists at all, the Riemann mapping theorem. Part II's complex-analysis chapter carries neither: Chapter 8 ends at Theorem 8.24 and has no conformal-mapping material, which is a real gap and is recorded as such. Nothing above needs it, because the map Equation (A.1199) and its inverse Equation (A.1200) are both written down explicitly, and the only property used is that a composition of holomorphic functions is holomorphic — which is Theorem 8.6 and the chain rule.

The transformation is degenerate at $\zeta = \pm b$, where $\mathrm{d}z/\mathrm{d}\zeta = 0$. This is not an accident of the map but the definition of a sharp edge: the interior angle of the profile at $z = 2b$ is zero, and a smooth curve is being folded onto itself. Equation (A.1201) then says that the physical velocity at the trailing edge is infinite — *unless* the numerator vanishes there too.

A.62.3 The Kutta condition and the lift

Theorem A.737 (The lift-curve slope of the flat plate)**.** *Of the one-parameter family of flows Equation (A.1196) with $R = b$, exactly one has a finite velocity at the trailing edge $z = 2b$, namely that with*

$$\Gamma = -4\pi U b \sin\alpha = -\pi c U \sin\alpha\,, \qquad c = 4b\,, \tag{A.1202}$$

and for it Equation (31.59) *gives the lift per unit span and lift coefficient*

$$Y = \pi\rho U^2 c \sin\alpha\,, \qquad C_{\mathrm{L}} = \frac{Y}{\frac{1}{2}\rho U^2 c} = 2\pi\sin\alpha \approx 2\pi\alpha\,, \tag{A.1203}$$

which is Equation (31.60).

Rests on Lemma A.735 and Theorem 31.68.

Proof. *Derives Theorem A.737.*

By Equation (A.1201) the velocity at $z = 2b$ is the quotient of $\mathrm{d}w/\mathrm{d}\zeta$ and $1 - b^2/\zeta^2$ as $\zeta \to b$ along the circle. The denominator has a simple zero there: with $\zeta = b\mathrm{e}^{\mathrm{i}\theta}$, $1 - \mathrm{e}^{-2\mathrm{i}\theta} = 2\mathrm{i}\mathrm{e}^{-\mathrm{i}\theta}\sin\theta$, which vanishes linearly in θ. The numerator is Equation (A.1197) with $R = b$. The quotient is therefore

$$\frac{\mathrm{d}W}{\mathrm{d}z} = \frac{\mathrm{i}\mathrm{e}^{-\mathrm{i}\theta}\left[2U\sin(\theta-\alpha) - \Gamma/2\pi b\right]}{2\mathrm{i}\mathrm{e}^{-\mathrm{i}\theta}\sin\theta} = \frac{2U\sin(\theta-\alpha) - \Gamma/2\pi b}{2\sin\theta}\,,$$

and its limit as $\theta \to 0$ is finite if and only if the numerator vanishes at $\theta = 0$, that is $-2U\sin\alpha = \Gamma/2\pi b$, which is Equation (A.1202); every other value of Γ gives a velocity diverging like $1/\theta$. (When the condition holds, l'Hôpital's rule gives the finite edge velocity $U\cos\alpha$, the component of the stream along the plate — the flow leaves the edge smoothly, along the chord.)

For the force, Lemma A.735 places a circulation Γ around a body in a uniform stream of speed U, so Theorem 31.68 applies in axes aligned with the stream: the drag vanishes and the transverse force is $-\rho U\Gamma = \pi\rho U^2 c\sin\alpha$, directed perpendicular to the stream and, since $\Gamma < 0$ for $\alpha > 0$, upwards. Dividing by $\frac{1}{2}\rho U^2 c$ gives Equation (A.1203), and for small incidence $\sin\alpha = \alpha + O(\alpha^3)$, so $\Gamma \to -\pi c U\alpha$ and $C_{\mathrm{L}} \to 2\pi\alpha$ as in Equation (31.60). □

Remark A.738 (Why the circulation may be read off in either plane). The step that makes the calculation possible is that Γ is the same number in the two planes. It is worth isolating, because it is what licenses computing the circulation where the geometry is easy — a circle — and applying Theorem 31.68 where the geometry is the one that matters. The reason is that the circulation is a contour integral of an exact differential, $\oint \mathrm{d}W$, and a change of variable in a contour integral is a substitution and nothing more: no property of the map enters beyond its being holomorphic and one-to-one. The same remark explains why the Blasius formula Equation (31.58) may be evaluated on a large circle rather than on the profile — Corollary 8.15, used already in the chapter's proof of Lemma 31.67.

Remark A.739 (What the 2π is worth). Equation (A.1203) is a genuine prediction with no adjustable content, and measured slopes for thin two-dimensional sections at small incidence do come within a few percent of 2π per radian. Four qualifications are owed.

Thickness and camber. The circle of Lemma A.733 was concentric with the origin, which is what degenerated the profile to a segment. Displacing its centre gives thickness (a shift along the real axis) and camber (a shift along the imaginary axis), and the same argument then yields $C_{\mathrm{L}} = 2\pi\sin(\alpha - \alpha_0)$: camber moves the zero-lift angle α_0 and leaves the slope alone, which is why the number 2π is so much more robust than anything else in aerofoil theory.

Finite span. A real wing sheds trailing vorticity, whose downwash reduces the effective incidence, and the slope falls with aspect ratio. This is a three-dimensional effect and nothing in a plane flow can see it.

The Kutta condition is a viscous fact. It has been imposed here, not derived. Its justification is that the boundary layer of Section 31.7.2 cannot negotiate the infinite adverse pressure gradient implied by an infinite edge velocity and separates there instead — Proposition 31.73 — and its consistency with the conservation of circulation Corollary 31.65 is secured by the starting vortex described at Remark 31.69. An inviscid theory that selects

its solution by a viscous criterion is not a closed theory, and it should not be presented as one.

No stall. Equation (A.1203) rises without bound with α, which is false: beyond ten to fifteen degrees the flow separates from the upper surface and the lift collapses. The theory contains no mechanism for this whatever, because it contains no separation. The measured lift curve, its linear range and its breakdown are in Chapter 36.

Remark A.740. Appendix A.62 discharges Proposition 31.70 of Chapter 31, whose statement Equation (31.60) is proved here as Equation (A.1203), and completes Remark 31.69 by supplying the value of Γ that the chapter's discussion of the Kutta condition leaves open. It should be read against Appendix A.59: the circulation is the first of the two escapes from d'Alembert's theorem catalogued at Remark 31.31, and what this section computes is precisely how much of it a sharp trailing edge is worth. The drag is still exactly zero, here as there — Theorem 31.68 gives $X = 0$ — so the escape buys lift and nothing else. Kutta's own computation is [307]; the general circulation theorem is Joukowski's [362].

A.63 The Kármán–Howarth Relation and the Four-Fifths Law

This appendix proves Equation (31.74) of Remark 31.86 in Chapter 31:

$$\left\langle \left(\delta u_{\parallel}\right)^{3} \right\rangle = -\tfrac{4}{5}\,\varepsilon\, r \tag{A.1204}$$

in the inertial range of homogeneous isotropic turbulence, with no adjustable constant. The chapter calls this the one nontrivial statement about turbulence that is *derived* from the Navier–Stokes equations rather than assumed and tested, and sets it deliberately against the dimensional argument of Phenomenon 31.84, which is not derived. The whole weight of that claim rests on the pages below, and the section is written accordingly: everything is proved, the symmetry hypotheses are used explicitly at the four places where they are needed, and Remark A.750 states at the end exactly how much the word *exact* is buying. It is buying less than it sounds, and more than anything else in the subject.

A.63.1 Setting

Definition A.741 (The statistical setting)**.** Let $\boldsymbol{v}(\boldsymbol{x},t)$ be a random velocity field on $\mathbb{R}^3$ obeying the incompressible Navier–Stokes equations Equation (31.32) with kinematic viscosity ν in m^2/s and a body force $\boldsymbol{F}$ per unit mass, and let $\langle\,\cdot\,\rangle$ denote the ensemble average. The turbulence is assumed

1. *homogeneous*: every joint moment is invariant under translations of $\mathbb{R}^3$;
2. *isotropic in the strong sense*: every joint moment is invariant under the full orthogonal group $\mathrm{O}(3)$, rotations and reflections alike;
3. *statistically steady*: every moment is independent of t;
4. *forced at large scales only*: $\boldsymbol{F}$ is a random field with the same symmetries whose correlation with $\boldsymbol{v}$ varies on a single length L, the integral scale.

Write $\boldsymbol{v} := \boldsymbol{v}(\boldsymbol{x},t)$, $\boldsymbol{v}' := \boldsymbol{v}(\boldsymbol{x}+\boldsymbol{r},t)$, $\delta\boldsymbol{v} := \boldsymbol{v}' - \boldsymbol{v}$, $r = |\boldsymbol{r}|$, $\boldsymbol{n} = \boldsymbol{r}/r$, and $\delta u_{\parallel} := \delta\boldsymbol{v}\cdot\boldsymbol{n}$ for the longitudinal increment. Define

$$u^2 := \left\langle v_1^2 \right\rangle, \quad R(r) := \langle \boldsymbol{v}\cdot\boldsymbol{v}' \rangle, \quad S_2(r) := \left\langle \left(\delta u_{\parallel}\right)^{2} \right\rangle, \quad S_3(r) := \left\langle \left(\delta u_{\parallel}\right)^{3} \right\rangle, \tag{A.1205}$$

and let

$$\varepsilon := \nu \, \langle \partial_j v_i \, \partial_j v_i \rangle \tag{A.1206}$$

be the mean dissipation rate per unit mass, in W/kg=m^2/s^3.

Rests on Theorem 31.37 and Definition 11.4.

Hypothesis (2) is stronger than rotational invariance alone and the difference matters: a turbulence with a mean helicity is invariant under SO(3) but not under reflection, and the pseudo-tensor terms that reflection invariance removes below would then survive.

A.63.2 Isotropic tensor functions of one vector

Everything in this section rests on one algebraic lemma, which is proved here rather than quoted because the whole reduction from a field theory to two ordinary differential equations is contained in it.

Lemma A.742 (Isotropic representation)**.** *Let T be a Cartesian tensor field on $\mathbb{R}^3 \setminus \{0\}$, depending on the single vector $\boldsymbol{r}$, and covariant under* O(3)*: $T_{i\ldots}(\mathsf{O}\boldsymbol{r}) = \mathsf{O}_{ii'} \cdots T_{i'\ldots}(\boldsymbol{r})$ for every orthogonal O. Then, with $\boldsymbol{n} = \boldsymbol{r}/r$,*

$$\textit{rank } 1: \quad T_i = \phi(r)\, n_i \,, \tag{A.1207}$$

$$\textit{rank } 2,\ \textit{symmetric}: \quad T_{ij} = (\phi_1 - \phi_2)\, n_i n_j + \phi_2\, \delta_{ij} \,, \tag{A.1208}$$

$$\textit{rank } 3,\ \textit{symmetric in } i,j: \quad T_{ijk} = \mathcal{A}\, n_i n_j n_k + \mathcal{B}\, \delta_{ij} n_k + \mathcal{C}\, (\delta_{ik} n_j + \delta_{jk} n_i) \,, \tag{A.1209}$$

with scalar functions of r alone. A constant tensor with these symmetries and no $\boldsymbol{r}$ dependence is zero at odd rank and a multiple of δ_{ij} at rank two.

Rests on Theorem 5.128 and Definition 14.26.

Proof. *Derives Lemma A.742.*

Fix $r > 0$. Covariance under the rotations that move $\boldsymbol{r}$ shows that the components in a frame adapted to $\boldsymbol{r}$ depend on r only, so it suffices to work at one point. Choose axes with $\boldsymbol{n} = \hat{\boldsymbol{e}}_3$ and let Latin indices a, b, c run over the transverse values $1, 2$. The subgroup of O(3) fixing $\boldsymbol{r}$ is the group O(2) acting on the transverse plane, and each block of components must be an invariant tensor of that group.

At rank one: T_a is an invariant vector of O(2), hence zero (the element $-\mathsf{I}$ of O(2) reverses it), and T_3 is free. This is Equation (A.1207).

At rank two, symmetric: T_{3a} is again an invariant transverse vector, hence zero; T_{ab} is an invariant symmetric two-dimensional tensor, hence $\phi_2 \delta_{ab}$, since the traceless part carries the spin-two representation of SO(2), which has no invariant; and $T_{33} = \phi_1$ is free. Writing $\delta_{ab} = \delta_{ij} - n_i n_j$ in covariant form gives Equation (A.1208).

At rank three, symmetric in the first two indices, four blocks occur. T_{33a} is an invariant transverse vector: zero. T_{ab3} is an invariant symmetric transverse two-tensor: $\mathcal{B}\, \delta_{ab}$. $T_{3ab} = T_{a3b}$ is an invariant transverse two-tensor, not required symmetric, hence again $\mathcal{C}\, \delta_{ab}$ — the antisymmetric ϵ_{ab} is invariant under SO(2) but changes sign under a reflection of the plane, and hypothesis (2) of Definition A.741 excludes it. T_{abc} is an invariant transverse tensor of odd rank, and $-\mathsf{I} \in$ SO(2) reverses it: zero. Assembling with $\delta_{ab} = \delta_{ij} - n_i n_j$ and renaming the free coefficient of $n_i n_j n_k$ gives Equation (A.1209).

For a constant tensor the same argument applies at every $\boldsymbol{r}$ simultaneously, so the surviving coefficients must be independent of the direction $\boldsymbol{n}$; at odd rank every term in Equations (A.1207) and (A.1209) carries an odd number of factors n, and no such expression is direction independent unless it vanishes. □

Corollary A.743 (Two scalar functions instead of a tensor field)**.** *Write $B_{ij}(\boldsymbol{r}) := \left\langle v_i v'_j \right\rangle$. Then there is a single scalar f, with $f(0) = 1$, such that*

$$B_{ij} = u^2 \left[(f - g)\, n_i n_j + g\, \delta_{ij} \right] , \qquad g = f + \tfrac{1}{2} r f' \,, \tag{A.1210}$$

and $R(r) = B_{ii} = u^2\,(3f + rf')$*; moreover* $\langle v_i v_j v_k' \rangle$ *is determined by a single scalar* k*, namely* $\left\langle v_\parallel^2 v_\parallel' \right\rangle = u^3 k(r)$*, and* $\langle v_i v_j v_k \rangle = 0$*.*

Rests on Lemma A.742 and Corollary 31.13.

Proof. *Derives Corollary A.743.*

B_{ij} is symmetric under the simultaneous exchange $i \leftrightarrow j$, $\boldsymbol{r} \to -\boldsymbol{r}$, and by Equation (A.1208) it takes the displayed form with $f = B_{\parallel\parallel}/u^2$ and $g = B_{\perp\perp}/u^2$, the longitudinal and transverse correlations; $f(0) = 1$ by the definition of u^2. Incompressibility acts through $\partial B_{ij}/\partial r_j = \left\langle v_i\, \partial_j' v_j' \right\rangle = 0$. Writing $h := (f - g)/r^2$ so that the first term is $u^2 h\, r_i r_j$,

$$\partial_j\,(h\, r_i r_j) = h'\, r\, r_i + 4h\, r_i\,, \qquad \partial_j\,(g\,\delta_{ij}) = g'\frac{r_i}{r}\,,$$

using $\partial_j r = r_j/r$ and $\partial_j\,(r_i r_j) = 4r_i$. Their sum vanishes for all $\boldsymbol{r}$, so $h'r + 4h + g'/r = 0$; substituting h and clearing r^2 leaves $rf' + 2\,(f - g) = 0$, which is the second relation in Equation (A.1210). Contracting the first relation gives $R = u^2\,(f - g + 3g) = u^2\,(f + 2g) = u^2\,(3f + rf')$.

For the triple correlation put $B_{ij,k} := \langle v_i v_j v_k' \rangle$; it is symmetric in i, j, so Equation (A.1209) applies with coefficients $\mathcal{A}, \mathcal{B}, \mathcal{C}$. Incompressibility at the far point gives $\partial B_{ij,k}/\partial r_k = \langle v_i v_j \partial_k' v_k' \rangle = 0$; carrying out the differentiation as above,

$$\partial_k\,(\mathcal{A} n_i n_j n_k) = n_i n_j \left(\mathcal{A}' + \frac{2\mathcal{A}}{r}\right), \quad \partial_k\,(\mathcal{B}\delta_{ij} n_k) = \delta_{ij}\left(\mathcal{B}' + \frac{2\mathcal{B}}{r}\right),$$

$$\partial_k\Big[\mathcal{C}\,(\delta_{ik} n_j + \delta_{jk} n_i)\Big] = 2\mathcal{C}' n_i n_j + \frac{2\mathcal{C}}{r}\,(\delta_{ij} - n_i n_j)\,,$$

and since $n_i n_j$ and δ_{ij} are independent the two coefficients must vanish separately:

$$\mathcal{A}' + \frac{2\mathcal{A}}{r} + 2\mathcal{C}' - \frac{2\mathcal{C}}{r} = 0\,, \qquad \mathcal{B}' + \frac{2\mathcal{B}}{r} + \frac{2\mathcal{C}}{r} = 0\,. \tag{A.1211}$$

Two equations for three functions leave one free function, which may be taken to be $u^3 k := B_{\parallel\parallel,\parallel} = \mathcal{A} + \mathcal{B} + 2\mathcal{C}$. Finally $\langle v_i v_j v_k \rangle$ is a constant isotropic tensor of rank three, so it vanishes by the last clause of Lemma A.742. □

A.63.3 The pressure drops out

This is the step that makes the result exact rather than a closure, and it is the one a reader should doubt until it is shown, since a correlation involving the pressure is otherwise as intractable as anything in the subject.

Lemma A.744 (Vanishing of the pressure–velocity correlation)**.** *Under Definition A.741,* $\langle p\, v_i' \rangle = 0$ *identically, and likewise* $\left\langle |\boldsymbol{v}|^2\, v_i' \right\rangle = 0$*.*

Rests on Lemma A.742 and Corollary 31.13.

Proof. *Derives Lemma A.744.*

Both are isotropic vector functions of $\boldsymbol{r}$, so by Equation (A.1207) each equals $\phi(r) n_i$ for some scalar ϕ. Both are divergence free in $\boldsymbol{r}$: differentiating with respect to r_i is differentiating the far point, and

$$\partial_i\,\langle p\, v_i' \rangle = \langle p\, \partial_i' v_i' \rangle = 0\,, \qquad \partial_i \left\langle |\boldsymbol{v}|^2\, v_i' \right\rangle = \left\langle |\boldsymbol{v}|^2\, \partial_i' v_i' \right\rangle = 0\,,$$

because the field is incompressible (Corollary 31.13) and the near point is held fixed. For a radial field $\phi(r) n_i$ the divergence is $r^{-2}\,(r^2\phi)'$, so $r^2\phi$ is constant; the constant is zero because ϕ is bounded at the origin, both quantities being finite one-point moments there. Hence $\phi \equiv 0$. □

A.63.4 The two-point energy equation

Theorem A.745 (Kármán–Howarth–Monin relation)**.** *Under Definition A.741, and without any closure hypothesis whatever,*

$$\frac{\partial R}{\partial t} = \tfrac{1}{2}\,\boldsymbol{\nabla}_r \cdot \left\langle |\delta \boldsymbol{v}|^2\, \delta \boldsymbol{v} \right\rangle + 2\nu \nabla_r^2 R + \mathcal{F}(r)\,, \qquad \mathcal{F} := \left\langle \boldsymbol{F}\cdot\boldsymbol{v}' + \boldsymbol{v}\cdot\boldsymbol{F}' \right\rangle\,, \tag{A.1212}$$

and $\mathcal{F}(0) = 2\varepsilon$ in a steady state.
Rests on Theorem 31.37 and Lemma A.744.

Proof. *Derives Theorem A.745.*

By homogeneity every correlation depends on $\boldsymbol{r} = \boldsymbol{x}' - \boldsymbol{x}$ alone, so $\partial/\partial x_i = -\partial/\partial r_i$ and $\partial/\partial x_i' = +\partial/\partial r_i$ when applied to one. Write the Navier–Stokes equation Equation (31.32) at $\boldsymbol{x}$ and at $\boldsymbol{x}'$, multiply the first by v_i' and the second by v_i, add and average:

$$\frac{\partial R}{\partial t} = -\left\langle (v_j \partial_j v_i)\, v_i' \right\rangle - \left\langle v_i \left(v_j' \partial_j' v_i' \right) \right\rangle - \frac{1}{\rho}\left[\left\langle (\partial_i p)\, v_i' \right\rangle + \left\langle v_i \partial_i' p' \right\rangle \right] + \nu \left[\left\langle \left(\nabla^2 v_i \right) v_i' \right\rangle + \left\langle v_i \nabla'^2 v_i' \right\rangle \right] + \mathcal{F}\,.$$

The pressure bracket is $\partial_i \langle p\, v_i' \rangle - \partial_i \langle v_i p' \rangle$ after moving the derivatives outside the averages, and both terms vanish by Lemma A.744 — the second is the first with $\boldsymbol{r}$ reversed. The viscous bracket is $2\nu\nabla_r^2 R$, since each Laplacian acts on one factor and becomes ∇_r^2 on the correlation.

For the nonlinear terms use incompressibility to write $v_j \partial_j v_i = \partial_j (v_j v_i)$; then

$$-\left\langle \partial_j (v_j v_i)\, v_i' \right\rangle = +\partial_{r_j} \left\langle v_j v_i v_i' \right\rangle\,, \qquad -\left\langle v_i \partial_j' \left(v_j' v_i' \right) \right\rangle = -\partial_{r_j} \left\langle v_i v_j' v_i' \right\rangle\,,$$

so the nonlinear contribution is $\partial_{r_j}\left[\langle v_j v_i v_i' \rangle - \left\langle v_i v_j' v_i' \right\rangle \right]$. It remains to identify the bracket. Expand

$$\left\langle |\delta \boldsymbol{v}|^2\, \delta v_j \right\rangle = \left\langle \left(|\boldsymbol{v}'|^2 - 2\boldsymbol{v}\cdot\boldsymbol{v}' + |\boldsymbol{v}|^2 \right) \left(v_j' - v_j \right) \right\rangle\,.$$

The terms $\left\langle |\boldsymbol{v}'|^2\, v_j' \right\rangle$ and $\left\langle |\boldsymbol{v}|^2\, v_j \right\rangle$ are equal by homogeneity and cancel; $\left\langle |\boldsymbol{v}|^2\, v_j' \right\rangle$ and $\left\langle |\boldsymbol{v}'|^2\, v_j \right\rangle$ vanish by Lemma A.744; and what is left is

$$\left\langle |\delta \boldsymbol{v}|^2\, \delta v_j \right\rangle = 2\left\langle \boldsymbol{v}\cdot\boldsymbol{v}'\, v_j \right\rangle - 2\left\langle \boldsymbol{v}\cdot\boldsymbol{v}'\, v_j' \right\rangle = 2\left[\langle v_j v_i v_i' \rangle - \left\langle v_i v_j' v_i' \right\rangle \right]\,,$$

which is twice the bracket. This gives Equation (A.1212).

At $\boldsymbol{r} = \boldsymbol{0}$: the divergence term vanishes, because $\left\langle |\delta \boldsymbol{v}|^2\, \delta \boldsymbol{v} \right\rangle = O(r^3)$ there; the viscous term is $2\nu\nabla_r^2 R|_0 = 2\nu \langle v_i \nabla^2 v_i \rangle = -2\nu \langle \partial_j v_i \partial_j v_i \rangle = -2\varepsilon$ by Equation (A.1206) and homogeneity; and $\partial_t R(0) = 0$ in a steady state. Hence $\mathcal{F}(0) = 2\varepsilon$, which is the statement that in a steady state the force injects energy at exactly the rate viscosity destroys it. □

Proposition A.746 (The Kármán–Howarth equation in classical form)**.** *For unforced (decaying) homogeneous isotropic turbulence, Equation (A.1212) is equivalent to*

$$\frac{\partial}{\partial t}\left(u^2 f \right) = \frac{u^3}{r^4}\,\partial_r\left(r^4 k \right) + \frac{2\nu u^2}{r^4}\,\partial_r\left(r^4\, \partial_r f \right)\,, \tag{A.1213}$$

with f and k the scalars of Corollary A.743.
Rests on Theorem A.745 and Corollary A.743.

Proof. *Derives Proposition A.746.*

Write $T(r)$ for the scalar in $\left\langle |\delta \boldsymbol{v}|^2\, \delta v_j \right\rangle = T(r) n_j$, legitimate by Equation (A.1207); then $\boldsymbol{\nabla}_r \cdot \left\langle |\delta \boldsymbol{v}|^2\, \delta \boldsymbol{v} \right\rangle = r^{-2}\left(r^2 T \right)'$ and $\nabla_r^2 R = r^{-2}\left(r^2 R' \right)'$, so Equation (A.1212) unforced reads

$$\frac{\partial R}{\partial t} = \frac{1}{2r^2}\left(r^2 T \right)' + \frac{2\nu}{r^2}\left(r^2 R' \right)'\,. \tag{A.1214}$$

By Corollary A.743, $R = u^2\,(3f + rf') = u^2\,(r^3 f)'\,/r^2$, and Appendix A.63.5 below gives $T = u^3\,(8k + 2rk')$. Apply the operator $\mathcal{L}[\Phi] := r^{-2}\partial_r\,(r^3\Phi)$ to each term of Equation (A.1213). On the left, $\mathcal{L}\big[\partial_t(u^2 f)\big] = \partial_t R$. On the right,

$$\mathcal{L}\left[\frac{u^3}{r^4}\left(r^4 k\right)'\right] = \frac{u^3}{r^2}\left[4r^2 k + r^3 k'\right]' = \frac{u^3}{r^2}\left[8rk + 7r^2 k' + r^3 k''\right] = \frac{1}{2r^2}\left(r^2 T\right)' ,$$

the last step by direct differentiation of $r^2 T = u^3\,(8r^2 k + 2r^3 k')$; and

$$\mathcal{L}\left[\frac{2\nu u^2}{r^4}\left(r^4 f'\right)'\right] = \frac{2\nu u^2}{r^2}\left[4r^2 f' + r^3 f''\right]' = \frac{2\nu u^2}{r^2}\left[8rf' + 7r^2 f'' + r^3 f'''\right] = \frac{2\nu}{r^2}\left(r^2 R'\right)' ,$$

since $r^2 R' = u^2\,(4r^2 f' + r^3 f'')$. So Equation (A.1213) maps term by term onto Equation (A.1214); and $\mathcal{L}$ is injective on functions regular at the origin, since $\mathcal{L}[\Phi] = 0$ forces $r^3\Phi$ constant, hence $\Phi \propto r^{-3}$, hence $\Phi = 0$. □

Equation (A.1213) is the Kármán–Howarth relation, obtained by von Kármán and Howarth in 1938 (*Proceedings of the Royal Society of London* A **164**, 192–215). That paper is not in the bibliography of this treatise, and the statement is not being taken from it: everything above is derived here from Equation (31.32) and Definition A.741, so the attribution is historical and nothing rests on it. The equation is exact and it does not close: one equation relates the two unknown functions f and k, and nothing determines k. What Kolmogorov saw is that in one limit the undetermined function drops out.

A.63.5 Structure functions

Lemma A.747 (The third-order structure functions)**.** *With $S_{ijk} := \langle \delta v_i \delta v_j \delta v_k \rangle$ and $T(r)$ as above,*

$$S_3 = 6u^3 k\,, \qquad T = u^3\,(8k + 2rk') = S_3 + \tfrac{1}{3}\,(rS_3)'\ . \tag{A.1215}$$

Rests on Corollary A.743 and Lemma A.742.

Proof. *Derives Lemma A.747.*

Expand S_{ijk} in the eight products of v and v'. The two single-point terms $\langle v_i v_j v_k \rangle$ and $\langle v'_i v'_j v'_k \rangle$ vanish by Corollary A.743. Of the remaining six, three have two factors at $\boldsymbol{x}$ and three have two at $\boldsymbol{x} + \boldsymbol{r}$; using homogeneity to write the latter as B evaluated at $-\boldsymbol{r}$, and the fact that $B_{ij,k}$ is odd — every term of Equation (A.1209) carries an odd number of factors $\boldsymbol{n}$ — the two groups add rather than cancel:

$$S_{ijk} = 2\,[B_{ij,k} + B_{ik,j} + B_{jk,i}] = 6\mathcal{A}\,n_i n_j n_k + 2\,(\mathcal{B} + 2\mathcal{C})\,(\delta_{ij} n_k + \delta_{ik} n_j + \delta_{jk} n_i)\ ,$$

the second equality by adding the three copies of Equation (A.1209) with indices permuted. Write $W := \mathcal{A} + \mathcal{B} + 2\mathcal{C} = u^3 k$ and $V := \mathcal{B} + 2\mathcal{C}$. Contracting with $n_i n_j n_k$ gives $S_3 = 6\mathcal{A} + 6V = 6W$, the first relation in Equation (A.1215); contracting on $i = j$ and then with n_k gives $T = S_{iik} n_k = 6\mathcal{A} + 10V = S_3 + 4V$.

It remains to express V through W. Adding the two relations Equation (A.1211) and using $\mathcal{A} + \mathcal{B} = W - 2\mathcal{C}$,

$$W' + \frac{2\,(W - 2\mathcal{C})}{r} = 0 \quad \Longrightarrow \quad \mathcal{C} = \frac{rW' + 2W}{4}\,,$$

and substituting $\mathcal{B} = V - 2\mathcal{C}$ into the second of Equation (A.1211) gives $V' + 2V/r = 2\mathcal{C}' + 2\mathcal{C}/r$. With the expression just obtained for $\mathcal{C}$, the right-hand side is $[rW'' + 4W' + 2W/r]\,/2$, so

$$\left(r^2 V\right)' = r^2 V' + 2rV = \tfrac{1}{2}\left[r^3 W'' + 4r^2 W' + 2rW\right] = \tfrac{1}{2}\,\frac{\mathrm{d}}{\mathrm{d}r}\left[r^3 W' + r^2 W\right]\ ,$$

the last step because $(r^3W')' = 3r^2W' + r^3W''$ and $(r^2W)' = 2rW + r^2W'$. Integrating and discarding the r^{-2} homogeneous solution by regularity at the origin, $V = \frac{1}{2}(rW)'$. Hence $T = S_3 + 2(rW)' = S_3 + \frac{1}{3}(rS_3)'$, and in terms of k, $T = 6u^3k + 2u^3(k + rk') = u^3(8k + 2rk')$. □

Lemma A.748 (The second-order structure function)**.** $D(r) := \left\langle |\delta \boldsymbol{v}|^2 \right\rangle = 2[R(0) - R(r)] = 3S_2 + rS_2'$.

Rests on Corollary A.743.

Proof. *Derives Lemma A.748.*

$\left\langle |\delta \boldsymbol{v}|^2 \right\rangle = \left\langle |\boldsymbol{v}|^2 \right\rangle + \left\langle |\boldsymbol{v}'|^2 \right\rangle - 2\langle \boldsymbol{v} \cdot \boldsymbol{v}' \rangle$, and the first two are $R(0) = 3u^2$ each by homogeneity. For the second equality, Equation (A.1210) gives $S_2 = 2u^2(1 - f)$ and the transverse structure function $\left\langle (\delta u_\perp)^2 \right\rangle = 2u^2(1 - g) = S_2 + \frac{1}{2}rS_2'$, using $g = f + \frac{1}{2}rf'$; summing one longitudinal and two transverse contributions gives $D = 3S_2 + rS_2'$. □

A.63.6 The inertial range and the four-fifths law

Theorem A.749 (Kolmogorov's equation and the four-fifths law)**.** *Under Definition A.741, for every separation $r \ll L$,*

$$S_3(r) - 6\nu \frac{\mathrm{d}S_2}{\mathrm{d}r} = -\tfrac{4}{5}\varepsilon r, \tag{A.1216}$$

and consequently, in the inertial range $\eta \ll r \ll L$ where the viscous term is negligible,

$$\left\langle \left(\delta u_\parallel\right)^3 \right\rangle = -\tfrac{4}{5}\varepsilon r, \tag{A.1217}$$

which is Equation (31.74). Here $\eta = (\nu^3/\varepsilon)^{1/4}$ is the Kolmogorov length Equation (31.72).

Rests on Theorem A.745 and Lemmas A.747 and A.748.

Proof. *Derives Theorem A.749.*

In a steady state the left-hand side of Equation (A.1212) vanishes, and in radial form

$$0 = \frac{1}{2r^2}\left(r^2T\right)' + \frac{2\nu}{r^2}\left(r^2R'\right)' + \mathcal{F}(r).$$

Multiply by r^2 and integrate from 0 to r. The first term gives $\frac{1}{2}r^2T$, the boundary term at the origin vanishing because $T = O(r^3)$. The second gives $2\nu r^2 R'(r)$, likewise. For the third, $\mathcal{F}$ varies on the scale L by hypothesis (4), so for $r \ll L$ it may be replaced by $\mathcal{F}(0) = 2\varepsilon$, giving $\frac{2}{3}\varepsilon r^3$. Hence

$$0 = \tfrac{1}{2}r^2T + 2\nu r^2R' + \tfrac{2}{3}\varepsilon r^3, \qquad \text{i.e.} \qquad T = -4\nu R' - \tfrac{4}{3}\varepsilon r.$$

By Lemma A.748, $R = R(0) - \frac{1}{2}D$, so $R' = -\frac{1}{2}D'$ and

$$T = 2\nu D' - \tfrac{4}{3}\varepsilon r. \tag{A.1218}$$

This is already exact and already the whole content; the rest is translation. Substituting $T = (r^4S_3)'/3r^3$ — which is Equation (A.1215) rewritten, since $(r^4S_3)' = r^3(4S_3 + rS_3') = 3r^3\left[S_3 + \frac{1}{3}(rS_3)'\right]$ — and $D = (r^3S_2)'/r^2$ from Lemma A.748, one verifies that Equation (A.1216) solves Equation (A.1218): with $S_3 = 6\nu S_2' - \frac{4}{5}\varepsilon r$,

$$\frac{(r^4S_3)'}{3r^3} = \frac{6\nu\left(r^4S_2'\right)' - 4\varepsilon r^4}{3r^3} = 2\nu\left[4S_2' + rS_2''\right] - \tfrac{4}{3}\varepsilon r = 2\nu D' - \tfrac{4}{3}\varepsilon r,$$

because $D' = (3S_2 + rS_2')' = 4S_2' + rS_2''$. Since Equation (A.1218) determines S_3 given S_2 — it is a first-order linear equation with the regularity condition $S_3 = O(r^3)$ at the origin fixing the integration constant — Equation (A.1216) is the solution.

For Equation (A.1217): the viscous term $6\nu S_2'$ is of order $\nu S_2/r$, and in the inertial range $S_2 \sim (\varepsilon r)^{2/3}$, so the ratio of the viscous to the inertial term is of order $\nu\varepsilon^{2/3}r^{-4/3}/\varepsilon r = (\eta/r)^{4/3}$, which is negligible for $r \gg \eta$; and $r \ll L$ was used already. Dropping it leaves Equation (A.1217). □

The direction of the inequality is the physics. $S_3 < 0$ says that the odd moment of the longitudinal increment is negative: the fluid at $\boldsymbol{x}+\boldsymbol{r}$ is, on average, moving *towards* the fluid at $\boldsymbol{x}$ more strongly than away from it, in the cubic sense. That asymmetry is the cascade, and Equation (A.1217) measures it against ε with no free constant. Reversed sign would be an inverse cascade, which is what two-dimensional turbulence does and three-dimensional turbulence does not.

Remark A.750 (Exactly what was assumed). The chapter calls Equation (31.74) the one exact nontrivial result about turbulence, and the reader is owed the bill.

Homogeneity was used at every step where $\partial/\partial x_i = -\partial/\partial r_i$ was applied, and in Lemma A.748. No real flow is homogeneous — there is always a boundary and always a forcing region — so the statement is about an idealized ensemble that laboratory turbulence approximates locally.

Isotropy, including reflection, was used three times: in Lemma A.742 to reduce tensor fields to scalars, in Lemma A.744 to kill the pressure term, and in Lemma A.747. Anisotropy at the large scales survives into the inertial range more persistently than K41 supposes, and the four-fifths law is correspondingly harder to observe cleanly than its exactness suggests.

Stationarity set $\partial_t R = 0$. For decaying turbulence the same calculation retains a term in ∂_t and Equation (A.1217) acquires a correction that is small only when the decay time exceeds the eddy turnover time at separation r.

The ordering of the limits. Two neglects were made, $r \ll L$ and $r \gg \eta$, and they are compatible only when $L/\eta \gg 1$, that is at large Reynolds number by Equation (31.73). The four-fifths law is a statement about an asymptotic regime, and the inertial range at attainable Reynolds numbers is short.

Finite dissipation as $\nu \to 0$. The whole argument treats ε as a fixed quantity while the viscous term is dropped. That ε tends to a non-zero limit as $\nu \to 0$ — the dissipation anomaly — is an assumption, not a theorem; it is strongly supported by measurement and it is what makes the cascade picture consistent, but it is precisely the kind of statement whose proof would require knowing that the equations have the solutions Remark 31.48 says are not known to exist.

What survives all five qualifications is still remarkable, and the comparison with Phenomenon 31.84 is the point of stating it: the exponent $-5/3$ follows from hypotheses that measurement has falsified in detail — the intermittency corrections are real — while the coefficient $-4/5$ follows from the equations themselves, and measurement has found no correction to it. Remark 31.87 sets the whole position out, and Chapter 36 collects the measurements a future theory will be asked to reproduce.

Remark A.751 (Attribution). Equation (A.1217) is Kolmogorov's, and the paper that contains it is the companion of [857] — the dissipation paper, *Doklady Akademii Nauk SSSR* **32** (1941) 16–18, recorded in the bibliographic note of that entry. The entry [857] itself is the local-structure paper, which states the similarity hypotheses used for Equation (31.71). Remark 31.86 already warns that the K41 attributions must be read carefully, the spectral form being Obukhov's [861]; the same care applies within Kolmogorov's own output, and the two 1941 papers are not interchangeable.

Remark A.752. Appendix A.63 discharges Equation (31.74) inside Remark 31.86 of Chapter 31, and with it the chapter's claim that exactly one nontrivial consequence of Equation (31.32) about turbulence is derived rather than assumed. The reader returning there

should carry back two things this section supplies and the chapter cannot: that the Kármán–Howarth relation Equation (A.1213) is exact but does *not* close, one equation in two unknown functions, which is the closure problem of Remark 31.83 in its sharpest form; and that the four-fifths law survives the non-closure only because the undetermined function is exactly the one the inertial-range limit eliminates. Everything else in Section 31.9 is dimensional analysis and measurement, as Remark 31.87 says.

A.64 The Korteweg–de Vries Equation from the Free-Surface Problem

This appendix derives Equation (31.81) of Chapter 31 from the exact equations of an ideal free-surface layer. The chapter, in the derivation of Phenomenon 31.96, takes the Korteweg–de Vries equation as given, integrates it for a travelling wave, and obtains the profile Equation (31.82) with Russell's speed Equation (31.80); what it owes, and what is supplied here, is the equation itself [265]. The travelling-wave integration is *not* repeated below — Equation (31.82) stands where it is.

The derivation is an expansion in two small parameters, and the single most important thing about it is that the relation between them is *chosen*, not deduced. That choice is stated up front in Appendix A.64.2 and revisited at Remark A.753; a reader who takes it for a consequence has misunderstood the whole calculation.

A.64.1 The exact free-surface problem

Take an ideal, incompressible, irrotational layer of undisturbed depth h over a flat rigid bottom at $y = 0$, with the free surface at $y = h + \eta(x, t)$ and gravity g acting downwards. Surface tension is set to zero here and restored in Remark A.758. By Proposition 31.28 the velocity is $\boldsymbol{v} = \boldsymbol{\nabla}\phi$ with

$$\partial_x^2\phi + \partial_y^2\phi = 0 \quad \text{for } 0 < y < h + \eta\,, \qquad \partial_y\phi = 0 \text{ at } y = 0\,, \tag{A.1219}$$

the second being impermeability of the bottom. At the surface two conditions hold, both nonlinear and both imposed on a boundary whose position is itself unknown:

$$\partial_t\eta + \partial_x\phi\,\partial_x\eta = \partial_y\phi \qquad \text{at } y = h + \eta\,, \tag{A.1220}$$

$$\partial_t\phi + \tfrac{1}{2}\left[(\partial_x\phi)^2 + (\partial_y\phi)^2\right] + g\eta = 0 \qquad \text{at } y = h + \eta\,. \tag{A.1221}$$

Equation (A.1220) says the surface is material — a particle on it stays on it — and Equation (A.1221) is the unsteady Bernoulli equation Equation (31.21) evaluated at the surface, where the pressure equals the constant atmospheric value, absorbed into ϕ.

A.64.2 Two small parameters, and a choice

Let a be a typical wave amplitude and ℓ a typical horizontal length, and set

$$\epsilon := \frac{a}{h}\,, \qquad \delta^2 := \frac{h^2}{\ell^2}\,, \qquad c_0 := \sqrt{gh}\,. \tag{A.1222}$$

Nondimensionalize by

$$x = \ell\tilde{x}\,, \quad y = h\tilde{y}\,, \quad t = \frac{\ell}{c_0}\tilde{t}\,, \quad \eta = a\tilde{\eta}\,, \quad \phi = \frac{ga\ell}{c_0}\tilde{\phi}\,, \tag{A.1223}$$

the scale for ϕ being the one that makes Equation (A.1221) balance at leading order. Substituting and dropping tildes, Equations (A.1219) to (A.1221) become exactly

$$\delta^2 \partial_x^2 \phi + \partial_y^2 \phi = 0\,, \qquad \partial_y \phi = 0 \text{ at } y = 0\,, \tag{A.1224}$$

$$\partial_t \eta + \epsilon\, \partial_x \phi\, \partial_x \eta = \frac{1}{\delta^2}\, \partial_y \phi \qquad \text{at } y = 1 + \epsilon\eta\,, \tag{A.1225}$$

$$\partial_t \phi + \frac{\epsilon}{2}\left[(\partial_x \phi)^2 + \frac{1}{\delta^2}\,(\partial_y \phi)^2 \right] + \eta = 0 \qquad \text{at } y = 1 + \epsilon\eta\,. \tag{A.1226}$$

No approximation has yet been made: the three coefficients ϵ, $1/\delta^2$ and ϵ/δ^2 are what the substitution produces, using $ga/c_0^2 = a/h = \epsilon$ and $\ell^2/h^2 = 1/\delta^2$.

Remark A.753 (The distinguished limit is a choice). Nothing so far relates ϵ to δ^2, and different relations give different equations. Taking $\epsilon \ll \delta^2$ and keeping only δ^2 gives the linear dispersive equation whose relation is Equation (A.1239) below; taking $\delta^2 \ll \epsilon$ and keeping only ϵ gives the nonlinear non-dispersive equation, whose solutions steepen and break in finite time. The Korteweg–de Vries equation is the *distinguished limit*

$$\epsilon = O\!\left(\delta^2\right)\,, \qquad \text{equivalently} \qquad \frac{a\ell^2}{h^3} = O(1)\,, \tag{A.1227}$$

in which the two effects enter at the same order and can balance. This is the entire physical content of the solitary wave — steepening against spreading, as Phenomenon 31.96 says — and it is a hypothesis about the class of initial data being described, not a consequence of the equations. Data not satisfying Equation (A.1227) are described by one of the other two limits and do not produce solitary waves. The dimensionless group in Equation (A.1227) is the Ursell number; the solitary wave of Equation (31.82) has $\ell^2 = 4h^3/3a$, i.e. Ursell number $4/3$ exactly, which is the self-consistency of the whole construction.

Both parameters are treated as first order below: terms of order ϵ and δ^2 are retained, and terms of order ϵ^2, $\epsilon\delta^2$ and δ^4 are discarded.

A.64.3 Eliminating the depth

Lemma A.754 (Exact depth expansion)**.** *Every solution of Equation* (A.1224) *analytic in* y *is*

$$\phi(x,y,t) = \sum_{n=0}^{\infty} \frac{(-1)^n\, \delta^{2n} y^{2n}}{(2n)!}\, \partial_x^{2n} F(x,t)\,, \qquad F(x,t) := \phi(x,0,t)\,, \tag{A.1228}$$

which for the retained orders reads $\phi = F - \frac{1}{2}\delta^2 y^2 \partial_x^2 F + \frac{1}{24}\delta^4 y^4 \partial_x^4 F + O(\delta^6)$.

Rests on Equation (A.1224) *and Theorem 7.38.*

Proof. *Derives Lemma A.754.*

Write $\phi = \sum_{m\geq 0} y^m \phi_m(x,t)/m!$. The bottom condition kills ϕ_1, and Equation (A.1224) gives the recursion $\phi_{m+2} = -\delta^2 \partial_x^2 \phi_m$; hence every odd coefficient vanishes and $\phi_{2n} = \left(-\delta^2\right)^n \partial_x^{2n} \phi_0$, which is Equation (A.1228) with $\phi_0 = F$. □

The lemma is exact and is what makes the problem one-dimensional: the whole vertical structure is slaved to the single function F, and the long-wave parameter δ^2 is precisely the bookkeeping parameter of that slaving. Introduce the horizontal velocity at the bottom,

$$u(x,t) := \partial_x F\,, \tag{A.1229}$$

and read off from Equation (A.1228)

$$\frac{1}{\delta^2}\partial_y \phi = -y\, \partial_x u + \frac{\delta^2 y^3}{6}\, \partial_x^3 u + O\!\left(\delta^4\right)\,, \qquad \partial_x \phi = u + O\!\left(\delta^2\right)\,, \qquad \partial_t \phi = \partial_t F - \frac{\delta^2 y^2}{2}\, \partial_x \partial_t u + O\!\left(\delta^4\right)\,. \tag{A.1230}$$

Proposition A.755 (The Boussinesq pair)**.** *To first order in ϵ and in δ^2, the free-surface conditions Equations* (A.1225) *and* (A.1226) *reduce to the closed system*

$$\partial_t \eta + \partial_x u + \epsilon\, \partial_x (\eta u) - \frac{\delta^2}{6}\, \partial_x^3 u = 0\,, \tag{A.1231}$$

$$\partial_t u + \partial_x \eta + \epsilon\, u\, \partial_x u - \frac{\delta^2}{2}\, \partial_x^2 \partial_t u = 0\,. \tag{A.1232}$$

Rests on Lemma A.754 and Equation (A.1225)*.*

Proof. *Derives Proposition A.755.*

Evaluate Equation (A.1230) at $y = 1 + \epsilon\eta$ and substitute in Equation (A.1225). The right-hand side is

$$-(1+\epsilon\eta)\,\partial_x u + \frac{\delta^2}{6}\,(1+\epsilon\eta)^3\,\partial_x^3 u + O\Big(\epsilon\delta^2, \delta^4\Big) = -\partial_x u - \epsilon\eta\,\partial_x u + \frac{\delta^2}{6}\partial_x^3 u + \cdots\,,$$

while the left-hand side is $\partial_t \eta + \epsilon u\, \partial_x \eta$. Collecting and using $\epsilon u\, \partial_x \eta + \epsilon \eta\, \partial_x u = \epsilon\, \partial_x (\eta u)$ gives Equation (A.1231).

In Equation (A.1226) the term $\epsilon\,(\partial_y \phi)^2 / 2\delta^2$ is $O(\epsilon\delta^2)$ by Equation (A.1230) and is discarded, while $\epsilon\,(\partial_x \phi)^2 / 2 = \epsilon u^2/2 + O(\epsilon\delta^2)$. Evaluating $\partial_t \phi$ at $y = 1 + \epsilon\eta$ to the retained order,

$$\partial_t F - \frac{\delta^2}{2}\,\partial_x \partial_t u + \frac{\epsilon}{2} u^2 + \eta = 0\,,$$

and differentiating once in x, with $\partial_x F = u$, gives Equation (A.1232). □

A.64.4 Unidirectional reduction

At $\epsilon = \delta^2 = 0$ the pair Equations (A.1231) and (A.1232) is $\partial_t \eta + \partial_x u = 0$, $\partial_t u + \partial_x \eta = 0$, whence $\partial_t^2 \eta = \partial_x^2 \eta$: two waves, one running each way, with $u = \eta$ on the right-running one. Restrict to that branch and correct it.

Theorem A.756 (The Korteweg–de Vries equation)**.** *A right-running solution of Equations* (A.1231) *and* (A.1232)*, correct to first order in ϵ and δ^2, has*

$$u = \eta - \frac{\epsilon}{4}\eta^2 + \frac{\delta^2}{3}\,\partial_x^2 \eta + O\Big(\epsilon^2, \epsilon\delta^2, \delta^4\Big)\,, \tag{A.1233}$$

and η obeys

$$\partial_t \eta + \partial_x \eta + \tfrac{3}{2}\epsilon\,\eta\,\partial_x \eta + \tfrac{1}{6}\delta^2\,\partial_x^3 \eta = 0\,. \tag{A.1234}$$

In dimensional variables this is

$$\frac{\partial \eta}{\partial t} + c_0 \left(1 + \frac{3\eta}{2h}\right) \frac{\partial \eta}{\partial x} + \frac{c_0 h^2}{6}\,\frac{\partial^3 \eta}{\partial x^3} = 0\,, \qquad c_0 = \sqrt{gh}\,, \tag{A.1235}$$

which is Equation (31.81)*.*

Rests on Proposition A.755 and Equation (A.1227)*.*

Proof. *Derives Theorem A.756.*

Write $u = \eta + \epsilon A + \delta^2 B$ with A and B functions of η and its x derivatives, to be determined. Substituting into Equations (A.1231) and (A.1232) and discarding second-order terms,

$$\partial_t \eta + \partial_x \eta + \epsilon\,(\partial_x A + 2\eta\,\partial_x \eta) + \delta^2 \left(\partial_x B - \tfrac{1}{6}\partial_x^3 \eta\right) = 0\,, \tag{A.1236}$$

$$\partial_t \eta + \partial_x \eta + \epsilon\,(\partial_t A + \eta\,\partial_x \eta) + \delta^2 \left(\partial_t B - \tfrac{1}{2}\partial_x^2 \partial_t \eta\right) = 0\,. \tag{A.1237}$$

Inside a term already carrying a factor ϵ or δ^2 the leading-order relation $\partial_t = -\partial_x$ may be used, since the error is of second order; so $\partial_t A = -\partial_x A$, $\partial_t B = -\partial_x B$ and $\partial_x^2 \partial_t \eta = -\partial_x^3 \eta$, and Equation (A.1237) becomes

$$\partial_t \eta + \partial_x \eta + \epsilon \left(-\partial_x A + \eta\, \partial_x \eta\right) + \delta^2 \left(-\partial_x B + \tfrac{1}{2} \partial_x^3 \eta\right) = 0 \,.$$

The two equations must be *consistent*: a single function η cannot obey two different evolution laws. Subtracting them removes the leading part and leaves

$$\epsilon \left(2\partial_x A + \eta\, \partial_x \eta\right) + \delta^2 \left(2\partial_x B - \tfrac{2}{3} \partial_x^3 \eta\right) = 0 \,,$$

and since ϵ and δ^2 are independent parameters each bracket must vanish. Integrating, and taking the constants of integration to be zero so that u vanishes with η,

$$A = -\tfrac{1}{4} \eta^2 \,, \qquad B = \tfrac{1}{3} \partial_x^2 \eta \,, \tag{A.1238}$$

which is Equation (A.1233). Adding the two equations instead, the terms in A and B cancel identically and what survives is

$$2 \left(\partial_t \eta + \partial_x \eta\right) + 3\epsilon\, \eta\, \partial_x \eta + \tfrac{1}{3} \delta^2\, \partial_x^3 \eta = 0 \,,$$

which is Equation (A.1234).

For Equation (A.1235), undo Equation (A.1223): multiplying Equation (A.1234) by $a c_0 / \ell$ and using $\partial_{\tilde t} \tilde\eta = (\ell / a c_0)\, \partial_t \eta$, $\partial_{\tilde x} \tilde\eta = (\ell / a)\, \partial_x \eta$, $\epsilon \tilde\eta \partial_{\tilde x} \tilde\eta = (\ell / a h)\, \eta\, \partial_x \eta$ and $\delta^2 \partial_{\tilde x}^3 \tilde\eta = (h^2 \ell / a)\, \partial_x^3 \eta$, every occurrence of a and ℓ cancels and Equation (A.1235) results — as it must, since a and ℓ were bookkeeping devices and no physical statement may depend on them. □

Remark A.757 (No general perturbation theory was needed). The step just carried out is what is usually called the removal of secular terms, and it is often presented as an application of the method of multiple scales. Part II carries no such method — its asymptotic material is the WKB expansion of Section 9.6 and the matched expansions named at Definition 9.86 — and none is needed. The reason is visible in the proof: because Equations (A.1231) and (A.1232) are *two* equations for the same pair of unknowns, consistency alone fixes A and B, and the freedom that a general theory would have to organize into slow and fast variables has already been used up. Had the reduction been attempted on a single equation the situation would be different, and the apparatus would be owed.

A.64.5 Two checks

The chapter asserts, without demonstration, that the two nontrivial terms of Equation (31.81) are exactly the steepening and the dispersion. Both halves can be verified against results already proved.

Drop the third derivative. Equation (A.1235) becomes $\partial_t \eta + c_0 \left(1 + 3\eta/2h\right) \partial_x \eta = 0$, a quasilinear first-order equation whose solution is constant along the characteristics $\mathrm{d}x/\mathrm{d}t = c_0 \left(1 + 3\eta/2h\right)$. Higher parts of the profile therefore travel faster and overtake lower ones, the front steepens, and after a finite time the solution becomes multivalued: this is the simple-wave steepening of Remark 31.90, which in a compressible gas ends in a shock. Note that the amplitude-dependent speed $c_0 \left(1 + 3\eta/2h\right)$ is consistent with Russell's measured $c^2 = g\,(h + a)$ only through the factor $3/2$ that the expansion supplies and dimensional analysis cannot.

Drop the nonlinear term. Setting $\eta \propto \mathrm{e}^{\mathrm{i}(kx-\omega t)}$ in Equation (A.1235) without the $\eta\,\partial_x\eta$ term gives $-\mathrm{i}\omega + \mathrm{i}c_0 k + (c_0 h^2/6)\,(\mathrm{i}k)^3 = 0$, that is

$$\omega = c_0 k\left(1 - \tfrac{1}{6}\,(kh)^2\right) . \tag{A.1239}$$

Expanding the exact gravity-wave relation Equation (31.78) at $\gamma = 0$ with $\tanh(kh) = kh - \tfrac{1}{3}\,(kh)^3 + \cdots$,

$$\omega^2 = gk\tanh(kh) = ghk^2\left(1 - \tfrac{1}{3}\,(kh)^2 + \cdots\right) \quad\Longrightarrow\quad \omega = c_0 k\left(1 - \tfrac{1}{6}\,(kh)^2 + \cdots\right) ,$$

which is Equation (A.1239) exactly, coefficient included. The third-derivative term of Equation (31.81) is therefore the first dispersive correction to the shallow-water speed and nothing else, as the chapter says.

Remark A.758 (What is not in the equation). Four idealizations were made and each has an observable consequence.

No viscosity. Equation (A.1219) is the ideal-fluid problem, so the solitary wave of Equation (31.82) propagates without loss. Real waves in a channel decay, chiefly through the boundary layer on the bed and walls (Section 31.7.2), and Russell's own observation ended when his wave died away.

No surface tension. Restoring it means replacing the constant surface pressure in Equation (A.1221) by the Young–Laplace jump Equation (31.18), and the expansion then delivers the same equation with the dispersive coefficient $(c_0 h^2/2)\left(\tfrac{1}{3} - \tau\right)$, $\tau := \gamma/\rho g h^2$ the Bond parameter. The check above confirms the coefficient independently: expanding Equation (31.78) with γ retained gives $\omega = c_0 k\left[1 - \tfrac{1}{2}\,(kh)^2\left(\tfrac{1}{3} - \tau\right)\right]$. The sign of the dispersion therefore *reverses* at $\tau = 1/3$, that is for $h < \sqrt{3\gamma/\rho g}$, about 4.7 mm for clean water with $\gamma = 7.3 \times 10^{-2}\,\mathrm{N/m}$ and $\rho = 998\,\mathrm{kg/m^3}$. In a layer thinner than that there are no elevation solitary waves, and Equation (31.82) does not apply — a limitation invisible in the chapter's statement.

Irrotational and one-directional. The reduction of Appendix A.64.4 discards the left-running wave entirely. An initial disturbance at rest splits into two, and Equation (A.1235) describes one of them.

Small amplitude. The expansion is in $\epsilon = a/h$ with $\epsilon = O(\delta^2)$, so it is valid only for $a \ll h$ — Russell's regime, as the chapter notes in the derivation of Phenomenon 31.96. Solitary waves of large amplitude exist but are not described by Equation (31.81): they have a limiting height of about $0.8h$ and a corner at the crest, neither of which this equation knows about.

Remark A.759. Appendix A.64 discharges Equation (31.81) in the derivation of Phenomenon 31.96 in Chapter 31, which takes the equation as given and proceeds from it to the profile Equation (31.82) and to Russell's speed Equation (31.80) [116]. The reader returning there now knows what the two nontrivial terms are and where each comes from — the first from the ϵ ordering of the surface conditions, the second from the δ^2 ordering of the depth expansion — and, more importantly, that their coexistence was imposed by the choice Equation (A.1227) rather than discovered. The reading of Equation (31.82) as a soliton, with the elastic collisions and the infinite hierarchy of conserved quantities that follow, belongs to Chapter 32; nothing of that is visible in the derivation above, which is why Korteweg and de Vries did not see it [265].

A.65 The Lorenz System from Boussinesq Convection

This appendix proves Definition 32.62 of Chapter 32: that Equation (32.36), with the three parameters Equation (32.37), is what the equations of a convecting fluid layer become

when they are truncated to one velocity mode and two temperature modes. The point of writing it out is stated in Remark 32.2: the Lorenz system is almost always presented as a dimensionless curiosity, and it is only by carrying the reduction through in SI variables that σ, r and b can be read back as ratios of quantities a laboratory measures. Along the way the critical Rayleigh number $\mathrm{Ra_c} = 27\pi^4/4$ and the critical wavenumber $a^2 = \frac{1}{2}$, both quoted in Definition 32.62 and in Equation (31.68), are derived.

Nothing is imported from outside the treatise. The starting equations are those of Chapter 31 — the incompressible Navier–Stokes equations Equation (31.32) and the advection–diffusion equation for heat — specialised by the Boussinesq approximation, which is that chapter's business and is discussed at Phenomenon 31.78; the linear-stability calculation and its comparison with measurement are Section 36.4. The attribution of the mode set is to Saltzman, whose 1962 study of finite convective amplitude in the *Journal of the Atmospheric Sciences* supplied the expansion Lorenz truncated; that paper has no entry in this bibliography, so the attribution is made in words, and the truncation and its consequences are Lorenz's [1262].

A.65.1 The layer, in SI units

Definition A.760 (The convecting layer)**.** A horizontal layer of fluid occupies $0 \le z \le d$, with z measured upwards against gravity $\boldsymbol{g} = -g\hat{\boldsymbol{z}}$. The lower surface is held at temperature $T_0 + \Delta T$ and the upper at T_0, so that $\Delta T > 0$ means heating from below. The fluid is characterised by four measured properties, all functions of the working substance and of its mean state:

$$\nu \ \left(\mathrm{m^2/s}\right), \quad \kappa \ \left(\mathrm{m^2/s}\right), \quad \alpha_T \ \left(1/\mathrm{K}\right), \quad \rho_0 \ \left(\mathrm{kg/m^3}\right), \tag{A.1240}$$

the kinematic viscosity, the thermal diffusivity, the coefficient of thermal expansion and the reference density; d is in m, ΔT in K and g in $\mathrm{m/s^2}$.

Rests on Theorem 31.37 and Definition 31.51.

Proposition A.761 (The Boussinesq equations)**.** *Under the Boussinesq approximation — the density is treated as the constant ρ_0 everywhere except in the buoyancy force, where it is $\rho = \rho_0\left[1 - \alpha_T\left(T - T_0\right)\right]$, and the flow is treated as incompressible — the motion of the layer of Definition A.760 obeys*

$$\frac{\partial \boldsymbol{u}}{\partial t} + \left(\boldsymbol{u}\cdot\boldsymbol{\nabla}\right)\boldsymbol{u} = -\frac{1}{\rho_0}\boldsymbol{\nabla}p' + \nu\nabla^2\boldsymbol{u} + g\alpha_T\left(T - T_0\right)\hat{\boldsymbol{z}}\,, \tag{A.1241}$$

$$\frac{\partial T}{\partial t} + \left(\boldsymbol{u}\cdot\boldsymbol{\nabla}\right)T = \kappa\nabla^2 T\,, \qquad \boldsymbol{\nabla}\cdot\boldsymbol{u} = 0\,, \tag{A.1242}$$

with p' the departure of the pressure from its hydrostatic value. The state of rest, $\boldsymbol{u} = \boldsymbol{0}$, is a solution with the conducting *temperature profile*

$$T_{\mathrm{c}}(z) = T_0 + \Delta T\left(1 - \frac{z}{d}\right). \tag{A.1243}$$

Rests on Definition A.760, Theorem 31.37, and Phenomenon 31.78.

Proof. *Derives Proposition A.761.*

Equation (A.1241) is Equation (31.32) of Theorem 31.37 with the body force $\boldsymbol{g}$ retained and the density in that force alone allowed to vary. Writing $\rho\boldsymbol{g} = -\rho_0 g\hat{\boldsymbol{z}} + \rho_0 g\alpha_T(T - T_0)\hat{\boldsymbol{z}}$ and absorbing the first, constant, piece into the pressure — which is what p' means — leaves the buoyancy term displayed. Equation (A.1242) is the advection–diffusion equation for the temperature of an incompressible fluid, viscous heating being of order $\nu U^2/(\kappa\Delta T)$ relative to the terms kept and negligible in every laboratory convection experiment. For the conducting state, put $\boldsymbol{u} = \boldsymbol{0}$ and seek a steady T: Equation (A.1242) becomes $\nabla^2 T = 0$, whose solution with the imposed boundary values is the linear profile Equation (A.1243), and Equation (A.1241) is then satisfied by a p' depending on z alone. □

Remark A.762 (What is taken from Part III and not proved here). The Boussinesq approximation is an approximation and not a limit theorem: it is justified when $\alpha_T \Delta T \ll 1$ and when the layer is thin against the density scale height, and the honest statement of its domain belongs with the convection material of Chapter 31, not here. This is an internal dependency of Part III on itself rather than a debt owed by Part II, and it is the only thing in this section taken from elsewhere. For air at room temperature $\alpha_T \approx 3.4 \times 10^{-3}/\mathrm{K}$, so a layer driven by $\Delta T = 10\,\mathrm{K}$ has $\alpha_T \Delta T = 0.034$: the approximation is good to a few per cent, which is the accuracy at which Section 36.4 tests the threshold.

A.65.2 Rolls, the stream function, and the elimination of the pressure

Definition A.763 (Two-dimensional rolls)**.** Attention is restricted to motions independent of the horizontal coordinate y — *rolls* with axes along y. The velocity is then written in terms of a *stream function* $\psi(x, z, t)$ of SI dimension m^2/s,

$$\boldsymbol{u} = (-\partial_z \psi,\ 0,\ \partial_x \psi)\ , \tag{A.1244}$$

and the temperature by its departure from the conducting profile,

$$\theta(x, z, t) = T - T_{\mathrm{c}}(z)\ \ (\mathrm{K})\ . \tag{A.1245}$$

For any pair of functions the Jacobian is written

$$J\,(f, h) = \partial_x f\, \partial_z h - \partial_z f\, \partial_x h\,, \tag{A.1246}$$

so that $(\boldsymbol{u} \cdot \boldsymbol{\nabla})\, h = J(\psi, h)$ for the field Equation (A.1244).
Rests on Proposition A.761 and Equation (31.11).

Remark A.764 (The roll ansatz is a symmetry restriction, not a two-dimensional world). Definition A.763 restricts attention to solutions of the three-dimensional equations Equation (A.1241) and Equation (A.1242) that happen not to depend on one of the three spatial coordinates. It is a symmetry ansatz inside the observed $3 + 1$ spacetime, exactly like the axisymmetric ansatz used for Stokes flow, and it is not a model of a two-dimensional universe; the fluid, the layer and the rolls are all three-dimensional objects. The ansatz is a genuine restriction — real convection at large Ra is not roll-like — and that restriction, not the dimensionality of space, is what has to be watched: it is one of the approximations listed in Remark A.771.

Proposition A.765 (The roll equations)**.** *For motions of the form Equation (A.1244), the system Equation (A.1241)–Equation (A.1242) is equivalent to the pair*

$$\partial_t \nabla^2 \psi + J\left(\psi, \nabla^2 \psi\right) = \nu \nabla^4 \psi + g \alpha_T\, \partial_x \theta\,, \tag{A.1247}$$

$$\partial_t \theta + J\,(\psi, \theta) = \frac{\Delta T}{d}\, \partial_x \psi + \kappa \nabla^2 \theta\,, \tag{A.1248}$$

in which the pressure has disappeared and ∇^2, ∇^4 act in the (x, z) plane.
Rests on Definition A.763 and Proposition A.761.

Proof. *Derives Proposition A.765.*

Incompressibility. $\boldsymbol{\nabla} \cdot \boldsymbol{u} = -\partial_x \partial_z \psi + \partial_z \partial_x \psi = 0$ identically, so Equation (A.1244) solves the constraint of Equation (A.1242) and no Lagrange multiplier is needed.

Vorticity. For a y-independent flow the vorticity has only a y component,

$$\omega_y = \partial_z u_x - \partial_x u_z = -\partial_z^2 \psi - \partial_x^2 \psi = -\nabla^2 \psi\,. \tag{A.1249}$$

Taking the y component of the curl of Equation (A.1241) annihilates the pressure gradient, since the curl of a gradient vanishes; the buoyancy term $g \alpha_T \theta \hat{\boldsymbol{z}}$ — the z-dependent part

of $T - T_0$ having been absorbed into p' along with the hydrostatic piece — contributes $-g\alpha_T \partial_x \theta$; and the advective term contributes $(\boldsymbol{u}\cdot\boldsymbol{\nabla})\,\omega_y = J(\psi,\omega_y)$, the vortex-stretching term $(\boldsymbol{\omega}\cdot\boldsymbol{\nabla})\,\boldsymbol{u}$ vanishing because $\boldsymbol{\omega}$ points along y and nothing depends on y. Hence

$$\partial_t \omega_y + J(\psi,\omega_y) = \nu\nabla^2\omega_y - g\alpha_T \partial_x\theta\,, \tag{A.1250}$$

and substituting Equation (A.1249) and multiplying through by -1 gives Equation (A.1247).

Temperature. Substituting $T = T_c + \theta$ into Equation (A.1242), and using $\nabla^2 T_c = 0$ because Equation (A.1243) is linear in z,

$$\partial_t\theta + J(\psi,\theta) + u_z \frac{\mathrm{d}T_c}{\mathrm{d}z} = \kappa\nabla^2\theta\,, \tag{A.1251}$$

and $u_z = \partial_x\psi$ with $\mathrm{d}T_c/\mathrm{d}z = -\Delta T/d$ turns the third term into $-(\Delta T/d)\,\partial_x\psi$, which moved to the right is Equation (A.1248). The physical content of that term is the whole instability: fluid rising through the mean gradient ($\partial_x\psi > 0$) arrives warmer than its surroundings, which increases θ, which by Equation (A.1247) drives more rising motion. □

A.65.3 The scaling, and the two dimensionless groups

Proposition A.766 (Nondimensionalisation)**.** *Scale lengths by d, time by d^2/κ, the stream function by κ and the temperature departure by $\nu\kappa/(g\alpha_T d^3)$,*

$$x = d\tilde{x}\,,\quad z = d\tilde{z}\,,\quad t = \frac{d^2}{\kappa}\tilde{t}\,,\quad \psi = \kappa\tilde{\psi}\,,\quad \theta = \frac{\nu\kappa}{g\alpha_T d^3}\tilde{\theta}\,. \tag{A.1252}$$

Then Equation (A.1247)–Equation (A.1248) become, with the tildes dropped,

$$\frac{1}{\sigma}\left[\partial_t\nabla^2\psi + J\left(\psi,\nabla^2\psi\right)\right] = \nabla^4\psi + \partial_x\theta\,, \tag{A.1253}$$

$$\partial_t\theta + J(\psi,\theta) = \mathrm{Ra}\,\partial_x\psi + \nabla^2\theta\,, \tag{A.1254}$$

and exactly two dimensionless groups survive, the Prandtl and Rayleigh numbers

$$\sigma = \frac{\nu}{\kappa}\,,\qquad \mathrm{Ra} = \frac{g\alpha_T\,\Delta T\,d^3}{\nu\kappa}\,, \tag{A.1255}$$

which are Equation (32.37) and Equation (32.38).

Rests on Proposition A.765 and Definition 31.51.

Proof. *Derives Proposition A.766.*

Under Equation (A.1252), $\nabla^2 = d^{-2}\tilde{\nabla}^2$, $\partial_t = (\kappa/d^2)\,\partial_{\tilde{t}}$ and $J = d^{-2}\tilde{J}$ acting on the scaled fields. The four terms of Equation (A.1247) then carry the prefactors

$$\frac{\kappa^2}{d^4}\,,\quad \frac{\kappa^2}{d^4}\,,\quad \frac{\nu\kappa}{d^4}\,,\quad g\alpha_T\cdot\frac{1}{d}\cdot\frac{\nu\kappa}{g\alpha_T d^3} = \frac{\nu\kappa}{d^4}\,, \tag{A.1256}$$

so dividing by κ^2/d^4 leaves the factor $\nu/\kappa = \sigma$ on the right-hand pair and gives Equation (A.1253). The four terms of Equation (A.1248) carry

$$\frac{\nu\kappa^2}{g\alpha_T d^5}\,,\quad \frac{\nu\kappa^2}{g\alpha_T d^5}\,,\quad \frac{\Delta T\,\kappa}{d^2}\,,\quad \frac{\nu\kappa^2}{g\alpha_T d^5}\,, \tag{A.1257}$$

and dividing by the first leaves the third with the factor

$$\frac{\Delta T\,\kappa}{d^2}\cdot\frac{g\alpha_T d^5}{\nu\kappa^2} = \frac{g\alpha_T\Delta T d^3}{\nu\kappa} = \mathrm{Ra}\,, \tag{A.1258}$$

which is Equation (A.1254).

The dimension check. It is worth carrying out in full, because it is what allows σ and r to be read back as measurements:

$$[\mathrm{Ra}] = \frac{(\mathrm{m/s^2})\,(1/\mathrm{K})\,(\mathrm{K})\,(\mathrm{m^3})}{(\mathrm{m^2/s})\,(\mathrm{m^2/s})} = \frac{\mathrm{m^4/s^2}}{\mathrm{m^4/s^2}} = 1\,, \tag{A.1259}$$

and $\sigma = \nu/\kappa$ is a ratio of two quantities in $\mathrm{m^2/s}$, so both are pure numbers, as Definition 31.51 requires. That no third group appears is the substance of the reduction: the four material properties Equation (A.1240) and the three imposed quantities $g, \Delta T, d$ enter the scaled equations only through σ and Ra, and ρ_0 has dropped out entirely, having been absorbed into p'. □

A.65.4 Linear stability and the critical Rayleigh number

Theorem A.767 (Marginal stability of the conducting state)**.** *Let the boundaries $z = 0, 1$ be* stress-free *and perfectly conducting, so that $\psi = \partial_z^2 \psi = \theta = 0$ there. Then the conducting state is marginally stable to the roll disturbance of dimensionless horizontal wavenumber πa precisely when*

$$\mathrm{Ra} = \mathrm{Ra_c}(a) \equiv \frac{\pi^4 \left(1 + a^2\right)^3}{a^2}\,, \tag{A.1260}$$

and the minimum of Equation (A.1260) over a is attained at $a^2 = \frac{1}{2}$, where

$$\mathrm{Ra_c} = \frac{\pi^4\,(3/2)^3}{1/2} = \frac{27\pi^4}{4} = 657.5\,, \tag{A.1261}$$

the value quoted in Definition 32.62 and in Equation (31.68).

Rests on Proposition A.766 and Phenomenon 31.78.

Proof. *Derives Theorem A.767.*

Linearisation. Drop the Jacobians from Equation (A.1253)–Equation (A.1254); they are quadratic in the disturbance and cannot affect the threshold.

The modes. Take

$$\psi = \Psi \sin(\pi a x) \sin(\pi z)\,, \qquad \theta = \Theta \cos(\pi a x) \sin(\pi z)\,, \tag{A.1262}$$

which satisfy every boundary condition: $\sin(\pi z)$ and its second derivative vanish at $z = 0, 1$. Both are eigenfunctions of the Laplacian, $\nabla^2 \to -k^2$ with

$$k^2 = \pi^2 \left(1 + a^2\right)\,, \tag{A.1263}$$

the sum of the squared horizontal wavenumber πa and the squared vertical wavenumber π. Marginal stability means a steady disturbance, so set $\partial_t = 0$.

The two-by-two system. With $\partial_x \theta = -\pi a \Theta \sin(\pi a x) \sin(\pi z)$ and $\partial_x \psi = \pi a \Psi \cos(\pi a x) \sin(\pi z)$, the two linearised equations reduce to

$$0 = k^4 \Psi - \pi a \Theta\,, \qquad 0 = \mathrm{Ra}\,\pi a \Psi - k^2 \Theta\,. \tag{A.1264}$$

A nonzero solution exists exactly when the determinant vanishes, $k^4 \cdot k^2 = \mathrm{Ra}\,\pi^2 a^2$, that is

$$\mathrm{Ra} = \frac{k^6}{\pi^2 a^2} = \frac{\pi^6 \left(1 + a^2\right)^3}{\pi^2 a^2} = \frac{\pi^4 \left(1 + a^2\right)^3}{a^2}\,, \tag{A.1265}$$

which is Equation (A.1260).

The minimum. Write $X = a^2 > 0$ and $F(X) = (1+X)^3/X$. Then

$$F'(X) = \frac{3(1+X)^2 X - (1+X)^3}{X^2} = \frac{(1+X)^2(2X-1)}{X^2}, \tag{A.1266}$$

which is negative for $X < \frac{1}{2}$ and positive for $X > \frac{1}{2}$: the unique minimum is at $X = a^2 = \frac{1}{2}$, and substituting gives Equation (A.1261). Numerically $27\pi^4/4 = 657.51$. The corresponding horizontal wavelength is $2\pi/(\pi a) = 2/a = 2\sqrt{2}$ in units of d, which is the $\lambda_c = 2\sqrt{2}\,d$ of Equation (31.68): convection cells are about 1.4 times as wide as the layer is deep, a prediction with no free parameter that Section 36.4 tests. □

Remark A.768 (Two conventions for the wavenumber). Chapter 31 writes the marginal curve as $\mathrm{Ra}(a) = (\pi^2 + a^2)^3/a^2$ and Chapter 32 writes it as Equation (A.1260); the two are the same curve in different variables, and a reader comparing them will otherwise think one of them wrong. In Chapter 31 the symbol a is the horizontal wavenumber itself, in units of $1/d$; here and in Definition 32.62 it is that wavenumber in units of π/d, so that $a_{\text{ch. 14}} = \pi a$. Substituting turns one expression into the other, and the minimum sits at $a^2 = \pi^2/2$ in the first convention and $a^2 = \frac{1}{2}$ in the second. The second is used here because it is the one in which Equation (32.37) reads $b = 4/(1+a^2)$, giving Lorenz's $b = 8/3$.

Rests on Theorem A.767 and Equation (31.68).

A.65.5 The Galerkin truncation

Theorem A.769 (The Lorenz system)**.** *Fix a horizontal wavenumber a. Write $\tilde{x}$ for the dimensionless horizontal coordinate and z for the dimensionless vertical one, reserving $x(s)$, $y(s)$ and $z_*(s)$ for the three amplitudes — these last are the x, y and z of Equation (32.36), decorated here only so that no symbol does two jobs. Substitute into Equation (A.1253)–Equation (A.1254) the three-mode ansatz*

$$\psi = \frac{\sqrt{2}\,(1+a^2)}{a}\, x(s)\, \sin(\pi a \tilde{x}) \sin(\pi z), \tag{A.1267}$$

$$\theta = \frac{\mathrm{Ra}_c(a)}{\pi}\left[\sqrt{2}\, y(s) \cos(\pi a \tilde{x}) \sin(\pi z) - z_*(s) \sin(2\pi z)\right], \tag{A.1268}$$

with the dimensionless time

$$s = \pi^2\left(1+a^2\right)\tilde{t} = \frac{\pi^2(1+a^2)\,\kappa t}{d^2}, \tag{A.1269}$$

and project the resulting equations onto the three modes. Discarding the single term that leaves the retained set, the amplitudes obey

$$\dot{x} = \sigma(y - x), \qquad \dot{y} = x(r - z_*) - y, \qquad \dot{z}_* = xy - b z_*, \tag{A.1270}$$

with the dot denoting $\mathrm{d}/\mathrm{d}s$ *and*

$$\sigma = \frac{\nu}{\kappa}, \qquad r = \frac{\mathrm{Ra}}{\mathrm{Ra}_c(a)}, \qquad b = \frac{4}{1+a^2}. \tag{A.1271}$$

These are Equation (32.36) and Equation (32.37); at the critical wavenumber $a^2 = \frac{1}{2}$ they give $b = 8/3$.

Rests on Proposition A.766, Theorem A.767, and Definition 32.62.

Proof. *Derives Theorem A.769.*

Write $\tilde{x}$ for the horizontal coordinate throughout, to keep it apart from the amplitude $x(s)$, and z_* for the third amplitude, to keep it apart from the vertical coordinate z. Put

$$\psi = A\, x\, S_1, \qquad \theta = B\, y\, C_1 - C\, z_* S_2, \tag{A.1272}$$

with constants A, B, C to be determined and the abbreviations

$$S_1 = \sin(\pi a\tilde{x})\sin(\pi z)\ , \quad C_1 = \cos(\pi a\tilde{x})\sin(\pi z)\ , \quad S_2 = \sin(2\pi z)\ . \tag{A.1273}$$

All three are mutually orthogonal over one horizontal period and over $0 \le z \le 1$, and all satisfy the boundary conditions of Theorem A.767.

Step 1: the vorticity equation has no nonlinearity. Since $\nabla^2\psi = -k^2\psi$ with k^2 from Equation (A.1263), the Jacobian $J(\psi, \nabla^2\psi) = -k^2 J(\psi,\psi) = 0$ identically: a single roll does not advect its own vorticity. Using $\partial_{\tilde{t}} = k^2 \mathrm{d}/\mathrm{d}s$ from Equation (A.1269), Equation (A.1253) becomes

$$-\frac{k^4 A\dot{x}}{\sigma} S_1 = k^4 A\, x\, S_1 - \pi a B\, y\, S_1\,, \tag{A.1274}$$

because $\partial_{\tilde{x}} C_1 = -\pi a S_1$ and the S_2 term of θ is independent of $\tilde{x}$. Dividing by $-k^4 A/\sigma$,

$$\dot{x} = \sigma\left(\frac{\pi a B}{k^4 A}\, y - x\right)\ , \tag{A.1275}$$

which is the first of Equation (A.1270) provided

$$\pi a B = k^4 A\,. \tag{A.1276}$$

Step 2: the Jacobian in the temperature equation, in full. This is the step that decides whether three modes close, and it cannot be seen without doing it. From Equation (A.1272),

$$\begin{aligned} \partial_{\tilde{x}}\psi &= \pi a A\, x\, C_1\,, \qquad \partial_z\psi = \pi A\, x\, \sin(\pi a\tilde{x})\cos(\pi z)\ , \\ \partial_{\tilde{x}}\theta &= -\pi a B\, y\, S_1\,, \quad \partial_z\theta = \pi B\, y \cos(\pi a\tilde{x})\cos(\pi z) - 2\pi C\, z_* \cos(2\pi z)\ . \end{aligned} \tag{A.1277}$$

Assembling $J(\psi,\theta) = \partial_{\tilde{x}}\psi\,\partial_z\theta - \partial_z\psi\,\partial_{\tilde{x}}\theta$ gives three products. The two involving y combine, since

$$\pi^2 a A B\, xy\left[\cos^2(\pi a\tilde{x}) + \sin^2(\pi a\tilde{x})\right]\sin(\pi z)\cos(\pi z) = \frac{\pi^2 a A B}{2}\, xy\, S_2\,, \tag{A.1278}$$

using $\sin\phi\cos\phi = \frac{1}{2}\sin 2\phi$: the horizontal dependence cancels completely, and what is left is a mode with *twice* the vertical wavenumber and no horizontal structure. That is the physical origin of the third mode — a roll carrying warm fluid up on one side and cool fluid down on the other distorts the horizontally averaged temperature profile — and it is why z_* must be kept. The remaining product is

$$-2\pi^2 a A C\, x z_* \cos(\pi a\tilde{x})\sin(\pi z)\cos(2\pi z) = -\pi^2 a A C\, x z_* \cos(\pi a\tilde{x})\left[\sin(3\pi z) - \sin(\pi z)\right]\ , \tag{A.1279}$$

by $\sin\phi\cos 2\phi = \frac{1}{2}\left[\sin 3\phi - \sin\phi\right]$. Its $\sin(\pi z)$ half is $+\pi^2 a A C\, x z_* C_1$, a term in the retained set; its $\sin(3\pi z)$ half is not, and it is the *only* term produced anywhere in the calculation that leaves the three-mode set. Discarding it is the entire content of the truncation.

Step 3: projection. Insert Equation (A.1278), the retained half of Equation (A.1279), and $\partial_{\tilde{x}}\psi = \pi a A\, x\, C_1$ into Equation (A.1254), use $\nabla^2 C_1 = -k^2 C_1$ and $\nabla^2 S_2 = -4\pi^2 S_2$, and collect the coefficients of the two orthogonal modes. The C_1 component gives

$$k^2 B\dot{y} + \pi^2 a A C\, x z_* = \mathrm{Ra}\,\pi a A\, x - k^2 B\, y\,, \tag{A.1280}$$

and the S_2 component, remembering the minus sign carried by z_* in Equation (A.1272), gives

$$-k^2 C\dot{z}_* + \frac{\pi^2 a A B}{2}\, xy = 4\pi^2 C\, z_*\,. \tag{A.1281}$$

Step 4: fixing the constants. Dividing Equation (A.1280) by k^2B and Equation (A.1281) by $-k^2C$,

$$\dot{y} = \frac{\mathrm{Ra}\,\pi a A}{k^2 B}x - y - \frac{\pi^2 a A C}{k^2 B}xz_* \,, \qquad \dot{z}_* = \frac{\pi^2 a A B}{2k^2 C}xy - \frac{4\pi^2}{k^2}z_* \,. \tag{A.1282}$$

Comparison with Equation (A.1270) imposes three conditions, to be read together with Equation (A.1276):

$$\frac{\mathrm{Ra}\,\pi a A}{k^2 B} = r \,, \qquad \frac{\pi^2 a A C}{k^2 B} = 1 \,, \qquad \frac{\pi^2 a A B}{2k^2 C} = 1 \,. \tag{A.1283}$$

The last two give $C = k^2 B/\left(\pi^2 a A\right)$ and $C = \pi^2 a A B/\left(2k^2\right)$; equating them yields $\pi^4 a^2 A^2 = 2k^4$, hence

$$A = \frac{\sqrt{2}\,k^2}{\pi^2 a} = \frac{\sqrt{2}\,(1+a^2)}{a} \,, \tag{A.1284}$$

by Equation (A.1263), which is the coefficient in Equation (A.1267). Then Equation (A.1276) gives

$$B = \frac{k^4 A}{\pi a} = \frac{\sqrt{2}\,k^6}{\pi^3 a^2} = \frac{\sqrt{2}}{\pi}\,\frac{k^6}{\pi^2 a^2} = \frac{\sqrt{2}\,\mathrm{Ra_c}(a)}{\pi} \,, \tag{A.1285}$$

the last equality being Equation (A.1265), and $C = k^2 B/(\pi^2 a A) = B/\sqrt{2} = \mathrm{Ra_c}(a)/\pi$ after substituting Equation (A.1284). With $\theta = By\,C_1 - Cz_* S_2$ this is exactly Equation (A.1268). Finally the first of Equation (A.1283) reads, using Equation (A.1276),

$$r = \frac{\mathrm{Ra}\,\pi a A}{k^2 B} = \mathrm{Ra}\,\frac{\pi^2 a^2}{k^6} = \frac{\mathrm{Ra}}{\mathrm{Ra_c}(a)} \,, \tag{A.1286}$$

and the last term of Equation (A.1282) gives

$$b = \frac{4\pi^2}{k^2} = \frac{4\pi^2}{\pi^2\,(1+a^2)} = \frac{4}{1+a^2} \,, \tag{A.1287}$$

which completes Equation (A.1271). At $a^2 = \frac{1}{2}$, $b = 4/(3/2) = 8/3$. □

A.65.6 Reading the parameters back

Remark A.770 (What the three variables and three parameters are). Undoing the scaling Equation (A.1252) makes every symbol of Equation (32.36) a statement about the layer. *The variables.* x is the amplitude of the convective roll: the physical stream function is $\kappa\,A\,x\,S_1$, so the fluid speed is of order $(\kappa/d)\,(1+a^2)\,|x|$ — $2\times10^{-5}\,\mathrm{m^2/s}$ divided by a centimetre, of order 1 mm/s for air at $|x|$ of order unity. y measures the horizontal temperature variation at the roll's own wavenumber, and z_* the horizontally averaged distortion of the vertical temperature profile. Their common temperature scale is not arbitrary: substituting Equation (A.1285) into Equation (A.1252) gives

$$\frac{\nu\kappa}{g\alpha_T d^3}\cdot\frac{\mathrm{Ra_c}(a)}{\pi} = \frac{\Delta T_\mathrm{c}}{\pi} \,, \tag{A.1288}$$

where ΔT_c is the temperature difference at which that wavenumber first becomes unstable — so y and z_* are temperature departures measured in units of the critical driving difference divided by π. *The parameters.* $\sigma = \nu/\kappa$ is the Prandtl number of the working fluid alone: about 0.71 for air, 7 for water at 20 °C, of order 0.02 for liquid sodium and 10^2 or more for oils. Lorenz's $\sigma = 10$ is therefore a plausible fluid and not a dial setting. $r = \mathrm{Ra}/\mathrm{Ra_c}$ is the imposed temperature difference in units of the one that starts convection, so $r = 28$ means a layer driven 28 times past onset. $b = 4/(1+a^2)$ is a pure function of the horizontal wavenumber of the roll and of nothing else at all.

Rests on Theorem A.769 and Remark 32.2.

Remark A.771 (What was assumed, and where it fails). Five approximations were made, and they are of quite different standing. *One* is the Boussinesq approximation (Remark A.762), good to a few per cent in ordinary laboratory convection. *Two* is the restriction to rolls (Remark A.764), which is a fact about the observed flow only near onset. *Three* is stress-free boundaries, chosen because they make $\sin \pi z$ an exact eigenfunction; the laboratory case of two rigid plates gives $\mathrm{Ra_c} \approx 1708$ instead of 657.5 (Phenomenon 31.78) and no closed-form modes at all, so the tidy arithmetic above is bought with a boundary condition no experiment has. *Four* is the fixing of a single horizontal wavenumber a, which suppresses every interaction between cells of different sizes. *Five*, and the serious one, is the discarding of the $\sin(3\pi z)$ term at Equation (A.1279). That discarded term is small only while the convection is weak. At Lorenz's $r = 28$ it is not small, the neglected modes are not small, and Lorenz said so plainly in the paper that introduced the system [1262]. The projection is *exact* on the linear terms — which is why Theorem A.767 is a genuine result about fluids — and an approximation on the nonlinear ones, which is why Equation (32.36) beyond onset is a model of convection and not convection. Remark 32.63 makes the same point in the chapter, and the two statements are meant to stand together: what Equation (32.36) is good for is the study of a low-dimensional dissipative flow that happens to have been derived from a fluid, not the prediction of a heat flux.

Rests on Theorem A.769 and Remark 32.63.

Remark A.772. Appendix A.65 discharges the derivation owed at Definition 32.62 of Chapter 32. The four stages announced there are Appendix A.65.2 (the stream function, which eliminates the pressure), Appendix A.65.3 (the explicit scaling and the two dimensionless groups Equation (32.38)), Appendix A.65.4 (the linear stability calculation giving $\mathrm{Ra_c} = 27\pi^4/4$ at $a^2 = \frac{1}{2}$ for stress-free boundaries [438]), and Appendix A.65.5 (the Galerkin truncation producing Equation (32.36) with the parameters Equation (32.37)). Everything the chapter builds on Equation (32.36) — the volume contraction, the fixed points, the strange attractor — is derived there and does not depend on this section; what this section supplies is the licence to call σ, r and b measurements rather than dials, which is the demand Remark 32.2 makes of every model in that chapter.

A.66 Rayleigh Acoustic Streaming Above a Vibrating Surface

This appendix supplies the derivation owed at Phenomenon 35.8 of Chapter 35: the steady second-order flow that an oscillating boundary drives in the fluid above it, and the direction of its outer branch, which is what carries a light powder to the antinodes of a sounding plate where sand collects at the nodes [39, 88].

The scope is fixed in advance by Remark 35.9 of the chapter and is not widened here. What is derived is the streaming velocity, its coefficient, and the sense of the circulation. What is *not* derived is a threshold grain radius separating sand from lycopodium: that comparison turns on the grain's adhesion to the plate, which this treatise does not model. The reader should hold the chapter's bound in view throughout, because the calculation below is exact enough to invite being pushed further than it can go.

A.66.1 What is quoted here

No theorem. The whole argument is an expansion of the incompressible Navier–Stokes equations Equation (31.32) of Chapter 31 in the amplitude of the motion, and every step — the linear boundary-layer solution, the time averages, and five elementary integrals — is carried out here.

Three things are *assumed* rather than proved, and all three are statements about the physical regime rather than about mathematics. The fluid is treated as incompressible

within a plate wavelength, which requires the acoustic wavelength in air to be much the longer of the two (Lemma A.777 states the condition and Example A.779 checks it). The motion is assumed to have settled into a state that is steady in the mean, so that $\langle \partial_t \boldsymbol{v}_2 \rangle = 0$. And the expansion is assumed to be asymptotic in the amplitude, which is the usual and unproved status of such expansions in fluid mechanics.

The result derived below is Rayleigh's, published in 1884 in the *Philosophical Transactions* under the title "On the circulation of air observed in Kundt's tubes, and on some allied acoustical problems". That paper has no key in `references.bib` — `Rayleigh:1883` there is the paper on the equilibrium of a heavy fluid of variable density, a different work, and citing it here would be exactly the misattribution the editorial rules warn against — so the attribution is made in words, on the footing of Darboux's memoir in Remark A.81. Nothing below rests on it.

A.66.2 Why the effect cannot appear before second order

Write $\langle \cdot \rangle$ for the average over one period $2\pi/\omega$ of the driving, and expand every field in the dimensionless amplitude ϵ of the boundary motion:

$$\boldsymbol{v} = \epsilon\, \boldsymbol{v}_1 + \epsilon^2 \boldsymbol{v}_2 + \cdots , \qquad p = p_0 + \epsilon\, p_1 + \epsilon^2 p_2 + \cdots . \tag{A.1289}$$

At first order the equations are linear with coefficients independent of t and the forcing is $\propto \cos \omega t$, so every first-order field is a harmonic function of time of the same frequency and

$$\langle \boldsymbol{v}_1 \rangle = 0 . \tag{A.1290}$$

A tracer carried by the fluid therefore returns, at first order, to where it started after each period: there is no steady transport whatever. Steady transport first appears at order ϵ^2, and it appears there because the average of a *product* of two oscillating quantities of the same frequency need not vanish even though each factor averages to zero. That is the entire physical content of the phenomenon, and it is why Phenomenon 35.8 cannot be obtained from any first-order acoustic quantity, however cleverly combined.

A.66.3 The first-order Stokes layer

Proposition A.773 (The oscillating boundary layer)**.** *Let a plane wall occupy $y = 0$ with fluid in $y > 0$, and let the outer acoustic field impose, just outside the layer, the tangential velocity $u_\infty = U(x) \cos \omega t$, with U varying on a length scale much greater than the layer thickness. Then the first-order velocity satisfying no slip at the wall is*

$$u_1 = U(x) \left[\cos \omega t - \mathrm{e}^{-\eta} \cos\left(\omega t - \eta\right) \right] , \qquad \eta := \frac{y}{\delta} , \tag{A.1291}$$

with the Stokes-layer thickness

$$\delta := \sqrt{\frac{2\nu}{\omega}} , \tag{A.1292}$$

in m*, and the wall-normal component follows from continuity as*

$$v_1 = -\frac{\mathrm{d}U}{\mathrm{d}x}\, \delta\, \Re\left[H(\eta)\, \mathrm{e}^{\mathrm{i}\omega t} \right] , \qquad H(\eta) := \eta - \frac{h(\eta)}{1+\mathrm{i}} , \tag{A.1293}$$

where $h(\eta) := 1 - E(\eta)$ and $E(\eta) := \mathrm{e}^{-(1+\mathrm{i})\eta}$, so that $u_1 = U\, \Re\left[h\, \mathrm{e}^{\mathrm{i}\omega t} \right]$.
Rests on Equations (31.32) *and* (A.1289).

Proof. *Derives Proposition A.773.*

At first order Equation (31.32) linearizes to $\partial_t u_1 = -\rho^{-1} \partial_x p_1 + \nu\, \partial_y^2 u_1$, the convective terms being of second order and the streamwise viscous term smaller than the transverse

one by the square of the ratio of the layer thickness to the scale of U. The outer field carries no shear, so it satisfies $\partial_t u_\infty = -\rho^{-1}\partial_x p_1$; and by Equation (A.1289) applied to the pressure together with the thinness of the layer, p_1 has the same value inside the layer as just outside it. Subtracting,

$$\partial_t \left(u_1 - u_\infty\right) = \nu\, \partial_y^2 \left(u_1 - u_\infty\right) , \tag{A.1294}$$

since $\partial_y^2 u_\infty = 0$. Seek $u_1 - u_\infty = \Re\left[A(x)\, \mathrm{e}^{\mathrm{i}\omega t}\mathrm{e}^{-\gamma y}\right]$: then $\mathrm{i}\omega = \nu\gamma^2$, so $\gamma = \sqrt{\mathrm{i}\omega/\nu} = (1+\mathrm{i})/\delta$ with δ as in Equation (A.1292), the root with positive real part being the one that decays. No slip at $y = 0$ requires $u_1 = 0$ there, so $A = -U(x)$ and

$$u_1 = U\, \Re\left[\left(1 - \mathrm{e}^{-(1+\mathrm{i})\eta}\right) \mathrm{e}^{\mathrm{i}\omega t}\right] = U\, \Re\left[h\, \mathrm{e}^{\mathrm{i}\omega t}\right] , \tag{A.1295}$$

and expanding the real part with $\mathrm{e}^{-(1+\mathrm{i})\eta}\mathrm{e}^{\mathrm{i}\omega t} = \mathrm{e}^{-\eta}\mathrm{e}^{\mathrm{i}(\omega t - \eta)}$ gives Equation (A.1291).

For v_1, integrate continuity $\partial_x u_1 + \partial_y v_1 = 0$ upward from the wall, where $v_1 = 0$:

$$v_1 = -\int_0^y \partial_x u_1 \, \mathrm{d}y' = -\frac{\mathrm{d}U}{\mathrm{d}x}\, \delta\, \Re\left[\mathrm{e}^{\mathrm{i}\omega t} \int_0^\eta h \, \mathrm{d}\eta'\right] , \tag{A.1296}$$

and

$$\int_0^\eta h \, \mathrm{d}\eta' = \int_0^\eta \left(1 - \mathrm{e}^{-(1+\mathrm{i})\eta'}\right) \mathrm{d}\eta' = \eta - \frac{1-E}{1+\mathrm{i}} = \eta - \frac{h}{1+\mathrm{i}} = H , \tag{A.1297}$$

which is Equation (A.1293). Note that v_1 carries the factor $\mathrm{d}U/\mathrm{d}x$: a spatially uniform oscillation drives no normal motion, and it will drive no streaming either. □

A.66.4 The second-order mean flow and the slip velocity

Lemma A.774 (The layer is driven by the excess Reynolds stress)**.** *Let $\langle u_2 \rangle$ be the time-averaged second-order streamwise velocity. Then, to leading order in the thinness of the layer,*

$$\mu\, \partial_y^2 \langle u_2 \rangle = F(y) , \qquad F := \rho \left[\langle u_1 \partial_x u_1 + v_1 \partial_y u_1 \rangle - \langle u_\infty \partial_x u_\infty \rangle\right] , \tag{A.1298}$$

with $\langle u_2 \rangle = 0$ at $y = 0$ and $\partial_y \langle u_2 \rangle \to 0$ as $\eta \to \infty$. Consequently

$$u_s := \lim_{\eta\to\infty} \langle u_2 \rangle = -\frac{1}{\mu} \int_0^\infty y\, F(y) \, \mathrm{d}y . \tag{A.1299}$$

Rests on Proposition A.773 and Equations (31.32) and (A.1290).

Proof. *Derives Lemma A.774.*

Take the streamwise component of Equation (31.32) at order ϵ^2 and average over a period. The unsteady term averages to zero in a state steady in the mean; the convective terms contribute $\langle u_1 \partial_x u_1 + v_1 \partial_y u_1 \rangle$, since the second-order velocity's own convection is of fourth order; and of the viscous term only $\nu\, \partial_y^2 \langle u_2 \rangle$ survives, by the same comparison of transverse with streamwise gradients used in Proposition A.773. Hence

$$\mu\, \partial_y^2 \langle u_2 \rangle = \rho \langle u_1 \partial_x u_1 + v_1 \partial_y u_1 \rangle + \partial_x \langle p_2 \rangle . \tag{A.1300}$$

Now evaluate the same equation just outside the layer, where the field is the irrotational u_∞ and there is no mean shear. There

$$0 = \rho \langle u_\infty \partial_x u_\infty \rangle + \partial_x \langle p_2 \rangle , \tag{A.1301}$$

that is, the Reynolds stress of an irrotational oscillation is balanced entirely by the second-order mean pressure and drives nothing. The layer is thin, so $\langle p_2 \rangle$ is the same function of x inside it as immediately outside; subtracting Equation (A.1301) from Equation (A.1300)

eliminates the pressure and leaves Equation (A.1298). By construction $F \to 0$ as $\eta \to \infty$, and exponentially, since $u_1 \to u_\infty$ exponentially.

For the boundary conditions: no slip holds at every order, so $\langle u_2 \rangle (0) = 0$; and the mean shear at the outer edge of the layer belongs to the outer streaming, which varies on the acoustic length scale rather than on δ and is therefore negligible here. Then integrating Equation (A.1298) downward from infinity, $\mu\, \partial_y \langle u_2 \rangle (y) = -\int_y^\infty F \,\mathrm{d}y'$, and integrating that upward from the wall,

$$\mu\, u_s = -\int_0^\infty \int_y^\infty F(y')\,\mathrm{d}y'\,\mathrm{d}y = -\int_0^\infty F(y') \int_0^{y'} \mathrm{d}y\,\mathrm{d}y' = -\int_0^\infty y' F(y')\,\mathrm{d}y' \,, \tag{A.1302}$$

the exchange of the order of integration being legitimate because F decays exponentially. That is Equation (A.1299). □

Theorem A.775 (Rayleigh's limiting velocity)**.** *With U and δ as above,*

$$u_s = -\frac{3}{4\omega}\, U \frac{\mathrm{d}U}{\mathrm{d}x} = -\frac{3}{4\omega} \frac{\mathrm{d}\,\langle u_\infty^2 \rangle}{\mathrm{d}x} \,, \tag{A.1303}$$

in m/s. *The viscosity has cancelled: u_s does not contain ν, and the thickness δ of the layer that produced it does not appear.*

Rests on Lemma A.774 and Equations (A.1291) *and* (A.1293).

Proof. *Derives Theorem A.775.*

Write $g(\eta, t) := \Re\left[h\, \mathrm{e}^{\mathrm{i}\omega t}\right]$ and $G(\eta, t) := \Re\left[H\, \mathrm{e}^{\mathrm{i}\omega t}\right]$, so that by Proposition A.773

$$u_1 = U g \,, \qquad \partial_x u_1 = U' g \,, \qquad \partial_y u_1 = \frac{U}{\delta} \partial_\eta g \,, \qquad v_1 = -U' \delta\, G \,, \tag{A.1304}$$

with $U' = \mathrm{d}U/\mathrm{d}x$. The two Reynolds-stress terms are therefore

$$\langle u_1 \partial_x u_1 \rangle = U U' \left\langle g^2 \right\rangle \,, \qquad \langle v_1 \partial_y u_1 \rangle = -U U' \left\langle G\, \partial_\eta g \right\rangle \,, \tag{A.1305}$$

the factor δ cancelling between v_1 and $\partial_y u_1$ — which is already the reason the answer will not contain the layer thickness. Since $\langle u_\infty \partial_x u_\infty \rangle = U U' \left\langle \cos^2 \omega t \right\rangle = \frac{1}{2} U U'$,

$$F = \rho\, U U'\, \Psi(\eta) \,, \qquad \Psi := \left\langle g^2 \right\rangle - \left\langle G\, \partial_\eta g \right\rangle - \tfrac{1}{2} \,. \tag{A.1306}$$

Evaluating Ψ. For two quantities written as $\Re\left[A \mathrm{e}^{\mathrm{i}\omega t}\right]$ and $\Re\left[B \mathrm{e}^{\mathrm{i}\omega t}\right]$ the period average of the product is $\frac{1}{2} \Re\left[A \bar{B}\right]$. With $\partial_\eta g = \Re\left[h' \mathrm{e}^{\mathrm{i}\omega t}\right]$ and $h' = (1 + \mathrm{i})\, E$,

$$2\Psi = |h|^2 - 1 - \Re\left[H \overline{h'}\right] \,. \tag{A.1307}$$

Now $h = 1 - E$ with $E = \mathrm{e}^{-\eta} \mathrm{e}^{-\mathrm{i}\eta}$, so

$$|h|^2 - 1 = -2\Re E + |E|^2 = -2\mathrm{e}^{-\eta} \cos\eta + \mathrm{e}^{-2\eta} \,, \tag{A.1308}$$

and, using $\overline{h'} = (1 - \mathrm{i})\, \bar{E}$ together with $(1 - \mathrm{i}) \,/\, (1 + \mathrm{i}) = -\mathrm{i}$,

$$H \overline{h'} = \left[\eta - \frac{1 - E}{1 + \mathrm{i}}\right] (1 - \mathrm{i})\, \bar{E} = \eta\, (1 - \mathrm{i})\, \bar{E} + \mathrm{i} \bar{E} - \mathrm{i}\, |E|^2 \,. \tag{A.1309}$$

Taking real parts with $\bar{E} = \mathrm{e}^{-\eta}\, (\cos\eta + \mathrm{i} \sin\eta)$,

$$\Re\left[H \overline{h'}\right] = \eta \mathrm{e}^{-\eta}\, (\cos\eta + \sin\eta) - \mathrm{e}^{-\eta} \sin\eta \,, \tag{A.1310}$$

the last term of Equation (A.1309) being purely imaginary. Assembling Equations (A.1308) and (A.1310),

$$2\Psi = -2\mathrm{e}^{-\eta}\cos\eta + \mathrm{e}^{-2\eta} - \eta\mathrm{e}^{-\eta}\left(\cos\eta + \sin\eta\right) + \mathrm{e}^{-\eta}\sin\eta\,. \tag{A.1311}$$

The moment. By Equations (A.1299) and (A.1306), with $y = \delta\eta$,

$$u_s = -\frac{\rho U U'\delta^2}{\mu}\int_0^\infty \eta\,\Psi\,\mathrm{d}\eta = -\frac{2UU'}{\omega}\int_0^\infty \eta\,\Psi\,\mathrm{d}\eta\,, \tag{A.1312}$$

since $\rho\delta^2/\mu = \delta^2/\nu = 2/\omega$ by Equation (A.1292). The required integrals follow from

$$\int_0^\infty \eta^n \mathrm{e}^{-\eta}\mathrm{e}^{\mathrm{i}\eta}\,\mathrm{d}\eta = \frac{n!}{(1-\mathrm{i})^{n+1}}\,, \tag{A.1313}$$

with $(1-\mathrm{i})^2 = -2\mathrm{i}$ and $(1-\mathrm{i})^3 = -2-2\mathrm{i}$. For $n=1$ the right-hand side is $1/(-2\mathrm{i}) = \mathrm{i}/2$, so

$$\int_0^\infty \eta\mathrm{e}^{-\eta}\cos\eta\,\mathrm{d}\eta = 0\,, \qquad \int_0^\infty \eta\mathrm{e}^{-\eta}\sin\eta\,\mathrm{d}\eta = \tfrac{1}{2}\,, \tag{A.1314}$$

and for $n=2$ it is $2/(-2-2\mathrm{i}) = -1/(1+\mathrm{i}) = (-1+\mathrm{i})/2$, so

$$\int_0^\infty \eta^2\mathrm{e}^{-\eta}\cos\eta\,\mathrm{d}\eta = -\tfrac{1}{2}\,, \qquad \int_0^\infty \eta^2\mathrm{e}^{-\eta}\sin\eta\,\mathrm{d}\eta = \tfrac{1}{2}\,, \tag{A.1315}$$

while $\int_0^\infty \eta\,\mathrm{e}^{-2\eta}\mathrm{d}\eta = \frac{1}{4}$. Multiplying Equation (A.1311) by η and integrating term by term,

$$2\int_0^\infty \eta\,\Psi\,\mathrm{d}\eta = -2\cdot 0 + \tfrac{1}{4} - \left(-\tfrac{1}{2}+\tfrac{1}{2}\right) + \tfrac{1}{2} = \tfrac{3}{4}\,, \tag{A.1316}$$

so $\int_0^\infty \eta\Psi\,\mathrm{d}\eta = \frac{3}{8}$ and Equation (A.1312) gives $u_s = -(2/\omega)(3/8)UU'$, which is the first member of Equation (A.1303). The second member follows from $\langle u_\infty^2\rangle = \frac{1}{2}U^2$, whose x derivative is UU'. □

Proposition A.776 (The inner counter-flow)**.** *The mean flow at the wall itself runs the* other *way. Its shear there is*

$$\left(\partial_y\langle u_2\rangle\right)_{y=0} = \frac{1}{2\omega\delta}\,U\frac{\mathrm{d}U}{\mathrm{d}x}\,, \tag{A.1317}$$

which has the sign of $U\,\mathrm{d}U/\mathrm{d}x$*, opposite to that of* u_s *in Equation* (A.1303)*. The mean profile therefore reverses once within the layer, at a height of order* δ*.*

Rests on Lemma A.774, Equation (A.1311)*, and Theorem A.775.*

Proof. *Derives Proposition A.776.*

From the proof of Lemma A.774, $\mu\left(\partial_y\langle u_2\rangle\right)_{y=0} = -\int_0^\infty F\,\mathrm{d}y = -\rho UU'\delta\int_0^\infty \Psi\,\mathrm{d}\eta$. The zeroth moments needed are $\int_0^\infty \mathrm{e}^{-\eta}\cos\eta\,\mathrm{d}\eta = \int_0^\infty \mathrm{e}^{-\eta}\sin\eta\,\mathrm{d}\eta = \frac{1}{2}$, from Equation (A.1313) at $n=0$, together with $\int_0^\infty \mathrm{e}^{-2\eta}\mathrm{d}\eta = \frac{1}{2}$ and Equation (A.1314). Integrating Equation (A.1311),

$$2\int_0^\infty \Psi\,\mathrm{d}\eta = -2\cdot\tfrac{1}{2} + \tfrac{1}{2} - \left(0+\tfrac{1}{2}\right) + \tfrac{1}{2} = -\tfrac{1}{2}\,, \tag{A.1318}$$

so $\int_0^\infty \Psi\,\mathrm{d}\eta = -\frac{1}{4}$ and $\mu\left(\partial_y\langle u_2\rangle\right)_{y=0} = \frac{1}{4}\rho\delta UU'$. Dividing by $\mu = \rho\nu$ and using $\nu = \omega\delta^2/2$ gives Equation (A.1317). Since $\langle u_2\rangle$ starts from zero at the wall with a shear of one sign and ends at u_s of the other, it changes sign once, at a height that the explicit profile places within a small multiple of δ. □

A.66.5 The direction of the circulation over a plate

Everything so far holds for any oscillating tangential field. To reach Phenomenon 35.8 one further step is needed, and it is the step at which the answer is decided: the relation between the tangential air velocity $U(x)$ and the plate's *normal* motion.

Lemma A.777 (The tangential field above a bending plate)**.** *Let the plate vibrate with normal velocity* $v(x,0,t) = V_0 \sin(k_p x)\cos\omega t$*, so that its nodal lines are at* $\sin(k_p x) = 0$ *and its antinodes midway between them. Suppose the bending wavelength is much shorter than the acoustic wavelength in the fluid,* $k_p \gg \omega/c$*, and much longer than the Stokes layer,* $k_p\delta \ll 1$*. Then the air motion within a bending wavelength is incompressible and irrotational, with*

$$\phi = -\frac{V_0}{k_p}\sin(k_p x)\,\mathrm{e}^{-k_p y}\cos\omega t\,, \tag{A.1319}$$

and the tangential velocity imposed on the layer is

$$U(x) = -V_0\cos(k_p x)\ . \tag{A.1320}$$

Its magnitude is therefore greatest over the plate's nodal lines *and vanishes over its* antinodes.
Rests on Proposition 31.28 and Equations (31.25) and (A.1292).

Proof. *Derives Lemma A.777.*

When $k_p \gg \omega/c$ the compressible wave equation for the velocity potential, $\nabla^2\phi = c^{-2}\partial_t^2\phi$, reduces within a bending wavelength to Equation (31.25), because the term on the right is smaller than $\partial_x^2\phi$ by $(\omega/ck_p)^2$. Separating with the x dependence imposed by the plate and requiring decay as $y\to\infty$ gives $\phi \propto \sin(k_p x)\,\mathrm{e}^{-k_p y}$, and $\nabla^2\phi = \left(-k_p^2 + k_p^2\right)\phi = 0$ confirms it. Fixing the constant by $\partial_y\phi = v(x,0,t)$ at $y=0$ gives Equation (A.1319), whence

$$u = \partial_x\phi = -V_0\cos(k_p x)\,\mathrm{e}^{-k_p y}\cos\omega t\,. \tag{A.1321}$$

Since $k_p\delta \ll 1$, the exponential is indistinguishable from unity across the Stokes layer, so the field Equation (A.1321) is what Proposition A.773 sees as u_∞, and Equation (A.1320) follows.

The physical reading is worth one sentence, because the result is the opposite of the naive guess. Over an antinode the plate pushes air straight up and down and the horizontal motion vanishes by symmetry; over a nodal line the plate does not move at all, but the air expelled from the antinode on one side must cross to the other, and it is there that the horizontal velocity is greatest. □

Corollary A.778 (The powder collects at the antinodes)**.** *With Equation (A.1320), Equation (A.1303) gives*

$$u_s = \frac{3V_0^2 k_p}{8\omega}\sin(2k_p x)\ , \tag{A.1322}$$

which is directed from each nodal line towards the antinodes on either side of it. The outer branch of the circulation therefore sweeps the fluid just above the layer from the nodes to the antinodes, rising there and returning above; a grain carried by that branch collects at the antinodes, where sand does not, which is Phenomenon 35.8.
Rests on Theorem A.775, Lemma A.777, and Phenomenon 35.5.

Proof. *Derives Corollary A.778.*

$U^2 = V_0^2\cos^2(k_p x)$, so $\mathrm{d}\left(U^2\right)/\mathrm{d}x = -V_0^2 k_p\sin(2k_p x)$ and $u_s = -(3/8\omega)\,\mathrm{d}\left(U^2\right)/\mathrm{d}x$ is Equation (A.1322). Take a nodal line at $x=0$ and the neighbouring antinode at $x=\pi/2k_p$: on the interval between them $\sin(2k_p x) > 0$, so $u_s > 0$ and the flow is directed towards the antinode. By the reflection symmetry about the nodal line the same holds on the other side, so the nodal lines are lines of divergence of the slip flow and the antinodes are lines of

convergence. Mass conservation then requires the fluid to rise above each antinode and to descend over each node, closing the circulation with an outward branch aloft.

The statement Equation (A.1303) makes about $|U|$ is general; what is special to the plate is Lemma A.777, which places the maxima of $|U|$ over the nodes. The two together are what invert the figure. □

Example A.779 (The scales, in SI)**.** Take a plate sounding at $f = 500\,\mathrm{Hz}$ with a bending wavelength $\lambda_p = 0.10\,\mathrm{m}$, so $\omega = 3.14 \times 10^3/\mathrm{s}$ and $k_p = 63/\mathrm{m}$, in air of kinematic viscosity $1.5 \times 10^{-5}\,\mathrm{m}^2/\mathrm{s}$ and sound speed $343\,\mathrm{m/s}$. Then

$$\delta = \sqrt{\frac{2 \times 1.5 \times 10^{-5}\,\mathrm{m}^2/\mathrm{s}}{3.14 \times 10^3/\mathrm{s}}} = 9.8 \times 10^{-5}\,\mathrm{m} \approx 0.1\,\mathrm{mm}\,, \tag{A.1323}$$

against an acoustic wavelength $c/f = 0.69\,\mathrm{m}$. The two hypotheses of Lemma A.777 are met with room to spare in one case and by about a factor of seven in the other: $k_p\delta = 6.3 \times 10^{-3} \ll 1$, and $k_p/(\omega/c) = 63/9.2 = 6.8 \gg 1$. The second ratio is the one to watch, since it fails at the coincidence frequency where the bending wave becomes sonic, and above it the plate radiates and the near field is no longer evanescent.

With a plate displacement amplitude $A_p = 50\,\mu\mathrm{m}$, so $V_0 = \omega A_p = 0.16\,\mathrm{m/s}$, Equation (A.1322) gives a peak slip velocity

$$\frac{3V_0^2 k_p}{8\omega} = \tfrac{3}{8}\,\omega A_p^2 k_p = 1.9 \times 10^{-4}\,\mathrm{m/s} \approx 0.2\,\mathrm{mm/s}\,, \tag{A.1324}$$

which moves a grain across a five-centimetre cell in a few minutes — slow, steady and unmistakable, which is what the observation reports. The same amplitude gives a peak plate acceleration $\omega^2 A_p = 4.9 \times 10^2\,\mathrm{m/s}^2$, some fifty times g, so sand is thrown vigorously; the two mechanisms are operating simultaneously and on different powders, exactly as the chapter says.

Rests on Equations (A.1292) *and* (A.1322).

A.66.6 The same mechanism in Kundt's tube

Corollary A.780 (Dust ridges at the displacement nodes)**.** *In a gas column carrying a standing wave of wavenumber k along a tube, the tangential velocity at the wall is $U(x) = U_0 \sin(kx)$ with its maxima at the displacement antinodes. Equation* (A.1303) *then gives*

$$u_s = -\frac{3U_0^2 k}{8\omega}\sin(2kx) = -\frac{3U_0^2}{8c}\sin(2kx)\,, \tag{A.1325}$$

directed from each displacement antinode towards the displacement nodes on either side. A powder swept along the wall by that flow therefore accumulates at the displacement nodes, spaced by half a wavelength — which is Phenomenon 35.12.

Rests on Theorem A.775 and Equations (35.17) *and* (A.1303).

Proof. *Derives Corollary A.780.*

In a standing wave the velocity amplitude is greatest at the displacement antinodes and zero at the nodes, and the wall is parallel to the axis, so the tangential field imposed on the Stokes layer is $U_0 \sin(kx)$ with U_0 the velocity amplitude. Then $\mathrm{d}(U^2)/\mathrm{d}x = U_0^2 k \sin(2kx)$ and Equation (A.1303) gives Equation (A.1325), the second form using $\omega = ck$. Between a node at $x = 0$ and the antinode at $x = \pi/2k$, $\sin(2kx) > 0$ and $u_s < 0$: the flow runs from the antinode back to the node. So the displacement nodes are lines of convergence and the ridges form there.

Phenomenon 35.12 asserts this collection and uses the ridge spacing to measure a wavelength; the chapter takes the location of the ridges from the observation. It is worth

noting that the mechanism is the same as the plate's and the *apparent* reversal between them is not in the streaming at all but in Lemma A.777: in the tube the maxima of $|U|$ coincide with the visible antinodes of the wave, whereas over a plate they sit above its nodal lines. In both cases the powder goes where $|U|$ is least. □

A.66.7 What is not derived here

Remark A.781 (Three gaps, and why they are left open). *Which branch a given grain samples.* By Proposition A.776 the mean flow reverses within the layer, so a grain lying in contact with the plate is not in the same current as one riding above it. A lycopodium spore is some 30 µm across against the $\delta \approx 0.1$ mm of Equation (A.1323): it protrudes into the layer but does not clear it, so which branch dominates the drag on it is a quantitative question about a body of comparable size to the layer, and neither Theorem A.775 nor Proposition A.776 settles it. What is derived here is the outer branch and its direction, which is precisely the bound Remark 35.9 sets.

Adhesion. The competition the chapter names — between the streaming drag and the residual contact friction — requires a model of the grain's adhesion to the plate. There is none in this treatise, so no threshold radius separating the two powders is predicted, and none should be read into Equation (A.1324).

The figure itself. Equation (A.1322) was computed for a one-dimensional mode shape. A real Chladni figure is two-dimensional, and the streaming above it is a two-dimensional pattern of cells whose stagnation structure is not obtained by writing $\sin(2k_p x)$ twice. That the powder ends up on the antinodal regions follows from the sign of Equation (A.1303) along any line crossing a nodal curve, which is all that is claimed.

Remark A.782. Appendix A.66 discharges the derivation owed at Phenomenon 35.8 of Chapter 35, in the Chladni experiment Section 35.3. The reader returning there should carry back the reason the chapter keeps the phenomenon at all. The sand figure and the lycopodium figure are traced by the same mode of the same plate at the same amplitude, and they are complementary: one records where the *plate* is still, the other where the *air* is still. The first is a threshold in $\omega^2 A$ against g, obtained in Chapter 30; the second is Equation (A.1303), a second-order effect in a fluid that the plate merely stirs. Neither figure is the eigenfunction, and an experiment that images a field through a tracer measures the tracer as well as the field — which is the standing warning Chapter 35 attaches to Phenomenon 35.8, and which this derivation makes quantitative.

A.67 The Free-Streamline Jet: Kirchhoff's Contraction Coefficient

This appendix proves Proposition 36.3 of Chapter 36: the two-dimensional efflux of an ideal incompressible liquid through a sharp-edged slit of width a in a plane wall contracts to an asymptotic jet width a_j with

$$C_c = \frac{a_j}{a} = \frac{\pi}{\pi + 2} = 0.611\,, \tag{A.1326}$$

which is Equation (36.6), and does so with no empirical input whatever [172, 175].

The chapter's paragraph after the `prooflink` explains why the problem is hard and what the hodograph does about it; that discussion is not repeated here. This section begins where it stops: it builds the hodograph region explicitly, maps it, and integrates back.

A.67.1 What is quoted here

One theorem is imported, and it is the only one.

Theorem A.783 (Riemann mapping with boundary correspondence, quoted)**.** *Let $D \subsetneq \mathbb{C}$ be a simply connected domain whose boundary on the Riemann sphere is a Jordan curve. Then there is a holomorphic bijection of D onto the upper half plane $\mathbb{H} := \{t \in \mathbb{C} : \Im t > 0\}$, it extends to a homeomorphism of the closures, and it is unique once three boundary points and their cyclic order are prescribed. Consequently two such maps that agree on three boundary points agree everywhere.*

Rests on Definition 8.5 and Theorem 8.6.

Remark A.784 (What is quoted here)*.* Chapter 8 builds holomorphy (Definition 8.5), the Cauchy–Riemann equations (Theorem 8.6), Cauchy's theorem and the residue calculus, but no theory of conformal mapping: it has no Riemann mapping theorem, no boundary-correspondence theorem and no Schwarz–Christoffel formula. Theorem A.783 is therefore imported, and it is used for exactly one purpose — to identify the parameter t reached from the hodograph plane with the parameter t reached from the potential plane. Everything else below is elementary and is verified here: the mapping properties of exp, of $\chi \mapsto \chi^2$ and of the Joukowski map are established by tracking their boundary values corner by corner, so no general mapping theorem is needed for them, and the Schwarz–Christoffel formula, which the standard treatments reach for at this point, is not used at all.

The imported theorem has no key in `references.bib` — the only Riemann and Carathéodory entries there are a paper on electrodynamics and one on the foundations of thermodynamics — so its attribution is made in words, on the footing of Darboux's memoir in Remark A.81: Riemann's inaugural dissertation of 1851 for the mapping, Carathéodory's papers of 1913 for the extension to the boundary. A reader who grants Theorem A.783 is granted everything else in this section.

Two further limitations are honest to state here rather than at the end. The construction below is a *verification*: it exhibits a flow satisfying every condition of the problem and computes its contraction. That the free-boundary problem has no other solution is not proved, and the treatise does not carry the machinery to prove it. And gravity is neglected *within* the jet, so that the speed on the free streamline is the single constant q_0; this is exact only in the limit $a \ll h$, and the chapter's measurements are made in that regime.

A.67.2 Formulation

Let the wall occupy the plane $x = 0$ with a slit $|y| < a/2$, the reservoir the region $x < 0$, and the jet issue into $x > 0$; the flow is two-dimensional, steady, incompressible and irrotational, so by Proposition 31.28 it has a harmonic velocity potential Equation (31.25) and, with the stream function Equation (31.12), a holomorphic complex potential $w(z) = \phi + \mathrm{i}\psi$ of $z = x + \mathrm{i}y$, whose derivative is the complex velocity Equation (31.57),

$$\Omega := \frac{\mathrm{d}w}{\mathrm{d}z} = v_x - \mathrm{i}v_y = q\,\mathrm{e}^{-\mathrm{i}\theta}\,, \tag{A.1327}$$

with $q \geq 0$ the speed in m/s and θ the direction of the velocity.

Three conditions define the problem.

1. *Impermeability* on the wall: ψ is constant there.
2. *Free surface*: the jet is bounded by two streamlines on which the pressure equals the atmospheric pressure, so by Theorem 31.24 and Equation (36.2) the speed on them is the constant
$$q_0 = \sqrt{2gh}\,, \tag{A.1328}$$
h being the head in m and g the acceleration of free fall.
3. *Position of the free surface*: unknown. It is a streamline whose location is part of the answer.

The third condition is what makes this a free-boundary problem, and it is the reason no direct solution of Equation (31.25) is available: the domain on which the equation is to be solved is not given.

The configuration is symmetric about $y = 0$, so it suffices to treat the upper half. Its boundary consists of three arcs, on each of which the stream function is constant:

- the axis $y = 0$, $-\infty < x < +\infty$, on which $\psi = 0$;
- the wall $x = 0$, $y \geq a/2$, on which $\psi = m$;
- the free streamline, leaving the edge $E = (0, a/2)$ and running downstream to $x = +\infty$, $y = a_j/2$, on which also $\psi = m$.

Here m is half the volume flux per unit span; evaluating it far downstream, where the jet is uniform at speed q_0 and width a_j,

$$m = \tfrac{1}{2} q_0 a_j \,, \tag{A.1329}$$

in m^2/s. The image of the flow region in the w plane is therefore the strip $0 < \psi < m$: the reservoir at infinity is the end $\phi \to -\infty$, the jet at infinity the end $\phi \to +\infty$, and ϕ is monotone along every streamline.

A.67.3 The hodograph region is a half-strip

Lemma A.785 (The hodograph image)**.** *Put*

$$\zeta := \log \frac{q_0}{\Omega} = \log \frac{q_0}{q} + \mathrm{i}\theta =: \sigma + \mathrm{i}\theta \,. \tag{A.1330}$$

Then the flow region maps into the semi-infinite strip

$$S := \left\{ \sigma + \mathrm{i}\theta \;:\; \sigma > 0 \,,\; -\tfrac{\pi}{2} < \theta < 0 \right\} , \tag{A.1331}$$

with the three boundary arcs going to the three sides as follows: the free streamline to $\sigma = 0$, the wall to $\theta = -\pi/2$, the axis to $\theta = 0$, and the reservoir at infinity to $\sigma = +\infty$.

Rests on Equations (A.1327) *and* (A.1328) *and Definition 8.3.*

Proof. *Derives Lemma A.785.*

Take the boundary arcs in turn. On the free streamline $q = q_0$ by Equation (A.1328), so $\sigma = 0$ exactly; the direction turns from $\theta = -\pi/2$ at the edge, where the fluid is still moving down the inner face of the wall, to $\theta = 0$ far downstream, where the jet is parallel to the axis. On the wall $x = 0$, $y > a/2$, the velocity is tangent to the wall and directed towards the slit, that is in the $-y$ direction, so $\theta = -\pi/2$ throughout, while the speed rises from 0 deep in the reservoir to q_0 at the edge — so σ falls from $+\infty$ to 0. On the axis $\theta = 0$ by symmetry, and the speed rises from 0 far upstream to q_0 far downstream, so σ falls from $+\infty$ to 0.

Everywhere in the flow $0 < q < q_0$, since by Theorem 31.24 the speed is greatest where the pressure is least and the least pressure in the field is the atmospheric pressure on the free surface; and $-\pi/2 < \theta < 0$, since the flow turns monotonically from the wall direction to the axis direction between the two. Hence the image lies in S, and the three sides of S carry the three boundary arcs as listed. The corner $\zeta = 0$ is the edge E, and the corner $\zeta = -\mathrm{i}\pi/2$ at $\sigma = 0$ does not occur: the wall and the free streamline meet only at E. □

This is the step the chapter's prose promises, and it is worth naming what it has achieved. The unknown of the problem was the shape of the free surface. In the ζ plane that surface is the segment $\sigma = 0$, $-\pi/2 \leq \theta \leq 0$ — a known set, fixed before anything has been solved. The price is that the map from the physical plane to the hodograph plane is itself unknown; but that map is what the potential will supply.

A.67.4 Two maps onto the same half plane

Lemma A.786 (From the half-strip to the half plane)**.** *Define*

$$\chi = \mathrm{e}^{-\zeta} = \frac{\Omega}{q_0}\,, \qquad s = \chi^2\,, \qquad t = -\frac{1}{2}\left(s + \frac{1}{s}\right). \tag{A.1332}$$

Then $\zeta \mapsto t$ carries S holomorphically and bijectively onto $\mathbb{H}$, with the boundary correspondence

$$\textit{axis} \mapsto t \le -1\,, \qquad \textit{free streamline} \mapsto -1 \le t \le 1\,, \qquad \textit{wall} \mapsto t \ge 1\,, \tag{A.1333}$$

the edge E going to $t = 1$, the jet at infinity to $t = -1$ and the reservoir at infinity to $t = \infty$. On the free streamline the parametrization is

$$\theta = -\alpha\,, \qquad t = -\cos 2\alpha\,, \qquad 0 \le \alpha \le \frac{\pi}{2}\,. \tag{A.1334}$$

Rests on Lemma A.785, Proposition 8.4, and Definition 8.3.

Proof. *Derives Lemma A.786.*

Each map is holomorphic where used, and each is checked on the boundary.

The exponential. $\chi = \mathrm{e}^{-\zeta} = \mathrm{e}^{-\sigma}\mathrm{e}^{-\mathrm{i}\theta}$ has $|\chi| = \mathrm{e}^{-\sigma} \le 1$ and $\arg\chi = -\theta \in [0, \pi/2]$, and $\zeta \mapsto \chi$ is injective on S because the imaginary part of ζ spans an interval of length $\pi/2 < 2\pi$. So χ ranges over the open quarter disc $\{0 < |\chi| < 1,\ 0 < \arg\chi < \pi/2\}$, and the three sides of S go to the two radii and the arc.

The square. On the quarter disc $\chi \mapsto s = \chi^2$ is injective, since $\arg\chi$ spans an interval of length $\pi/2$ and doubling it spans $\pi < 2\pi$. Its image is the open half disc $\{0 < |s| < 1,\ 0 < \arg s < \pi\}$; the arc $|\chi| = 1$ goes to the arc $|s| = 1$, the radius $\arg\chi = 0$ to $s \in (0, 1)$ and the radius $\arg\chi = \pi/2$ to $s \in (-1, 0)$.

The Joukowski map. On the half disc, write $s = \varrho\mathrm{e}^{\mathrm{i}\vartheta}$ and

$$t = -\frac{1}{2}\left(s + \frac{1}{s}\right) = -\frac{1}{2}\left(\varrho + \frac{1}{\varrho}\right)\cos\vartheta - \frac{\mathrm{i}}{2}\left(\varrho - \frac{1}{\varrho}\right)\sin\vartheta\,. \tag{A.1335}$$

For $0 < \varrho < 1$ the bracket $\varrho - 1/\varrho$ is negative and $\sin\vartheta > 0$, so $\Im t > 0$: the half disc goes into $\mathbb{H}$. Injectivity is the observation that s and $1/s$ are the two preimages of a given t and that exactly one of them has modulus less than one. Surjectivity onto $\mathbb{H}$ follows because for each $t \in \mathbb{H}$ the quadratic $s^2 + 2ts + 1 = 0$ has roots with product 1 and neither on the unit circle, since a root of modulus one would make t real by Equation (A.1335).

On the boundary: $|s| = 1$, $s = \mathrm{e}^{\mathrm{i}\vartheta}$, gives $t = -\cos\vartheta \in [-1, 1]$; $s \in (0, 1)$ gives $t = -\frac{1}{2}(s + 1/s) \le -1$; and $s \in (-1, 0)$ gives $t \ge 1$. Tracing back through the two earlier maps, $s \in (0, 1)$ is the axis and $s \in (-1, 0)$ is the wall, which is Equation (A.1333). On the free streamline $\Omega = q_0\mathrm{e}^{-\mathrm{i}\theta}$, so $\chi = \mathrm{e}^{\mathrm{i}\alpha}$ with $\alpha = -\theta$, $s = \mathrm{e}^{2\mathrm{i}\alpha}$ and $t = -\cos 2\alpha$, which is Equation (A.1334). Its endpoints are $t = 1$ at $\alpha = \pi/2$ (the edge) and $t = -1$ at $\alpha = 0$ (downstream). □

Lemma A.787 (From the potential strip to the half plane)**.** *Fix the origin of the velocity potential at the edge E and define*

$$t = -1 - 2\,\mathrm{e}^{-\pi w/m}\,. \tag{A.1336}$$

Then $w \mapsto t$ carries the strip $0 < \psi < m$ holomorphically and bijectively onto $\mathbb{H}$, with the same boundary correspondence Equation (A.1333), and

$$\mathrm{d}w = -\frac{m}{\pi}\,\frac{\mathrm{d}t}{t + 1}\,. \tag{A.1337}$$

Rests on Equation (A.1329), Definition 8.3, and Lemma A.786.

Proof. *Derives Lemma A.787.*

For $0 < \psi < m$ the argument of $\mathrm{e}^{-\pi w/m}$ is $-\pi\psi/m \in (-\pi, 0)$, so the argument of $-2\mathrm{e}^{-\pi w/m}$ lies in $(0, \pi)$ and $\Im t > 0$; the map is injective because the imaginary part of $-\pi w/m$ spans an interval of length $\pi < 2\pi$, and it is onto $\mathbb{H}$ because $\mathrm{e}^{-\pi w/m}$ covers the lower half plane.

On $\psi = 0$, $t = -1 - 2\mathrm{e}^{-\pi\phi/m}$ decreases through $(-\infty, -1)$ as ϕ runs from $-\infty$ to $+\infty$: the reservoir goes to $t = \infty$ and the jet at infinity to $t = -1$. On $\psi = m$, $\mathrm{e}^{-\pi(\phi+\mathrm{i}m)/m} = -\mathrm{e}^{-\pi\phi/m}$, so $t = -1 + 2\mathrm{e}^{-\pi\phi/m}$, which is $+\infty$ deep in the reservoir, equals 1 at $\phi = 0$, and tends to -1 far downstream. The choice of origin therefore puts the edge at $t = 1$, matching Lemma A.786 arc for arc.

Differentiating $t + 1 = -2\mathrm{e}^{-\pi w/m}$ gives $\mathrm{d}t = -(\pi/m)(t+1)\,\mathrm{d}w$, which is Equation (A.1337). □

Corollary A.788 (The two parameters are the same parameter)**.** *Lemmas A.786 and A.787 are two conformal maps of the flow region onto $\mathbb{H}$ agreeing at the three boundary points E, the jet at infinity, and the reservoir at infinity. By Theorem A.783 they are the same map. Hence Ω and w are both explicit functions of one parameter t, and*

$$\mathrm{d}z = \frac{\mathrm{d}w}{\Omega} = -\frac{m}{\pi}\,\frac{1}{\Omega(t)}\,\frac{\mathrm{d}t}{t+1}\,. \tag{A.1338}$$

Rests on Theorem A.783 and Lemmas A.786 and A.787.

This is the whole solution. The physical plane has been eliminated in favour of t, and Equation (A.1338) recovers it by quadrature.

A.67.5 Integrating back along the free streamline

Theorem A.789 (Kirchhoff's contraction coefficient)**.** *The free streamline leaves the edge of the slit at height $a/2$ and approaches the height $a_j/2$ downstream, with*

$$\frac{a_j}{2} - \frac{a}{2} = -\frac{a_j}{\pi}\,, \tag{A.1339}$$

so that $a = a_j(\pi + 2)/\pi$ and Equation (A.1326) holds.
Rests on Corollary A.788 and Equations (A.1329) and (A.1334).

Proof. *Derives Theorem A.789.*

Parametrize the free streamline by α as in Equation (A.1334), so that $\alpha = \pi/2$ at the edge and $\alpha = 0$ downstream. Then

$$t + 1 = 1 - \cos 2\alpha = 2\sin^2\alpha\,, \qquad \mathrm{d}t = 2\sin 2\alpha\,\mathrm{d}\alpha\,, \tag{A.1340}$$

and Equation (A.1337) gives

$$\mathrm{d}w = -\frac{m}{\pi}\,\frac{2\sin 2\alpha\,\mathrm{d}\alpha}{2\sin^2\alpha} = -\frac{2m}{\pi}\cot\alpha\,\mathrm{d}\alpha\,, \tag{A.1341}$$

using $\sin 2\alpha = 2\sin\alpha\cos\alpha$. The sign is right: along the streamline α decreases and $\cot\alpha > 0$, so $\mathrm{d}\phi > 0$ and the potential increases downstream.

On the free streamline $\Omega = q_0\mathrm{e}^{-\mathrm{i}\theta} = q_0\mathrm{e}^{\mathrm{i}\alpha}$, so

$$\mathrm{d}z = \frac{\mathrm{d}w}{\Omega} = -\frac{2m}{\pi q_0}\cot\alpha\,\mathrm{e}^{-\mathrm{i}\alpha}\,\mathrm{d}\alpha\,, \tag{A.1342}$$

whose imaginary part is

$$\mathrm{d}y = -\frac{2m}{\pi q_0}\cot\alpha\,(-\sin\alpha)\,\mathrm{d}\alpha = \frac{2m}{\pi q_0}\cos\alpha\,\mathrm{d}\alpha\,. \tag{A.1343}$$

Integrating from the edge to the far downstream station,

$$\Delta y = \frac{2m}{\pi q_0}\int_{\pi/2}^{0}\cos\alpha\,\mathrm{d}\alpha = \frac{2m}{\pi q_0}\Big[\sin\alpha\Big]_{\pi/2}^{0} = -\frac{2m}{\pi q_0}\,, \tag{A.1344}$$

and Equation (A.1329) turns $2m/q_0$ into a_j, giving Equation (A.1339). Since the streamline starts at $y = a/2$ and ends at $y = a_j/2$,

$$\frac{a}{2} = \frac{a_j}{2} + \frac{a_j}{\pi} = a_j\,\frac{\pi+2}{2\pi} \quad\Longrightarrow\quad \frac{a_j}{a} = \frac{\pi}{\pi+2}\,, \tag{A.1345}$$

which is Equation (A.1326). Numerically $\pi/(\pi+2) = 0.611\,01$.

Note what has and has not entered. The head h appears only through q_0, and q_0 cancels between Equation (A.1329) and Equation (A.1344); so does the density, which never appeared at all. The result is a pure number, as Proposition 36.3 claims, and it is the same number at every head. □

Remark A.790 (Where the two constants come from). The π and the 2 of Equation (A.1326) have different origins, and the calculation is worth reading once with that in mind. The π is the width of the potential strip: it enters through the exponential map Equation (A.1336), whose exponent is $\pi w/m$ precisely because the strip has height m and must be opened into a half plane. It is therefore a statement about the *flux*. The 2 is $\int_0^{\pi/2}\cos\alpha\,\mathrm{d}\alpha = 1$ counted for the two halves of the jet — a statement about the *turning of the velocity through a right angle* at the edge. Nothing else survives. (No arctangent occurs anywhere in the evaluation, and no Schwarz–Christoffel integral is needed: the one quadrature to be done is Equation (A.1344), and it is elementary.)

Remark A.791 (Two checks on the solution). *The edge.* At $\alpha = \pi/2$ the speed is q_0, finite. A free-streamline solution is admissible only if the velocity is finite where the free surface leaves the solid boundary, and here that condition holds automatically, because $|\Omega| = q_0$ on the whole free streamline including its endpoint. Nothing had to be imposed to secure it, which is a feature of the sharp-edged geometry and is not true of a rounded mouthpiece.

The asymptote. The real part of Equation (A.1342) is $\mathrm{d}x = -\,(2m/\pi q_0)\,(\cos^2\alpha/\sin\alpha)\,\mathrm{d}\alpha$, whose integrand behaves as $1/\alpha$ as $\alpha \to 0$. The streamline therefore runs off to $x = +\infty$ logarithmically in α, while Equation (A.1343) shows the remaining drop in y is of order α^2: the jet approaches its asymptotic width exponentially in x, so "the" contraction is reached within a few slit widths and is a measurable quantity rather than a limit that is never attained.

A.67.6 What the theorem does not cover

Remark A.792 (The round hole is a different problem). The hodograph is a two-dimensional device. It works because the velocity of a plane irrotational flow is a holomorphic function of position, so that the map $z \mapsto \Omega$ can be treated as a conformal change of variable and an unknown boundary in one plane becomes a known boundary in another. In three dimensions there is no such structure: the velocity is a harmonic vector field, the "hodograph" is a map from a three-dimensional region to another and carries no conformal group beyond the Möbius transformations, and no closed solution of the axisymmetric free-boundary problem is known. The measured contraction coefficient for a sharp-edged circular orifice is near 0.61 — close enough to Equation (A.1326) that the coincidence is often quoted as though the theorem covered it. It does not, and Proposition 36.3 says so.

Remark A.793 (Why Borda's mouthpiece needs none of this). Proposition 36.2 obtains $C_c = 1/2$ exactly for the re-entrant mouthpiece, and it does so in half a page with no complex analysis at all. The contrast is instructive rather than embarrassing. What made

the flush slit hard was that the pressure over the wall around the orifice is unknown, so the momentum balance carries an undetermined term; the whole apparatus above exists to determine it by finding the flow. The re-entrant geometry removes the term instead: the tube is wetted on both faces, so it transmits no net force, and every other wetted surface carries a hydrostatic pressure. The unknown was arranged out of the problem rather than computed.

The two results are consistent and they bracket the observations: $\frac{1}{2}$ for the re-entrant mouthpiece, $\pi/(\pi+2)$ for the flush slit, and measurements in between for intermediate geometries. Neither is an approximation to the other.

Remark A.794. Appendix A.67 discharges the derivation owed at Proposition 36.3 of Chapter 36, in the efflux experiment Section 36.1. The reader returning there should carry back the division the chapter draws in its *Interpretation*: Bernoulli's theorem gives the speed Equation (36.2) exactly and gives the discharge not at all, because it says nothing about the area of the bundle of streamlines that reaches the jet. This section supplies that area for one geometry — and the reason it can is that the geometry is two-dimensional and sharp-edged, so the free surface has a known image in the hodograph plane. That is a narrower statement than "the ideal theory predicts the discharge", and the narrowness is the point.

A.68 Prandtl's Boundary-Layer Equations and the Blasius Similarity Solution

This appendix proves Proposition 36.15 of Chapter 36: that at large Reynolds number the Navier–Stokes system Equation (31.32) reduces, within the layer against a body, to Prandtl's equations Equation (36.26); that for a flat plate at zero incidence those equations admit a similarity solution governed by the Blasius ordinary differential equation Equation (36.27); and that the three constants quoted in Phenomenon 36.12 — the 5.0 of the thickness, the 0.664 of the local friction coefficient and the 1.328 of the plate drag — are consequences of two numbers read off the numerical solution of that equation [315, 341].

The chapter reaches Equation (36.23) by a dominant-balance estimate. This section derives what that estimate guessed: the exponent $-1/2$ is obtained rather than assumed, and the estimate's silence about the pressure is replaced by a statement of where the pressure comes from.

A.68.1 What is quoted here

Two things, of very different kinds.

The matching principle. The reduction below is a matched asymptotic expansion, and this treatise builds no theory of matched asymptotics. Section 9.6 of Chapter 9 carries the WKB approximation, which is a singular perturbation of the same family — a small parameter multiplying the highest derivative, an outer solution that cannot satisfy every boundary condition, and an inner solution on a stretched variable — and its connection formulae play the part that matching plays here. But WKB is a theorem about one linear second-order equation, not a general principle, and nothing in Part II licenses what follows. The principle is therefore stated outright and used as stated:

Postulate A.795 (Matching, quoted)**.** Let a problem carry a small parameter ε, let F_{out} be the leading term of an expansion valid away from the wall in the original variable $\hat{y}$, and let F_{in} be the leading term of an expansion valid near the wall in a stretched variable $Y=\hat{y}/\varepsilon^{p}$. Then the two expansions are assumed to possess a common domain of validity in which

$$\lim_{Y\to\infty} F_{\mathrm{in}}\left(\hat{x},Y\right)=\lim_{\hat{y}\to 0^{+}} F_{\mathrm{out}}\left(\hat{x},\hat{y}\right)\,, \tag{A.1346}$$

applied separately to each dependent variable.
Rests on Equation (31.32) *and Theorem 9.72.*

Two numbers. Equation (36.27) has no solution in closed form. The values

$$f''(0) = 0.3321\,, \qquad f'(\eta) = 0.99 \text{ at } \eta = 5.0\,, \tag{A.1347}$$

are quadratures of a numerical integration, quoted from [341] and not computed here. Every algebraic manipulation that turns them into the three constants of Phenomenon 36.12 *is* carried out below, so what is imported is exactly two decimal numbers and nothing structural.

Remark A.796 (What is quoted here). Postulate A.795 is an assumption about the solution, not a theorem: it asserts that the two expansions overlap. For the flat plate the assertion can be checked *a posteriori* — the similarity solution constructed in Appendix A.68.5 approaches its free-stream value exponentially in η, so the overlap region is genuine and wide — but that is a verification in one case, not a proof in general. The debt is Part II's, and it is named in the chapter's prose after the `prooflink` as well as here.

The two numbers of Equation (A.1347) are the only external inputs to the arithmetic. Note in particular that $f''(0)$ enters the friction coefficient linearly and the drag coefficient linearly, so the relation $1.328 = 2 \times 0.664$ between the last two constants is exact and independent of the numerics, as Appendix A.68.6 shows.

A.68.2 Scaling, and why the inviscid limit is singular

Take steady, two-dimensional, incompressible flow past a body of streamwise extent L in a stream of speed U, with gravity absorbed into the pressure. Equation (31.32) reads

$$u\,\partial_x u + v\,\partial_y u = -\frac{1}{\rho}\partial_x p + \nu\left(\partial_x^2 + \partial_y^2\right) u\,, \tag{A.1348}$$

$$u\,\partial_x v + v\,\partial_y v = -\frac{1}{\rho}\partial_y p + \nu\left(\partial_x^2 + \partial_y^2\right) v\,, \tag{A.1349}$$

$$\partial_x u + \partial_y v = 0\,. \tag{A.1350}$$

Scale on the body: $x = L\hat{x}$, $y = L\hat{y}$, $u = U\hat{u}$, $v = U\hat{v}$, $p = p_\infty + \rho U^2 \hat{p}$. Every hatted quantity is dimensionless and, by construction, of order unity in the outer flow. Dividing Equation (A.1348) by U^2/L and Equation (A.1349) likewise,

$$\hat{u}\,\partial_{\hat{x}}\hat{u} + \hat{v}\,\partial_{\hat{y}}\hat{u} = -\partial_{\hat{x}}\hat{p} + \frac{1}{\mathrm{Re}}\left(\partial_{\hat{x}}^2 + \partial_{\hat{y}}^2\right)\hat{u}\,, \tag{A.1351}$$

$$\hat{u}\,\partial_{\hat{x}}\hat{v} + \hat{v}\,\partial_{\hat{y}}\hat{v} = -\partial_{\hat{y}}\hat{p} + \frac{1}{\mathrm{Re}}\left(\partial_{\hat{x}}^2 + \partial_{\hat{y}}^2\right)\hat{v}\,, \tag{A.1352}$$

$$\partial_{\hat{x}}\hat{u} + \partial_{\hat{y}}\hat{v} = 0\,, \tag{A.1353}$$

with $\mathrm{Re} = UL/\nu$ the Reynolds number Equation (36.9). The small parameter is $\varepsilon = 1/\mathrm{Re}$, and it multiplies the highest derivative — which is the definition of a singular perturbation and the whole source of the difficulty.

Proposition A.797 (The outer limit loses a boundary condition)**.** *Setting $\varepsilon = 0$ in Equations* (A.1351) *and* (A.1352) *gives the Euler equations Equation* (31.19)*, whose solution for flow past a body is the potential flow of Proposition 31.28. That solution satisfies impermeability, $\hat{v} = 0$ on the surface, and cannot in general satisfy no slip, $\hat{u} = 0$ there. The limit $\mathrm{Re} \to \infty$ is therefore not uniform in $\hat{y}$.*
Rests on Theorem 31.22, Proposition 31.28, and Equation (A.1351)*.*

Proof. *Derives Proposition A.797.*

With $\varepsilon = 0$ the system is first order in $\hat{y}$ and admits one condition on the normal component; the potential solution of Equation (31.25) with $\partial\phi/\partial n = 0$ supplies it and leaves the tangential velocity at the wall determined — and non-zero, by Equation (31.57) and the geometry, except at stagnation points. Since the true solution has $\hat{u} = 0$ at the wall for every Re, however large, $\lim_{\mathrm{Re}\to\infty} \hat{u}$ is discontinuous at $\hat{y} = 0$ and the convergence cannot be uniform. This is d'Alembert's error stated as an analytic fact rather than a physical one, and Phenomenon 36.12 is its resolution. □

A.68.3 The inner expansion: Prandtl's equations

Theorem A.798 (Prandtl's layer equations)**.** *Introduce the stretched wall-normal coordinate and the rescaled normal velocity*

$$Y = \hat{y}\,\mathrm{Re}^{1/2}\,, \qquad \hat{v} = \mathrm{Re}^{-1/2}\,V\,, \tag{A.1354}$$

with Y and V of order unity. Then, to leading order in Re^{-1},

$$\hat{u}\,\partial_{\hat{x}}\hat{u} + V\,\partial_Y\hat{u} = -\frac{\mathrm{d}\hat{p}}{\mathrm{d}\hat{x}} + \partial_Y^2\hat{u}\,, \tag{A.1355}$$

$$\partial_Y\hat{p} = 0\,, \tag{A.1356}$$

$$\partial_{\hat{x}}\hat{u} + \partial_Y V = 0\,. \tag{A.1357}$$

Restoring dimensions, with $\delta \sim L\,\mathrm{Re}^{-1/2}$ the layer thickness of Equation (36.23), this is Equation (36.26). The exponent $\frac{1}{2}$ in Equation (A.1354) is forced: it is the only choice for which the viscous term survives the limit without dominating it.

Rests on Equations (36.23), (A.1351) and (A.1353).

Proof. *Derives Theorem A.798.*

The exponent. Try $Y = \hat{y}\,\mathrm{Re}^{p}$ with $p > 0$. In Equation (A.1351) the convective term $\hat{u}\,\partial_{\hat{x}}\hat{u}$ is of order unity, while the surviving viscous term is $\mathrm{Re}^{-1}\partial_{\hat{y}}^2\hat{u} = \mathrm{Re}^{2p-1}\partial_Y^2\hat{u}$. If $2p - 1 < 0$ the viscous term vanishes in the limit and the no-slip condition is again lost; if $2p - 1 > 0$ it dominates and the leading-order equation is $\partial_Y^2\hat{u} = 0$, whose solution is linear in Y and cannot match a bounded outer flow at $Y \to \infty$ while vanishing at the wall, except trivially. Only $p = \frac{1}{2}$ retains both, which is Equation (A.1354). Note that this *derives* $\delta/L \sim \mathrm{Re}^{-1/2}$, which Equation (36.23) obtained by comparing orders of magnitude.

The normal velocity. With Y as above, Equation (A.1353) reads $\partial_{\hat{x}}\hat{u} + \mathrm{Re}^{1/2}\partial_Y\hat{v} = 0$. For continuity to survive at leading order, $\hat{v}$ must itself be of order $\mathrm{Re}^{-1/2}$, which is the second member of Equation (A.1354), and then Equation (A.1357) follows exactly. The layer is thin *and* the flow through it is weak, in the same ratio.

Streamwise momentum. Substituting into Equation (A.1351),

$$\hat{u}\,\partial_{\hat{x}}\hat{u} + V\,\partial_Y\hat{u} = -\partial_{\hat{x}}\hat{p} + \mathrm{Re}^{-1}\partial_{\hat{x}}^2\hat{u} + \partial_Y^2\hat{u}\,, \tag{A.1358}$$

every term of which is of order unity except $\mathrm{Re}^{-1}\partial_{\hat{x}}^2\hat{u}$, which is smaller by Re^{-1} and is dropped. That is Equation (A.1355), the pressure gradient being written as a total derivative in anticipation of Equation (A.1356).

Normal momentum, and the pressure. This is the step usually waved through, and it carries the most important consequence, so it is done in full. Substituting $\hat{v} = \mathrm{Re}^{-1/2}V$ and $\partial_{\hat{y}} = \mathrm{Re}^{1/2}\partial_Y$ into Equation (A.1352), the convective terms are

$$\hat{u}\,\partial_{\hat{x}}\hat{v} + \hat{v}\,\partial_{\hat{y}}\hat{v} = \mathrm{Re}^{-1/2}\left(\hat{u}\,\partial_{\hat{x}}V + V\,\partial_Y V\right)\,, \tag{A.1359}$$

the pressure term is $-\partial_{\hat{y}}\hat{p} = -\mathrm{Re}^{1/2}\partial_Y\hat{p}$, and the viscous term is

$$\mathrm{Re}^{-1}\left(\partial_{\hat{x}}^2 + \mathrm{Re}\,\partial_Y^2\right)\mathrm{Re}^{-1/2}V = \mathrm{Re}^{-3/2}\partial_{\hat{x}}^2 V + \mathrm{Re}^{-1/2}\partial_Y^2 V\,. \tag{A.1360}$$

Multiplying the equation through by $\mathrm{Re}^{-1/2}$ collects the orders as

$$\partial_Y \hat{p} = \mathrm{Re}^{-1}\left(-\hat{u}\,\partial_{\hat{x}} V - V\,\partial_Y V + \partial_Y^2 V\right) + \mathrm{Re}^{-2}\partial_{\hat{x}}^2 V\,, \tag{A.1361}$$

so $\partial_Y \hat{p} = O\left(\mathrm{Re}^{-1}\right)$ and at leading order Equation (A.1356) holds. In words: the pressure is uniform *across* the layer. It is therefore not an unknown of the layer at all — it is whatever the outer flow imposes at the wall — and this is exactly the sentence Equation (36.26) makes when it writes $\partial_y p = 0$. □

A.68.4 Matching hands over the pressure

Corollary A.799 (The impressed pressure gradient)**.** *Let $U_e(x)$ be the tangential velocity of the outer potential solution evaluated at the surface. Then Postulate A.795 gives*

$$\lim_{Y\to\infty} \hat{u}\,(\hat{x}, Y) = \frac{U_e\,(x)}{U}\,, \tag{A.1362}$$

and, applied to the pressure,

$$-\frac{1}{\rho}\frac{\mathrm{d}p}{\mathrm{d}x} = U_e \frac{\mathrm{d}U_e}{\mathrm{d}x}\,, \tag{A.1363}$$

so the coefficient in Equation (A.1355) is a known function of x before the layer problem is posed.

Rests on Postulate A.795 and Theorems 31.24 and A.798.

Proof. *Derives Corollary A.799.*

Equation (A.1362) is Equation (A.1346) applied to $\hat{u}$: the inner solution at large Y must agree with the outer solution at small $\hat{y}$, and the latter is the wall value U_e of the potential flow, since the potential solution is smooth up to the wall. Applied to the pressure and combined with Equation (A.1356), which makes $\hat{p}$ independent of Y, it gives $\hat{p}\,(\hat{x}) = \hat{p}_{\mathrm{out}}\,(\hat{x}, 0)$. In the outer flow Theorem 31.24 holds along the wall streamline, so $p + \frac{1}{2}\rho U_e^2$ is constant there, which on differentiating is Equation (A.1363).

The logical shape is worth stating plainly, because it is what makes the boundary-layer method a method and not merely an approximation. Nothing has been solved simultaneously. The outer problem is solved first, in ignorance of the layer; its wall pressure is then handed to the inner problem as a coefficient; and the inner problem is solved afterwards. The coupling is one-way at this order, and it is Equation (A.1356) — the pressure being constant across the layer — that makes it so. □

A.68.5 The flat plate: similarity and the Blasius equation

For a flat plate aligned with a uniform stream the outer flow is undisturbed, $U_e = U$ constant, and Equation (A.1363) gives $\mathrm{d}p/\mathrm{d}x = 0$. Restoring dimensions, Equation (36.26) becomes

$$u\,\partial_x u + v\,\partial_y u = \nu\,\partial_y^2 u\,, \qquad \partial_x u + \partial_y v = 0\,, \tag{A.1364}$$

with $u = v = 0$ at $y = 0$ for $x > 0$ and $u \to U$ as $y \to \infty$.

Theorem A.800 (The similarity reduction)**.** *Put*

$$\eta = y\sqrt{\frac{U}{\nu x}}\,, \qquad \psi\,(x, y) = \sqrt{\nu x U}\, f\,(\eta)\,, \tag{A.1365}$$

with ψ the stream function Equation (31.12). Then Equation (A.1364) is satisfied identically in x if and only if f obeys the Blasius equation Equation (36.27),

$$2f''' + f f'' = 0\,, \qquad f(0) = f'(0) = 0\,, \qquad f'(\infty) = 1\,. \tag{A.1366}$$

Here η is dimensionless and ψ carries m^2/s, so f is dimensionless too.

Rests on Equations (31.12) and (A.1364) and Theorem A.798.

Proof. *Derives Theorem A.800.*

Continuity is satisfied identically by the use of ψ, with $u = \partial_y \psi$ and $v = -\partial_x \psi$. Compute the four derivatives that occur, using

$$\partial_y \eta = \sqrt{\frac{U}{\nu x}}\,, \qquad \partial_x \eta = -\frac{\eta}{2x}\,, \tag{A.1367}$$

the second because η carries $x^{-1/2}$. Then

$$u = \partial_y \psi = \sqrt{\nu x U}\, f' \sqrt{\frac{U}{\nu x}} = U f'\,, \tag{A.1368}$$

$$v = -\partial_x \psi = -\left[\tfrac{1}{2} \sqrt{\frac{\nu U}{x}} f + \sqrt{\nu x U}\, f' \left(-\frac{\eta}{2x} \right) \right] = \tfrac{1}{2} \sqrt{\frac{\nu U}{x}} \left(\eta f' - f \right)\,, \tag{A.1369}$$

$$\partial_x u = U f'' \, \partial_x \eta = -\frac{U \eta f''}{2x}\,, \tag{A.1370}$$

$$\partial_y u = U f'' \sqrt{\frac{U}{\nu x}}\,, \qquad \partial_y^2 u = \frac{U^2}{\nu x} f'''\,. \tag{A.1371}$$

Now assemble the two convective terms. The first is

$$u\, \partial_x u = U f' \left(-\frac{U \eta f''}{2x} \right) = -\frac{U^2}{2x}\, \eta f' f''\,, \tag{A.1372}$$

and the second, using $\sqrt{\nu U/x}\,\sqrt{U/\nu x} = U/x$,

$$v\, \partial_y u = \tfrac{1}{2} \sqrt{\frac{\nu U}{x}} \left(\eta f' - f \right) \cdot U f'' \sqrt{\frac{U}{\nu x}} = \frac{U^2}{2x} \left(\eta f' - f \right) f''\,. \tag{A.1373}$$

The terms in $\eta f' f''$ cancel between Equations (A.1372) and (A.1373) — this is the cancellation on which the whole reduction turns — leaving

$$u\, \partial_x u + v\, \partial_y u = -\frac{U^2}{2x}\, f f''\,. \tag{A.1374}$$

The viscous term is $\nu\, \partial_y^2 u = \nu U^2 f'''/\nu x = (U^2/x)\, f'''$ by Equation (A.1371). Equating,

$$-\frac{U^2}{2x}\, f f'' = \frac{U^2}{x}\, f'''\,, \tag{A.1375}$$

and the factor U^2/x divides out of both sides — *every* explicit occurrence of x has cancelled, which is precisely the statement that the ansatz Equation (A.1365) is a similarity solution. What remains is $f''' = -\frac{1}{2} f f''$, that is Equation (A.1366).

The boundary conditions transcribe as follows. At $y = 0$, $\eta = 0$: $u = 0$ gives $f'(0) = 0$ by Equation (A.1368), and then $v = 0$ gives $\eta f' - f = 0$ at $\eta = 0$, hence $f(0) = 0$ by Equation (A.1369). As $y \to \infty$, $u \to U$ gives $f'(\infty) = 1$. Three conditions for a third-order equation, which is why the problem is well posed and why $f''(0)$ is determined rather than free. □

A.68.6 The three constants

Proposition A.801 (Thickness, local friction, and plate drag)**.** *With* $\mathrm{Re}_x = Ux/\nu$ *and* $\mathrm{Re}_L = UL/\nu$*, the solution of Equation* (A.1366) *gives*

$$\delta_{99}(x) = 5.0\, x\, \mathrm{Re}_x^{-1/2}\,, \tag{A.1376}$$

$$c_f(x) := \frac{\tau_w(x)}{\frac{1}{2}\rho U^2} = 2 f''(0)\, \mathrm{Re}_x^{-1/2} = 0.664\, \mathrm{Re}_x^{-1/2}\,, \tag{A.1377}$$

$$C_D := \frac{F}{\frac{1}{2}\rho U^2 L} = 4 f''(0)\, \mathrm{Re}_L^{-1/2} = 1.328\, \mathrm{Re}_L^{-1/2}\,, \tag{A.1378}$$

the last for one side of a plate of length L and unit span, F being in N/m *of span.*
Rests on Equations (A.1347), (A.1366) *and* (A.1371).

Proof. *Derives Proposition A.801.*

Thickness. By Equation (A.1368), $u/U = f'(\eta)$, so the station at which the velocity has reached 99 % of the free stream is the station at which $\eta = 5.0$, by the second member of Equation (A.1347). Inverting Equation (A.1365),

$$\delta_{99} = 5.0\sqrt{\frac{\nu x}{U}} = 5.0\,x\sqrt{\frac{\nu}{Ux}} = 5.0\,x\,\mathrm{Re}_x^{-1/2}\,. \tag{A.1379}$$

Local friction. The wall stress is $\tau_w = \mu\,(\partial_y u)_{y=0}$, in Pa, and by Equation (A.1371)

$$\tau_w(x) = \mu U f''(0)\sqrt{\frac{U}{\nu x}}\,. \tag{A.1380}$$

Dividing by the dynamic pressure $\frac{1}{2}\rho U^2$ and using $\mu = \rho\nu$,

$$c_f = \frac{2\rho\nu U f''(0)}{\rho U^2}\sqrt{\frac{U}{\nu x}} = 2f''(0)\sqrt{\frac{\nu}{Ux}} = 2f''(0)\,\mathrm{Re}_x^{-1/2}\,, \tag{A.1381}$$

which with $f''(0) = 0.3321$ is 0.6642, the 0.664 of Phenomenon 36.12.

Plate drag. Integrate Equation (A.1380) along the plate:

$$F = \int_0^L \tau_w\,\mathrm{d}x = \mu U f''(0)\sqrt{\frac{U}{\nu}}\int_0^L x^{-1/2}\mathrm{d}x = 2\mu U f''(0)\sqrt{\frac{UL}{\nu}}\,, \tag{A.1382}$$

the integral converging at the leading edge despite the singularity of Equation (A.1380) there. Then

$$C_D = \frac{2F}{\rho U^2 L} = \frac{4\rho\nu U f''(0)}{\rho U^2 L}\,\mathrm{Re}_L^{1/2} = 4f''(0)\,\mathrm{Re}_L^{-1/2}\,, \tag{A.1383}$$

which is 1.3284. The relation $C_D = 2c_f(L)$ is exact and independent of the numerical value of $f''(0)$: it is the statement that the mean of $x^{-1/2}$ over $(0, L)$ is twice its endpoint value. □

Proposition A.802 (Consistency with the wake momentum deficit)**.** *The momentum thickness Equation* (36.25) *of the Blasius profile is*

$$\vartheta(x) = I\sqrt{\frac{\nu x}{U}}\,, \qquad I := \int_0^\infty f'\,(1 - f')\,\mathrm{d}\eta = 2f''(0)\,, \tag{A.1384}$$

so that Equation (36.25) *returns exactly the drag Equation* (A.1382) *computed from the wall stress.*
Rests on Equations (36.25) *and* (A.1366) *and Proposition A.801.*

Proof. *Derives Proposition A.802.*

The first member is Equation (A.1368) substituted into the definition of ϑ in Equation (36.25), with $\mathrm{d}y = \sqrt{\nu x/U}\,\mathrm{d}\eta$. For the identity, differentiate the product $f\,(1 - f')$ and use the Blasius equation Equation (A.1366) in the form $ff'' = -2f'''$:

$$\frac{\mathrm{d}}{\mathrm{d}\eta}\left[f\,(1 - f')\right] = f'\,(1 - f') - ff'' = f'\,(1 - f') + 2f'''\,. \tag{A.1385}$$

Integrate from 0 to ∞. On the left, $f(0) = 0$ kills the lower limit, and at the upper limit $1 - f'$ vanishes exponentially while f grows only linearly, so the product vanishes; the left

side is therefore zero. On the right the first term is I and the second is $2\,[f']_0^\infty = -2f''(0)$, since $f'' \to 0$ with $1 - f'$. Hence $I = 2f''(0)$.

Substituting into Equation (36.25), $F = \rho U^2 \vartheta(L) = 2f''(0)\rho U^2\sqrt{\nu L/U} = 2\mu U f''(0)\sqrt{UL/\nu}$, which is Equation (A.1382). The two routes to the drag — integrating the stress the fluid exerts on the plate, and traversing the wake far downstream — agree exactly, as Proposition 36.14 requires, and neither uses the other in its derivation. □

Example A.803 (The chapter's worked number, in SI)**.** A plate 1 m long and of unit span, held edge-on in water of kinematic viscosity $1.0 \times 10^{-6}\,\mathrm{m^2/s}$ and density $1.0 \times 10^{3}\,\mathrm{kg/m^3}$, at 1 m/s. Then $\mathrm{Re}_L = 10^6$, $\mathrm{Re}_L^{-1/2} = 10^{-3}$, and the dynamic pressure is $\frac{1}{2}\rho U^2 = 500\,\mathrm{Pa}$, so

$$\begin{aligned} \delta_{99}(L) &= 5.0 \times 10^{-3} \times 1\,\mathrm{m} = 5\,\mathrm{mm}\,, \\ \tau_w(L) &= 0.664 \times 10^{-3} \times 500\,\mathrm{Pa} = 0.33\,\mathrm{Pa}\,, \\ F &= 1.328 \times 10^{-3} \times 500\,\mathrm{Pa} \times 1\,\mathrm{m} = 0.66\,\mathrm{N/m}\,, \end{aligned} \tag{A.1386}$$

per side. The layer is half a percent of the plate, which is the number Phenomenon 36.12 quotes, and the drag on a square metre of wetted surface is under a newton — a useful calibration of how small viscous friction is, and of how completely it nevertheless governs the flow when it separates.

Rests on Proposition A.801 and Phenomenon 36.12.

A.68.7 What these equations cannot describe

Remark A.804 (Three limits, all of them real). *Transition.* The solution above is laminar. The plate's own layer becomes turbulent at Re_x of order 5×10^5, so in Example A.803 the laminar solution is honest over roughly the first half metre and the quoted whole-plate drag is the laminar figure carried past its own domain of validity. The chapter records the same transition for the pipe at Section 36.3, and the threshold is no better determined here than it is there.

Separation. Equation (A.1355) is *parabolic* in x: it is marched downstream from an initial profile, and information travels only forwards. That is exactly what fails at separation. As the wall stress approaches zero under a rising external pressure, the marching solution develops a square-root singularity in x at the station where $(\partial_y u)_{y=0}$ vanishes — Goldstein's singularity, established in 1948 — and the computation cannot be continued through it. The layer equations therefore cannot describe the separated region whose existence is the principal observation of Phenomenon 36.12. This is why Proposition 36.13 is proved in the chapter by an expansion of the *full* equations at the wall, and not from Equation (36.26): the criterion Equation (36.24) has to be obtained by an argument that survives at the point where these equations break down. Goldstein's paper has no key in `references.bib` and the attribution here is made in words.

Leading edge. Equation (A.1380) diverges as $x \to 0$, where δ is comparable with x and the assumption $\partial_x^2 u \ll \partial_y^2 u$ used in Theorem A.798 fails. The divergence is integrable, so Equation (A.1382) is finite and the drag coefficient is unaffected at leading order; but the stress distribution near the leading edge is not given correctly by this theory.

Remark A.805. Appendix A.68 discharges the derivation owed at Proposition 36.15 of Chapter 36, in the boundary-layer experiment Section 36.5. Three things done here are used there and are worth carrying back. Theorem A.798 derives the exponent that Equation (36.23) estimated, so the chapter's resolution of the d'Alembert paradox rests on a reduction rather than on an order-of-magnitude argument. Corollary A.799 identifies what the outer flow gives the layer, which is the content of the chapter's remark that the pressure is "impressed" on the layer from outside and is the hypothesis under which Proposition 36.13 is stated. And Proposition A.802 closes the loop with Proposition 36.14: the drag measured by a

traverse of the wake and the drag computed from the stress at the wall are the same number, exactly, for the one flow in which both can be evaluated in closed form.

Appendix B

Physical Constants and SI Units

Since the revision that entered into force on 20 May 2019, the International System of Units (SI) is defined by assigning exact numerical values to seven defining constants of nature; every SI unit is then realised as a consequence of these fixed values [2333]. All other physical constants are determined experimentally, and this treatise uses throughout the recommended values of the CODATA 2018 adjustment [2392]. The present appendix collects, first, the seven defining constants with their exact values (Appendix B.2); second, the derived and measured constants that recur in the main text, quoted with their standard uncertainties (Appendix B.3); and third, the seven SI base units (Appendix B.5).

B.1 Mathematical constants

Two dimensionless numbers precede every physical constant in this appendix, since they are not measured but proven: $\mathrm{e} = 2.718\,281\,828\ldots$ and $\pi = 3.141\,592\,653\ldots$, both derived in full — e as the sum $\sum 1/n!$ and the limit $\lim(1+1/n)^n$ (Definition 7.53 and Proposition 7.57), π as twice the first positive zero of the cosine series and independently as the circle constant (Definition 7.61 and Proposition 7.62) — in Section 7.9.1 of Chapter 7. They are listed here only for numerical reference; their proofs are not repeated.

The digits are a separate claim from the existence of the constants, and worth separating explicitly. A definition that converges establishes that a number exists; it does not by itself justify writing down a single decimal. For e both steps are carried out: the truncation bound $\frac{1}{(n+1)!} \le \mathrm{e} - \sum_{k\le n} 1/k! < \frac{1}{n\cdot n!}$ (Lemma 7.54) traps e between two explicit rationals, and twelve terms already force the nine decimals quoted above (Corollary 7.55). The trailing … is a theorem too, not a typographical hedge: e is irrational (Proposition 7.56), so no finite decimal in this appendix equals it. Every entry below is a truncation; the only question is whether its error is stated.

The same two claims for π are asserted here but not yet derived.

Derivation pending #281

Digits and irrationality of π: an explicit error bound pinning $\pi = 3.141592653\ldots$, and Niven's proof that π is irrational. The latter needs $\sin\pi = 0$ and $\cos\pi = -1$, hence the addition formulas, which the real-analysis chapter does not yet establish — it defines π as twice the first positive zero of the cosine series and proves it is the circle constant, but computes no decimal of it.

B.2 The seven defining constants of the SI

The 2019 revision fixes the numerical values listed in Table B.1 exactly, by definition and without uncertainty [2333]. Each constant anchors one base unit, although the definitions are interlocking: the kilogram, for instance, is realised through the fixed value of the Planck constant together with the definitions of the second and the metre.

Table B.1: The seven defining constants of the SI (2019 revision). All values are exact by definition [2333].

Defining constant	Symbol	Exact value	Anchors
hyperfine transition frequency of ^{133}Cs	$\Delta\nu_{\mathrm{Cs}}$	$9\,192\,631\,770\,\mathrm{Hz}$	s
speed of light in vacuum	c	$299\,792\,458\,\mathrm{m/s}$	m
Planck constant	h	$6.626\,070\,15 \times 10^{-34}\,\mathrm{J\,s}$	kg
elementary charge	e	$1.602\,176\,634 \times 10^{-19}\,\mathrm{C}$	A
Boltzmann constant	k	$1.380\,649 \times 10^{-23}\,\mathrm{J/K}$	K
Avogadro constant	N_{A}	$6.022\,140\,76 \times 10^{23}/\mathrm{mol}$	mol
luminous efficacy of $540 \times 10^{12}\,\mathrm{Hz}$ radiation	K_{cd}	$683\,\mathrm{lm/W}$	cd

B.3 CODATA 2018 derived and measured constants

Table B.2 lists the constants used most frequently in this treatise, with the CODATA 2018 recommended values and standard uncertainties [2392]. Two entries deserve comment. The reduced Planck constant $\hbar = h/2\pi$ is exact because h is exact; its decimal representation is merely truncated in the table. The standard acceleration of free fall g_0 is not a constant of nature at all but a conventional exact value, adopted by the third Conférence Générale des Poids et Mesures in 1901 and retained in the SI Brochure [2333]; the local acceleration of free fall differs from it at the level of a few parts in 10^3 and is what absolute gravimeters actually measure [1906].

B.4 Planck units

The constants $\hbar$, c, and G together fix a length, mass, and time with no free numerical factor left undetermined by dimensional analysis alone.

Proposition B.1 (Planck units)**.** *The unique (up to a dimensionless constant) combinations of $\hbar$, c, G with dimensions of length, mass, and time are*

$$\ell_{\mathrm{P}} = \sqrt{\frac{\hbar G}{c^3}}\,, \qquad m_{\mathrm{P}} = \sqrt{\frac{\hbar c}{G}}\,, \qquad t_{\mathrm{P}} = \sqrt{\frac{\hbar G}{c^5}} = \frac{\ell_{\mathrm{P}}}{c}\,. \tag{B.1}$$

Rests on Theorem 2.3 and Axiom 2.2.

Proof. *Derives Proposition B.1.*

Write $\hbar^a c^b G^d$ and demand dimension L (length). In SI, $[\hbar] = \mathsf{M}\mathsf{L}^2\mathsf{T}^{-1}$, $[c] = \mathsf{L}\mathsf{T}^{-1}$, $[G] = \mathsf{M}^{-1}\mathsf{L}^3\mathsf{T}^{-2}$. Matching powers of $\mathsf{M}, \mathsf{L}, \mathsf{T}$ gives the linear system $a - d = 0$ (M), $2a + b + 3d = 1$ (L), $-a - b - 2d = 0$ (T); solving, $a = d = 1/2$, $b = -3/2$, i.e. $\hbar^{1/2} c^{-3/2} G^{1/2} = \sqrt{\hbar G/c^3}$. By the Buckingham π theorem (Theorem 2.3), three quantities built from three dimensionally independent constants leave zero dimensionless combinations, so this exponent solution is unique and no undetermined dimensionless prefactor can be fixed by dimensional analysis alone — exactly the freedom absorbed into the convention that defines ℓ_{P} with prefactor 1. The mass and time forms follow by the same linear system with target dimension M and T

Table B.2: Derived and measured constants, CODATA 2018 recommended values [2392]. The column u_{r} gives the relative standard uncertainty.

Quantity	Symbol	Value	u_{r}
Newtonian constant of gravitation	G	$(6.674\,30 \pm 0.000\,15) \times 10^{-11}\,\mathrm{m^3/(kg\,s^2)}$	2.2×10^{-5}
reduced Planck constant	$\hbar$	$1.054\,571\,817 \times 10^{-34}\,\mathrm{J\,s}$	exact[a]
electron mass	m_{e}	$(9.109\,383\,701\,5 \pm 0.000\,000\,002\,8) \times 10^{-31}\,\mathrm{kg}$	3.0×10^{-10}
proton mass	m_{p}	$(1.672\,621\,923\,69 \pm 0.000\,000\,000\,51) \times 10^{-27}\,\mathrm{kg}$	3.1×10^{-10}
vacuum magnetic permeability	μ_0	$(1.256\,637\,062\,12 \pm 0.000\,000\,000\,19) \times 10^{-6}\,\mathrm{N/A^2}$	1.5×10^{-10}
vacuum electric permittivity	ϵ_0	$(8.854\,187\,812\,8 \pm 0.000\,000\,001\,3) \times 10^{-12}\,\mathrm{F/m}$	1.5×10^{-10}
fine-structure constant	α	$(7.297\,352\,569\,3 \pm 0.000\,000\,001\,1) \times 10^{-3}$	1.5×10^{-10}
Bohr magneton	μ_{B}	$(9.274\,010\,078\,3 \pm 0.000\,000\,002\,8) \times 10^{-24}\,\mathrm{J/T}$	3.0×10^{-10}
standard acceleration of free fall	g_0	$9.806\,65\,\mathrm{m/s^2}$	exact[b]

[a] Exact because $\hbar = h/2\pi$ with h fixed; the decimal digits shown are truncated. [b] Conventional exact value, not a constant of nature [2333].

respectively (or, more quickly, from $m_{\mathrm{P}} = \hbar/(\ell_{\mathrm{P}} c)$ and $t_{\mathrm{P}} = \ell_{\mathrm{P}}/c$, using $[\hbar] = \mathsf{ML^2T^{-1}}$ to fix the mass combination and dimensional consistency to fix the time combination). □

Numerically, from the CODATA values of Table B.2,

$$\ell_{\mathrm{P}} \approx 1.616 \times 10^{-35}\,\mathrm{m}\,, \qquad m_{\mathrm{P}} \approx 2.176 \times 10^{-8}\,\mathrm{kg}\,, \qquad t_{\mathrm{P}} \approx 5.391 \times 10^{-44}\,\mathrm{s}\,, \tag{B.2}$$

the length and time scales at which quantum and gravitational effects are expected to become comparable in magnitude, and the mass scale against which the hierarchy problem of Appendix C is stated quantitatively.

B.5 SI base units

The seven base units of the SI, from which all coherent derived units are formed by products of powers, are collected in Table B.3 [2333]. Every quantity in this treatise is expressed in these units or in coherent derived units built from them, in accordance with the axiom stated in the front matter.

Table B.3: The seven SI base units [2333].

Base quantity	Base unit	Symbol
time	second	s
length	metre	m
mass	kilogram	kg
electric current	ampere	A
thermodynamic temperature	kelvin	K
amount of substance	mole	mol
luminous intensity	candela	cd

Appendix C

The Free Parameters of Physics

This appendix catalogs the complete set of dimensionless (or, where noted, dimensionful-but-irreducible) parameters that the evidence-based physics of this treatise — the Standard Model of particle physics and the base ΛCDM cosmological model — treats as free: numbers no confirmed theory yet predicts from anything more basic. The mathematical constants π and e (Section 7.9.1) and the dimensionful SI constants c, $\hbar$, G, ϵ_0, and the fine-structure constant α are catalogued separately in Appendix B, since they are either proven mathematical facts or exactly-defined/precisely-measured physical constants rather than free parameters in the sense used here.

Every entry below states, where one exists, how the quantity is *constructed* from more basic measured inputs; where no such construction exists, the entry says so plainly — the quantity is itself one of the truly free numbers of physics. Entries marked **(open)** are ones whose value, nature, or theoretical status is not yet settled by current evidence; each says explicitly what is and is not yet known, in keeping with this treatise's evidence-only scope (Chapter 1). None of the speculative theoretical programs sometimes proposed to explain these numbers — supersymmetry, extra dimensions, or similar — is invoked here as an explanation, since none is yet supported by direct evidence; where relevant this is stated explicitly, and the broader question is returned to in Chapter 133.

C.1 Electroweak and Higgs

The parameters catalogued here fix the electroweak sector of the Standard Model: the strength and mixing of the $SU(2)_L \times U(1)_Y$ gauge interactions, the scale of spontaneous symmetry breaking, and the mass and self-coupling of the Higgs boson that breaks it. The fine-structure constant α, the third traditional input of electroweak fits alongside G_F and m_Z, is already catalogued in Appendix B (`docs/latex/appendices/B-constants-units.tex`) and is not repeated here. All numerical values below are taken from the Particle Data Group's 2024 Review of Particle Physics. Because several of these quantities (the weak mixing angle, the gauge boson masses) are related by tree-level and loop-corrected Standard Model relations, they overdetermine the electroweak Lagrangian and their mutual consistency is itself a stringent test of the theory.

Fermi coupling constant G_F: $(1.166\,378\,7 \pm 0.000\,000\,6) \times 10^{-5}/\mathrm{GeV}^2$.

measured directly (muon lifetime: $1/\tau_\mu = \dfrac{G_F^2 m_\mu^5}{192\pi^3}(1 + \Delta q)$, Δq the known QED radiative correction).

The Fermi coupling constant G_F parametrizes the strength of charged-current weak interactions at energies far below the W-boson mass, in the effective four-fermion contact-interaction language that predates the discovery of the W and Z bosons. It is extracted

Table C.1: Electroweak and Higgs: summary of catalogued parameters.

Quantity	Symbol	Value
Fermi coupling constant	G_F	$(1.166\,378\,7 \pm 0.000\,000\,6) \times 10^{-5}/\mathrm{GeV}^2$
Higgs vacuum expectation value	v	$(246.219\,65 \pm 0.000\,06)$ GeV
Weak mixing angle	$\sin^2\hat{\theta}_W(m_Z)$	$0.231\,22 \pm 0.000\,04$
W boson mass	m_W	(80.3692 ± 0.0133) GeV
Z boson mass	m_Z	(91.1876 ± 0.0021) GeV
Higgs boson mass	m_H	(125.20 ± 0.11) GeV
Higgs quartic self-coupling	λ	0.1293 ± 0.0002

with extraordinary precision from the muon lifetime, measured most accurately by the MuLan experiment at PSI, combined with QED radiative corrections computed to several loop orders. Because G_F is known to a relative precision of order 5×10^{-7}, it – rather than v directly – is used as one of the primary electroweak input parameters, alongside α (Appendix B) and m_Z, in global electroweak fits. Through $v = (\sqrt{2}G_F)^{-1/2}$ it fixes the overall scale of electroweak symmetry breaking. [2427]

Higgs vacuum expectation value v: $(246.219\,65 \pm 0.000\,06)$ GeV.

$v \equiv (\sqrt{2}\,G_F)^{-1/2}$.

The vacuum expectation value v of the neutral component of the Higgs doublet sets the scale at which $SU(2)_L \times U(1)_Y$ electroweak symmetry breaks spontaneously to the electromagnetic $U(1)_{\mathrm{em}}$, and through the Yukawa couplings $y_f = \sqrt{2}\,m_f/v$ it fixes the overall normalization of every fermion mass in the Standard Model. It is not measured directly but derived from the far more precisely known Fermi constant via $v = (\sqrt{2}G_F)^{-1/2}$, since G_F and v describe the same low-energy strength of the charged-current weak interaction. Its numerical value, close to 246 GeV, together with the Higgs mass m_H fixes the Higgs quartic self-coupling λ (see below). [2427]

Weak mixing angle $\sin^2\hat{\theta}_W(m_Z)$: $0.231\,22 \pm 0.000\,04$.

$\overline{\mathrm{MS}}$ scheme: $\sin^2\hat{\theta}_W(\mu = m_Z) \equiv \dfrac{\hat{g}'^2}{\hat{g}^2 + \hat{g}'^2}\Big|_{\overline{\mathrm{MS}}}$; on-shell scheme: $\sin^2\theta_W \equiv 1 - m_W^2/m_Z^2$.

The weak mixing (Weinberg) angle θ_W rotates the neutral $SU(2)_L \times U(1)_Y$ gauge fields W_μ^3, B_μ into the physical Z boson and the photon, and its sine-squared is the single additional number, beyond α and G_F (or m_Z), needed to fix all electroweak neutral-current couplings at tree level. Because $\sin^2\theta_W$ is a ratio of couplings, its numerical value is renormalization-scheme dependent: the value quoted here is the $\overline{\mathrm{MS}}$ value evaluated at $\mu = m_Z$, obtained from global electroweak fits to Z-pole asymmetries and low-energy neutral-current data. The alternative on-shell definition, $\sin^2\theta_W \equiv 1 - m_W^2/m_Z^2$, gives a numerically different value – using the PDG-2024 m_W and m_Z listed below, $1 - m_W^2/m_Z^2 \approx 0.2232$ – because it absorbs electroweak radiative corrections differently order by order. [2427]

W boson mass m_W: (80.3692 ± 0.0133) GeV.

$m_W = \frac{1}{2}gv$, fixing the $SU(2)_L$ gauge coupling g once v is known; measured directly.

The $W^\pm$ boson mass is one of the two masses generated by the Higgs mechanism through the covariant derivative of the Higgs doublet, $m_W = \frac{1}{2}gv$, so its measurement, combined with the independently fixed v, determines the $SU(2)_L$ gauge coupling g. It is measured kinematically from the transverse-mass and transverse-momentum distributions

of leptons in $W \to \ell\nu$ decays at hadron colliders (Tevatron, LHC) and, less precisely, from $e^+e^- \to W^+W^-$ threshold scans at LEP2. The value quoted is the PDG-2024 world average; the 2022 CDF-II measurement ($(80.4335 \pm 0.0094)\,\mathrm{GeV}$) lies in tension of several standard deviations with this average and with the Standard Model electroweak fit, a discrepancy still under active experimental scrutiny following subsequent 2024 measurements (including a CMS result and a revised ATLAS analysis) that favor the lower, SM-consistent value. [2427]

Z boson mass m_Z: $(91.1876 \pm 0.0021)\,\mathrm{GeV}$.

$m_Z = \frac{1}{2}v\sqrt{g^2 + g'^2}$, fixing the combination $g^2 + g'^2$ once v is known; measured directly.

The Z boson mass is fixed, like m_W, by electroweak symmetry breaking, $m_Z = \frac{1}{2}v\sqrt{g^2 + g'^2}$, so its measurement fixes the combination of $SU(2)_L$ and $U(1)_Y$ gauge couplings $g^2 + g'^2$ once v is known from G_F. It is by far the most precisely known electroweak boson mass, extracted from the $e^+e^- \to Z$ resonance line shape scanned at LEP1 and at the SLC, where it appears as the peak of the total hadronic and leptonic cross sections. Its relative precision of about 2×10^{-5} makes it, together with α and G_F, one of the three canonical input parameters of the electroweak Lagrangian in most global-fit conventions. [2427]

Higgs boson mass m_H: $(125.20 \pm 0.11)\,\mathrm{GeV}$.

measured directly (resonance peak in $H \to \gamma\gamma$ and $H \to ZZ^* \to 4\ell$); fixes the quartic self-coupling via $m_H^2 = 2\lambda v^2$.

The Higgs boson mass, established in 2012 by ATLAS and CMS through the $H \to \gamma\gamma$ and $H \to ZZ^* \to 4\ell$ decay channels, is measured directly as the invariant-mass peak of the decay products; unlike the fermion and gauge-boson masses, it is not predicted from a more fundamental parameter within the Standard Model but is itself a genuinely free input, fixing the strength of the Higgs field's quartic self-interaction λ through $m_H^2 = 2\lambda v^2$. The value quoted is the PDG-2024 world average combining the high-resolution di-photon and four-lepton mass measurements of both experiments. Once m_H and v are fixed, every other tree-level Higgs property – total width, branching ratios, and the self-coupling λ – follows with no further free parameters, which is precisely what ongoing LHC Higgs-coupling measurements continue to test. [2427]

Higgs quartic self-coupling λ: 0.1293 ± 0.0002.

$\lambda = m_H^2/(2v^2)$.

The Higgs quartic self-coupling λ multiplies the $\lambda(\Phi^\dagger\Phi)^2$ term of the Higgs potential and, together with v, sets both the shape of the electroweak vacuum and the physical Higgs boson mass, $m_H^2 = 2\lambda v^2$. Unlike m_H, λ is not itself measured to comparable precision: its value quoted here is inferred algebraically from the two directly measured quantities m_H and v, giving $\lambda \approx 0.129$. A genuinely independent, direct determination of λ requires observing Higgs pair production ($pp \to HH$) and extracting the Higgs trilinear self-coupling, a measurement that remains statistics-limited at the LHC and has so far only placed loose bounds around the Standard Model expectation. The measured smallness of λ relative to the top-quark Yukawa coupling squared is also central to the (unresolved) question of the stability of the electroweak vacuum under renormalization-group running to high energy scales. [2427]

C.2 Quantum Chromodynamics

Quantum chromodynamics (QCD), the $\mathrm{SU}(3)_c$ gauge sector of the Standard Model, is characterized by a running coupling α_s and six quark mass parameters whose numerical values are, unlike the electroweak sector, deeply entangled with the choice of renormalization

scheme and scale: light-quark masses are conventionally quoted in $\overline{\text{MS}}$ at a fixed scale of 2 GeV, the charm and bottom masses in $\overline{\text{MS}}$ at their own mass scale, and the top mass – uniquely among quarks, since it decays before hadronizing – as an approximate pole mass reconstructed from collider kinematics. This scheme-dependence is not a bookkeeping nuisance but reflects the underlying fact that confined color charges have no scheme-independent, asymptotic-state definition of mass in the way leptons do. The sector also harbors one of the cleanest open problems in physics: the QCD vacuum angle $\bar{\theta}_{\text{QCD}}$, which the symmetries of the Standard Model permit to take any value of order unity but which experiment constrains to be smaller than one part in 10^{10}, with no confirmed dynamical explanation.

Table C.2: Quantum Chromodynamics: summary of catalogued parameters.

Quantity	Symbol	Value
Strong coupling constant	$\alpha_s(M_Z)$	0.1180 ± 0.0009
Up-quark mass	m_u	$2.16^{+0.49}_{-0.26}$ MeV
Down-quark mass	m_d	$4.67^{+0.48}_{-0.17}$ MeV
Strange-quark mass	m_s	$93.4^{+8.6}_{-3.4}$ MeV
Charm-quark mass	$m_c(m_c)$	(1.27 ± 0.02) GeV
Bottom-quark mass	$m_b(m_b)$	$4.18^{+0.03}_{-0.02}$ GeV
Top-quark mass	m_t	(172.57 ± 0.29) GeV
QCD vacuum angle (strong CP problem) [(open)]	$\bar{\theta}_{\text{QCD}}$	10^{-10} (see text)

Strong coupling constant $\alpha_s(M_Z)$: 0.1180 ± 0.0009.

$\alpha_s \equiv g_s^2/(4\pi)$, where g_s is the QCD gauge coupling; the value is scale-dependent (renormalization-group running governed by the QCD β-function) and is conventionally quoted at $\mu = M_Z$, the world average from lattice QCD, τ-decay, deep-inelastic scattering, event-shape, and electroweak precision-fit determinations.

The strong coupling $\alpha_s(\mu)$ measures the strength of the color force at renormalization scale μ; unlike the electromagnetic fine-structure constant α, which is essentially scale-independent at laboratory energies, α_s runs rapidly and grows large at low energy, producing confinement, and shrinks logarithmically at high energy, producing asymptotic freedom – the property for which the 2004 Nobel Prize was awarded. By convention it is quoted at the reference scale $\mu = M_Z \approx 91.19$ GeV, where the PDG world average combines lattice-QCD sum rules, τ-lepton hadronic decays, deep-inelastic scattering structure functions, e^+e^- jet event shapes, and the running of α_s inferred from Z-pole electroweak fits. Its value sets the size of perturbative QCD corrections throughout the treatise (hadron collider cross sections, jet physics, hadronic decay widths) and, via dimensional transmutation, fixes the intrinsic QCD scale $\Lambda_{\text{QCD}} \sim 200$ MeV at which the coupling formally diverges and confinement sets in. [2427]

Up-quark mass m_u: $2.16^{+0.49}_{-0.26}$ MeV.

measured directly, as a Lagrangian mass parameter (coefficient of $\bar{u}u$) in the $\overline{\text{MS}}$ renormalization scheme at $\mu = 2$ GeV; extracted from lattice QCD combined with QCD sum rules, chiral perturbation theory mass ratios, and hadron spectroscopy.

The up-quark mass is a free parameter of the Standard Model Lagrangian, fixed by the Yukawa coupling of u to the Higgs field, and is never observed as a free-particle mass because of color confinement. It is instead extracted as a running $\overline{\text{MS}}$-scheme mass parameter,

conventionally quoted at $\mu = 2\,\mathrm{GeV}$, from lattice QCD combined with chiral perturbation theory constraints on light-quark mass ratios and QCD sum rules applied to hadron spectra. This scheme dependence is physically essential: quoting "the" up-quark mass without specifying scheme and scale is meaningless, since the value shifts under renormalization-group running exactly as α_s does. The smallness and asymmetric uncertainty of m_u relative to Λ_{QCD} (light-quark masses are a small perturbation on hadron masses, most of which arises from gluon binding energy) also underlies the near-exact isospin symmetry of nuclear physics. [2427]

Down-quark mass m_d: $4.67^{+0.48}_{-0.17}\,\mathrm{MeV}$.

measured directly, as a Lagrangian mass parameter in the $\overline{\mathrm{MS}}$ scheme at $\mu = 2\,\mathrm{GeV}$; extracted from lattice QCD, chiral perturbation theory, and QCD sum rules, jointly with m_u and m_s.

Like m_u, the down-quark mass is a free Standard-Model parameter quoted in the $\overline{\mathrm{MS}}$ scheme at $\mu = 2\,\mathrm{GeV}$, obtained jointly with the other light-quark masses from lattice QCD and chiral perturbation theory fits to pion, kaon, and eta meson masses and decay constants. That $m_d > m_u$ by roughly a factor of two is the dominant source of the proton-neutron mass difference (partially offset by electromagnetic self-energy), and is responsible for the neutron being heavier than the proton – a fact of considerable cosmological importance, since it permits free-neutron beta decay and shapes primordial nucleosynthesis. As with m_u, no experiment isolates a free down quark; all determinations are indirect, via QCD-mediated observables. [2427]

Strange-quark mass m_s: $93.4^{+8.6}_{-3.4}\,\mathrm{MeV}$.

measured directly, as a Lagrangian mass parameter in the $\overline{\mathrm{MS}}$ scheme at $\mu = 2\,\mathrm{GeV}$; extracted principally from lattice QCD and QCD sum rules applied to kaon and η/η' physics.

The strange-quark mass, quoted in the $\overline{\mathrm{MS}}$ scheme at the same reference scale $\mu = 2\,\mathrm{GeV}$ used for m_u and m_d, is roughly twenty times larger than the down-quark mass and is the dominant explicit breaking term for flavor SU(3) symmetry among the light hadrons. It is determined mainly from lattice QCD (moments of correlators, kaon masses and decay constants) and from QCD sum rules constrained by τ-decay and e^+e^- data; its uncertainty, while still asymmetric and scheme-dependent, has shrunk considerably as lattice methods have matured. Together, m_u, m_d, m_s set the size of chiral symmetry breaking effects that organize the light hadron spectrum (pions and kaons as pseudo-Goldstone bosons of spontaneously broken chiral symmetry). [2427]

Charm-quark mass $m_c(m_c)$: $(1.27 \pm 0.02)\,\mathrm{GeV}$.

measured directly, as a Lagrangian mass parameter in the $\overline{\mathrm{MS}}$ scheme evaluated at its own mass scale, $\mu = m_c$ (the conventional choice for heavy quarks, distinct from the fixed $\mu = 2\,\mathrm{GeV}$ used for u, d, s); extracted from charmonium sum rules and lattice QCD.

Unlike the light quarks, the charm-quark mass is conventionally quoted in the $\overline{\mathrm{MS}}$ scheme evaluated at its own mass, $\mu = m_c(m_c)$, rather than at the fixed 2 GeV reference used for u, d, s – a scheme choice that avoids large logarithms in the perturbative relation between the running mass and observables near the charm threshold. The dominant determinations come from QCD sum rules applied to $e^+e^- \to$ charm-quark-pair cross-section data and charmonium spectroscopy, cross-checked by lattice QCD. Because m_c sits close to Λ_{QCD} times a moderate factor, charm physics occupies an intermediate regime where both perturbative QCD and nonperturbative (lattice, effective field theory) methods are needed and mutually validated. [2427]

Bottom-quark mass $m_b(m_b)$: $4.18^{+0.03}_{-0.02}\,\mathrm{GeV}$.

measured directly, as a Lagrangian mass parameter in the $\overline{\text{MS}}$ scheme evaluated at its own mass scale, $\mu = m_b$; extracted from bottomonium sum rules, lattice QCD, and inclusive/exclusive B-meson semileptonic decay spectra.

The bottom-quark mass, like the charm mass, is quoted in the $\overline{\text{MS}}$ scheme at its own scale $\mu = m_b(m_b)$, which keeps the perturbative series for mass-dependent observables well behaved. It is determined from a combination of bottomonium (Υ-system) sum rules, lattice QCD, and QCD-based analyses of inclusive and exclusive semileptonic B-meson decay spectra, all of which now agree to sub-percent precision. The bottom mass is a key input to CKM-matrix determinations from B-physics (Part on flavor physics) and to Higgs-boson branching-ratio predictions, since $H \to b\bar{b}$ is the dominant Higgs decay channel and its rate depends quadratically on m_b. [2427]

Top-quark mass m_t: $(172.57 \pm 0.29)\,\text{GeV}$.

measured directly, as a pole mass (not an $\overline{\text{MS}}$ running mass, unlike the other five quarks) from kinematic reconstruction of top-antitop pair-production events at the Tevatron and LHC.

The top quark is the only quark reported as a pole mass rather than an $\overline{\text{MS}}$ running mass, because it decays via the electroweak interaction ($t \to W^+ b$) before it can hadronize – it is the one quark whose mass can be reconstructed directly from the kinematics of its (quasi-free) decay products, bypassing the scheme ambiguities inherent to confined quarks. The world average combines direct kinematic reconstructions from ATLAS, CMS, and the Tevatron experiments (CDF, D0). It should be noted that the "pole mass" extracted this way carries a residual, formally ill-defined nonperturbative ambiguity of order Λ_{QCD} (the renormalon ambiguity), so the quoted value is understood as an operationally defined Monte-Carlo mass closely related to, but not rigorously identical to, the theoretical pole mass; conversion to a well-defined short-distance mass scheme (e.g. $\overline{\text{MS}}$) shifts the central value down by roughly 9 GeV to 10 GeV (e.g. $\overline{m}_t(\overline{m}_t) \approx 163\,\text{GeV}$ versus the pole-like value above). At $\sim 173\,\text{GeV}$, comparable to the electroweak scale, the top mass gives the largest Yukawa coupling in the Standard Model ($y_t \approx 1$) and dominates radiative corrections to the Higgs mass and to electroweak precision observables. [2427]

QCD vacuum angle (strong CP problem) (open) $\bar{\theta}_{\text{QCD}}$: $\left|\bar{\theta}_{\text{QCD}}\right| \lesssim 10^{-10}$ (90% C.L., from the neutron electric dipole moment bound).

appears as the coefficient of the CP-violating topological term $\mathcal{L}_\theta = \theta_{\text{QCD}} \dfrac{g_s^2}{32\pi^2} G^a_{\mu\nu} \tilde{G}^{a\,\mu\nu}$ in the QCD Lagrangian; the physically observable combination $\bar{\theta}_{\text{QCD}} = \theta_{\text{QCD}} + \arg\det(M_u M_d M_s \cdots)$ absorbs an equal, in-principle-independent phase from the quark mass matrix, and is bounded from above by the non-observation of a neutron electric dipole moment.

The QCD Lagrangian admits a gauge-invariant, Lorentz-invariant, renormalizable term $\theta_{\text{QCD}}\,(g_s^2/32\pi^2)\,G\tilde{G}$ built from the gluon field strength and its dual, which violates parity and time-reversal (hence CP, by CPT) and is entirely permitted by the symmetries of the Standard Model; the physical angle $\bar{\theta}_{\text{QCD}}$ also receives a contribution from the phase of the determinant of the quark mass matrix, so it is not removable by a field redefinition once electroweak symmetry breaking generates quark masses. A nonzero $\bar{\theta}_{\text{QCD}}$ of order unity is the generic theoretical expectation, since it is an allowed, unsuppressed term with no symmetry reason to vanish, and it would produce an observably large neutron electric dipole moment $d_n \sim \bar{\theta}_{\text{QCD}} \times e\,10^{-16}\,\text{cm}$. Experimentally, the most sensitive constraint comes from ultracold-neutron electric-dipole-moment experiments, whose current upper bound on $|d_n|$ (of order $e\,10^{-26}\,\text{cm}$) translates into $\left|\bar{\theta}_{\text{QCD}}\right| \lesssim 10^{-10}$, a suppression by roughly ten orders of magnitude below its theoretically natural size. This unexplained fine-tuning – why a

free, dimensionless parameter of the strong interaction sits so close to zero when nothing in the Standard Model forces it to – constitutes the strong CP problem, one of the cleanest and longest-standing naturalness puzzles in particle physics; it remains open within the evidence-based scope of this treatise; proposed dynamical solutions (e.g. a spontaneously broken Peccei–Quinn symmetry and its associated axion) are not yet supported by direct experimental evidence and are noted here only for completeness, not asserted. [2427]

C.3 Charged Lepton Masses and Quark Mixing (CKM)

The charged-lepton sector of the Standard Model exhibits a mass hierarchy spanning more than three orders of magnitude between the electron, muon, and tau, with no accepted dynamical explanation for the specific ratios observed – this is the long-standing "flavor puzzle." In the quark sector, the mismatch between the mass eigenbasis and the weak-interaction eigenbasis of the up- and down-type quarks is encoded in the unitary Cabibbo–Kobayashi–Maskawa (CKM) matrix V_{CKM}, conventionally written in the standard parametrization as a product of three Euler-like rotations through mixing angles $\theta_{12}, \theta_{13}, \theta_{23}$ and a single physical complex phase δ_{13} that is the sole source of CP violation in the quark sector at tree level in the SM. All four parameters, together with the nine $|V_{ij}|$ moduli they generate, are extracted from a global fit to semileptonic decays, meson mixing, and CP-violating observables (e.g., ϵ_K, $\sin 2\beta$) tabulated by the Particle Data Group. The Jarlskog invariant J packages $\theta_{12}, \theta_{13}, \theta_{23}, \delta_{13}$ into the unique rephasing- and basis-independent scalar measure of CP violation, and its smallness relative to the maximal value permitted by unitarity ($J_{\max} = 1/(6\sqrt{3}) \approx 0.096$) is what makes CP-violating effects in flavor-conserving SM processes generically tiny.

Table C.3: Charged Lepton Masses and Quark Mixing (CKM): summary of catalogued parameters.

Quantity	Symbol	Value
Muon-to-electron mass ratio	m_μ/m_e	$206.768\,283\,0 \pm 0.000\,004\,6$
Tau-to-electron mass ratio	m_τ/m_e	3477.23 ± 0.23
Cabibbo angle	θ_{12}	$(13.02 \pm 0.04)^\circ$
CKM mixing angle (13)	θ_{13}	$(0.212 \pm 0.006)^\circ$
CKM mixing angle (23)	θ_{23}	$(2.40 \pm 0.05)^\circ$
CKM CP-violating phase	δ_{13}	(1.144 ± 0.027) rad
Jarlskog invariant	J	$(3.08 \pm 0.15) \times 10^{-5}$

Muon-to-electron mass ratio m_μ/m_e: $206.768\,283\,0 \pm 0.000\,004\,6$.

m_μ/m_e(ratio of the independently measured muon and electron pole masses).

The muon-to-electron mass ratio is one of the most precisely known numbers in particle physics, determined from the independently measured muon mass (itself pinned down via muonium hyperfine spectroscopy and muon spin rotation in magnetic fields) and the electron mass from Penning-trap g-factor measurements. Both leptons couple identically to the electroweak gauge fields and differ only through their Yukawa couplings to the Higgs field, so this ratio is, in the Standard Model, simply the ratio of two a priori independent, unrelated Yukawa parameters. No symmetry or dynamical principle within the SM fixes or explains why $m_\mu/m_e \approx 207$ rather than some other value; this is the leptonic instance of the flavor puzzle. The ratio enters directly in tests of lepton universality, muonium spectroscopy, and the theoretical prediction of the muon's anomalous magnetic moment. [2427]

Tau-to-electron mass ratio m_τ/m_e: 3477.23 ± 0.23.

m_τ/m_e(ratio of the measured tau and electron pole masses).

The tau lepton mass, and hence this ratio, is measured principally from the tau pair production threshold scan in e^+e^- collisions (BES, Belle) via precise reconstruction of the threshold cross-section shape, giving a much larger relative uncertainty than the muon case because the tau's short lifetime prevents the ultra-precise spectroscopic techniques available for the muon and electron. As with m_μ/m_e, the Standard Model provides three independent Yukawa couplings for the charged leptons with no built-in relation between them, so the value $m_\tau/m_e \approx 3477$ is an unexplained input rather than a derived consequence of any known symmetry. Together with m_μ/m_e, this ratio is a central piece of evidence for the flavor puzzle: three generations of otherwise identical particles (same electroweak quantum numbers) with masses set by numerically unrelated, hierarchically spread coupling constants that the SM does not predict. [2427]

Cabibbo angle θ_{12}: $(13.02 \pm 0.04)^\circ$.

$\sin\theta_{12} = |V_{us}| / \sqrt{|V_{ud}|^2 + |V_{us}|^2}$(standard parametrization of V_{CKM}).

The Cabibbo angle is the largest of the three CKM mixing angles, first introduced by Cabibbo in 1963 to explain the suppression of strangeness-changing weak decays relative to strangeness-conserving ones, well before the third quark generation was known to exist. It is extracted from a combination of superallowed nuclear β decays and pion/kaon semileptonic decays (fixing $|V_{ud}|$ and $|V_{us}|$) together with the CKM unitarity constraint. Its near-maximal size relative to θ_{13} and θ_{23} reflects the empirical fact that quark mixing is strongly hierarchical, concentrated between the first two generations, with the corresponding value $\sin\theta_{12} \approx 0.225$ often denoted the Wolfenstein parameter λ. [2427]

CKM mixing angle (13) θ_{13}: $(0.212 \pm 0.006)^\circ$.

$\sin\theta_{13} = |V_{ub}|$(standard parametrization of V_{CKM}).

This is the smallest of the three CKM mixing angles, governing the direct coupling between the first- and third-generation quarks. It is fixed essentially by $|V_{ub}|$, determined from semileptonic $b \to u\ell\nu$ transitions in both inclusive and exclusive ($B \to \pi\ell\nu$) decay channels; a persistent few-percent-level tension between the inclusive and exclusive extractions of $|V_{ub}|$ remains one of the more actively studied discrepancies in flavor physics. The extreme smallness of θ_{13} compared to θ_{12} is part of the same unexplained mixing hierarchy that characterizes the quark sector. [2427]

CKM mixing angle (23) θ_{23}: $(2.40 \pm 0.05)^\circ$.

$\sin\theta_{23} = |V_{cb}| / \sqrt{|V_{cb}|^2 + |V_{tb}|^2} \approx |V_{cb}|$(standard parametrization of V_{CKM}).

This angle governs mixing between the second and third quark generations and is fixed principally by $|V_{cb}|$, measured from semileptonic $B \to D^{(*)}\ell\nu$ exclusive decays and from inclusive $b \to c\ell\nu$ moment analyses. As with θ_{13}, mild tension persists between inclusive and exclusive determinations, currently at roughly the 1–2σ level and under continued scrutiny with improved lattice QCD form factors. Its intermediate size, between the large θ_{12} and the tiny θ_{13}, completes the hierarchical pattern of quark mixing angles that has no accepted first-principles explanation within the Standard Model. [2427]

CKM CP-violating phase δ_{13}: (1.144 ± 0.027) rad.

measured directly, as the complex phase of V_{CKM} in the standard (Chau–Keung) parametrization, from a global fit to CP-violating and CP-conserving flavor observables.

The phase δ_{13} is the single irreducible complex parameter of the CKM matrix once unphysical quark-field rephasings are removed, and it is the origin of all CP violation

observed in flavor-changing weak processes within the Standard Model, first evidenced in neutral kaon decays and later confirmed in the B-meson system by the BaBar and Belle experiments. It is extracted from a global fit combining CP-violating observables, most importantly the indirect CP violation parameter ϵ_K in the kaon system and the mixing-induced CP asymmetry $\sin 2\beta$ measured in $B^0 \to J/\psi K^0_S$ decays, together with the CP-conserving $|V_{ij}|$ measurements that fix the angles. That a single phase in a 3×3 unitary mixing matrix accounts for essentially all quark-sector CP violation measured to date is itself a strong, quantitatively successful prediction of the three-generation Standard Model, dating to Kobayashi and Maskawa's 1973 proposal. [2427]

Jarlskog invariant J: $(3.08 \pm 0.15)\times 10^{-5}$.

$$J = \Im\left(V_{us}V_{cb}V_{ub}^{*}V_{cs}^{*}\right) = \sin\theta_{12}\sin\theta_{13}\sin\theta_{23}\cos\theta_{12}\cos^{2}\theta_{13}\cos\theta_{23}\sin\delta_{13}$$

The Jarlskog invariant J is the unique combination of CKM angles and phase that is invariant under rephasing of the quark fields, and it appears as an overall multiplicative factor in every CP-violating asymmetry computable in the Standard Model quark sector, making it the single basis-independent scalar measure of how much CP violation the CKM mechanism can generate. Its value is obtained by propagating the fitted $\theta_{12},\theta_{13},\theta_{23},\delta_{13}$ (or equivalently the fitted V_{ij} moduli and phase convention) through the defining combination above. That $J \sim 3\times 10^{-5}$ is many orders of magnitude below both the naive $\mathcal{O}(1)$ scale set by the largest mixing angle and the unitarity bound $J_{\max} = 1/(6\sqrt{3}) \approx 0.096$ is the quantitative statement of why CP-violating effects, while firmly established, are numerically small throughout the flavor-conserving sector of the Standard Model – and why the observed matter-antimatter asymmetry of the universe cannot be explained by SM CP violation alone. [2427]

C.4 Neutrino Oscillations and the PMNS Matrix

Neutrino flavour oscillation, observed in solar, atmospheric, reactor, and accelerator beams, established that neutrinos are massive and that the weak-interaction flavour eigenstates ν_e,ν_μ,ν_τ are related to the mass eigenstates ν_1,ν_2,ν_3 by a unitary mixing matrix, the Pontecorvo–Maki–Nakagawa–Sakata (PMNS) matrix U, in direct analogy with the CKM matrix of the quark sector. In the standard three-flavour parametrization, U is written as a product of three rotations through the angles θ_{12}, θ_{13}, θ_{23}, one Dirac CP-violating phase δ_{CP}, and (if neutrinos are Majorana particles) two additional Majorana phases that do not affect oscillation probabilities. Oscillation probabilities depend on the mixing angles and on the two independent mass-squared splittings Δm^2_{21} and Δm^2_{32} (equivalently $\Delta m^2_{31} = \Delta m^2_{32} + \Delta m^2_{21}$), never on the absolute neutrino masses themselves, which remain a separate and still-open experimental question tied to the equally open question of whether the neutrino mass term is of Dirac or Majorana type. Values below are global-fit results as compiled in the Particle Data Group review of neutrino mixing.

Solar mixing angle θ_{12}: 33.41°.

$\theta_{12} = \arcsin\sqrt{\sin^2\theta_{12}}$, $\sin^2\theta_{12} = 0.303 \pm 0.011$ measured directly.

The solar mixing angle governs the ν_2–ν_1 admixture and, together with Δm^2_{21}, sets the survival probability $P(\nu_e \to \nu_e)$ observed in solar-neutrino experiments (Homestake, GALLEX/SAGE, Super-Kamiokande, SNO) and in the long-baseline reactor experiment KamLAND, which probes the same oscillation parameters in vacuum rather than through solar matter effects. Because θ_{12} is unambiguously bounded away from both 0 and 45°, it is often called the best-measured of the three angles once matter (MSW) effects inside the Sun

Table C.4: Neutrino Oscillations and the PMNS Matrix: summary of catalogued parameters.

Quantity	Symbol	Value
Solar mixing angle	θ_{12}	33.41°
Reactor mixing angle	θ_{13}	8.54°
Atmospheric mixing angle	θ_{23}	49.1°
Solar mass-squared splitting	Δm^2_{21}	$(7.53 \pm 0.18) \times 10^{-5}\,\mathrm{eV}^2$
Atmospheric mass-squared splitting	Δm^2_{32}	$(2.453 \pm 0.034) \times 10^{-3}\,\mathrm{eV}^2$
PMNS CP-violating phase (open)	δ_{CP}	197°
Absolute neutrino mass scale and Dirac/Majorana nature (open)	$m_i,\ \sum_i m_i$	0.12 eV (see text)

– confirmed decisively by SNO's neutral-current measurement – are accounted for. The value quoted is the current global-fit best fit to the combined solar and KamLAND data set; it is essentially identical for the normal and inverted mass orderings, since ordering sensitivity enters mainly through θ_{13} and Δm^2_{31}. [2427]

Reactor mixing angle θ_{13}: 8.54°.

$\theta_{13} = \arcsin\sqrt{\sin^2\theta_{13}}$, $\sin^2\theta_{13} = 0.0220 \pm 0.0007$ measured directly.

θ_{13} is the smallest of the three PMNS angles and was the last to be measured, established at high significance in 2012 by the short-baseline reactor experiments Daya Bay, RENO, and Double Chooz through the disappearance $P(\bar{\nu}_e \to \bar{\nu}_e) \simeq 1 - \sin^2(2\theta_{13})\sin^2(\Delta m^2_{31} L/4E)$ at $\mathcal{O}(1\,\mathrm{km})$ baselines. Although numerically small, a nonzero θ_{13} is what makes the CP-violating phase δ_{CP} observable in $\nu_\mu \to \nu_e$ appearance channels and what allows matter-effect sensitivity to the neutrino mass ordering in long-baseline accelerator experiments; its discovery reopened the experimental programme now pursued by T2K, NOvA, JUNO, DUNE, and Hyper-Kamiokande. The value is now known to about three percent precision and is essentially ordering-independent at this level. [2427]

Atmospheric mixing angle θ_{23}: 49.1°.

$\theta_{23} = \arcsin\sqrt{\sin^2\theta_{23}}$, $\sin^2\theta_{23} = 0.572 \pm 0.020$ measured (normal-ordering best fit).

The atmospheric angle controls ν_μ disappearance in atmospheric neutrinos (Super-Kamiokande, IceCube DeepCore) and in accelerator long-baseline experiments (T2K, NOvA, MINOS), and is close to, but not proven exactly equal to, the maximal-mixing value 45°. Current global fits place the best fit in the upper octant ($\theta_{23} > 45^\circ$, equivalently $\sin^2\theta_{23} > 0.5$) as quoted above, with a statistically nearly degenerate solution in the lower octant near $\sin^2\theta_{23} \approx 0.45$; resolving this octant ambiguity, which affects both δ_{CP} extraction and mass-ordering sensitivity, is a stated goal of NOvA, T2K-II, DUNE, and Hyper-Kamiokande. The value is only mildly ordering-dependent and is the least precisely known of the three angles, at roughly the four percent level. [2427]

Solar mass-squared splitting Δm^2_{21}: $(7.53 \pm 0.18) \times 10^{-5}\,\mathrm{eV}^2$.

$\Delta m^2_{21} \equiv m_2^2 - m_1^2 > 0$ (sign fixed by the MSW matter resonance in the Sun); measured directly.

Δm^2_{21} is the smaller of the two independent squared-mass splittings and, together with θ_{12}, fixes the long oscillation length responsible for solar-neutrino conversion and for the

KamLAND reactor-antineutrino oscillation pattern at $\mathcal{O}(100\,\mathrm{km})$ baselines. Unlike the atmospheric splitting, its sign is unambiguously determined (positive, i.e. $m_2 > m_1$) because solar matter effects (the MSW mechanism) break the vacuum degeneracy between the two sign choices; this is the only mass-ordering information oscillation experiments obtain without appeal to θ_{13}-driven matter effects on the atmospheric splitting. The quoted global-fit value combines solar data with the reactor measurement from KamLAND and is known to about 2 % precision. [2427]

Atmospheric mass-squared splitting Δm^2_{32}: $(2.453 \pm 0.034) \times 10^{-3}\,\mathrm{eV}^2$.

$\Delta m^2_{32} \equiv m_3^2 - m_2^2$; magnitude measured directly, value quoted for Normal Ordering ($m_3 > m_2 > m_1$); equivalently $\Delta m^2_{31} = \Delta m^2_{32} + \Delta m^2_{21} \approx 2.528 \times 10^{-3}\,\mathrm{eV}^2$.

Δm^2_{32} sets the fast oscillation frequency probed by atmospheric neutrinos and by accelerator long-baseline experiments and, together with θ_{23}, dominates ν_μ disappearance in that regime. Its magnitude is known to about 1.5 %, essentially identically whichever mass ordering is assumed, but its *sign* is not yet established at high statistical significance from oscillation data alone: this sign is precisely the neutrino mass-ordering (normal-vs-inverted) question. Combined global fits including reactor, atmospheric, and accelerator data presently favour Normal Ordering, the convention used above, at roughly the 2–3σ level; JUNO's precision reactor measurement, together with continued running of atmospheric (IceCube-Upgrade, Super-K/Hyper-K) and accelerator (DUNE, T2K-II/NOvA) experiments, is expected to resolve the ordering within the coming decade. [2427]

PMNS CP-violating phase (open) δ_{CP}: 197°.

measured via the CP-asymmetry between $\nu_\mu \to \nu_e$ and $\bar\nu_\mu \to \bar\nu_e$ appearance probabilities in long-baseline accelerator experiments, combined with the reactor constraint on θ_{13}.

The Dirac CP phase δ_{CP} is the PMNS analogue of the CKM phase and, if nonzero and different from π, allows leptonic CP violation in oscillations; it enters the appearance probabilities $P(\nu_\mu \to \nu_e)$ and $P(\bar\nu_\mu \to \bar\nu_e)$ measured by T2K and NOvA through terms proportional to $\sin\delta_{CP}\sin\theta_{13}$. This is genuinely one of the least well-determined parameters in the Standard Model sector: current global fits give a best fit near $\delta_{CP} \approx 197°$, closer to the CP-conserving value π (180°) than to maximal CP violation ($-\pi/2$, i.e. 270°); consistent with this, the CP-conserving values (0 or π) are disfavoured only around the

$$2\sigma$$

level, so this does not constitute a discovery of leptonic CP violation, and the allowed range widens substantially – covering most of the $[0, 2\pi)$ interval – once the mass-ordering degeneracy is marginalized over; T2K and NOvA show some mutual tension in δ_{CP} depending on the assumed ordering. Next-generation long-baseline experiments, principally DUNE and Hyper-Kamiokande, are designed to reach

$$5\sigma$$

sensitivity to CP violation over a substantial fraction of the δ_{CP} range; until such a measurement, the true value – and even the sign of CP violation – remains an open experimental question. [2427]

Absolute neutrino mass scale and Dirac/Majorana nature (open) m_i, $\sum_i m_i$: $\sum_i m_i < 0.12\,\mathrm{eV}$ (95% CL, cosmological bound, model-dependent).

not determined by oscillations, which fix only Δm^2_{21} and Δm^2_{32}; bounded independently by β-decay kinematics (KATRIN), cosmology (CMB+BAO), and $0\nu\beta\beta$ searches.

Oscillation phases depend only on $\Delta m^2_{ij} L/E$, so oscillation data are completely insensitive to the overall additive mass scale: they fix the two independent squared-mass splittings but

not any individual m_i, nor even the lightest mass m_{lightest}, which could in principle be zero. Three independent, complementary methods bound the absolute scale: direct kinematic spectroscopy of the tritium β-decay endpoint (KATRIN gives $m_\beta \lesssim 0.45\,\text{eV}$ at 90 % CL from its early data run, with a design sensitivity down to about 0.2 eV); cosmological structure formation and CMB lensing, which constrain the sum $\sum_i m_i$ under ΛCDM assumptions (Planck 2018 combined with baryon acoustic oscillation data gives the bound quoted above); and searches for neutrinoless double beta decay ($0\nu\beta\beta$), which additionally probe whether the neutrino mass term is of Majorana type. Whether neutrinos are Dirac or Majorana fermions is a genuinely open question with no experimental resolution to date: $0\nu\beta\beta$ would violate lepton number by two units and can occur only if neutrinos are massive Majorana particles, but current searches (KamLAND-Zen, GERDA, and successors) report no signal, placing only an upper bound on the effective Majorana mass parameter $m_{\beta\beta}$ at the few-tens-of-meV level (with sizeable nuclear-matrix-element uncertainty); a positive detection remains one of the primary open experimental goals of the field, bearing directly on the origin of neutrino mass (e.g. seesaw-type mechanisms) and on leptogenesis as a possible explanation of the cosmic baryon asymmetry. [2348, 2427]

C.5 Lambda-CDM Cosmological Parameters

The base ΛCDM model describes the observed universe with six free parameters fit jointly to the cosmic microwave background (and, for some derived quantities, external distance-ladder and large-scale-structure data): the physical baryon and cold-dark-matter densities $\Omega_b h^2$ and $\Omega_c h^2$, the amplitude and tilt of the primordial scalar power spectrum A_s and n_s, the reionization optical depth τ, and the acoustic angular scale (from which H_0 and Ω_Λ are derived under the flatness assumption). All values below are taken from the Planck 2018 final data release, specifically the TT,TE,EE+lowE+lensing combination reported in Planck Collaboration VI, unless otherwise noted. The sector also includes the baryon-to-photon ratio η, a derived cross-check quantity linking the CMB-era baryon density to the independent, much earlier Big Bang nucleosynthesis epoch, and it flags explicitly the Hubble tension, the unresolved several-sigma discrepancy between CMB-inferred and locally measured values of H_0 that remains one of the most actively debated open problems in the field.

Table C.5: Lambda-CDM Cosmological Parameters: summary of catalogued parameters.

Quantity	Symbol	Value
Baryon density parameter	$\Omega_b h^2$	$0.022\,37 \pm 0.000\,15$
Cold dark matter density parameter	$\Omega_c h^2$	0.1200 ± 0.0012
Dark energy density parameter	Ω_Λ	0.6847 ± 0.0073
Hubble constant (open)	H_0	$(67.36 \pm 0.54)\,\text{km}/(\text{s}\,\text{Mpc})$ (see text)
Scalar spectral index	n_s	0.9649 ± 0.0042
Amplitude of the primordial scalar power spectrum	A_s	2.101×10^{-9} (see text)
Optical depth to reionization	τ	0.0544 ± 0.0073
Baryon-to-photon ratio	η	$(6.12 \pm 0.04) \times 10^{-10}$

Baryon density parameter $\Omega_b h^2$: $0.022\,37 \pm 0.000\,15$.

$\Omega_b h^2 \equiv (\rho_b/\rho_{\mathrm{crit},0})\, h^2$; measured directly from the relative heights of the odd/even acoustic peaks in the CMB temperature and polarization power spectra.

The physical baryon density $\Omega_b h^2$ fixes the ratio of baryonic (ordinary) matter to the critical density, scaled by h^2 to remove the degeneracy with H_0 that would otherwise plague a bare Ω_b. It is pinned down by the CMB because baryons load the photon-baryon plasma before recombination, compressing odd acoustic peaks and suppressing even ones relative to a baryon-free plasma; the Planck 2018 TT,TE,EE+lowE+lensing fit gives $\Omega_b h^2 = 0.022\,37 \pm 0.000\,15$, in excellent agreement with the independent value inferred from primordial deuterium abundances via Big Bang nucleosynthesis. This parameter is one of the six free numbers of the base ΛCDM model and is measured to better than one percent precision. [2348]

Cold dark matter density parameter $\Omega_c h^2$: 0.1200 ± 0.0012.

$\Omega_c h^2 \equiv (\rho_c/\rho_{\mathrm{crit},0})\, h^2$; measured directly, chiefly from the amplitude of the third acoustic peak and the overall peak-height envelope of the CMB power spectrum.

$\Omega_c h^2$ is the physical density of cold (pressureless, collisionless) dark matter, the dominant matter component of the universe. In base ΛCDM all non-baryonic matter is assumed cold, so this parameter is equivalently quoted as the total non-baryonic dark-matter density $\Omega_{\mathrm{dm}} h^2$; some analyses distinguish Ω_c (cold) from a possible hot/warm component, but Planck finds no evidence requiring one. The Planck 2018 fit gives $\Omega_c h^2 = 0.1200 \pm 0.0012$, roughly 5.4 times the baryon density, driven observationally by the enhanced gravitational driving of the third and higher acoustic peaks and by the low-ℓ lensing potential power spectrum. Combined with $\Omega_b h^2$ this yields a present-day total matter density $\Omega_m = 0.3153 \pm 0.0073$. [2348]

Dark energy density parameter Ω_Λ: 0.6847 ± 0.0073.

$\Omega_\Lambda \equiv \rho_\Lambda/\rho_{\mathrm{crit},0}$; in a spatially flat universe,$\Omega_\Lambda = 1 - \Omega_m - \Omega_r$, derived from the CMB angular-diameter-distance constraint combined with the measured matter density.

Ω_Λ is the fractional contribution of the cosmological constant (or, phenomenologically, dark energy with equation of state consistent with $w = -1$) to the total energy density today. It is not measured by a single spectral feature but emerges from the combination of the CMB's precise measurement of the angular acoustic scale θ_* (which fixes the comoving distance to last scattering) together with the flatness prior and the measured matter density, and is corroborated independently by baryon acoustic oscillation (BAO) distance measurements and Type Ia supernova Hubble-diagram fits. Planck 2018 (TT,TE,EE+lowE+lensing) gives $\Omega_\Lambda = 0.6847 \pm 0.0073$, confirming that dark energy dominates the present energy budget by roughly a factor of two over matter. Its microphysical origin — vacuum energy, a slowly rolling field, or a modification of gravity — remains unidentified, though its phenomenological value is measured to sub-percent precision. [2348]

Hubble constant (open) H_0: $(67.36 \pm 0.54)\,\mathrm{km/(s\,Mpc)}$ (Planck 2018, TT,TE,EE+lowE+lensing, CMB-inferred within base ΛCDM); local distance-ladder determinations give values near $(73.0 \pm 1.0)\,\mathrm{km/(s\,Mpc)}$ [2407], in tension with the Planck value at the 4–5σ level.

$H_0 \equiv \dot{a}/a\big|_{t_0}$, the present-day cosmic expansion rate; measured either model-dependently from the CMB acoustic scale within an assumed ΛCDM background, or directly and locally from the distance-redshift relation of the cosmic distance ladder.

H_0 sets the present expansion rate of the universe and, through $1/H_0$, the characteristic age and size scale of the observable universe. Two broad classes of measurement exist: CMB/early-universe methods, which infer H_0 indirectly by fitting the full ΛCDM model (including $\Omega_b h^2$, $\Omega_c h^2$, and the acoustic scale θ_*) to the Planck power spectra and obtain

$H_0 = (67.36 \pm 0.54)\,\mathrm{km/(s\,Mpc)}$; and late-universe, model-independent distance-ladder methods (Cepheid-calibrated Type Ia supernovae, and independently the tip-of-the-red-giant-branch and Mira-variable calibrations), which cluster around $73\,\mathrm{km/(s\,Mpc)}$. The discrepancy between these two families of measurement — the *Hubble tension* — now exceeds 4–5σ in the highest-precision comparisons and has resisted resolution by known systematics on either side; it is one of the most actively studied open problems in cosmology, with proposed resolutions ranging from unrecognized systematics to genuine early- or late-time extensions of ΛCDM (e.g. early dark energy, modified recombination physics), none yet confirmed. This entry reports the Planck (CMB) value as the primary ΛCDM-model parameter but flags the tension explicitly rather than presenting a single settled number. [2348, 2407]

Scalar spectral index n_s: 0.9649 ± 0.0042.

power-law index of the primordial scalar (curvature) power spectrum,$\mathcal{P}_\mathcal{R}(k) \propto k^{n_s-1}$; measured directly from the scale dependence (tilt) of the CMB TT, TE, and EE power spectra across the observed multipole range.

n_s characterizes the near-scale-invariant tilt of the spectrum of primordial curvature perturbations laid down (in the standard picture) during an early inflationary epoch: $n_s = 1$ would correspond to exact scale invariance (Harrison-Zel'dovich), while the measured value slightly below unity indicates a small red tilt. Planck 2018 measures $n_s = 0.9649 \pm 0.0042$ from the shape of the CMB angular power spectrum, excluding exact scale invariance at high significance ($n_s = 1$ is disfavored by more than 8σ). This is one of the most precisely determined ΛCDM parameters and is a key discriminant among inflationary models, though the underlying inflaton dynamics (if any) remain outside the evidence-based scope of this treatise. [2348]

Amplitude of the primordial scalar power spectrum A_s: 2.101×10^{-9} at pivot scale $k_0 = 0.05/\mathrm{Mpc}$, conventionally reported as $\ln(10^{10} A_s) = 3.044 \pm 0.014$; the corresponding late-time, nonlinearly evolved amplitude is $\sigma_8 = 0.8111 \pm 0.0060$.

$A_s \equiv \mathcal{P}_\mathcal{R}(k_0)$, the amplitude of the dimensionless primordial curvature power spectrum at the pivot scale; measured directly from the overall (multipole-averaged) amplitude of the CMB temperature and polarization power spectra, degenerate with τ through the combination $A_s e^{-2\tau}$.

A_s fixes the overall normalization of the primordial curvature perturbations from which all later structure grows; because CMB anisotropies are damped by rescattering after reionization, the direct CMB observable is the combination $A_s e^{-2\tau}$, so an independent handle on τ (from large-scale polarization) is needed to break the degeneracy. Planck 2018 reports $\ln(10^{10} A_s) = 3.044 \pm 0.014$, i.e. $A_s \approx 2.101 \times 10^{-9}$. For late-time, nonlinear structure the amplitude is more commonly quoted as σ_8, the rms mass-density fluctuation in spheres of radius 8 Mpc/h obtained by evolving A_s forward through the transfer function and linear growth factor; Planck finds $\sigma_8 = 0.8111 \pm 0.0060$. This treatise uses A_s (with $\ln(10^{10} A_s)$) as the primary ΛCDM parameter and cites σ_8 as its late-time, structure-formation-friendly equivalent. [2348]

Optical depth to reionization τ: 0.0544 ± 0.0073.

$\tau \equiv \int_0^{t_0} n_e(t)\,\sigma_T\,c$, dt, the Thomson-scattering optical depth integrated from the observer back through the reionized intergalactic medium; measured directly from the suppression and large-angle bump of the CMB E-mode polarization power spectrum at low multipoles.

τ measures the integrated column of free electrons that CMB photons scatter from after the universe reionizes (following the formation of the first stars and galaxies), which damps the temperature and E-mode power spectra on scales inside the horizon at reionization and

generates a distinctive large-angle polarization bump. Planck 2018's low-ℓ EE likelihood gives $\tau = 0.0544 \pm 0.0073$, corresponding to an inferred midpoint reionization redshift around $z_{\rm re} \sim 7$–9 under simple reionization histories, consistent with the epoch inferred from quasar Gunn-Peterson trough studies. Because τ is degenerate with A_s in the small-scale CMB spectra (only the combination $A_s e^{-2\tau}$ is well constrained there), its independent determination from large-angle polarization is essential to breaking that degeneracy and obtaining A_s itself. [2348]

Baryon-to-photon ratio η: $(6.12 \pm 0.04) \times 10^{-10}$.

$\eta \equiv n_b/n_\gamma \approx 273.9\,\Omega_b h^2 \times 10^{-10}$, derived by combining the CMB-measured baryon density $\Omega_b h^2$ with the photon number density fixed by the measured CMB blackbody temperature.

The baryon-to-photon ratio η (equivalently often quoted as $\eta_{10} \equiv 10^{10}\eta$) measures the tiny excess of baryons over antibaryons that survived annihilation in the early universe, expressed relative to the number density of CMB photons; it is the single parameter controlling the light-element yields (D, ^{3}He, ^{4}He, ^{7}Li) of Big Bang nucleosynthesis. It is not measured independently in this catalog but is derived as a cross-check quantity from the CMB-fit baryon density $\Omega_b h^2 = 0.022\,37 \pm 0.000\,15$ combined with the precisely known photon number density, giving $\eta = (6.12 \pm 0.04) \times 10^{-10}$. The remarkable agreement between this CMB-derived value and the value independently required to match observed primordial deuterium and helium abundances is one of the strongest quantitative successes of standard Big Bang cosmology, cross-validating two entirely different physical epochs (nucleosynthesis at $t \sim 1$ s–200 s versus recombination at $t \sim 380\,000$ yr). [2348]

C.6 Gravitational Coupling, Planck Units, and the Hierarchy Problem

This sector collects the scales at which the treatise's two most disparate confirmed frameworks – quantum mechanics, governed by $\hbar$, and general relativity, governed by G and c – become comparably important, together with the dimensionless measures of just how far current particle-physics scales sit from that regime. The Planck length, mass, and time are not free parameters but are fixed by dimensional analysis alone: the Buckingham π theorem (Theorem 2.3), proved in Section 2.2.1 from the rank-nullity theorem applied to the matrix of dimensional exponents, shows that $\{\hbar, G, c\}$ admit no dimensionless combination among themselves, which is precisely the condition that makes the length, mass, and time built from them unique up to an unresolvable $O(1)$ prefactor. The gravitational coupling constant α_G then expresses, in the same dimensionless language as the fine-structure constant, how weak gravity is between two protons compared with the other measured interactions. The final three entries are mass ratios between confirmed particle-physics scales and the Planck mass; their extreme smallness is directly observed and uncontroversial, but the absence of any experimentally confirmed dynamical principle that explains why the scales are so separated – especially for the Higgs vacuum expectation value, whose radiative stability is not protected by any confirmed symmetry – constitutes the hierarchy (naturalness) problem, recorded here strictly as an open observational puzzle per this treatise's evidence-only scope.

Planck length ℓ_P: $(1.616\,255 \pm 0.000\,018) \times 10^{-35}$ m.

$\ell_P = \sqrt{\dfrac{\hbar G}{c^3}}$.

The Planck length is the unique length scale constructible from the reduced Planck constant $\hbar$, the Newtonian gravitational constant G, and the speed of light c – the three constants that respectively govern quantum mechanics, gravitation, and relativity. Its

Table C.6: Gravitational Coupling, Planck Units, and the Hierarchy Problem: summary of catalogued parameters.

Quantity	Symbol	Value
Planck length	ℓ_P	$(1.616\,255 \pm 0.000\,018) \times 10^{-35}\,\mathrm{m}$
Planck mass	M_P	$(2.176\,434 \pm 0.000\,024) \times 10^{-8}\,\mathrm{kg}$
Planck time	t_P	$(5.391\,247 \pm 0.000\,060) \times 10^{-44}\,\mathrm{s}$
Gravitational coupling constant	α_G	5.91×10^{-39}
Electron-to-Planck mass ratio (open)	m_e/M_P	4.19×10^{-23}
Proton-to-Planck mass ratio (open)	m_p/M_P	7.69×10^{-20}
Higgs vacuum expectation value to Planck mass ratio (open)	v/M_P	2.01×10^{-17}

dimensional exponents are fixed, not merely suggested, by the Buckingham π theorem (Theorem 2.3): among the three quantities $\{\hbar, G, c\}$, whose dimension exponents span the full $r = 3$-dimensional space of mechanical base dimensions $\{\mathsf{M}, \mathsf{L}, \mathsf{T}\}$, the theorem's exponent matrix M has trivial kernel ($n - r = 3 - 3 = 0$), so no dimensionless combination of $\hbar$, G, c alone exists; augmenting M with the target dimension L then yields a 3×3 linear system in the exponents of $\hbar^a G^b c^d$ with a unique solution $a = \frac{1}{2}$, $b = \frac{1}{2}$, $d = -\frac{3}{2}$, i.e. $\ell_P = \sqrt{\hbar G/c^3}$. The same rank-nullity argument that proves the theorem shows explicitly what it cannot deliver: any dimensionless numerical prefactor multiplying ℓ_P is invisible to dimensional analysis and is fixed here by convention to 1. Numerically, using the CODATA 2018 values of $\hbar$, G, c tabulated in Appendix B, $\ell_P \approx 1.6 \times 10^{-35}\,\mathrm{m}$, some fifteen orders of magnitude below the smallest length probed directly by any collider experiment to date. [2392]

Planck mass M_P: $(2.176\,434 \pm 0.000\,024) \times 10^{-8}\,\mathrm{kg}$.

$$M_P = \sqrt{\frac{\hbar c}{G}}.$$

By the same application of Theorem 2.3 used for the Planck length – the exponent system for a quantity of dimension M built from $\{\hbar, G, c\}$ has a unique solution because the three quantities admit no dimensionless combination among themselves – the Planck mass is fixed up to the same unresolvable $O(1)$ prefactor as $M_P = \sqrt{\hbar c/G}$. Equivalently $M_P = \hbar/(\ell_P c)$. Its numerical value, about 22 µg, is unremarkable on laboratory scales – comparable to a fine dust grain – which is itself notable: the mass scale conventionally associated with quantum-gravitational effects becoming significant is macroscopic in mass even though the associated length (ℓ_P) and energy ($M_P c^2 \approx 1.22 \times 10^{19}\,\mathrm{GeV}$) are wildly inaccessible to any existing or foreseeable particle experiment. [2392]

Planck time t_P: $(5.391\,247 \pm 0.000\,060) \times 10^{-44}\,\mathrm{s}$.

$$t_P = \sqrt{\frac{\hbar G}{c^5}} = \ell_P/c.$$

Completing the triad, the Planck time is the unique time scale formed from $\{\hbar, G, c\}$, fixed by exactly the same rank-3 exponent argument furnished by Theorem 2.3: $t_P = \sqrt{\hbar G/c^5} = \ell_P/c$, again with a convention-fixed prefactor of 1 that dimensional analysis alone cannot supply. Numerically $t_P \approx 5.4 \times 10^{-44}\,\mathrm{s}$, conventionally quoted as the timescale below which no confirmed physical theory – classical general relativity least of all, since it

treats spacetime as a smooth continuum – is expected to remain a reliable description; no experiment has probed timescales anywhere near this regime. [2392]

Gravitational coupling constant α_G: 5.91×10^{-39}.

$\alpha_G \equiv \dfrac{Gm_p^2}{\hbar c}$.

In direct structural analogy with the electromagnetic fine-structure constant $\alpha = e^2/(4\pi\epsilon_0\hbar c)$, which measures the strength of the electromagnetic coupling between two elementary charges in dimensionless form, the gravitational coupling constant α_G measures the strength of the Newtonian gravitational attraction between two protons in the same dimensionless units. It is built entirely from constants already tabulated in Appendix B: G, the proton mass m_p, $\hbar$, and c. Its value, $\alpha_G \approx 5.9 \times 10^{-39}$, is smaller than α by roughly thirty-six orders of magnitude, making α_G the quantitative, dimensionless measure of the empirical fact that gravity is by far the weakest of the interactions accessible to laboratory and particle-physics measurement. [2392]

Electron-to-Planck mass ratio (open) m_e/M_P: 4.19×10^{-23}.

m_e/M_P, m_e measured, $M_P = \sqrt{\hbar c/G}$.

The electron mass, measured directly, is smaller than the Planck mass by a factor of about 4.2×10^{-23}. For a chiral fermion such as the electron, standard effective-field-theory power counting makes this smallness *technically natural*: radiative corrections to a fermion mass are proportional to the mass itself (protected by the approximate chiral symmetry restored as $m_e \to 0$) rather than being pulled up quadratically toward the ultraviolet cutoff, so no fine-tuning is strictly required to keep m_e small under quantum corrections. The ratio is nonetheless recorded here as part of the same hierarchy-of-scales puzzle: no confirmed dynamical principle explains why the Yukawa coupling that ultimately sets m_e (via the Higgs mechanism, Part XI) takes the minuscule value it does rather than some other value of order unity; that the coupling itself is unexplained – not that it is radiatively unstable – is the open question here. [2392]

Proton-to-Planck mass ratio (open) m_p/M_P: 7.69×10^{-20}.

m_p/M_P, m_p measured, $M_P = \sqrt{\hbar c/G}$.

The proton mass is smaller than the Planck mass by a factor of about 7.7×10^{-20}, some three orders of magnitude larger a ratio than the electron's because most of the proton's mass arises not from the Higgs mechanism but from the strong-interaction confinement scale Λ_{QCD} (Part XI), with the current-quark Higgs-generated masses contributing only a small fraction. The ratio is nonetheless part of the same observed hierarchy: no confirmed dynamical mechanism explains why Λ_{QCD}, and hence the mass of ordinary baryonic matter, sits so far below the Planck scale rather than comparably close to it, even though the running of the strong coupling (asymptotic freedom, itself experimentally confirmed) makes the smallness only logarithmically – not quadratically – sensitive to the ultraviolet completion, unlike the scalar case below. [2392]

Higgs vacuum expectation value to Planck mass ratio (open) v/M_P: 2.01×10^{-17}.

$v/(M_Pc^2)$, $v \approx 246\,\mathrm{GeV}$(measured), $M_Pc^2 \approx 1.22 \times 10^{19}\,\mathrm{GeV}$.

The Higgs vacuum expectation value $v \approx 246\,\mathrm{GeV}$, which sets the electroweak scale and, through it, the masses of the W and Z bosons and (via Yukawa couplings) the charged fermions, is smaller than the Planck energy $M_Pc^2 \approx 1.22 \times 10^{19}\,\mathrm{GeV}$ by a factor of about 2.0×10^{-17}. This is the ratio at the heart of the hierarchy (naturalness) problem: unlike a fermion mass, the Higgs boson is a fundamental scalar, and nothing within the confirmed Standard Model protects its mass-squared parameter from receiving radiative corrections

that scale quadratically with whatever ultraviolet cutoff the theory is embedded in – if that cutoff is the Planck scale, the corrections are technically expected to be some seventeen orders of magnitude larger than the observed electroweak scale itself, requiring an extreme and unexplained cancellation to keep v as small as it is measured to be. No experimentally confirmed symmetry or dynamical mechanism protecting the electroweak scale from such corrections has been observed to date (in particular, no signal of any such protecting structure has been seen at the LHC), so the smallness of v/M_P remains, strictly on the evidence, an open naturalness puzzle rather than a solved problem. [2392, 2427]

Appendix D

The Dimensionless Constants

Appendix C tabulates the free parameters of the Standard Model and of ΛCDM with their measured values. This appendix asks a different question about the same numbers: *which* of them mean anything independently of us. The answer is sharp — only the dimensionless ones — and it has a formal statement, a complete construction, and a consequence that reaches beyond physics into what could in principle be compared with a civilization that shares none of our history.

D.1 Why only dimensionless numbers carry content

The speed of light in vacuum is exactly 299 792 458 m/s. That statement contains no physics whatever. Since 1983 the metre has been *defined* as the distance light travels in 1/299792458 of a second (Chapter 2), so the number records a decision of the Conférence Générale des Poids et Mesures, not a property of light. Had the committee chosen differently, c would read differently and not one experimental outcome would change.

This is not a peculiarity of the SI. Any dimensional constant carries the same defect in weaker form: its numerical value is a statement about the relation between the quantity and an arbitrarily chosen yardstick.

Remark D.1 (Convention and content). The distinction is the one drawn in Section 1.3.2 between convention and content, and it is why that section insists the conventions be declared. A theory's empirical content is what survives every allowed change of convention. For units, the allowed changes are rescalings of the base quantities, and what survives them is exactly the dimensionless combinations.

D.1.1 The dimension map

Make the claim precise. Let $q_1, \dots, q_n$ be physical quantities and let there be k base dimensions — in mechanics $\mathsf{M}, \mathsf{L}, \mathsf{T}$, so $k = 3$; in the SI, seven. Each q_a has a dimension

$$[q_a] = \mathsf{X}_1^{d_{1a}} \mathsf{X}_2^{d_{2a}} \cdots \mathsf{X}_k^{d_{ka}} \,, \tag{D.1}$$

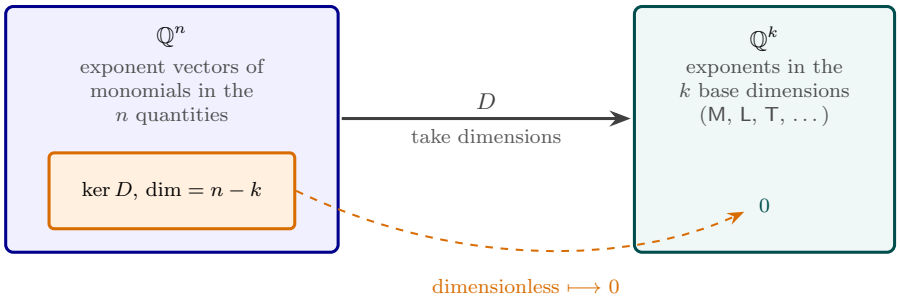
with rational exponents d_{ia}. A monomial in the quantities,

$$\Pi = q_1^{p_1} q_2^{p_2} \cdots q_n^{p_n} \,, \qquad p \in \mathbb{Q}^n \,, \tag{D.2}$$

then has dimension $\mathsf{X}_i^{\sum_a d_{ia} p_a}$. Writing D for the $k \times n$ matrix of exponents d_{ia}, the monomial is dimensionless precisely when

$$Dp = 0 \,, \tag{D.3}$$

so the dimensionless combinations are the kernel of a linear map. Taking logarithms has turned a multiplicative question into linear algebra, and Figure D.1 is the whole content of the subject in one picture.



A change of units rescales each base dimension: it acts on $\mathbb{Q}^n$ by a shift that is invisible on $\ker D$. Only the elements of $\ker D$ therefore carry information independent of the choice of units — which is why the numbers a distant civilisation could compare with ours are exactly the ones living in that kernel.

Figure D.1: Dimensional analysis as linear algebra. Monomials in the n quantities are represented by their exponent vectors in $\mathbb{Q}^n$; the dimension map D records the exponents of the k base dimensions. The dimensionless combinations are exactly $\ker D$. A change of units acts on $\mathbb{Q}^n$ in a way that leaves the kernel pointwise fixed, which is the precise sense in which only dimensionless numbers are convention-free.

Theorem D.2 (Buckingham's Π theorem)**.** *Let n quantities involve k base dimensions, and let r be the rank of the dimension matrix D. Then the dimensionless monomials form a $\mathbb{Q}$-vector space of dimension $n - r$, and any physical law relating the n quantities can be written as a relation among $n - r$ independent dimensionless groups [413].*

Rests on Equation (D.3).

Remark D.3 (Two footnotes on the theorem's name and its statement). The attribution is conventional rather than historical: the general statement was published by Vaschy in 1892 and, apparently independently, by Federman and Riabouchinsky in 1911, and Buckingham himself later ceded priority to Riabouchinsky. Second, the theorem is often quoted with r replaced by the *number* of base dimensions. That is the imprecise version, and it is not Buckingham's: he defines the subtracted quantity as the size of a maximal independent set, which is the rank. Where the dimensional matrix is rank-deficient the two differ, and the careless form undercounts the groups. Bridgman's monograph [485] is the standard early treatment.

Proof. *Derives Theorem D.2.*

That the dimensionless monomials are $\ker D$ is Equation (D.3), and the rank–nullity theorem (Chapter 5) gives $\dim \ker D = n - r$ at once. Choose a basis $\Pi_1, \dots, \Pi_{n-r}$ of the kernel.

For the second statement, let $f(q_1, \dots, q_n) = 0$ be a law. A change of units multiplies each q_a by $\prod_i \lambda_i^{d_{ia}}$ for positive scale factors λ_i. If the law is to hold in every system of units — which is what it means for it to be a law about nature rather than about a bureau of standards — then f must be invariant under the whole k-parameter group of such rescalings. The orbits of that group are the level sets of the map $q \longmapsto (\Pi_1, \dots, \Pi_{n-r})$, since two configurations have the same Π's exactly when a rescaling carries one to the other. A function constant on orbits factors through the orbit space, so f is a function of the Π's alone. □

Example D.4 (The theorem doing work)**.** A pendulum's period T can depend on its length ℓ, its mass m and g. Here $n = 4$ and the dimension matrix in $(\mathsf{M}, \mathsf{L}, \mathsf{T})$ has rank 3, so there is $4 - 3 = 1$ independent group. It is $\Pi = T\sqrt{g/\ell}$, whence $T = C\sqrt{\ell/g}$ with C a pure number — and the mass cannot appear. Two lines of linear algebra have produced the form of the answer, the independence of the period from the mass, and the impossibility of any

other scaling, without solving an equation of motion (Chapter 28 supplies $C = 2\pi$ for small amplitude).

D.1.2 How many dimensionful constants are fundamental?

If dimensional constants are conventions, why keep any? The question was put sharply in a three-way exchange between Duff, Okun and Veneziano, who argued respectively for zero, three and two fundamental dimensionful constants [2026]. The disagreement is not empirical: all three agree on every measurable prediction. It is about what one calls fundamental, and it resolves once the roles are separated.

One caveat on that source: Veneziano's count of two is explicitly conditional on superstring theory, which this treatise excludes from scope by editorial rule 1. His position is reported here as a position held in the literature, not as a result. And the paper cannot be cited in support of any particular count — its three authors never converged, which is precisely its value: it establishes that the count is not fixed by physics.

Constants such as c, $\hbar$ and G do two jobs. As *conversion factors* they relate quantities we had historically thought distinct — c converts time to length, $\hbar$ converts frequency to energy, G converts mass to length — and in that role they are pure convention, and can be set to 1, which is what natural units do. As *markers of a regime* they say where new physics appears: relativity when speeds approach c, quantum mechanics when actions approach $\hbar$, and strong gravity near the Planck scale built from all three. That second role is physical, but it is a statement about *ratios* — v/c, $S/\hbar$ — and ratios are dimensionless. Nothing is lost by the reduction.

D.2 The systematic construction

Theorem D.2 says how many independent dimensionless numbers exist; this section constructs them for the quantities physics actually has.

D.2.1 Planck units and the mass ratios

From $\hbar$, c and G alone — three quantities, three dimensions, rank three — the kernel is trivial: there is *no* dimensionless combination of the three. That is precisely why they can be used to build a unique system of units,

$$m_{\mathrm{P}} = \sqrt{\frac{\hbar c}{G}}\,, \qquad \ell_{\mathrm{P}} = \sqrt{\frac{\hbar G}{c^3}}\,, \qquad t_{\mathrm{P}} = \sqrt{\frac{\hbar G}{c^5}}\,, \tag{D.4}$$

and it is why the Planck scale is the natural yardstick against which every other scale becomes a pure number. Adjoin any fourth quantity and a dimensionless group appears immediately: adjoining a mass m gives the single group m/m_{P}.

Every particle mass therefore contributes one dimensionless number. Two families of ratio are worth separating, because they are physically very different:

1. **Ratios to the Planck mass**, such as

$$\frac{m_e}{m_{\mathrm{P}}} \approx 4.19 \times 10^{-23}\,, \qquad \frac{m_p}{m_{\mathrm{P}}} \approx 7.69 \times 10^{-20}\,, \tag{D.5}$$

which measure how feebly gravity acts on elementary particles. Their extreme smallness is the hierarchy problem (Appendix C.6). Equivalently one writes the *gravitational coupling*

$$\alpha_G = \frac{G m_e^2}{\hbar c} = \left(\frac{m_e}{m_{\mathrm{P}}}\right)^2 \approx 1.75 \times 10^{-45}\,, \tag{D.6}$$

the exact gravitational analogue of Equation (D.8) below. The ratio $\alpha/\alpha_G \approx 4 \times 10^{42}$ is the number Dirac found suspicious enough to build a cosmology on [812]; that cosmology, which required G to vary with time, is excluded by the bounds of Appendix D.3.4.

2. **Ratios among the particles themselves**, which involve no gravity at all:

$$\frac{m_p}{m_e} \approx 1836.15\,, \qquad \frac{m_\mu}{m_e} \approx 206.768\,, \qquad \frac{m_\tau}{m_\mu} \approx 16.817\,. \tag{D.7}$$

These are the numbers that fix chemistry, the size of atoms relative to nuclei, and the pattern of the three generations. In the Standard Model they are not independent inputs but consequences of the Yukawa couplings, themselves dimensionless (Appendix C.1).

D.2.2 The couplings

Definition D.5 (Fine-structure constant)**.**

$$\alpha := \frac{e^2}{4\pi\varepsilon_0 \hbar c}\,. \tag{D.8}$$

Every dimensional quantity in Equation (D.8) cancels: α is a pure number, the same in SI, Gaussian or natural units, and the same for any observer anywhere. It measures the strength of the electromagnetic interaction — more precisely, it is the square of the electric charge in units where $\hbar = c = 1$, and it is the expansion parameter of the perturbation series of quantum electrodynamics (Chapter 100). Its smallness is why that series works.

The recommended value is

$$\alpha^{-1} = 137.035\,999\,177 \pm 0.000\,000\,021\,, \tag{D.9}$$

a relative uncertainty of 1.6×10^{-10} [2431].

Remark D.6 (The last digits are less settled than they look). Equation (D.9) is not a straight statistical combination. The two most precise determinations — caesium recoil at Berkeley, $\alpha^{-1} = 137.035\,999\,046 \pm 0.000\,000\,027$ [2316], and rubidium recoil at the Kastler–Brossel laboratory, $\alpha^{-1} = 137.035\,999\,206 \pm 0.000\,000\,011$ [2363] — disagree with each other by more than 5σ, and the disagreement is unresolved. The recommended uncertainty in Equation (D.9) has been inflated by an expansion factor to cover it. Quoting ten significant figures without that caveat would misrepresent the state of the measurement, which is precisely the kind of thing the availability grading of Chapter 1 exists to prevent.

The other interactions contribute their own couplings, α_s for the strong force and the electroweak pair g, g'; unlike α they are not small at all accessible energies, which is why perturbation theory fails for the strong interaction at low energy (Chapter 102).

D.2.3 The full catalogue

Collecting: the dimensionless numbers of established physics are the gauge couplings, the Yukawa couplings (equivalently the mass ratios), the CKM and PMNS mixing angles and phases, the strong CP angle θ_{QCD}, the Higgs self-coupling and the ratio of the Higgs vacuum expectation value to the Planck mass, together with the cosmological parameters — the density fractions Ω_i, the baryon-to-photon ratio η, the scalar spectral index n_s. Their measured values occupy Appendix C; the count is about twenty-six for the Standard Model plus a handful for cosmology.

Remark D.7 (What a "theory of everything" would have to do). The catalogue is the honest statement of what physics does not explain. Feynman's verdict on α — "a magic number that comes to us with no understanding by man" [1752] — applies to every entry. A theory that derived even one of them from something more basic would be a decisive advance, and none has. This is worth stating plainly because it is often obscured: the Standard Model is not incomplete in the sense of failing a measurement, but in the sense that roughly two dozen numbers must be handed to it from outside. Programmes that claim to derive them are assessed on that claim and no other, and Chapter 135 records that none currently succeeds.

D.3 Universality: the numbers a stranger could check

D.3.1 Why α and not a metre

Suppose we wished to establish, with a civilization that shares nothing of our history, that we had found the same physics. Almost everything we might send fails. A length in metres is meaningless without the metre. A temperature in kelvin, a mass in kilograms, an energy in joules: all encode the Earth, the water molecule, a platinum cylinder, a French committee. Worse, much of what we would think to describe is *local*: the luminosity of our star, the surface gravity of our planet, the composition of our atmosphere, the strength of our magnetic field. A recipient orbiting a different star has different values for every one of them, and no disagreement about those would indicate any disagreement about physics.

What survives is $\ker D$. The dimensionless constants are the same for them as for us — not by convention but because they are what remains when all conventions are quotiented away. If their measurement of α disagreed with ours, that would be a discovery of the first order; if their measurement of the local gravitational acceleration disagreed with ours, that would be a weather report.

D.3.2 The message that needs no dictionary

α can be communicated with no shared units, no shared numerals and no shared language, because it is a *ratio of counts*, and counting is not a convention. Figure D.2 draws it: one stroke, a divider, one hundred and thirty-seven strokes.

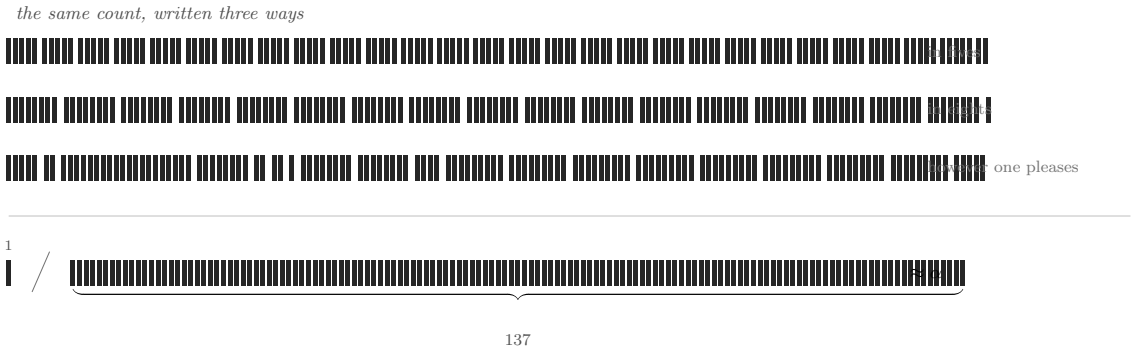


Figure D.2: The fine-structure constant drawn without conventions. Above: the same count of 137 grouped in fives, in eights, and irregularly — the grouping is notation and varies freely, the total does not. Below: the invariant itself, one stroke against 137. A recipient needs no unit, no base, no numeral system and no language, only the ability to count. The approximation is discussed in Remark D.8.

This is not an idle conceit. The Pioneer plaque used exactly this strategy, taking as

its unit the hyperfine transition of neutral hydrogen — the most common object in the universe, with a frequency any radio astronomer anywhere must know — and expressing every other quantity as a multiple of it [1482]. The design principle is the one above: build the message out of $\ker D$, never out of a chosen yardstick.

D.3.3 A primer built from nothing

A single ratio is not a message. To make α mean anything to a recipient one must first establish what a count is, what a ratio is, and what the two things are whose coupling is being reported — and each of those must be established using only what has already been established. Figures D.3 and D.4 carry that construction out.

The governing constraint is strict and is what makes the exercise instructive: *no glyph may be used before a panel has defined it by exhibiting instances.* Nothing is translated, because there is no shared language to translate into; everything is shown. That forces an order. Counting must come before equality, since equality is defined as sameness of count. Equality must come before the marks for TRUE and FALSE, which are introduced by attaching them to one true and one false statement — an ostensive definition, and the only kind available. Only then can anything be *asserted*, so only then can the naturals, sets, division and the reals follow.

Two features of the second board deserve comment. First, α is introduced *as a coupling before it is a number*: panel 10 shows the vertex at which an electron emits or absorbs a photon, and identifies α as how strongly that joining happens. This is the right order, because Equation (D.8) is not a definition a stranger could parse — it presupposes e, ε_0, $\hbar$ and c, none of which is available — whereas the vertex is a picture. Second, the alphabet is introduced last and is anchored: panel 13 pairs each written word with the thing already drawn, because a list of 26 shapes carries no information whatever until at least one of them is tied to something the recipient can independently identify. That is the same requirement Frege's sense and reference imposes (Section 3.7.1), arriving here as an engineering constraint rather than a philosophical one.

What the boards cannot do is worth stating as plainly as what they can. They convey $\alpha \approx 1/137$ and not $\alpha^{-1} = 137.035\,999\,177 \pm 0.000\,000\,021$; they do not specify the energy scale at which the coupling was measured, for the reason given in Remark D.8; and they assume the recipient shares our arithmetic, which is the one assumption the construction cannot itself justify. They are a demonstration of what a convention-free message would have to look like, not a protocol ready to transmit.

Remark D.8 (Three honest qualifications). The picture is a good deal less tidy than the slogan, and the qualifications matter more than the slogan does.

First, 137 *is not the value.* The measured quantity is $\alpha^{-1} = 137.035\,999$ to the digits shown, and no tally can draw a non-integer. What Figure D.2 transmits is a rational approximation good to about four parts in 10^5 — impressive for a row of scratches, useless for physics. Eddington's insistence that the value must be exactly an integer, first 136 and then 137 when measurement moved, is the cautionary tale here [889]: the integer was the artefact, and the digits after the decimal point were the physics.

Second, α runs. The number $1/137$ is the low-energy limit, measured at zero momentum transfer. At the mass of the Z boson the same coupling is near $1/128$ (Chapter 108). A civilization measuring at a different scale and reporting the result without saying so would appear to disagree with us while agreeing perfectly. Any serious message would have to specify the scale — which can itself be done dimensionlessly, as a ratio to a particle mass.

Third, agreement is expected, not guaranteed. That α takes the same value everywhere is an empirical claim, and Appendix D.3.4 reports how well it is established. It is exactly the kind of claim that would be most interesting to find false.

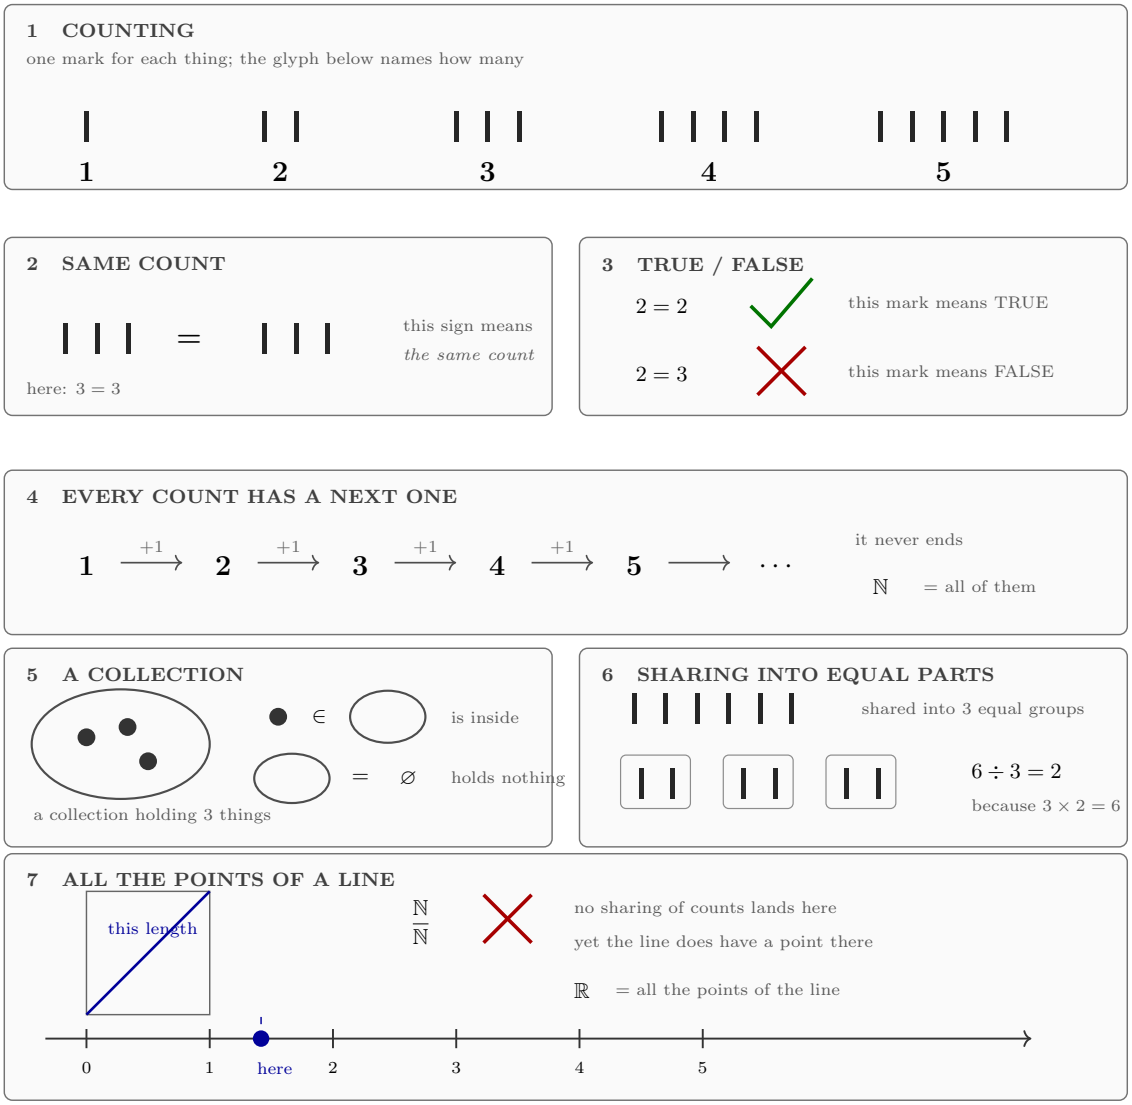

Figure D.3: An ostensive primer, first board: mathematics. Counting is established by tally, then the equality sign as sameness of count, then the marks for TRUE and FALSE by exhibiting a true and a false statement. Those three panels make assertion possible; the rest follow. The unit square in panel 7 is drawn to scale, its side equal to the 0-to-1 spacing of the line, so the transferred diagonal really does land at $\sqrt{2}$ — a point no sharing of counts reaches, which is what forces $\mathbb{R}$ beyond $\mathbb{N}/\mathbb{N}$.

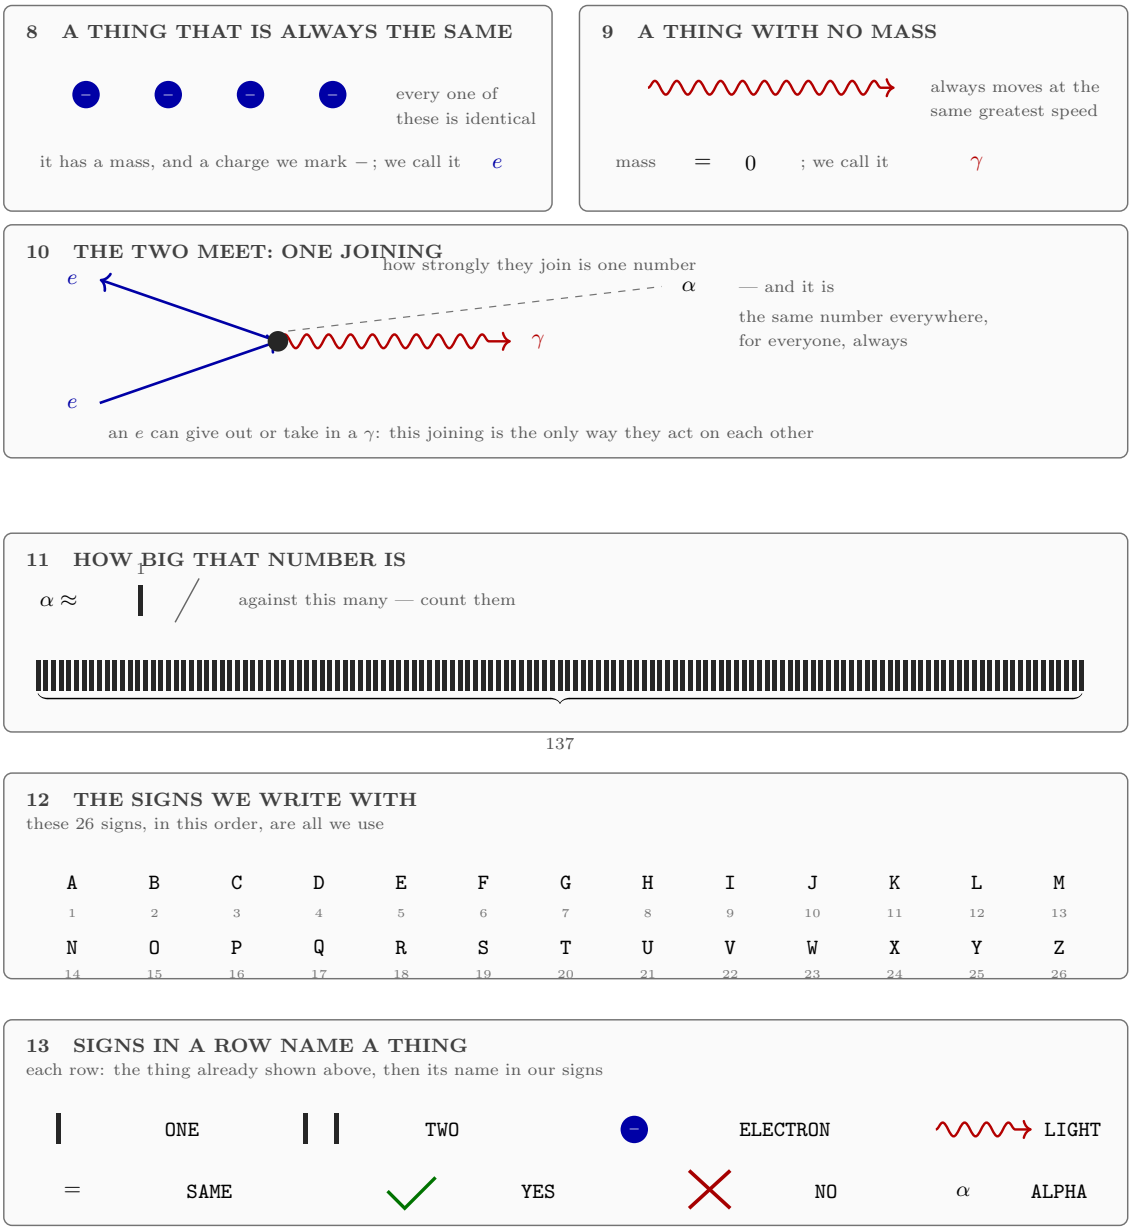

Figure D.4: Second board: physics and language. The electron is introduced as a thing of which every instance is identical, the photon as a thing with no mass moving always at the greatest speed, and α as the strength of the single joining by which the two act on each other — which is what α *is*, before it is a number. Panel 11 then gives its size as a count. Panels 12 and 13 attach a written language to referents already fixed on the boards: an alphabet in isolation is uninterpretable, so the words are grounded in things the recipient has just been shown.

D.3.4 Is it actually constant?

The universality argument is worth only as much as the evidence that α does not vary. Three independent probes bound it.

1. **Laboratory clocks** give the cleanest bound, with no astrophysical modelling at all. Comparing an aluminium-ion with a mercury-ion optical clock over a year — transitions whose frequencies depend on α with different powers — gives

$$\frac{\dot{\alpha}}{\alpha} = (-1.6 \pm 2.3) \times 10^{-17}/\mathrm{yr}\,, \tag{D.10}$$

   consistent with zero [2134, 2183].

2. **The Oklo natural reactor.** Isotope ratios left by a natural fission reactor that operated in Gabon about 2×10^9 years ago constrain the position of a samarium neutron resonance, and through it α at that epoch [1919]:

$$-0.9 \times 10^{-7} < \frac{\Delta\alpha}{\alpha} < 1.2 \times 10^{-7} \tag{D.11}$$

   at two standard deviations.

3. **Quasar absorption spectra** probe α at large redshift and in distant directions — the only probe that tests *spatial* universality. Here the evidence is contested, and must be reported as such. The many-multiplet analyses of Keck and VLT data are mutually inconsistent: Keck/HIRES gives $\Delta\alpha/\alpha = (-0.57 \pm 0.11) \times 10^{-5}$, a nominal five-sigma detection of variation, while VLT/UVES on the same method gives $(-0.06 \pm 0.06) \times 10^{-5}$, consistent with none [2183]. The proposed reconciliation — that α varies spatially, the two telescopes viewing different hemispheres — was reported as a 4.2σ dipole [2184]. That claim has since been substantially undercut, and from inside the original collaboration: long-range wavelength-scale distortions of order $\pm 200\,\mathrm{m/s}$ per 100 nm are ubiquitous in both instruments' archives, and reproduce important features of the reported signal [2261].

The laboratory and geophysical bounds are robust and consistent with no variation; the astrophysical detection is contested and is recorded here as contested rather than omitted, because a claim of that kind is exactly what the universality argument stands or falls on. Reporting only the comfortable evidence would be a failure of the editorial rule, and the contested item is in any case the more interesting one: it is the one that could still turn out to matter.

The universality of Appendix D.3.1 is therefore an experimentally supported statement about this universe, not an assumption — and it is falsifiable, which by Remark 1.2 is the most that can be asked of it.

D.4 Relations to mathematical constants

If the dimensionless constants are pure numbers, it is natural to ask whether they are *recognizable* numbers — whether α or the mass ratios are built from π, from e, from small integers. The history of that question is mostly a history of error, and it is worth setting out carefully, because the failure mode is seductive and the criterion for distinguishing sense from nonsense is sharp.

D.4.1 When a mathematical constant legitimately appears

Mathematical constants appear throughout physics with impeccable credentials. The 2π in the pendulum period of Example D.4 comes from integrating the equation of motion; the π in the Gaussian integral of Chapter 11 comes from the integral; the 4π in Equation (D.8) comes from the surface area of a sphere in Gauss's law. In every case the constant enters as the *output of a derivation*, and one can point to the step that produced it.

Definition D.9 (The criterion)**.** A proposed relation between a measured dimensionless constant and a mathematical one is physics if and only if it is *derived* — if there is an argument from stated premises whose conclusion is the relation, and which would have predicted the value before it was measured. A relation obtained by searching for a formula that reproduces a known value is *numerology*, however many digits it matches.

The asymmetry is the same one that separates a prediction from a fit (Section 1.4), and the reason for the strictness is counting: the supply of short expressions built from π, e and small integers is enormous, so agreement to a few digits with *some* such expression is expected by chance and carries no information.

D.4.2 Eddington, and the failure mode

Eddington argued that α^{-1} must be exactly the integer 136, on a group-theoretic counting argument; when measurements moved, he produced a revised derivation giving exactly 137 [889]. The modern value is 137.035 999, and neither derivation survives. The instructive part is not that he was wrong but *how*: the argument was adjusted to track the data while retaining the appearance of derivation, which is the signature Definition D.9 is designed to catch.

D.4.3 The Koide relation

The most serious modern case is Koide's [1691, 1723]. Form, from the three charged-lepton masses, the ratio

$$Q := \frac{m_e + m_\mu + m_\tau}{\left(\sqrt{m_e} + \sqrt{m_\mu} + \sqrt{m_\tau}\right)^2} \,. \tag{D.12}$$

Q is dimensionless by construction, and it is bounded: writing $v_i = \sqrt{m_i}$, Equation (D.12) is $|\boldsymbol{v}|^2 \,/\, (\boldsymbol{v}\cdot\boldsymbol{u})^2$ with $\boldsymbol{u} = (1,1,1)/\sqrt{3}$ up to normalization, so by Cauchy–Schwarz

$$\frac{1}{3} \le Q \le 1 \,, \tag{D.13}$$

the lower bound attained when the three masses are equal and the upper when one dominates. The measured value sits almost exactly at the midpoint of that range: with the current pole masses,

$$Q_{\text{obs}} = 0.666\,664\,5 \pm 0.000\,005\,1 \,, \qquad \frac{2}{3} = 0.666\,666\,7 \,, \tag{D.14}$$

a deviation of 0.43σ, or agreement at the level of a few parts in 10^6.

What should be made of it? Three observations, in the spirit of Definition D.9.

1. The agreement is genuinely striking, and *much* better than the bounds Equation (D.13) alone would make likely. It has the predictive character Definition D.9 demands: the relation was written down when the τ mass was poorly known, and it survived the subsequent measurements — indeed the agreement *improved* when the world average moved after the Belle II determination. That is the reason it is discussed here rather than dismissed.

2. It has no accepted derivation. Lepton masses in the Standard Model are free Yukawa parameters with no reason to satisfy any relation, and no mechanism in or beyond it produces Equation (D.14).

3. **The precision is a fact about pole masses, and only about pole masses** — which is the crux, and is usually stated carelessly. Masses run with scale (Chapter 108), so "the mass of the electron" is a function of where it is defined. Two results must be held together. Li and Ma showed the *running* Koide ratio is very nearly scale-independent, drifting by less than one part in 10^5 from 1 GeV to 2×10^{16} GeV [2099] — but the value it is frozen at is about 0.19 % *above* 2/3, not 2/3. Sumino showed the same thing from the other side: the QED self-energy term $-\frac{3\alpha}{4\pi} m_i \log m_i^2$, coming from the infrared region of the loop, rotates the vector $(\sqrt{m_e}, \sqrt{m_\mu}, \sqrt{m_\tau})$, so that if the running masses satisfied the relation at a high scale the pole masses would violate it by roughly 0.1 % — about 120 times the experimental error [2150].

   The two are not in conflict, and it is worth being explicit because they are routinely quoted against each other: the running ratio is stable but sits off 2/3, while the pole ratio sits on 2/3. Nothing carries the running value onto 2/3. And that is precisely what is suspicious — pole masses are infrared-sensitive, low-energy quantities that no known symmetry singles out, whereas a fundamental relation would be expected to hold at a high scale where a symmetry is unbroken.

4. The extension to quarks does not work, and fails asymmetrically: $Q \approx 0.669$ for the heavy triplet and $Q \approx 0.57$ for the light one, and it must be applied to *running* masses there — the opposite prescription from the charged leptons. A relation needing a different mass definition in each sector to look good is a relation whose status is unresolved.

The honest verdict is that the Koide relation is an unexplained numerical regularity of the right shape to be meaningful, which in four decades has been neither derived nor explained away. Koide himself allows that it "may be an accidental coincidence". This treatise records it as exactly that, and Definition D.9 says what would have to be supplied to settle it: a derivation, from stated premises, of why the relation should hold for pole masses.

Remark D.10 (A cautionary detail about which paper says what). The relation $Q = 2/3$ is that of Koide's earlier "model I" [1691, 1723]. The often-cited 1983 Brief Report [1724] proposes a *modified* relation with an extra parameter $\delta = 0.040\,026$, giving $Q = (2 + \delta^2)/3$ and predicting $m_\tau = 1786.45$ MeV — which the measured (1776.93 ± 0.09) MeV excludes overwhelmingly. Citing that paper for $Q = 2/3$, as is common, attributes the surviving relation to the one Koide paper whose headline prediction is dead.

D.4.4 Fine-tuning and the anthropic move

Several of the constants appear to lie in narrow windows outside which complex structure would not form. Weinberg's bound on the cosmological constant is the sharpest instance: he argued, before the measurement, that Λ could not greatly exceed a value set by the requirement that galaxies form, and the measured value (Appendix C.5) is of that order [1799].

Whether such reasoning explains anything is disputed, and this treatise does not adjudicate it. What can be said within its editorial rules is narrow and worth saying: an anthropic argument requires an ensemble of universes with varying constants for the selection to act on, and there is at present no observational evidence that such an ensemble exists. It therefore falls under the same rule as the programmes named in Chapter 135 — it may be named,

and it is named here, but it is not evidence-based physics and is not presented as such. The measured values in Appendix C stand as measurements whatever their eventual explanation.

D.5 Summary

The content of physics that is independent of every human choice is exactly $\ker D$: the dimensionless combinations. There are about thirty of them in established physics; none is derived; and they are the same throughout the observable universe to the precision of Appendix D.3.4. They are therefore simultaneously the deepest unexplained facts we possess and the only quantitative statements we could compare, without any shared convention, against a measurement made by anyone else anywhere.

Figure D.2 is the smallest complete expression of that idea: one stroke, then one hundred and thirty-seven. It is not the value of α, and it does not say at what scale it was measured. But it is the part of our physics that needs no dictionary — and the part that a stranger could confirm or refute.

Appendix E

Notation

This appendix is the treatise's single, canonical reference for notation: general typographic conventions (Appendix E.1), the macro-to-meaning dictionary (Appendix E.3), and a pointer to the dimension-and-index ladder used throughout the geometric chapters (Appendix E.2). The editorial *rules* that govern how the treatise is written — the SI axiom, the proofs-always rule, the experiment-detail rule — are stated once, in the front matter (*Editorial Conventions*); this appendix does not repeat them, only the symbols.

E.1 General conventions

- Vectors are set in bold, $\boldsymbol{x}$; operators wear no hats unless ambiguity demands them.
- The upright d denotes the differential, i the imaginary unit, e Euler's number — never the italic d, i, e used for ordinary variables (Chapter 1 macro policy).
- Einstein summation over repeated indices is understood unless stated otherwise.
- The metric signature in relativistic chapters is $(-,+,+,+)$. Geometric chapters of Part II are written for general dimension $D = p{+}q$ with signature (p, q) (Appendix E.2).
- A tensor's *type* is written (r, s): r contravariant (upper) and s covariant (lower) slots. The pair (p, q) is reserved for metric signature, never for tensor type.
- Label prefixes identify what a cross-reference points to: `ch:` chapter, `sec:` section, `eq:` equation, `fig:` figure, `tab:` table, `exp:` experiment, `phen:` phenomenon, `app:` appendix section, `part:` part, `thm:`/`def:`/`prop:`/ `cor:`/`lem:` the corresponding theorem-family environment.

E.2 Index conventions for general dimension

Chapters that develop geometry in general dimension $D = p + q$ (Part II, Chapters 13 and 14) fix a specific ladder of index letters, embedding spaces, and symmetry groups — $\mu, \nu, \ldots$ versus $a, b, \ldots$ for diffeomorphism- and local-Lorentz-covariant objects, extended to $m, n, \ldots / A, B, \ldots$ and $M, N, \ldots / I, J, \ldots$ for the $(p{+}q{+}1)$- and $(p{+}q{+}2)$-dimensional embeddings of the (anti-)de Sitter and conformal geometries. Rather than duplicate that material, this appendix points to it: the full statement, with the symmetry-ladder table (Poincaré, Lorentz, translations, anti-de Sitter, de Sitter, conformal), is Section 13.1 of Chapter 13.

E.3 Macro-to-meaning dictionary

Every macro used in the mathematics of this treatise is defined once, in `preamble/macros.tex`, and used identically in every chapter; none is redefined locally. Table E.1 is the complete dictionary.

Remark E.1 (Banned redefinitions). The kernel commands `\d`, `\i`, `\c`, `\L` are never redefined in this treatise (CLAUDE.md macro policy): old ported sources that redefined them as differential/imaginary-unit/speed-of-light/ Lagrangian have been translated on port to `\dd`, `\ii`, plain c, and `\Lag` respectively. The `physics` package is banned outright, since its `\qty` collides with siunitx v3's.

Table E.1: Macro-to-meaning dictionary. Every symbol in this treatise's mathematics resolves to exactly one row of this table.

Macro	Renders as	Meaning
`\dd`	d	differential (upright)
`\ii`	i	imaginary unit (upright)
`\ee`	e	Euler's number (upright)
`\pp`	∂	partial derivative symbol
`\dv{f}{x}`	$\frac{\mathrm{d}f}{\mathrm{d}x}$	total derivative
`\pdv{f}{x}`	$\frac{\partial f}{\partial x}$	partial derivative
`\abs{x}`	$\lvert x \rvert$	absolute value / modulus
`\norm{x}`	$\lVert x \rVert$	norm
`\set{x}`	$\{x\}$	set-builder braces
`\gen{x}`	$\langle x \rangle$	generated subgroup/subspace
`\avg{x}`	$\langle x \rangle$	ensemble or expectation average
`\ket{\psi}`	$\lvert \psi \rangle$	quantum ket
`\bra{\psi}`	$\langle \psi \rvert$	quantum bra
`\braket{\phi}{\psi}`	$\langle \phi \vert \psi \rangle$	inner product
`\ketbra{\phi}{\psi}`	$\lvert \phi \rangle\langle \psi \rvert$	outer product
`\ev{A}{\psi}`	$\langle \psi \vert A \vert \psi \rangle$	expectation value
`\comm{A}{B}`	$[A, B]$	commutator
`\acomm{A}{B}`	$\{A, B\}$	anticommutator
`\pb{A}{B}`	$\{A, B\}$	Poisson bracket
`\tr`	tr	trace
`\transpose`	$^{\mathsf{T}}$ (superscript)	matrix transpose
`\sgn`	sgn	sign function
`\diag`	diag	diagonal matrix
`\im`	im	image of a map
`\id`	id	identity map
`\grad`, `\curl`, `\Div`	$\mathrm{grad}, \mathrm{curl}, \mathrm{div}$	gradient, curl, divergence
`\SO`, `\SU`, `\ISO`	$\mathrm{SO}, \mathrm{SU}, \mathrm{ISO}$	special orthogonal, unitary, inhomogeneous
`\U`, `\Ogrp`, `\GL`, `\SL`	$\mathrm{U}, \mathrm{O}, \mathrm{GL}, \mathrm{SL}$	unitary, orthogonal, general/special linear
`\Sp`, `\Spin`	$\mathrm{Sp}, \mathrm{Spin}$	symplectic, spin group
`\R`, `\C`, `\N`, `\Z`, `\Q`	$\mathbb{R}, \mathbb{C}, \mathbb{N}, \mathbb{Z}, \mathbb{Q}$	reals, complexes, naturals, integers, rationals
`\identity`	$\mathbb{1}$	identity operator
`\Lag`	$\mathcal{L}$	Lagrangian (never `\L`)
`\Ham`	$\mathcal{H}$	Hamiltonian
`\vect{x}`	$\boldsymbol{x}$	vector (bold)
`\ec`	,	equation-final comma
`\ep`	.	equation-final period
`\nn`	(no output)	suppress an equation number

Bibliography

Boyle. *A Defence of the Doctrine Touching the Spring and Weight of the Air.* Appendix to the second edition of New Experiments Physico-Mechanicall, Touching the Spring of the Air; contains the pressure-volume data now called Boyle's law (reply to Linus and Hobbes). Oxford: Thomas Robinson, 1662.

[7] B. Pascal. *Traitez de l'équilibre des liqueurs et de la pesanteur de la masse de l'air*. Posthumous (Pascal died 1662). Pascal's principle and the hydraulic press. Paris: Guillaume Desprez, 1663.

[8] F. M. Grimaldi. *Physico-mathesis de lumine, coloribus, et iride, aliisque adnexis libri duo*. Posthumous; the work in which diffraction is named and reported, which is exactly the claim cited. The title page reads 'adnexis'; many modern citations modernise it to 'annexis' – prefer the printed 'adnexis'. Imprint is sometimes given as 'heirs of Vittorio Benacci for Girolamo Bernia'. Pre-1990 book, no DOI. Bologna: Ex typographia haeredis Victorij Benatij, 1665.

[9] E. Bartholinus. *Experimenta crystalli Islandici disdiaclastici quibus mira & insolita refractio detegitur*. The report of double refraction in Iceland spar. Published at Hafniae (Copenhagen), 1669, 4to, [4] + 60 pp. The title page prints the Latinised name (Erasmi Bartholini / Erasmus Bartholinus); the Danish form Rasmus Bartholin and the anglicised 'Bartholin' used in the chapter prose are the same man. Keep the ampersand '&' as printed. Public-domain scans exist, so a URL can make this GREEN. Sumptibus Danielis Paulli, 1669.

[10] I. Newton. "A letter of Mr. Isaac Newton, Professor of the Mathematicks in the University of Cambridge; containing his new theory about light and colors: sent by the author to the publisher from Cambridge, Febr. 6. 1671/72; in order to be communicated to the R. Society". In: *Philosophical Transactions of the Royal Society of London* 6.80 (1672). Issue no. 80, dated 19 February 1671/72 – Old Style, i.e. 1672 in modern reckoning, which is why the DOI string carries 1671 while the year is 1672. Volume 6 spans 1671–1672. The long title above is the one Crossref and the Royal Society print; a shortened 'New Theory about Light and Colours' is customary in prose but is not the published title., pp. 3075–3087. DOI: 10.1098/rstl.1671.0072.

[11] C. Huygens. *Horologium Oscillatorium sive de motu pendulorum ad horologia aptato demonstrationes geometricae*. Cycloidal pendulum, centre of oscillation/compound pendulum; theorems on centrifugal force stated at the end. Paris: F. Muguet, 1673.

[12] O. Rømer. "Démonstration touchant le mouvement de la lumière trouvé par M. Römer de l'Académie Royale des Sciences". In: *Journal des Sçavans* (1676). The first evidence that light propagates at a finite speed, from the timing of the eclipses of Io. No DOI; digitised by the Bibliothèque nationale de France, pp. 233–236.

[13] R. Hooke. *Lectures de Potentia Restitutiva, or of Spring Explaining the Power of Springing Bodies*. States 'ut tensio, sic vis', announced as the anagram ceiiinosssttuv in 1676. London: John Martyn, 1678.

[14] I. Newton. *Philosophiæ Naturalis Principia Mathematica*. London: Royal Society, 1687.

[15] C. Huygens. *Traité de la lumière*. Leiden: Pierre van der Aa, 1690.

[16] J. Bernoulli. "Solutio problematis funicularii". In: *Acta Eruditorum* (1691). Catenary solution, June 1691 issue; Leibniz and Huygens published solutions in the same issue. Author is Johann Bernoulli (same surname as the 1696 entry, different problem).

[17] J. Bernoulli. "Problema novum ad cuius solutionem Mathematici invitantur". In: *Acta Eruditorum* (1696). The brachistochrone challenge, June 1696 issue; solutions by Newton, Leibniz, l'Hopital and the Bernoullis appeared in the May 1697 issue., p. 269.

[18] I. Newton. *Opticks: or, A Treatise of the Reflexions, Refractions, Inflexions and Colours of Light. Also Two Treatises of the Species and Magnitude of Curvilinear Figures*. First edition, London, 1704, published anonymously (Newton's name does not appear on the title page). The two mathematical treatises appended in 1704 were dropped from the 1717 second edition, so an edition field is worth carrying: cite the 1704 first edition, since Newton's rings are described in Book II of that edition. Address: London. Sam. Smith and Benj. Walford, Printers to the Royal Society, 1704.

[19] J. Bradley. "A letter from the Reverend Mr. James Bradley Savilian Professor of Astronomy at Oxford, and F. R. S. to Dr. Edmond Halley Astronom. Reg. &c. giving an account of a new discovered motion of the fix'd stars". In: *Philosophical Transactions of the Royal Society of London* 35.406 (1728). The discovery of stellar aberration. Crossref dates the issue 1728-12-31 and gives vol. 35, pp. 637-661, so year 1728 is the publisher's dating and matches the key. The DOI suffix reads 'rstl.1727' because Phil. Trans. vol. 35 spans the years 1727-1728 – that is not an error, do not 'correct' it to 1728. Crossref prefixes the title with the Royal Society's modern article number 'IV.', which is a digitisation artefact and is omitted here; the DOI title check should still match. Article number 406., pp. 637–661. DOI: 10.1098/rstl.1727.0064.

[20] H. Pitot. "Description d'une machine pour mesurer la vitesse des eaux courantes et le sillage des vaisseaux". In: *Mémoires de l'Académie Royale des Sciences (Paris)*. Volume for the year 1732, printed 1735; the series is numbered by year, not by volume (academy-proceedings rule). The Pitot tube. 1732, pp. 363–376.

[21] G. Hadley. "Concerning the cause of the general trade-winds". In: *Philosophical Transactions of the Royal Society of London* 39.437 (1735). Explanation of the trade winds by the Earth's rotation. Volume 39 spans 1735-1736; customarily dated 1735., pp. 58–62. DOI: 10.1098/rstl.1735.0014.

[22] D. Bernoulli. *Hydrodynamica, sive de viribus et motibus fluidorum commentarii*. The pressure-velocity relation appears via a vis viva argument; the modern local form of Bernoulli's theorem is Euler's (see Euler:1757). The chapter records this attribution explicitly. Strasbourg (Argentorati): Johann Reinhold Dulsecker, 1738.

[23] L. Euler. *Methodus inveniendi lineas curvas maximi minimive proprietate gaudentes, sive solutio problematis isoperimetrici latissimo sensu accepti*. Founding monograph of the calculus of variations; Additamentum II states the least-action principle for mechanics (relevant to the Maupertuis misattribution remark). Lausanne and Geneva: Marcum-Michaelem Bousquet, 1744.

[24] P. L. M. de Maupertuis. "Les loix du mouvement et du repos déduites d'un principe métaphysique". In: *Histoire de l'Académie Royale des Sciences et des Belles-Lettres de Berlin*. Volume for the year 1746 (printed 1748); customarily cited as 1746. His 1744 Paris memoir treats only the refraction of light – the mechanical least-action claim is here, and the mathematically correct statement is Euler:1744 Additamentum II (misattribution noted in the chapter prose). 1746, pp. 267–294.

[25] J. le Rond d'Alembert. "Recherches sur la courbe que forme une corde tendue mise en vibration". In: *Histoire de l'Académie royale des sciences et des belles-lettres de Berlin* 3 (1747). The wave equation and its travelling-wave solution. Volume for 1747, printed 1749; keyed by the customary/nominal volume year (no DOI exists to arbitrate). A continuation follows at pp. 220-249., pp. 214–219.

[26] J. Bradley. “A letter to the Right honourable George Earl of Macclesfield concerning an apparent motion observed in some of the fixed stars; by James Bradley D. D. F. R. S”. In: *Philosophical Transactions of the Royal Society of London* 45.485 (1748). Discovery of the nutation of the Earth’s axis., pp. 1–41. DOI: 10.1098/rstl.1748.0002.

[27] J. le Rond d’Alembert. *Essai d’une nouvelle théorie de la résistance des fluides*. Source of the d’Alembert paradox: steady potential flow exerts no drag. Paris: David l’aîné, 1752.

[28] D. Bernoulli. “Réflexions et éclaircissemens sur les nouvelles vibrations des cordes exposées dans les mémoires de l’Académie de 1747 et 1748”. In: *Histoire de l’Académie royale des sciences et des belles-lettres de Berlin* 9 (1753). Superposition of trigonometric modes on the vibrating string. Volume for 1753, printed 1755; keyed by the nominal volume year, matching customary citation., pp. 147–172.

[29] J. A. Segner. *Specimen theoriae turbinum*. Discovery that every rigid body has three mutually orthogonal principal axes. Halle: Gebauer, 1755.

[30] L. Euler. “Principes généraux du mouvement des fluides”. In: *Mémoires de l’Académie Royale des Sciences et des Belles-Lettres de Berlin*. Vol. 11. Presented 1755; the volume for 1755 was printed in 1757. Contains the Euler equations and the continuity equation in field form. 1757, pp. 274–315.

[31] J. L. Lagrange. “Essai d’une nouvelle méthode pour déterminer les maxima et les minima des formules intégrales indéfinies”. In: *Miscellanea Taurinensia* 2 (1762). Volume for 1760–61, printed 1762; customarily dated 1760/1762. Introduces the delta-calculus derivation of the Euler–Lagrange equation., pp. 173–195.

[32] L. Euler. *Theoria motus corporum solidorum seu rigidorum*. Enestrom E289. Euler’s equations, the inertia tensor and moments of inertia, free precession of the symmetric top, prediction of the Earth’s free wobble (period near 305 days). Rostock and Greifswald: A. F. Röse, 1765.

[33] N. Maskelyne. “An account of observations made on the mountain Schehallien for finding its attraction”. In: *Philosophical Transactions of the Royal Society of London* 65.65 (1775). The Schiehallion plumb-line experiment; the paper spells the mountain ’Schehallien’., pp. 500–542. DOI: 10.1098/rstl.1775.0050.

[34] L. Euler. “Formulae generales pro translatione quacunque corporum rigidorum”. In: *Novi Commentarii Academiae Scientiarum Imperialis Petropolitanae* 20 (1776). Enestrom E478. Euler’s rotation theorem and the general rotation formulae; volume for 1775, published 1776., pp. 189–207.

[35] C. Hutton. “An account of the calculations made from the survey and measures taken at Schehallien, in order to ascertain the mean density of the Earth”. In: *Philosophical Transactions of the Royal Society of London* 68.68 (1778). Reduction of the Schiehallion survey; mean density near 4.5 times water., pp. 689–788. DOI: 10.1098/rstl.1778.0034.

[36] C.-A. de Coulomb. “Recherches théoriques et expérimentales sur la force de torsion et sur l’élasticité des fils de métal”. In: *Mémoires de l’Académie Royale des Sciences (Paris)*. Volume for the year 1784, printed 1787; the series is numbered by year, not volume (academy-proceedings rule), and the customary citation year 1784 is kept as key since no DOI arbitrates. Torsion law of metal fibres; independent invention of the torsion balance. 1784, pp. 229–269.

[37] J. Michell. “On the Means of Discovering the Distance, Magnitude, &c. of the Fixed Stars, in Consequence of the Diminution of the Velocity of Their Light”. In: *Philosophical Transactions of the Royal Society of London* 74 (1784). The dark-star argument. Metadata confirmed against Crossref., pp. 35–57. DOI: 10.1098/rstl.1784.0008.

[38] C. A. d. Coulomb. “Premier mémoire sur l’électricité et le magnétisme”. In: *Histoire de l’Académie Royale des Sciences, avec les Mémoires de Mathématique et de Physique, Année 1785*. Academy proceedings: @inproceedings with a booktitle and NO volume – the series has none, do not invent one. DATING: the volume bears ’Année 1785’ on its title page (the memoir was read to the Académie in 1785), but it was actually printed in 1788; the customary citation, and the key, follow 1785. Record the 1788 imprint in a bib note. The full printed title continues ’Construction & usage d’une balance électrique, fondée sur la propriété qu’ont les fils de métal, d’avoir une force de réaction de torsion proportionnelle à l’angle de torsion.’ – the torsion-balance inverse-square measurement the chapter cites. Pages 569-577 verified. No DOI; scans on Gallica/Internet Archive (Coulomb, *Mémoires sur l’électricité et le magnétisme*) give a real access route. 1785, pp. 569–577.

[39] E. F. F. Chladni. *Entdeckungen über die Theorie des Klanges*. The sand figures of vibrating plates. Leipzig: Weidmanns Erben und Reich, 1787.

[40] J.-L. Lagrange. *Méchanique analitique*. Original spelling of the first edition; later editions titled Mécanique analytique. General theory of small oscillations and the heavy symmetric top. Paris: la Veuve Desaint, 1788.

[41] A.-M. Legendre. “Mémoire sur la manière de distinguer les maxima des minima dans le calcul des variations”. In: *Mémoires de l’Académie Royale des Sciences de Paris*. Read to the Academy in 1786; printed in the volume for the year 1786, which appeared in 1788. Customarily cited as Legendre 1786 – keyed by publication year per house rule. 1788, pp. 7–37.

[42] G. B. Venturi. *Recherches expérimentales sur le principe de la communication latérale du mouvement dans les fluides appliqué à l’explication de différens phénomènes hydrauliques*. The Venturi effect and meter. Paris: Houel et Ducros, 1797.

[43] C. R. Benjamin Thompson. “An inquiry concerning the source of the heat which is excited by friction”. In: *Philosophical Transactions of the Royal Society of London* 88 (1798), pp. 80–102. DOI: 10.1098/rstl.1798.0006.

[44] H. Cavendish. “Experiments to determine the density of the earth”. In: *Philosophical Transactions of the Royal Society of London* 88 (1798). The torsion-balance experiment; credits John Michell for conceiving and building the apparatus., pp. 469–526. DOI: 10.1098/rstl.1798.0022.

[45] P.-S. Laplace. *Traité de mécanique céleste, Tome premier*. The potential equation appears in Book II; the equation itself dates to his 1780s memoirs on spheroidal attraction. Paris: J. B. M. Duprat, 1799.

[46] J. Dalton. “Experimental Essays on the Constitution of Mixed Gases; on the Force of Steam or Vapour from Water and Other Liquids in Different Temperatures, Both in a Torricellian Vacuum and in Air; on Evaporation; and on the Expansion of Gases by Heat”. In: *Memoirs of the Literary and Philosophical Society of Manchester* 5 (1802). Society memoirs but carries a volume number; the partial-pressure law and the gas-expansion law., pp. 535–602.

[47] J. L. Gay-Lussac. “Recherches sur la dilatation des gaz et des vapeurs”. In: *Annales de Chimie* 43 (1802). Credits earlier unpublished work by Charles (customary ’Charles’s law’)., pp. 137–175.

[48] T. Young. “The Bakerian Lecture. On the theory of light and colours”. In: *Philosophical Transactions of the Royal Society of London* 92 (1802). Verified via Crossref. Two cautions. (1) The leading "II." is the Royal Society's article number as Crossref stores it; the 1802 printing reads "The Bakerian Lecture. On the Theory of Light and Colours". I give Crossref's exact string so the machine title-check cannot reject the DOI — drop the numeral in the printed bibliography if the house style prefers. (2) The lecture was READ 12 November 1801 and is often cited as 1801; the issue year of Phil. Trans. vol. 92 is 1802, which is what the key uses, so no discrepancy to record. Distinct from Young's other 1802 Phil. Trans. paper, "An account of some cases of the production of colours, not hitherto described" (vol. 92, 387-397) — if that one is ever needed it takes key Young:1802b., pp. 12–48. DOI: 10.1098/rstl.1802.0004.

[49] T. Young. “The Bakerian Lecture. Experiments and calculations relative to physical optics”. In: *Philosophical Transactions of the Royal Society of London* 94 (1804). Verified via Crossref. Same leading-numeral caveat as Young:1802: "I." is the Royal Society article number carried by Crossref, not part of the 1804 printed title. This is the paper carrying the two-source interference experiments and the wavelength calculations that both citing chapters attribute to it., pp. 1–16. DOI: 10.1098/rstl.1804.0001.

[50] T. Young. “An essay on the cohesion of fluids”. In: *Philosophical Transactions of the Royal Society of London* 95 (1805). Surface tension and contact angles; Young's half of the Young-Laplace equation (Laplace's half is the 1806 supplement to Mécanique Céleste, Book X)., pp. 65–87. DOI: 10.1098/rstl.1805.0005.

[51] M.-A. P. des Chênes. “Mémoire sur les séries et sur l'intégration complète d'une équation aux différences partielles linéaires du second ordre, à coefficients constants”. In: *Mémoires présentés à l'Institut des Sciences, Lettres et Arts, par divers savans, Sciences mathématiques et physiques*. Vol. 1. Read in 1799, printed 1806; customarily dated 1799. Full surname 'Parseval des Chênes'. 1806, pp. 638–648.

[52] J. L. Gay-Lussac. “Premier essai pour déterminer les variations de température qu'éprouvent les gaz en changeant de volume, et considérations sur leur capacité pour le calorique”. In: *Mémoires de Physique et de Chimie de la Société d'Arcueil*. Vol. 1. Free-expansion experiment. 1807.

[53] T. Young. *A Course of Lectures on Natural Philosophy and the Mechanical Arts*. Two volumes. Introduces the modulus of elasticity (Young's modulus). London: Joseph Johnson, 1807.

[54] É. L. Malus. “Sur une propriété de la lumière réfléchie”. In: *Mémoires de physique et de chimie de la Société d'Arcueil*. Vol. 2. Tome 2 of the Société d'Arcueil memoirs, 1809. Malus made the observation in late 1808; the memoir is 1809, so the key year is correct. A short prior notice appeared in Nouveau Bulletin des Sciences par la Société Philomathique de Paris 1 (1809) 266-269 — the Arcueil memoir is the substantive paper and the one containing the cos^2 law. No DOI; French Wikisource carries the full text, which is the access route to declare. 1809, pp. 143–158.

[55] A. Avogadro. “Essai d'une manière de déterminer les masses relatives des molécules élémentaires des corps, et les proportions selon lesquelles elles entrent dans ces combinaisons”. In: *Journal de Physique, de Chimie, d'Histoire Naturelle et des Arts* 73 (1811), pp. 58–76.

[56] P.-S. Laplace. *Théorie analytique des probabilités*. Cited as the origin of the (Laplace) generating-function transform. Paris: Veuve Courcier, 1812.

[57] S. D. Poisson. “Remarques sur une équation qui se présente dans la théorie des attractions des sphéroïdes”. In: *Nouveau Bulletin des Sciences, par la Société Philomatique de Paris* 3 (1813). The Poisson equation., pp. 388–392.

[58] D. Brewster. “On the laws which regulate the polarisation of light by reflexion from transparent bodies. By David Brewster, LL. D. F. R. S. Edin. and F. S. A. Edin. In a letter addressed to Right Hon. Sir Joseph Banks, Bart. K. B. P. R. S”. In: *Philosophical Transactions of the Royal Society of London* 105.105 (1815). Crossref confirmed: vol. 105, pp. 125-159, issued 1815. The Crossref record carries the article number ’IX.’ and the trailing dedication ’In a letter addressed to Right Hon. Sir Joseph Banks, Bart. K. B. P. R. S.’; both are omitted here as digitisation/period boilerplate. This is the paper establishing Brewster’s angle (tan i = n)., pp. 125–159. DOI: 10.1098/rstl.1815.0010.

[59] P.-S. Laplace. “Sur la vitesse du son dans l’air et dans l’eau”. In: *Annales de Chimie et de Physique* 3 (1816). The adiabatic correction to Newton’s isothermal sound speed., pp. 238–241.

[60] J. Fraunhofer. “Bestimmung des Brechungs- und des Farbenzerstreungs-Vermögens verschiedener Glasarten, in Bezug auf die Vervollkommnung achromatischer Fernröhre”. In: *Annalen der Physik*. Vol. 56. 7. Academy Denkschriften, not a journal article. Umlauts: Vermoegens = Vermögens, Fernroehre = Fernröhre, Koeniglichen = Königlichen, Muenchen = München. 1817, pp. 264–313. DOI: 10.1002/andp.18170560706.

[61] A. Fresnel. “Lettre de M. Fresnel à M. Arago sur l’influence du mouvement terrestre dans quelques phénomènes d’optique”. In: *Annales de chimie et de physique* 9 (1818). The partial-drag coefficient (1 - 1/n^2), September 1818 issue of tome 9; a short addendum by Fresnel follows at pp. 286-287 of the same tome (November 1818). Journal article, not an academy memoir – kind is article. No DOI; freely readable on Gallica., pp. 57–66.

[62] H. Kater. “An Account of experiments for determining the length of the pendulum vibrating seconds in the latitude of London”. In: *Philosophical Transactions of the Royal Society of London* 108.108 (1818). Read to the Royal Society 29 January 1818; the reversible (Kater) pendulum and the first absolute determination of g. The Royal Society prints the title with the volume article number ’IV.’ prefixed; dropped here per the house convention already used for Cavendish:1798 (’XXI. Experiments to determine the Density of the Earth’). Typed @article, not @inproceedings: Philosophical Transactions is a numbered journal volume and the sibling Phil. Trans. entry Cavendish:1798 is @article with volume 88 and an rstl DOI. Volume 108 is printed on the volume (JSTOR ’Vol. 108, 1818’; Royal Society ’Phil. Trans. R. Soc. (1818) 108: 33-102’) and is not invented – Crossref’s record for this DOI stores 108 in the ’issue’ field and leaves ’volume’ empty, which is a metadata quirk of the pre-1900 rstl deposits. TRAP: Kater serialized the same memoir in The Philosophical Magazine 52 (1818) as four separate DOI-bearing pieces (pp. 90-100, 173-182, 364-370, 415-431), all with near-identical titles; the memoir read to the Royal Society is the Phil. Trans. paper cited here., pp. 33–102. DOI: 10.1098/rstl.1818.0006.

[63] F. Arago and A. Fresnel. “Mémoire sur l’action que les rayons de lumière polarisée exercent les uns sur les autres”. In: *Annales de chimie et de physique* 10 (1819). The joint Arago–Fresnel memoir establishing the Fresnel–Arago laws (perpendicularly polarized beams do not interfere), which is exactly what the citing sentence claims. Série 2, tome 10, 1819; the journal prints it ’par MM. Arago et Fresnel’, hence keying by Arago is right. Some dealer catalogues give the range as 288–306; 288–305

is the more commonly recorded. No DOI; digitised on Gallica. English translation by H. Crew in 'The Wave Theory of Light' (1900)., pp. 288–305.

[64] P. L. Dulong and A. T. Petit. "Recherches sur quelques points importants de la théorie de la chaleur". In: *Annales de Chimie et de Physique* 10 (1819), pp. 395–413.

[65] A.-T. Petit and P.-L. Dulong. "Recherches sur quelques points importants de la Théorie de la Chaleur". In: *Annales de Chimie et de Physique* 10 (1819). The Dulong–Petit law; keyed by first listed author, Petit., pp. 395–413.

[66] A.-M. Ampère. "Mémoire présenté à l'Académie royale des Sciences, le 2 octobre 1820, où se trouve compris le résumé de ce qui avait été lu à la même Académie les 18 et 25 septembre 1820, sur les effets des courans électriques". In: *Annales de chimie et de physique* 15 (1820). The memoir announcing the force between two currents. Published in two instalments in the same volume (série 2, tome 15): pp. 59–76 and, as the 'suite', pp. 170–218; the CNRS Ampère catalogue gives the first instalment as 59–74, most physics bibliographies as 59–76 – both refer to the same instalment, so keep the compound range rather than picking one. Note the period spelling 'courans', not 'courants'. No DOI; digitised on Gallica and at ampere.cnrs.fr., pp. 59–76, 170–218.

[67] J.-B. Biot and F. Savart. "Note sur le magnétisme de la pile de Volta". In: *Annales de chimie et de physique* 15 (1820). The two-page note reporting the 1/r force of a long straight current on a magnetic pole – the measurement the chapter describes. Série 2, tome 15, 1820; presented to the Académie 30 October 1820. The co-author is Félix Savart (not the acoustician's namesake Nicolas Savart, whom some catalogues wrongly list). No DOI; digitised on Gallica and at ampere.cnrs.fr., pp. 222–223.

[68] H. C. Ørsted. *Experimenta circa effectum conflictus electrici in acum magneticam.* A privately printed four-page Latin pamphlet (2 leaves, paginated [1] 2–4), dated at the end 21 July 1820, which Ørsted mailed to natural philosophers across Europe – hence kind=misc, not article: it appeared in no journal. Surname: the pamphlet itself uses the Latinised 'Oersted' and auction/library catalogues (Christie's, WorldCat) file it under OERSTED; the Danish form Ørsted is what the treatise prose uses. Contemporary reprints, if a retrievable route is wanted for the availability grade: Journal für Chemie und Physik (Schweigger's Journal) 29, 275–281 (1820), and the German version 'Versuche über die Wirkung des elektrischen Conflicts auf die Magnetnadel', Annalen der Physik 66 (1820) 295–304 – I have not verified a DOI for either, so do not attach one. Scans are open at the Internet Archive (Experimentacirc00Orst) and the Smithsonian Libraries, and an English translation is in Jelved, Jackson & Knudsen (eds.), Selected Scientific Works of Hans Christian Oersted (Princeton, 1998), pp. 413–420. 1820.

[69] J. Fraunhofer. "Neue Modifikation des Lichtes durch gegenseitige Einwirkung und Beugung der Strahlen, und Gesetze derselben". In: *Denkschriften der Königlichen Akademie der Wissenschaften zu München.* Vol. 8. Academy memoirs, so inproceedings; the Denkschriften do number their Bände, and Band 8 covers the years 1821-1822 – the volume number is real, not invented. This is the grating/diffraction memoir (wire and ruled gratings, the grating equation, first absolute wavelength determinations). No DOI. Distinct from Fraunhofer:1817, the solar dark-line catalogue, which the same chapter cites separately. 1821, pp. 3–76.

[70] S. Germain. *Recherches sur la théorie des surfaces élastiques.* The prize essay on the vibrating-plate equation, answering Chladni's figures. Paris: Veuve Courcier, 1821.

[71] F. Arago. “Résultats des expériences faites, par ordre du Bureau des Longitudes, pour la détermination de la vitesse du son dans l’atmosphère”. In: *Annales de Chimie et de Physique* 20 (1822). Série 2, tome 20 (1822). Verified page-by-page against the scanned volume (archive.org item s3id13207880): the memoir opens on p. 210 immediately after Wollaston’s note, runs through the printed page markers 211-223, and closes with Arago’s Annales siglum ’(Ar.)’; the volume’s own Table du vingtième volume lists it at p. 210. Unsigned in the heading, but written in the first person as one of the commission (’MM. de Prony, Bouvard, Mathieu et moi’), which identifies Arago as the reporter. Commission: Prony, Bouvard, Mathieu and Arago, joined by Humboldt and Gay-Lussac; the reciprocal Villejuif-Montlhéry cannon firings of 21-22 June 1822. Pre-DOI: no DOI exists, so this needs a manifest "access": "open" entry pointing at https://archive.org/details/s3id13207880 or it grades RED as a DOI-less @article. Do not confuse with Laplace:1816 (already in the bibliography) or with Laplace’s separate ’Note sur la vitesse du son’ in the same tome 20., pp. 210–223.

[72] J. B. J. Fourier. *Théorie analytique de la chaleur*. Fourier series and the decomposition of arbitrary initial data. Paris: Firmin Didot, 1822.

[73] A.-L. Cauchy. “Recherches sur l’équilibre et le mouvement intérieur des corps solides ou fluides, élastiques ou non élastiques”. In: *Bulletin de la Société Philomathique de Paris* (1823). Read to the Académie 30 September 1822 and universally cited as Cauchy (1822); keyed by the printing year per the house publisher’s-year rule. Announces the stress and strain tensors; the full development followed in the Exercices de mathématiques (1827-1828). The Bulletin has no volume numbers., pp. 9–13.

[74] J. Fraunhofer. “Kurzer Bericht von den Resultaten neuerer Versuche über die Gesetze des Lichtes, und die Theorie derselben”. In: *Annalen der Physik* 74.8 (1823). Verified against Crossref (issue 8 of volume 74; author printed ’Jos. Fraunhofer’). Volume 74 of the Annalen is Gilbert’s Annalen der Physik – record it as Annalen der Physik, which is what Wiley and Crossref use. This is the follow-up to the 1821 Munich memoir and is the more accessible of the two., pp. 337–378. DOI: 10.1002/andp.18230740802.

[75] C.-L. Navier. “Mémoire sur les lois du mouvement des fluides”. In: *Mémoires de l’Académie Royale des Sciences de l’Institut de France*. Vol. 6. Read 1822; the volume for 1823 was printed in 1827. Universally cited as 1823, and keyed so here since no DOI exists to arbitrate; record the dating in the entry note. 1823, pp. 389–440.

[76] S. Carnot. *Réflexions sur la puissance motrice du feu et sur les machines propres à développer cette puissance*. Paris: Bachelier, 1824.

[77] A.-M. Ampère. *Théorie des phénomènes électro-dynamiques, uniquement déduite de l’expérience*. The book the chapter names in italics. Paris, Méquignon-Marvis, 1826 (first edition; LoC and Internet Archive hold it). Do NOT retitle it ’Théorie mathématique des phénomènes électro-dynamiques...’ – that is the 1827 Mémoires de l’Académie version and the 1883 second edition; the 1826 title page has no ’mathématique’. Public-domain scans exist, so this can grade GREEN with a URL. Méquignon-Marvis, 1826.

[78] A. Fresnel. “Mémoire sur la diffraction de la lumière, où l’on examine particulièrement le phénomène des franges colorées que présentent les ombres des corps éclairés par un point lumineux”. In: *Mémoires de l’Académie royale des sciences de l’Institut de France*. Vol. 5. The prize memoir: submitted 29 July 1818, crowned 15 March 1819, PRINTED only in 1826 in tome V (covering 1821-1822) – so the key year 1826 is

the publisher's year and is correct, while the work is customarily dated 1818/1819. This is the memoir containing the Poisson–Arago spot, the Fresnel integrals, and the biprism and two-mirror arrangements, which is why the same key is cited in four different places in 10-exp-wave-optics.tex. Academy memoirs, hence inproceedings; the tome number is genuine. Reprinted in Œuvres complètes d'Augustin Fresnel, tome I (1866), pp. 247-383, which is the freely available route. 1826, pp. 339–475.

[79] T. J. Seebeck. "Ueber die magnetische Polarisation der Metalle und Erze durch Temperatur-Differenz". In: *Annalen der Physik* 82.1 (1826), pp. 1–20. DOI: 10.1002/andp.18260820102.

[80] C.-L. Navier. "Mémoire sur les lois de l'équilibre et du mouvement des corps solides élastiques". In: *Mémoires de l'Académie Royale des Sciences de l'Institut de France*. Vol. 7. Read 14 May 1821; customarily cited as Navier (1821). Molecular derivation of the elastodynamic (Navier-Cauchy) equations. 1827, pp. 375–393.

[81] G. S. Ohm. *Die galvanische Kette, mathematisch bearbeitet*. T. H. Riemann, 1827.

[82] R. Brown. "A brief account of microscopical observations made in the months of June, July and August 1827, on the particles contained in the pollen of plants; and on the general existence of active molecules in organic and inorganic bodies". In: *The Philosophical Magazine* 4.21 (1828). Series 2 (new series); also privately printed 1828., pp. 161–173. DOI: 10.1080/14786442808674769.

[83] G. Green. *An Essay on the Application of Mathematical Analysis to the Theories of Electricity and Magnetism*. Privately printed essay; origin of the Green's function and the reciprocity theorem. Nottingham: Printed for the author by T. Wheelhouse, 1828.

[84] W. R. Hamilton. "Theory of Systems of Rays". In: *The Transactions of the Royal Irish Academy* 15 (1828). Hamilton's characteristic-function optics, the work the eikonal section names. Read before the Royal Irish Academy 23 April 1827, printed in the volume dated 1828. Only Part First appeared in his lifetime; three Supplements followed in Trans. R. Irish Acad. 16 and 17 (1830, 1831, 1837). No DOI; JSTOR stable id 30078906. Transactions carries a volume number, so @article is appropriate despite being an academy series., pp. 69–174.

[85] P. G. L. Dirichlet. "Sur la convergence des séries trigonométriques qui servent à représenter une fonction arbitraire entre des limites données". In: *Journal für die reine und angewandte Mathematik (Crelles Journal)* 4.4 (1829). Byline 'Lejeune Dirichlet'., pp. 157–169. DOI: 10.1515/crll.1829.4.157.

[86] S. D. Poisson. "Mémoire sur l'équilibre et le mouvement des corps élastiques". In: *Mémoires de l'Académie Royale des Sciences de l'Institut de France*. Vol. 8. Read April 1828. Derives the two distinct elastic wave speeds (P and S) and the ratio now called Poisson's ratio. 1829, pp. 357–570.

[87] M. Chasles. "Note sur les propriétés générales du système de deux corps semblables entr'eux et placés d'une manière quelconque dans l'espace; et sur le déplacement fini ou infiniment petit d'un corps solide libre". In: *Bulletin des Sciences Mathématiques, Astronomiques, Physiques et Chimiques* 14 (1830). Bulletin de Férussac. Chasles' screw-displacement theorem., pp. 321–326.

[88] M. Faraday. "On a peculiar class of acoustical figures; and on certain forms assumed by groups of particles upon vibrating elastic surfaces". In: *Philosophical Transactions of the Royal Society of London* 121.121 (1831). First observation of the parametric (half-frequency) response, in the appendix on crispations., pp. 299–340. DOI: 10.1098/rstl.1831.0018.

[89] M. Faraday. “Experimental researches in electricity”. In: *Philosophical Transactions of the Royal Society of London* 122.122 (1832). The First Series – the induction of transient currents, moving-magnet induction and the flux rule. Crossref prints ’V. Experimental researches in electricity’ (the Royal Society article number) and records 122 as an issue, not a volume; cite as volume 122 with a series note. There is a parallel abridged printing in Phil. Mag., which is NOT this entry., pp. 125–162. DOI: 10.1098/rstl.1832.0006.

[90] A. Fresnel. “Mémoire sur la loi des modifications que la réflexion imprime à la lumière polarisée”. In: *Mémoires de l’Académie royale des sciences de l’Institut de France*. Vol. 11. Read to the Academy on 7 January 1823 but printed in tome XI in 1832 (the manuscript was mislaid and recovered among Fourier’s papers), so the key year is the publisher’s year and the customary dating is 1823 – the citing prose already says ’the memoir read in 1823’, which is consistent. Source of the Fresnel amplitude coefficients (sine law and tangent law) and of the transverse-vibration conclusion. Academy memoirs, hence inproceedings. A partial version appeared in Annales de chimie et de physique 46, 225-264 (1831); that is a different printing, not this key. 1832, pp. 393–433.

[91] J. Henry. “On the Production of Currents and Sparks of Electricity from Magnetism”. In: *The American Journal of Science and Arts* 22 (1832). July 1832 number; this is the paper carrying Henry’s independent observation of induction and his report of self-induction, which is what the citing sentence claims. No DOI (pre-1990)., pp. 403–408.

[92] F. Reich. *Fallversuche über die Umdrehung der Erde*. Eastward deflection of falling bodies in the Freiberg mineshaft; experiments performed 1831. Freiberg: J. G. Engelhardt, 1832.

[93] M. Faraday. “Experimental researches in electricity.— fourth series”. In: *Philosophical Transactions of the Royal Society of London* 123.123 (1833). Contains ’On a new law of electric conduction’ — the observation that the conducting power of silver sulfide increases on heating., pp. 507–522. DOI: 10.1098/rstl.1833.0022.

[94] T. Graham. “On the law of the diffusion of gases”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 2.9 (1833). Series 3; continued at pp. 269–276 and 351–358 of the same volume., pp. 175–190. DOI: 10.1080/14786443308648004.

[95] É. Clapeyron. “Mémoire sur la puissance motrice de la chaleur”. In: *Journal de l’École Royale Polytechnique* 14 (1834). Tome XIV, 23e cahier; ideal-gas equation, indicator diagram, analytic Carnot theory, coexistence-slope equation., pp. 153–190.

[96] W. R. Hamilton. “On a general method in dynamics; by which the study of the motions of all free systems of attracting or repelling points is reduced to the search and differentiation of one central relation, or characteristic function”. In: *Philosophical Transactions of the Royal Society of London* 124.124 (1834). The ’Second Essay’ is Phil. Trans. 125 (1835) 95–144, not cited in these chapters., pp. 247–308. DOI: 10.1098/rstl.1834.0017.

[97] E. Lenz. “Ueber die Bestimmung der Richtung der durch elektrodynamische Vertheilung erregten galvanischen Ströme”. In: *Annalen der Physik* 107.31 (1834). Crossref-confirmed. Wiley files it under the continuous volume 107 with ’issue 31’ — 31 is the contemporaneous Poggendorff series volume, so cite volume 107 (Wiley) and mention Poggendorffs Annalen Bd. 31 in a note if desired. Crossref’s container-title is the modern ’Annalen der Physik’; the 1834 imprint is ’Annalen der Physik und Chemie’., pp. 483–494. DOI: 10.1002/andp.18341073103.

[98] J. C. A. Peltier. “Nouvelles expériences sur la caloricité des courans électriques”. In: *Annales de Chimie et de Physique* 56 (1834), pp. 371–386.

[99] L. Poinsot. *Théorie nouvelle de la rotation des corps*. Geometric (rolling-ellipsoid) description of torque-free motion; polhode and herpolhode. An extended version appeared in J. Math. Pures Appl. 16 (1851). Paris: Bachelier, 1834.

[100] G.-G. Coriolis. “Sur les équations du mouvement relatif des systèmes de corps”. In: *Journal de l’École Royale Polytechnique* 15 (1835). Cahier 24, tome 15. The Coriolis force., pp. 142–154.

[101] C. G. J. Jacobi. “Zur Theorie der Variations-Rechnung und der Differential-Gleichungen”. In: *Journal für die reine und angewandte Mathematik (Crelles Journal)* 17.17 (1837). Source of the accessory (Jacobi) equation and conjugate points., pp. 68–82. DOI: 10.1515/crll.1837.17.68.

[102] H. Lloyd. “On a New Case of Interference of the Rays of Light”. In: *The Transactions of the Royal Irish Academy* 17 (1837). Dating is genuinely contested and the key’s 1834 is the customary date the experiment was described/read to the Academy. Transactions vol. 17 is dated 1837 by most catalogues (it is the volume carrying Hamilton’s Third Supplement, TRIA 17 (1837) 1-144, and MacCullagh’s papers); JSTOR labels the same volume 1831 (JSTOR stable/30078788, volume index i30078783). Recommend keying Lloyd:1834 as written with year 1837 and a note recording both the 1834 reading and the JSTOR 1831 label. No DOI. Access route: JSTOR (paywalled) — grade AMBER unless a copy is stored., pp. 171–177.

[103] G. B. Airy. “On the intensity of light in the neighbourhood of a caustic”. In: *Transactions of the Cambridge Philosophical Society* 6 (1838). The caustic integral (Airy function) explaining supernumerary rainbow bows. Read to the Society in 1836, printed in volume 6 part III, 1838 – so the customary date 1838 is the issue date and is correct. No DOI exists for this volume; the reader’s route is the digitised Transactions (archive.org / Google Books), not a publisher record., pp. 379–402.

[104] G. Hagen. “Ueber die Bewegung des Wassers in engen cylindrischen Röhren”. In: *Annalen der Physik* 122.3 (1839). Second-series volume 46 (volume 122 in the continuous numbering of Annalen der Physik). Independent discovery of the fourth-power pipe-flow law., pp. 423–442. DOI: 10.1002/andp.18391220304.

[105] J. L. M. Poiseuille. “Recherches expérimentales sur le mouvement des liquides dans les tubes de très-petits diamètres”. In: *Comptes Rendus des Séances de l’Académie des Sciences*. Vol. 11. Two notes in CR 11 (1840); continued in CR 12 (1841) 112-115; the full memoir appeared in 1846 (Mémoires des Savants Étrangers 9, 433-544). 1840, pp. 961–967, 1041–1048.

[106] C. F. Gauss. “Intensitas vis magneticae terrestris ad mensuram absolutam revocata”. In: *Commentationes Societatis Regiae Scientiarum Gottingensis Recentiores*. Vol. 8. CUSTOMARY-VS-PUBLISHER DATING, the Kretschmann trap: read to the Göttingen Society on 15 December 1832 and issued as a separate offprint in 1833, but the Commentationes volume VIII (covering 1832-1837) was published in 1841 – so the key year is the publisher’s year and is correct, and the note should record the 1832 reading. Society commentaries, hence inproceedings; volume 8 is genuine. Reprinted in Gauss, Werke V (Göttingen 1867), pp. 79-118. No DOI for the original: a Springer chapter DOI exists (10.1007/978-3-642-49319-5_10) but it points at a modern reprint, not this venue, so it should NOT be attached. 1841, pp. 3–44.

[107] C. Doppler. “Über das farbige Licht der Doppelsterne und einiger anderer Gestirne des Himmels”. In: *Abhandlungen der Königlichen Böhmischen Gesellschaft der Wissenschaften*. Academy series (V. Folge, Bd. 2, Prague), no journal volume number — @inproceedings per the house rule on academy proceedings. 1842, pp. 465–482.

[108] J. R. Mayer. “Bemerkungen über die Kräfte der unbelebten Natur”. In: *Justus Liebigs Annalen der Chemie* 42.2 (1842), pp. 233–240. DOI: 10.1002/jlac.18420420212.

[109] J. Joule. “On the calorific effects of magneto-electricity, and on the mechanical value of heat”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 23.153 (1843). Series 3; continued at pp. 347–355 and 435–443 of the same volume., pp. 347–355. DOI: 10.1080/14786444308644749.

[110] A. J. C. B. de Saint-Venant. “Note à joindre au Mémoire sur la dynamique des fluides”. In: *Comptes Rendus des Séances de l’Académie des Sciences*. Vol. 17. States the viscous flow equations in final form two years before Stokes; cited to keep the Navier-Stokes attribution honest. 1843, pp. 1240–1243.

[111] C. H. D. B. Ballot. “Akustische Versuche auf der Niederländischen Eisenbahn, nebst gelegentlichen Bemerkungen zur Theorie des Hrn. Prof. Doppler”. In: *Annalen der Physik und Chemie* 66 (1845). Experimental test of the Doppler effect for sound with musicians on a moving train. Poggendorff vol. 66 = Wiley continuous numbering vol. 142., pp. 321–351.

[112] J. Joule. “On the changes of temperature produced by the rarefaction and condensation of air”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 26.174 (1845). Series 3. Suffix a: two Joule works of 1845 are cited; this is the earlier (vol. 26)., pp. 369–383. DOI: 10.1080/14786444508645153.

[113] J. P. Joule. “On the existence of an equivalent relation between heat and the ordinary forms of mechanical power”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 27.179 (1845). Series 3. Suffix b: first paddle-wheel announcement (vol. 27)., pp. 205–207. DOI: 10.1080/14786444508645256.

[114] S. Kirchhoff. “Ueber den Durchgang eines elektrischen Stromes durch eine Ebene, insbesondere durch eine kreisförmige”. In: *Annalen der Physik* 140.4 (1845). Issue 4. The paper universally cited as the first statement of Kirchhoff’s circuit laws, matching the citing sentence. TWO TRAPS. (1) The volume is 140 in Wiley’s whole-series numbering, which is what the DOI and Crossref use; Poggendorff’s own running number for the same volume is 64, and many secondary sources cite ’Ann. Phys. Chem. 64, 497’. Use 140 so the DOI and volume agree. (2) Kirchhoff generalised the rules to arbitrary networks two years later in ’Ueber die Auflösung der Gleichungen, auf welche man bei der Untersuchung der linearen Vertheilung galvanischer Ströme geführt wird’, Ann. Phys. 148, 497–508 (1847) – if the prose ever needs the network form specifically, that is the paper, not this one., pp. 497–514. DOI: 10.1002/andp.18451400402.

[115] F. E. Neumann. “Die mathematischen Gesetze der inducirten elektrischen Ströme”. In: *Abhandlungen der Königlichen Akademie der Wissenschaften zu Berlin, aus dem Jahre 1845, Physikalische Abhandlungen*. Academy Abhandlungen: NO volume number – the series is designated by year (’aus dem Jahre 1845’). Read to the Berlin Academy on 27 October 1845; issued separately by G. Reimer, Berlin, 1846 (87 pp.), and Jackson & Okun date the collected Academy printing 1847, so 1845 is the volume’s own dating rather than the press date. TITLE TRAP: Jackson & Okun (Rev. Mod. Phys. 73, 663; arXiv hep-ph/0012061) cite this memoir as ’Allgemeine Gesetze der inducirten elektrischen Ströme’ – that is the title of the abridged extract in Annalen der Physik 143 (1846) 31–44, not of the Academy

memoir; several secondary sources have copied the conflation. The sequel is 'Über ein allgemeines Princip der mathematischen Theorie inducirter electrischer Ströme', Abh. Berlin aus dem Jahre 1847, 1–71 (Reimer 1848) – a different work. Reprinted as Ostwalds Klassiker Nr. 10, ed. C. Neumann (Engelmann, Leipzig 1889). No DOI. Note for the citing chapter: Neumann never displays the vector potential explicitly; the form A_N is attributed to him by later workers (Jackson & Okun say so in as many words), so 'introduced by Neumann' should be softened to 'implicit in Neumann's mutual-inductance integral'. 1845, pp. 1–87.

[116] J. S. Russell. "Report on Waves". In: *Report of the Fourteenth Meeting of the British Association for the Advancement of Science*. The 14th BAAS meeting was held at York in September 1844; the Report volume printed 1845 (keyed by print year). Contains the account of the solitary wave observed on the Union Canal in 1834 and the wave-tank experiments. 1845, pp. 311–390.

[117] G. G. Stokes. "On the Theories of the Internal Friction of Fluids in Motion, and of the Equilibrium and Motion of Elastic Solids". In: *Transactions of the Cambridge Philosophical Society* 8 (1845). Read 14 April 1845; the completed volume 8 is dated 1849. Universally cited as 1845 and keyed so here (no DOI to arbitrate); record the dating in the entry note., pp. 287–319.

[118] M. Faraday. "Experimental researches in electricity.—Nineteenth series". In: *Philosophical Transactions of the Royal Society of London* 136.136 (1846). The Faraday-effect paper; the series carries the descriptive subtitle 'On the magnetization of light and the illumination of magnetic lines of force'. Crossref title is 'I. Experimental researches in electricity.—Nineteenth series' (article number I) and it records 136 as an issue; cite as volume 136., pp. 1–20. DOI: 10.1098/rstl.1846.0001.

[119] M. Faraday. "Experimental researches in electricity.—Twentieth series". In: *Philosophical Transactions of the Royal Society of London* 136.136 (1846). The diamagnetism paper (bismuth repelled), descriptive subtitle 'On new magnetic actions, and on the magnetic condition of all matter'. Crossref title 'II. Experimental researches in electricity.—Twentieth series'; 136 recorded as issue. NOTE the DOI is ...1846.0003, not 0002 – 10.1098/rstl.1846.0002 is an unrelated errata page. The Twenty-first series (10.1098/rstl.1846.0004, pp. 41-62) continues the same work if a second key is ever needed., pp. 21–40. DOI: 10.1098/rstl.1846.0003.

[120] T. Graham. "On the motion of gases". In: *Philosophical Transactions of the Royal Society of London* 136.136 (1846). Effusion and transpiration., pp. 573–631. DOI: 10.1098/rstl.1846.0029.

[121] H. von Helmholtz. *Über die Erhaltung der Kraft, eine physikalische Abhandlung*. Berlin: G. Reimer, 1847.

[122] V. Regnault. "Relation des expériences entreprises pour déterminer les principales lois et les données numériques qui entrent dans le calcul des machines à vapeur". In: *Mémoires de l'Académie des Sciences de l'Institut de France*. Vol. 21. Memoir occupying the whole of volume 21; the full official title carries a ministerial commission clause – verify exact form when building the bib entry. 1847.

[123] W. Thomson. "On an Absolute Thermometric Scale Founded on Carnot's Theory of the Motive Power of Heat, and Calculated from Regnault's Observations". In: *Philosophical Magazine* 33 (1848). Series 3; author later Lord Kelvin. Also read to the Cambridge Philosophical Society, June 1848., pp. 313–317.

[124] H. Wilbraham. “On a certain periodic function”. In: *The Cambridge and Dublin Mathematical Journal* 3 (1848). First description of the overshoot customarily called the Gibbs phenomenon – misattribution recorded in the chapter prose per house rule., pp. 198–201.

[125] H. Fizeau. “Sur une expérience relative à la vitesse de propagation de la lumière”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 29. The toothed-wheel measurement over the Suresnes–Montmartre baseline, séance of 23 July 1849. Comptes rendus DOES carry tome numbers (t. XXIX), so volume 29 is real and not invented. A short addendum appears at p. 132 of the same tome. No DOI exists; the volume is free on Gallica, so it grades GREEN via a manifest URL rather than a DOI. booktitle should be the Comptes rendus series name, with no publisher volume beyond the tome. 1849, pp. 90–92.

[126] A. Bravais. “Mémoire sur les systèmes formés par des points distribués régulièrement sur un plan ou dans l’espace”. In: *Journal de l’École Polytechnique* 19 (1850), pp. 1–128.

[127] R. Clausius. “Ueber die bewegende Kraft der Wärme und die Gesetze, welche sich daraus für die Wärmelehre selbst ableiten lassen”. In: *Annalen der Physik* 155.4 (1850). Part II in the same volume, pp. 500–524. Poggendorff numbering; Wiley continuous numbering vol. 155., pp. 500–524. DOI: 10.1002/andp.18501550403.

[128] L. Foucault. “Méthode générale pour mesurer la vitesse de la lumière dans l’air et les milieux transparents. Vitesses relatives de la lumière dans l’air et dans l’eau. Projet d’expérience sur la vitesse de propagation du calorique rayonnant”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 30. Séance of 6 May 1850 (t. 30, no. 18). This is the rotating-mirror experiment showing light slower in water, i.e. the result that decided against the corpuscular theory; Foucault announced no numerical value for c until 1862. The title is long because the Comptes rendus prints all three parts as one heading – a shortened form ending at ’milieux transparents’ is acceptable if the bib writer prefers, but the above is what is printed. No DOI; free on Gallica. 1850, pp. 551–560.

[129] J. P. Joule. “On the mechanical equivalent of heat”. In: *Philosophical Transactions of the Royal Society of London* 140.140 (1850), pp. 61–82. DOI: 10.1098/rstl.1850.0004.

[130] G. Kirchhoff. “Über das Gleichgewicht und die Bewegung einer elastischen Scheibe”. In: *Journal für die reine und angewandte Mathematik (Crelles Journal)* 40.40 (1850). Consistent plate bending theory and boundary conditions., pp. 51–88. DOI: 10.1515/crll.1850.40.51.

[131] O. F. Mossotti. “Discussione analitica sull’influenza che l’azione di un mezzo dielettrico ha sulla distribuzione dell’elettricità alla superficie di più corpi elettrici disseminati in esso”. In: *Memorie di Matematica e di Fisica della Società Italiana delle Scienze Residente in Modena* 24 (1850). Received by the Society 15 August 1846 (per the Museo Galileo catalogue record) and printed in 1850, which fixes the key; the memoir is consequently sometimes dated 1846 or 1847. Some citations add ’parte seconda’ (part 2) to the volume. No DOI. Digitised copy catalogued by the Museo Galileo OPAC (record uri=1014641)., pp. 49–74.

[132] M. Ostrogradsky. “Mémoire sur les équations différentielles relatives au problème des isopérimètres”. In: *Mémoires de l’Académie Impériale des Sciences de Saint-Pétersbourg, VIe série*. Vol. 4. Higher-derivative variational calculus; origin of the Ostrogradsky Hamiltonian and instability. 1850, pp. 385–517.

[133] H. Fizeau. “Sur les hypothèses relatives à l’éther lumineux, et sur une expérience qui paraît démontrer que le mouvement des corps change la vitesse avec laquelle la lumière se propage dans leur intérieur”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences* 33.13 (1851). Reports fringe displacements only: 0.23 simple and 0.46 double, against Fresnel’s predicted 0.40. Fizeau prints no drag coefficient and no uncertainty; the figures often attributed to him are later back-derivations. No DOI; digitised by Gallica, pp. 349–355.

[134] L. Foucault. “Démonstration physique du mouvement de rotation de la Terre au moyen du pendule”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 32. The Foucault pendulum. 1851, pp. 135–138.

[135] G. G. Stokes. “On the Effect of the Internal Friction of Fluids on the Motion of Pendulums”. In: *Transactions of the Cambridge Philosophical Society* 9 (1851). Part II of volume 9. Source of the Stokes drag law F = 6 pi mu a v (creeping flow past a sphere)., pp. 8–106.

[136] L. Foucault. “Sur les phénomènes d’orientation des corps tournants entraînés par un axe fixe à la surface de la Terre”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 35. Names and demonstrates the gyroscope as a second proof of the Earth’s rotation. 1852, pp. 424–427.

[137] J. Joule and W. Thomson. “On the thermal effects experienced by air in rushing through small apertures”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 4.28 (1852). Series 4. First of the Joule–Thomson series 1852–1862; the porous-plug papers continue in Phil. Trans. R. Soc. vols. 143, 144, 150, 152., pp. 481–492. DOI: 10.1080/14786445208647169.

[138] G. Lamé. *Leçons sur la théorie mathématique de l’élasticité des corps solides*. The Lamé constants of isotropic elasticity. Paris: Bachelier, 1852.

[139] G. G. Stokes. “On the Composition and Resolution of Streams of Polarized Light from different Sources”. In: *Transactions of the Cambridge Philosophical Society* 9 (1852). No DOI; do not invent one. Read 9 March 1852 and printed in Part III of volume 9 of the Transactions, which appeared in parts between 1849 and 1856 – the ADS record is dated 1851 (bibcode 1851TCaPS...9..399S) while the paper itself and essentially all optics literature date it 1852. Keep 1852 and record the discrepancy. Reprinted in Stokes, Mathematical and Physical Papers, vol. 3 (Cambridge University Press, 1901), pp. 233-258, which is public-domain and scanned – the practical retrieval route for the availability grade., pp. 399–416.

[140] R. Franz and G. Wiedemann. “Ueber die Wärme-Leitungsfähigkeit der Metalle”. In: *Annalen der Physik* 165.8 (1853). Some indexes list the authors in the order Franz, Wiedemann; keyed here by the customary name of the law., pp. 497–531. DOI: 10.1002/andp.18531650802.

[141] W. Thomson. “XV.—On the Dynamical Theory of Heat, with numerical results deduced from Mr Joule’s Equivalent of a Thermal Unit, and M. Regnault’s Observations on Steam”. In: *Transactions of the Royal Society of Edinburgh* 20.2 (1853). Part I of the series; contains the Kelvin statement of the second law and the absolute thermodynamic scale. Read 17 March 1851 and customarily cited as 1851, but Cambridge and Crossref both date the issue (vol. 20, part 2) to 1853 – keyed by the publisher’s year per the Kretschmann rule, with the customary dating recorded here. Cambridge prints the title with the volume’s article number, ’XV.–’, dropped here., pp. 261–288. DOI: 10.1017/S0080456800033172.

[142] R. Clausius. “Ueber eine veränderte Form des zweiten Hauptsatzes der mechanischen Wärmetheorie”. In: *Annalen der Physik* 169.12 (1854). Poggendorff numbering; Wiley continuous numbering vol. 169., pp. 481–506. DOI: 10.1002/andp.18541691202.

[143] A. Fick. “Ueber Diffusion”. In: *Annalen der Physik* 170.1 (1855), pp. 59–86. DOI: 10.1002/andp.18551700105.

[144] A. J. C. B. de Saint-Venant. “Mémoire sur la torsion des prismes”. In: *Mémoires présentés par divers savants à l’Académie des Sciences*. Vol. 14. Torsion of prisms of arbitrary cross-section; also the customary source of Saint-Venant’s principle. 1855, pp. 233–560.

[145] A. Krönig. “Grundzüge einer Theorie der Gase”. In: *Annalen der Physik* 175.10 (1856), pp. 315–322. DOI: 10.1002/andp.18561751008.

[146] W. Weber and R. Kohlrausch. “Ueber die Elektricitätsmenge, welche bei galvanischen Strömen durch den Querschnitt der Kette fliesst”. In: *Annalen der Physik* 175.9 (1856). Verified via Crossref: Annalen der Physik 175(9), 10-25 (1856), authors Weber then Kohlrausch. VOLUME TRAP: the paper appeared as Poggendorff’s Annalen der Physik und Chemie Bd. 99, and virtually every historical citation says "vol. 99"; Wiley’s continuous re-numbering, which is what the DOI and Crossref carry, calls it vol. 175. Use 175 to match the resolving DOI and record "Poggendorffs Annalen Bd. 99" in the bib note. Keep the publisher’s spelling "Ueber" (not "Über") and "fliesst" (not "fließt") — that is how it is printed and how Crossref stores it. A duplicate key Kohlrausch:1856 for this same paper was merged here (first-listed-author rule); distinct from the 1857 Abhandlungen memoir "Elektrodynamische Maassbestimmungen", which is a different work., pp. 10–25. DOI: 10.1002/andp.18561750903.

[147] R. Clausius. “Ueber die Art der Bewegung, welche wir Wärme nennen”. In: *Annalen der Physik* 176.3 (1857). Kinetic hypothesis with molecular speeds; does NOT contain the mean free path (that is Clausius:1858) – the chapter says so explicitly., pp. 353–380. DOI: 10.1002/andp.18571760302.

[148] W. Thomson. “On a Mechanical Theory of Thermo-Electric Currents”. In: *Proceedings of the Royal Society of Edinburgh* 3 (1857). Predicts the bulk (Thomson) effect and gives the two Thomson relations from the thermodynamic argument Thomson knew to be incomplete. Read 15 December 1851 and customarily cited as 1851; PRSE volume 3 spans the 1850–1857 sessions and both Cambridge and Crossref date it 1857, so it is keyed by the publisher’s year (Kretschmann rule). Cambridge prints the title with the volume’s article number, ’4.’, dropped here. Distinct from Thomson’s later ’On the Dynamical Theory of Heat. Part VI. Thermo-electric currents’, Trans. Roy. Soc. Edinb. 21 (1857)., pp. 91–98. DOI: 10.1017/S0370164600027310.

[149] R. Clausius. “Ueber die mittlere Länge der Wege, welche bei der Molecularbewegung gasförmiger Körper von den einzelnen Molecülen zurückgelegt werden; nebst einigen anderen Bemerkungen über die mechanische Wärmetheorie”. In: *Annalen der Physik* 181.10 (1858). Mean free path, in reply to Buys Ballot; customarily mis-dated to the 1857 paper., pp. 239–258. DOI: 10.1002/andp.18581811005.

[150] H. von Helmholtz. “Über Integrale der hydrodynamischen Gleichungen, welche den Wirbelbewegungen entsprechen”. In: *Journal für die reine und angewandte Mathematik (Crelles Journal)* 55.55 (1858). The vortex theorems., pp. 25–55. DOI: 10.1515/crll.1858.55.25.

[151] U. J. J. L. Verrier. “Lettre de M. Le Verrier à M. Faye sur la théorie de Mercure et sur le mouvement du périhélie de cette planète”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 49. No DOI; scans on Gallica/BnF. 1859, pp. 379–383.

[152] G. Kirchhoff and R. Bunsen. “Chemische Analyse durch Spectralbeobachtungen”. In: *Annalen der Physik* 186.6 (1860). Suffix ’b’; companion to Kirchhoff:1860a. The founding paper of spectral analysis; led directly to the discovery of caesium and rubidium., pp. 161–189. DOI: 10.1002/andp.18601860602.

[153] G. Kirchhoff. “Ueber das Verhaeltniss zwischen dem Emissionsvermoegen und dem Absorptionsvermoegen der Koerper fuer Waerme und Licht”. In: *Annalen der Physik* 185 (1860). Suffix ’a’ because a second Kirchhoff 1860 paper (with Bunsen, spectral analysis) is cited in the same part as Kirchhoff:1860b. German title uses umlauts: Verhaeltniss = Verhältniss, Emissionsvermoegen = Emissionsvermögen, Koerper = Körper, fuer = für, Waerme = Wärme., pp. 275–301.

[154] J. C. Maxwell. “Illustrations of the dynamical theory of gases.—Part I. On the motions and collisions of perfectly elastic spheres”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 19.124 (1860). Series 4. Part II in vol. 20, pp. 21–37 (1860)., pp. 19–32. DOI: 10.1080/14786446008642818.

[155] F. Melde. “Ueber die Erregung stehender Wellen eines fadenförmigen Körpers”. In: *Annalen der Physik* 187.12 (1860). Standing waves on a driven string (Melde’s experiment). Poggendorff 2nd-series vol. 111 = Wiley continuous numbering vol. 187., pp. 513–537. DOI: 10.1002/andp.18601871202.

[156] B. Riemann. “Über die Fortpflanzung ebener Luftwellen von endlicher Schwingungsweite”. In: *Abhandlungen der Königlichen Gesellschaft der Wissenschaften zu Göttingen*. Vol. 8. Shock formation and Riemann invariants; the Abhandlungen series carries volume numbers. 1860, pp. 43–66.

[157] J. C. Maxwell. “On physical lines of force”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 21.139 (1861). Series 4. The paper runs in four parts across two volumes: Parts I-II in vol. 21 (1861) pp. 161-175, 281-291, 338-348 and Parts III-IV in vol. 23 (1862) pp. 12-24, 85-95 — the displacement current the chapter attributes to it is introduced in Part III (1862). The DOI given is Part I only (issue 139, pp. 161-175), Crossref-confirmed as ’On physical lines of force’; if the validator objects to the multi-range pages field, cite Part I’s range and record the full span in a note rather than inventing a single range., pp. 161–175. DOI: 10.1080/14786446108643033.

[158] L. Foucault. “Détermination expérimentale de la vitesse de la lumière; parallaxe du Soleil”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 55. Séance of 22 September 1862 – the absolute determination (298000 km/s), which revised the accepted solar parallax. A companion note, ’Détermination expérimentale de la vitesse de la lumière; description des appareils’, séance of 24 November 1862, appears at t. 55, pp. 792-796; if the chapter needs the apparatus it should cite that one too. No DOI; free on Gallica. 1862, pp. 501–503.

[159] H. von Helmholtz. *Die Lehre von den Tonempfindungen als physiologische Grundlage für die Theorie der Musik*. Helmholtz resonators, analysis of timbre. Braunschweig: Friedrich Vieweg und Sohn, 1863.

[160] A. Matthiessen and A. C. C. Vogt. “On the influence of temperature on the electric conducting-power of alloys”. In: *Philosophical Transactions of the Royal Society of London* 154.154 (1864), pp. 167–200. DOI: 10.1098/rstl.1864.0004.

[161] H. Tresca. “Mémoire sur l’écoulement des corps solides soumis à de fortes pressions”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 59. Plastic yield at a critical shear stress (Tresca criterion). 1864, pp. 754–758.

[162] R. Clausius. “Ueber verschiedene für die Anwendung bequeme Formen der Hauptgleichungen der mechanischen Wärmetheorie”. In: *Annalen der Physik* 201.7 (1865). Coins ’entropy’. Poggendorff numbering; Wiley continuous numbering vol. 201., pp. 353–400. DOI: 10.1002/andp.18652010702.

[163] J. Loschmidt. “Zur Grösse der Luftmoleküle”. In: *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Classe*. Vol. 52. Customary dating 1865 (session year); the volume for 1865 was printed 1866 – verify the publisher’s year against the copy before final keying (Kretschmann rule). 1865, pp. 395–413.

[164] J. C. Maxwell. “A dynamical theory of the electromagnetic field”. In: *Philosophical Transactions of the Royal Society of London* 155.155 (1865). Crossref-confirmed (it records 155 in the ’issue’ slot; 155 is the volume). Read 8 December 1864, published in the 1865 volume — the key year is the issue year and is correct., pp. 459–512. DOI: 10.1098/rstl.1865.0008.

[165] J. Tyndall. *Heat considered as a mode of motion: being a course of twelve lectures delivered at the Royal Institution of Great Britain in the season of 1862*. Second edition (London, 1865); first edition 1863. This is the source of the platinum-wire radiation data Stefan re-analysed: the ratio 11.7 between 525 C (798 K) and 1200 C (1473 K) that the chapter quotes. Crepeau’s history of the T^4 law cites it as ’Tyndall, J., 1865, Heat Considered as a Mode of Motion, Longman, Green, Longman Roberts and Green, London, Chapter 12’. No DOI (1865 book). Verified open-access scan of the London 1865 printing at archive.org identifier 10134906bsb (Bayerische Staatsbibliothek copy, https://archive.org/details/10134906bsb) – checked live via the archive.org metadata API, not guessed; suitable for a manifest "access": "open" entry. Do NOT cite the later retitled ’Heat: A Mode of Motion’ editions (1870s) for this key. Roberts & Green: Longman, Green, Longman, 1865.

[166] A. Kundt. “Ueber eine neue Art akustischer Staubfiguren und über die Anwendung derselben zur Bestimmung der Schallgeschwindigkeit in festen Körpern und Gasen”. In: *Annalen der Physik* 203.4 (1866). Issue 4. Volume/pages/year taken from Crossref, which uses Wiley’s continuous numbering; the printed source is Poggendorff’s Annalen der Physik und Chemie, Band 127, p. 497 (1866) — the numbering the chapter’s prose quotes. The +76 offset is the same convention already used by Clausius:1850 (Wiley 155 = Poggendorff 79) and Balmer:1885 in this bibliography, so 203 is the house-consistent volume. Consider recording the Poggendorff band in a BibTeX note., pp. 497–523. DOI: 10.1002/andp.18662030402.

[167] J. C. Maxwell. “The Bakerian Lecture .—On the viscosity or internal friction of air and other gases”. In: *Philosophical Transactions of the Royal Society of London* 156.156 (1866). Not a genuine collision: both claimed works are the same Bakerian Lecture, one record merely omitting the ’The Bakerian Lecture’ prefix and the DOI. No split; both citing chapters keep the bare key. Crossref prints the title with the article number and an em dash, ’XIII. The Bakerian Lecture.—On the viscosity or internal friction of air and other gases’; the colon form given here is the customary citation form. Volume 156 is not carried in the Crossref record but is the printed volume., pp. 249–268. DOI: 10.1098/rstl.1866.0013.

[168] L. Lorenz. “Ueber die Identität der Schwingungen des Lichts mit den elektrischen Strömen”. In: *Annalen der Physik* 207.6 (1867). Issue 6; Wiley continuous volume 207 (contemporaneous series (2) vol. 131). Crossref-confirmed. This is Ludvig Valentin Lorenz, the Danish physicist — the Lorenz gauge condition — and the chapter explicitly makes the point that he is not H. A. Lorentz, so the bib entry must carry the full given names. An author’s English version, ’On the identity of the vibrations of light with electrical currents’, appeared in Phil. Mag. ser. 4, 34 (1867) 287-301; the Annalen paper is the primary., pp. 243–263. DOI: 10.1002/andp.18672070606.

[169] J. C. Maxwell. “On the dynamical theory of gases”. In: *Philosophical Transactions of the Royal Society of London* 157.157 (1867), pp. 49–88. DOI: 10.1098/rstl.1867.0004.

[170] B. Riemann. “Ein Beitrag zur Elektrodynamik”. In: *Annalen der Physik* 207.6 (1867). Crossref-verified. Written in 1858 and submitted to the Gottingen Academy, then withdrawn by Riemann; published posthumously in 1867 (Poggendorff’s Annalen der Physik und Chemie). Wiley’s continuous volume numbering is 207; Poggendorff’s own series number for the same volume is Band 131, which is how nineteenth-century citations give it – worth a note in the entry so a reader chasing ’Ann. Phys. Chem. 131, 237’ finds it., pp. 237–243. DOI: 10.1002/andp.18672070605.

[171] L. Boltzmann. “Studien über das Gleichgewicht der lebendigen Kraft zwischen bewegten materiellen Punkten”. In: *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Classe*. Vol. 58. The Vienna Sitzungsberichte DO carry volume numbers, unlike the Berlin series. 1868, pp. 517–560.

[172] H. von Helmholtz. “Über discontinuirliche Flüssigkeitsbewegungen”. In: *Monatsberichte der Königlich Preussischen Akademie der Wissenschaften zu Berlin*. Academy Monatsberichte are numbered by year (1868), not by volume – do not invent a volume (cf. the Sitzungsberichte rule in CLAUDE.md). Vortex sheets and the Kelvin-Helmholtz instability, Helmholtz’s half. 1868, pp. 215–228.

[173] É. Mathieu. “Mémoire sur le mouvement vibratoire d’une membrane de forme elliptique”. In: *Journal de Mathématiques Pures et Appliquées* 13 (1868). Second series, vol. 13. Source of the Mathieu equation governing parametric resonance., pp. 137–203.

[174] T. Andrews. “The Bakerian Lecture .—On the continuity of the gaseous and liquid states of matter”. In: *Philosophical Transactions of the Royal Society of London* 159.159 (1869), pp. 575–590. DOI: 10.1098/rstl.1869.0021.

[175] G. Kirchhoff. “Zur Theorie freier Flüssigkeitsstrahlen”. In: *Journal für die reine und angewandte Mathematik (Crelles Journal)* 70.70 (1869). Crelle’s Journal. De Gruyter’s Crossref record files this as ’volume 1869, issue 70’ (year-as-volume) and carries no author name; the printed Band is 70, which is the number every bibliography uses – do not copy Crossref’s 1869 into the volume field. Crossref title carries a trailing full stop (’Zur Theorie freier Flüssigkeitsstrahlen.’). This is the paper that develops Helmholtz’s free-streamline method into a computation and yields the contraction coefficient pi/(pi+2) = 0.611 for the jet from a slit – i.e. the ’0.6’ the chapter says the ideal theory cannot supply., pp. 289–298. DOI: 10.1515/crll.1869.70.289.

[176] W. Thomson. “On Vortex Motion”. In: *Proceedings of the Royal Society of Edinburgh* 6 (1869). Author is Lord Kelvin. Source of the circulation theorem. Read 1867; volume 25 part I dated 1869 (customary citation 1869)., pp. 167–167. DOI: 10.1017/s0370164600045740.

[177] R. Clausius. “Ueber einen auf die Wärme anwendbaren mechanischen Satz”. In: *Annalen der Physik* 217.9 (1870). The virial theorem. English translation in Phil. Mag. Ser. 4, 40, 122–127 (1870)., pp. 124–130. DOI: 10.1002/andp.18702170911.

[178] W. J. M. Rankine. “On the thermodynamic theory of waves of finite longitudinal disturbance”. In: *Philosophical Transactions of the Royal Society of London* 160.160 (1870). Rankine’s half of the Rankine-Hugoniot shock conditions., pp. 277–288. DOI: 10.1098/rstl.1870.0015.

[179] J. C. Maxwell. *Theory of Heat*. Zeroth-law statement and the thermodynamic relations later called Maxwell relations. London: Longmans, Green, and Co., 1871.

[180] Sellmeier. “Zur Erklärung der abnormen Farbenfolge im Spectrum einiger Substanzen”. In: *Annalen der Physik* 219.6 (1871). Crossref-verified, and the only Sellmeier paper of 1871 – this is the standard source of the Sellmeier dispersion relation. Journal title on the issue is ’Annalen der Physik und Chemie’ (Poggendorff); Wiley’s continuous volume 219 = Poggendorff Band 143, issue 6. The better-known four-part series ’Ueber die durch die Aetherschwingungen erregten Mitschwingungen der Körpertheilchen...’ followed in 1872 (Ann. Phys. 221, 399-421 and 520-549; 223, 386-403 and 525-554); if the chapter intends the full theory rather than the 1871 announcement, those are 1872 papers and the key year would be wrong. The 1871 note is what the Sellmeier equation is universally cited to, so I have kept it., pp. 272–282. DOI: 10.1002/andp.18712190612.

[181] J. Strutt. “On the light from the sky, its polarization and colour”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 41.271 (1871). Crossref-verified. Philosophical Magazine series 4. PUBLISHER PRINTS THE AUTHOR AS ’J. W. Strutt’ – he succeeded to the barony and became Lord Rayleigh only in 1873, so the customary key ’Rayleigh:1871’ does not match the printed byline; record that in the entry. This first instalment is the one carrying the lambdaˆ-4 argument (the chapter cites it for the driven-oscillator polarizability at sec:rad-rayleigh). A continuation appeared in the same volume at pp. 274-279, doi 10.1080/14786447108640479. Crossref’s deposited title is prefixed ’XV. ’ (the issue article number); I have dropped the numeral, which is not part of the title., pp. 107–120. DOI: 10.1080/14786447108640452.

[182] W. Thomson. “XLVI.Hydrokinetic solutions and observations”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 42.281 (1871). Author is Lord Kelvin. Wind-over-water analysis; Kelvin’s half of the Kelvin-Helmholtz instability., pp. 362–377. DOI: 10.1080/14786447108640585.

[183] L. Boltzmann. “Weitere Studien über das Wärmegleichgewicht unter Gasmolekülen”. In: *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Classe*. Vol. 66. Boltzmann equation and H-theorem. 1872, pp. 275–370.

[184] E. Abbe. “Beiträge zur Theorie des Mikroskops und der mikroskopischen Wahrnehmung”. In: *Archiv für Mikroskopische Anatomie* 9.1 (1873). Crossref confirms title/volume/pages/DOI. The paper containing the resolution limit d = lambda/(2 n sin alpha); Crossref capitalises the journal as ’Archiv für Mikroskopische Anatomie’, the journal itself prints ’Archiv für mikroskopische Anatomie’., pp. 413–468. DOI: 10.1007/BF02956173.

[185] J. C. Maxwell. *A Treatise on Electricity and Magnetism*. First edition, 2 volumes, Oxford: Clarendon Press, 1873. Cited in four chapters for div B = 0, the stress tensor and radiation pressure; the radiation-pressure prediction is in vol. 2, art. 792-793. Later editions (2nd 1881, 3rd 1891) renumber articles, so the entry should

pin the 1873 first edition as the key year says. No DOI for the original; a Cambridge Library Collection reissue exists but should not be substituted. Clarendon Press, 1873.

[186] J. Plateau. *Statique expérimentale et théorique des liquides soumis aux seules forces moléculaires*. Two volumes; the soap-film experiments realising minimal surfaces. Paris: Gauthier-Villars, 1873.

[187] J. D. van der Waals. *Over de Continuïteit van den Gas- en Vloeistoftoestand*. Doctoral dissertation, Universiteit Leiden, printed by A. W. Sijthoff. Not a genuine collision: the two claimed works are the same dissertation, one record naming the printer and the other the awarding university. No DOI; a full scan is held in Leiden University Digital Collections (shelfmark DISL 1873: 17), which is the access route to declare in the manifest. A. W. Sijthoff, 1873.

[188] G. Cantor. "Ueber eine Eigenschaft des Inbegriffes aller reellen algebraischen Zahlen". In: *Journal für die reine und angewandte Mathematik* 77 (1874). Crelle's Journal is numbered by year in the Crossref record; cited here by the printed volume 77, pp. 258–262. DOI: 10.1515/crll.1874.77.258.

[189] J. Kerr. "A new relation between electricity and light: Dielectrified media birefringent". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 50.332 (1875). Series 4, issue 332. This is Part First, the discovery paper for the quadratic electro-optic (Kerr) effect that the citing sentence names. A 'Part second' follows in the same volume, pp. 446–458 (DOI 10.1080/14786447508641318) – not needed for this claim. Verified against Crossref., pp. 337–348. DOI: 10.1080/14786447508641302.

[190] S. von Kowalevsky. "Zur Theorie der partiellen Differentialgleichung". In: *Journal für die reine und angewandte Mathematik (Crelles Journal)* 80.80 (1875). Author also transliterated Kovalevskaya; keyed by the paper's byline spelling., pp. 1–32. DOI: 10.1515/crll.1875.80.1.

[191] J. C. Maxwell. "On the Dynamical Evidence of the Molecular Constitution of Bodies". In: *Nature* 11 (1875). Contains Maxwell's statement that the specific-heat discrepancy is the greatest difficulty facing the molecular theory, pp. 357–359.

[192] P. du Bois-Reymond. "Untersuchungen über die Convergenz und Divergenz der Fourierschen Darstellungsformeln". In: *Abhandlungen der Mathematisch-Physicalischen Classe der K. Bayerischen Akademie der Wissenschaften*. Contains the continuous function with divergent Fourier series. Volume/pagination (vol. 12, 1–103) should be verified against the Abhandlungen series before entry. 1876.

[193] J. W. Gibbs. "On the Equilibrium of Heterogeneous Substances". In: *Transactions of the Connecticut Academy of Arts and Sciences* 3 (1876). First part 1876; second part in the same volume, pp. 343–524, issued 1878., pp. 108–248.

[194] A. Kundt and E. Warburg. "Ueber die specifische Wärme des Quecksilbergases". In: *Annalen der Physik* 233.3 (1876). Issue 3. Crossref/Wiley volume 233 = Poggendorff's Annalen der Physik und Chemie, Band 157 (1876), same +76 offset as Kundt:1866. This is the Kundt's-tube measurement on mercury vapour giving c_p/c_V ≈ 1.67, i.e. the monatomic value — the paper that makes the claim the chapter attributes to it. Note the key departs from the house Surname:YYYY convention (it would collide with Kundt:1876 only if another Kundt 1876 paper is added); the key was supplied by the authoring agent and is used as given., pp. 353–369. DOI: 10.1002/andp.18762330302.

[195] J. Loschmidt. “Über den Zustand des Wärmegleichgewichtes eines Systems von Körpern mit Rücksicht auf die Schwerkraft. I.” In: *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Classe*. Vol. 73. The reversibility (Umkehr) objection to the H-theorem. 1876, pp. 128–142.

[196] L. Boltzmann. “Über die Beziehung zwischen dem zweiten Hauptsatze der mechanischen Wärmetheorie und der Wahrscheinlichkeitsrechnung respective den Sätzen über das Wärmegleichgewicht”. In: *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Classe, Abteilung II*. Vol. 76. The combinatorial definition of entropy; S = k log W is not written in this form here, it is Planck’s later notation. 1877, pp. 373–435.

[197] B. R. John William Strutt. *The Theory of Sound, Volume 1*. Keyed by the customary name Rayleigh (family name Strutt). London: Macmillan, 1877.

[198] B. R. John William Strutt. *The Theory of Sound, Volume I*. Volume II followed 1878. Suffix a: Rayleigh:1877b is the Proc. LMS progressive-waves paper of the same year. London: Macmillan, 1877.

[199] J. Kerr. “On rotation of the plane of polarization by reflection from the pole of a magnet”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 3.19 (1877), pp. 321–343. DOI: 10.1080/14786447708639245.

[200] Rayleigh. “On Progressive Waves”. In: *Proceedings of the London Mathematical Society* s1-9.1 (1877). The group-velocity vs phase-velocity distinction; read November 1877., pp. 21–26. DOI: 10.1112/plms/s1-9.1.21.

[201] P. Clifford. “Applications of Grassmann’s Extensive Algebra”. In: *American Journal of Mathematics* 1.4 (1878), p. 350. DOI: 10.2307/2369379.

[202] H. A. Rowland. “Magnetic effect of electric convection”. In: *American Journal of Science* s3-15.85 (1878). Crossref-verified (Crossref’s deposited title omits the leading ’On the’: ’Magnetic effect of electric convection’). American Journal of Science third series, volume 15, issue 85 – the volume must be cited as series 3 vol. 15 or it collides with the first-series volume 15. The chapter’s subsection heading says ’Rowland (1876)’ because the experiment was performed in Helmholtz’s Berlin laboratory in 1876 and first announced in German – ’Ueber die magnetische Wirkung electrischer Convection’, Ann. Phys. (Poggendorff) 158, 487-493 (1876), and in the Monatsberichte of the Berlin Academy. The key Rowland:1878 denotes the English publication; the heading/key mismatch is a real dating discrepancy and should be noted in the entry., pp. 30–38. DOI: 10.2475/ajs.s3-15.85.30.

[203] V. Strouhal. “Ueber eine besondere Art der Tonerregung”. In: *Annalen der Physik* 241.10 (1878). Neue Folge volume 5 (volume 241 in the continuous numbering). Aeolian tones; the Strouhal number., pp. 216–251. DOI: 10.1002/andp.18782411005.

[204] P. du Bois-Reymond. “Erläuterungen zu den Anfangsgründen der Variationsrechnung”. In: *Mathematische Annalen* 15.2 (1879). Sharpened fundamental lemma (du Bois-Reymond lemma). Particle ’du’ must not be dropped from the surname., pp. 283–314. DOI: 10.1007/bf01444144.

[205] J. C. (Cavendish H. (author); Maxwell. *The Electrical Researches of the Honourable Henry Cavendish, F.R.S., Written Between 1771 and 1781*. Edited from the original manuscripts in the possession of the Duke of Devonshire by J. Clerk Maxwell, Cambridge University Press, 1879. This is what the chapter means by ’Cavendish’s null test for the inverse-square law’ cited as Maxwell:1879 — Maxwell’s edition is where Cavendish’s unpublished concentric-shell experiment (and Maxwell’s own repetition of it) first appeared in print. Set biblatex ’editor = Maxwell, James Clerk’

with 'author = Cavendish, Henry'; the validator accepts editor in place of author for @book, and the key stays Maxwell:1879 as cited. No DOI; scans are on the Internet Archive. Cambridge University Press, 1879.

[206] R. Clausius. *Die mechanische Behandlung der Electricität*. Braunschweig, 1879. This volume is Band 2 of Clausius's *Die mechanische Wärmetheorie* – the full catalogue heading is 'Die mechanische Wärmetheorie, Band 2: Die mechanische Behandlung der Electricität', which the bib writer may want in a series/note field. It is the Clausius half of the Clausius-Mossotti relation, cited in the chapter beside Mossotti:1850. No DOI for the original; the Vieweg+Teubner facsimile reprint carries ISBN 978-3-663-20232-5 and is on SpringerLink, which is a usable access route for the availability grade. Free scan on archive.org. Friedrich Vieweg und Sohn, 1879.

[207] G. Frege. *Begriffsschrift, eine der arithmetischen nachgebildete Formelsprache des reinen Denkens*. English translation in van Heijenoort's source book, pp. 1–82. Halle a. S.: Louis Nebert, 1879.

[208] E. H. Hall. "On a New Action of the Magnet on Electric Currents". In: *American Journal of Mathematics* 2.3 (1879), p. 287. DOI: 10.2307/2369245.

[209] Rayleigh. "Investigations in optics, with special reference to the spectroscope". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 8.49 (1879). Crossref-verified. Philosophical Magazine series 5. First of four instalments under this title; the resolution criterion is in this one. The others are Phil. Mag. 8, 403-411 and 8, 477-486 (1879) and Phil. Mag. 9, 40-55 (1880). Byline is 'Lord Rayleigh, F.R.S.'; Crossref files the family name as 'Rayleigh'. Crossref's deposited title is prefixed 'XXXI. ' (issue article number), dropped here., pp. 261–274. DOI: 10.1080/14786447908639684.

[210] L. Rayleigh. "On the Stability, or Instability, of certain Fluid Motions". In: *Proceedings of the London Mathematical Society* s1-11.1 (1879). Series 1 volume (s1-11). The inflexion-point criterion for parallel shear flows., pp. 57–72. DOI: 10.1112/plms/s1-11.1.57.

[211] J. Stefan. "Ueber die Beziehung zwischen der Waermestrahlung und der Temperatur". In: *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Classe, Abtheilung II*. Vol. 79. Academy proceedings: no journal volume in the biblatex @article sense; the 79 is the Sitzungsberichte volume. Umlauts: Waermestrahlung = Wärmestrahlung. 1879, pp. 391–428.

[212] J. Curie and P. Curie. "Développement par compression de l'électricité polaire dans les cristaux hémièdres à faces inclinées". In: *Bulletin de la Société minéralogique de France* 3.4 (1880). Crossref/Persée confirmed: vol. 3, pp. 90-93, 1880, both Curie brothers (Jacques first, then Pierre – Pierre is NOT the first author here). The Persée record spells the last word 'hémiédres' (é, an OCR/period spelling); the correct and usual form 'hémièdres' is given above and should still pass a DOI title check. The same result was communicated to the Académie in the same year as C. R. Acad. Sci. Paris 91, 294-295 (1880), under a near-identical title – the Bulletin paper is the one with a resolvable DOI, so prefer it. Persée is open access, so this grades GREEN., pp. 90–93. DOI: 10.3406/bulmi.1880.1564.

[213] H. A. Lorentz. "Ueber die Beziehung zwischen der Fortpflanzungsgeschwindigkeit des Lichtes und der Körperdichte". In: *Annalen der Physik* 245.4 (1880). Issue 4; Wiley continuous volume 245 (contemporaneous series (3) vol. 9). Crossref-confirmed. This is H. A. Lorentz's half of the Lorentz-Lorenz relation; the companion key Lorenz:1880 in this same batch is L. V. Lorenz, a different man — the citing

sentence in 05-electrodynamics-matter.tex depends on the two entries being visibly distinct., pp. 641–665. DOI: 10.1002/andp.18802450406.

[214] L. Lorenz. “Ueber die Refractionsconstante”. In: *Annalen der Physik* 247.9 (1880). Issue 9; Wiley continuous volume 247 (contemporaneous series (3) vol. 11). Crossref-confirmed. L. V. Lorenz’s half of the Lorentz-Lorenz equation, deliberately paired with Lorentz:1880 in the same sentence — keep the two distinguishable by full given names., pp. 70–103. DOI: 10.1002/andp.18802470905.

[215] A. A. Michelson. “Experimental Determination of the Velocity of Light Made at the United States Naval Academy, Annapolis”. In: *Astronomical Papers Prepared for the Use of the American Ephemeris and Nautical Almanac* 1 (1880). The 1879 Annapolis measurement. Issued as Part III of volume 1 in 1880 (the memoir is dated 20 February 1880 and transmitted by Simon Newcomb); the collected volume 1 was published by the Bureau of Navigation, Navy Department, Washington, in 1882, which is why ADS bibcodes it 1882USNAO...1..109M. The key’s 1880 is the part’s own year and is defensible — record the 1882 collected-volume date in a note. No DOI. Full text is at Project Gutenberg ebook 11753, a GREEN access route., pp. 109–145.

[216] H. Poincaré. “Mémoire sur les courbes définies par une équation différentielle”. In: *Journal de Mathématiques Pures et Appliquées (3e série)* 7 (1881). First part of the four-part memoir (parts appeared 1881, 1882, 1885, 1886). Foundation of the qualitative theory of differential equations., pp. 375–422.

[217] H. von Helmholtz. “Die Thermodynamik chemischer Vorgänge”. In: *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften zu Berlin*. Academy proceedings; the series has no volume numbers (same rule as the Einstein Sitzungsberichte entries). Introduces the free energy. 1882, pp. 22–39.

[218] H. Hertz. “Ueber die Berührung fester elastischer Körper”. In: *crll* 92.92 (1882). Hertz contact theory., pp. 156–171. DOI: 10.1515/crll.1882.92.156.

[219] A. Lindstedt. “Ueber die Integration einer für die Störungstheorie wichtigen Differentialgleichung”. In: *Astronomische Nachrichten* 103.14 (1882). Frequency renormalization removing secular terms. Astron. Nachr. paginates by column; the paper begins at col. 211., pp. 211–220. DOI: 10.1002/asna.18821031404.

[220] H. Poincaré. “Mémoire sur les courbes définies par une équation différentielle (seconde partie)”. In: *Journal de Mathématiques Pures et Appliquées (3e série)* 8 (1882). Second part of the memoir; the term ’cycle limite’ (limit cycle) is introduced here – cite this part, not the 1881 first part, for limit cycles., pp. 251–296.

[221] Rayleigh. “Investigation of the Character of the Equilibrium of an Incompressible Heavy Fluid of Variable Density”. In: *Proceedings of the London Mathematical Society* s1-14.1 (1882). Series 1 volume (s1-14). The Rayleigh half of the Rayleigh-Taylor instability., pp. 170–177. DOI: 10.1112/plms/s1-14.1.170.

[222] H. Rowland. “Preliminary notice of the results accomplished in the manufacture and theory of gratings for optical purposes”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 13.84 (1882). Crossref-verified. Philosophical Magazine series 5; Crossref’s deposited title is prefixed ’LXI. ’, dropped here. The same notice appeared in Nature 26, 211-213 (1882), doi 10.1038/026211b0. Rowland’s concave grating paper is the following year: Phil. Mag. 16, 197-210 (1883)., pp. 469–474. DOI: 10.1080/14786448208627217.

[223] J. Gram. “Ueber die Entwickelung reeller Functionen in Reihen mittelst der Methode der kleinsten Quadrate”. In: *crll* 94.94 (1883), pp. 41–73. DOI: 10.1515/crll.1883.94.41.

[224] G. Kirchhoff. “Zur Theorie der Lichtstrahlen”. In: *Annalen der Physik* 254.4 (1883). Volume 254 in the continuous Wiedemann numbering = vol. 18 of the third series; also read to the Berlin Academy in 1882. Source of the Kirchhoff formula for the 3d wave equation., pp. 663–695. DOI: 10.1002/andp.18832540409.

[225] E. Mach. *Die Mechanik in ihrer Entwickelung historisch-kritisch dargestellt*. First edition; the original spelling Entwickelung is retained. The critique of Newton’s absolute space and of the bucket experiment is in chapter II. English translation: The Science of Mechanics, trans. T. J. McCormack, Open Court, Chicago (1893). Leipzig: F. A. Brockhaus, 1883.

[226] O. Reynolds. “An experimental investigation of the circumstances which determine whether the motion of water shall be direct or sinuous, and of the law of resistance in parallel channels”. In: *Philosophical Transactions of the Royal Society of London* 174.174 (1883). The dye experiment; origin of the Reynolds-number transition criterion., pp. 935–982. DOI: 10.1098/rstl.1883.0029.

[227] L. Boltzmann. “Ableitung des Stefan’schen Gesetzes, betreffend die Abhängigkeit der Wärmestrahlung von der Temperatur aus der electromagnetischen Lichttheorie”. In: *Annalen der Physik* 258.6 (1884). Wiedemann’s Annalen vol. 22 = whole-series vol. 258. Uses Bartoli’s radiation-pressure cycle., pp. 291–294. DOI: 10.1002/andp.18842580616.

[228] G. Frege. *Die Grundlagen der Arithmetik: eine logisch mathematische Untersuchung über den Begriff der Zahl*. The subtitle is unhyphenated in the original printing. Breslau: Wilhelm Koebner, 1884.

[229] J. H. Poynting. “On the transfer of energy in the electromagnetic field”. In: *Philosophical Transactions of the Royal Society of London* 175.175 (1884). Read 10 January 1884, issue dated 31 December 1884. Crossref records the title with the volume’s article number prefixed – ’XV. On the transfer of energy in the electromagnetic field’ – and puts 175 in the ’issue’ slot rather than ’volume’; the correct citation is volume 175. Drop the ’XV.’ from the title., pp. 343–361. DOI: 10.1098/rstl.1884.0016.

[230] J. J. Balmer. “Notiz über die Spectrallinien des Wasserstoffs”. In: *Annalen der Physik* 261.5 (1885). Also published the same year in Verhandlungen der Naturforschenden Gesellschaft in Basel 7, 548–560 and 750–752., pp. 80–87. DOI: 10.1002/andp.18852610506.

[231] J. A. Ewing. “Experimental researches in magnetism”. In: *Philosophical Transactions of the Royal Society of London* 176.176 (1885). The paper in which Ewing named and mapped hysteresis. Crossref prints the title with the Royal Society’s in-volume article number, ’X. Experimental researches in magnetism’, and files 176 as an ISSUE rather than a volume; the customary citation is volume 176. Author is ’James Alfred Ewing’ in Crossref, ’J. A. Ewing’ on the paper. Do not confuse with the short abstract of the same title in Proc. R. Soc. Lond. 38, 58-62 (10.1098/rspl.1884.0062)., pp. 523–640. DOI: 10.1098/rstl.1885.0010.

[232] L. Rayleigh. “On Waves Propagated along the Plane Surface of an Elastic Solid”. In: *Proceedings of the London Mathematical Society* s1-17.1 (1885). Rayleigh surface waves., pp. 4–11. DOI: 10.1112/plms/s1-17.1.4.

[233] L. Rayleigh. “On the self-induction and resistance of straight conductors”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 21.132 (1886). Crossref-verified. Philosophical Magazine series 5. This is the skin-effect paper the chapter means (high-frequency resistance of a straight conductor). Crossref’s deposited title is prefixed ’LII. ’, dropped here. Not to be confused with Rayleigh’s ’Notes on electricity and magnetism.–II. The self-induction and

resistance of compound conductors', Phil. Mag. 22, 469-500 (1886)., pp. 381–394. DOI: 10.1080/14786448608627863.

[234] H. Hertz. "Ueber einen Einfluss des ultravioletten Lichtes auf die electrische Entladung". In: *Annalen der Physik* 267.8 (1887). The photoelectric effect noticed as an unwanted disturbance during the experiments that produced the first electromagnetic waves., pp. 983–1000. DOI: 10.1002/andp.18872670827.

[235] E. Mach and P. Salcher. "Photographische Fixirung der durch Projectile in der Luft eingeleiteten Vorgänge". In: *Annalen der Physik* 268.10 (1887). The Vienna Sitzungsberichte DO carry volume numbers (unlike the Prussian ones), so @article with volume 95 is correct. Shock-cone photographs; origin of the Mach angle. Distinct from existing key Mach:1883., pp. 277–291. DOI: 10.1002/andp.18872681008.

[236] A. A. Michelson and E. W. Morley. "On the Relative Motion of the Earth and the Luminiferous Ether". In: *American Journal of Science* 34.203 (1887). Series 3. The bound is stated only as a fraction of the Earth's orbital velocity — probably below one sixth, certainly below one quarter — and no figure in kilometres per second appears in the paper, pp. 333–345. DOI: 10.2475/ajs.s3-34.203.333.

[237] R. Dedekind. *Was sind und was sollen die Zahlen?* 1st ed. Erklärung 64 defines a system as infinite when it is similar to a proper part of itself. No DOI. Beware the archive.org item WasSindUndWasSollenDieZahlen: it is a 2012 setting of the 4th edition, not the original. Braunschweig: Friedrich Vieweg und Sohn, 1888.

[238] W. Hallwachs. "Ueber den Einfluss des Lichtes auf electrostatisch geladene Körper". In: *Annalen der Physik* 269.2 (1888), pp. 301–312. DOI: 10.1002/andp.18882690206.

[239] H. Hertz. "Ueber electrodynamische Wellen im Luftraume und deren Reflexion". In: *Annalen der Physik* 270.8A (1888). Issue 8A. Chosen over Hertz's other 1888 papers because both citing passages are about standing waves: the experiment chapter describes reflection off a zinc sheet and mapping nodes/antinodes, which is this paper. Note for the writer: the prism-refraction and wire-grid-polarization demonstrations mentioned in the same reserved passage are from 'Ueber Strahlen electrischer Kraft', Ann. Phys. 272(4), 769–783 (1889), DOI 10.1002/andp.18892720402 – a separate key if that detail is ever written out. Crossref prints the old orthography 'electrodynamische' (with c)., pp. 609–623. DOI: 10.1002/andp.18882700802.

[240] F. Reinitzer. "Beiträge zur Kenntniss des Cholesterins". In: *Monatshefte für Chemie - Chemical Monthly* 9.1 (1888), pp. 421–441. DOI: 10.1007/BF01516710.

[241] H. Hertz. "Die Kräfte electrischer Schwingungen, behandelt nach der Maxwell'schen Theorie". In: *Annalen der Physik* 272.1 (1889). Issue 1. Hertz's dipole-radiation paper – the source for the multipole/finite-size-emitter claim in the citing sentence. TRAP: the DOI string reads '1888' although Crossref (and the volume) date the issue 1889; the DOI resolves and its title matches, so do not 'correct' it to 1889. Original orthography: 'electrischer', 'Kräfte' with umlaut., pp. 1–22. DOI: 10.1002/andp.18882720102.

[242] P.-H. Hugoniot. "Mémoire sur la propagation du mouvement dans les corps et spécialement dans les gaz parfaits (deuxième partie)". In: *Journal de l'École Polytechnique* 58 (1889). Posthumous. First part in volume 57 (1887) 3-97; the shock jump relations are in this second part., pp. 1–125.

[243] S. Kovalevskaya. "Sur le problème de la rotation d'un corps solide autour d'un point fixe". In: *Acta Mathematica* 12 (1889). Printed byline 'Sophie Kowalevski'. The Kovalevskaya integrable case of the heavy top., pp. 177–232.

[244] O. Lehmann. “Über fliessende Krystalle”. In: *Zeitschrift für Physikalische Chemie* 4U.1 (1889), pp. 462–472. DOI: 10.1515/zpch-1889-0434.

[245] G. Peano. *Arithmetices principia, nova methodo exposita*. In Latin; introduces the Peano axioms. Turin: Fratres Bocca, 1889.

[246] M. Couette. “Études sur le frottement des liquides”. In: *Annales de Chimie et de Physique (Série 6)* 21 (1890). The rotating-cylinder viscometry after which Couette flow is named., pp. 433–510.

[247] H. Poincaré. “Sur le problème des trois corps et les équations de la dynamique”. In: *Acta Mathematica* 13 (1890). The King Oscar II prize memoir, in its corrected second printing (the flawed first printing was withdrawn). Non-existence of further analytic integrals; homoclinic tangle., pp. 1–270.

[248] J. R. Rydberg. “On the structure of the line-spectra of the chemical elements”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 29.179 (1890). The full memoir is Recherches sur la constitution des spectres d’emission des elements chimiques, Kongliga Svenska Vetenskaps-Akademiens Handlingar 23 (11), 1890; the Philosophical Magazine paper is the accessible statement of the formula., pp. 331–337. DOI: 10.1080/14786449008619945.

[249] G. Cantor. “Ueber eine elementare Frage der Mannigfaltigkeitslehre”. In: *Jahresbericht der Deutschen Mathematiker-Vereinigung* 1 (1891). The diagonal argument. No DOI exists; digitised by GDZ Göttingen. Band 1 is dated 1890/91 by the publisher and was issued in 1892, pp. 75–78.

[250] S. C. Chandler. “On the variation of latitude,I”. In: *The Astronomical Journal* 11 (1891). Discovery of the 427-day polar motion (Chandler wobble)., p. 59. DOI: 10.1086/101603.

[251] A. Schoenflies. *Krystallsysteme und Krystallstructur*. B. G. Teubner, 1891.

[252] O. Heaviside. *Electrical Papers*. Two volumes; first edition 1892 (second 1894). This is the collection the citing sentence describes – it reprints the 1885 ’Electrician’ series in which Heaviside reduced Maxwell’s system to the four vector equations. Consider recording ’volumes = 2’. Macmillan, Co., London, and New York, 1892.

[253] A. M. Lyapunov. *Obshchaya zadacha ob ustoichivosti dvizheniya (The General Problem of the Stability of Motion)*. Doctoral dissertation, in Russian. French translation: Annales de la Faculté des Sciences de Toulouse (2) 9 (1907); English translation: International Journal of Control 55 (1992) 531-773. Kharkov: Kharkov Mathematical Society, 1892.

[254] S. Newcomb. “On the Dynamics of the Earth’s Rotation, with Respect to the Periodic Variations of Latitude”. In: *Monthly Notices of the Royal Astronomical Society* 52.5 (1892). Explains the Euler-to-Chandler period lengthening by the Earth’s elasticity., pp. 336–336. DOI: 10.1093/mnras/52.5.336.

[255] H. Poincaré. *Les méthodes nouvelles de la mécanique céleste*. Three volumes: I (1892), II (1893), III (1899); keyed by volume I. Poincaré sections and return maps; the homoclinic analysis is in volume III. Paris: Gauthier-Villars, 1892.

[256] J. J. Waterston and J. W. Strutt. “On the physics of media that are composed of free and perfectly elastic molecules in a state of motion”. In: *Philosophical Transactions of the Royal Society of London. (A.)* 183.183 (1892). Submitted 1845 and refused; printed 1892 with an introduction by Lord Rayleigh. Keyed by publication year per house rule., pp. 1–79. DOI: 10.1098/rsta.1892.0001.

[257] G. Frege. *Grundgesetze der Arithmetik, begriffsschriftlich abgeleitet*. Vol. 1. Band I 1893, Band II 1903. Basic Law V, the value-range axiom on which the logicist reduction rests, is the principle Russell's paradox refutes; Band II carries Frege's appendix on it. Partial English translation in van Heijenoort's source book. Jena: Hermann Pohle, 1893.

[258] O. Heaviside. *Electromagnetic Theory, Volume 1*. Operational calculus practised before justification. London: The Electrician Printing and Publishing Company, 1893.

[259] W. Wien. "Eine neue Beziehung der Strahlung schwarzer Koerper zum zweiten Hauptsatz der Waermetheorie". In: *Sitzungsberichte der Koeniglich Preussischen Akademie der Wissenschaften zu Berlin*. The displacement law. Academy proceedings, no volume number for the series. 1893, pp. 55–62.

[260] P. d. Fermat. *Œuvres de Fermat. Tome deuxième: Correspondance*. Ed. by P. Tannery and C. Henry. The 1662 letters to Marin Cureau de la Chambre, in which Fermat derives the sine law from least time, exist only as manuscripts; this Tannery-Henry critical edition is the standard printed source and is what the key must denote. Kind is book with an EDITOR and no author in the biblatex sense – editor satisfies the author requirement for @book under the project's validator. Freely readable on Gallica (ark:/12148/bpt6k6213616t) and archive.org (oeuvresdefermat02ferm), so it can be graded GREEN with a manifest URL. I did not verify the page span of the individual letters and have deliberately given none. Paris: Gauthier-Villars, 1894.

[261] J. H. Poynting. *The Mean Density of the Earth*. Adams Prize essay (1893). Reviews Cavendish and successors; records that Cavendish's printed mean 5.48 contains an arithmetic slip, his data giving 5.448. London: Charles Griffin and Company, 1894.

[262] C. V. Boys. "On the Newtonian constant of gravitation". In: *Philosophical Transactions of the Royal Society of London. (A.)* 186.186 (1895). Quartz-fibre small balance; reframes the Cavendish experiment as a measurement of G rather than of the Earth's density., pp. 1–72. DOI: 10.1098/rsta.1895.0001.

[263] H. Bruns. "Das Eikonal". In: *Abhandlungen der Königlich Sächsischen Gesellschaft der Wissenschaften, Mathematisch-Physische Classe*. Vol. 21. Pages given as customarily cited (this is the form Born & Wolf use: Abh. Kgl. Sächs. Ges. Wiss., math.-phys. Kl. 21, 321-436). Library catalogues (SLUB Dresden) record 323-435 for the same item, so if the bib writer prefers a catalogue-verifiable range, use 323-435 – but do not silently mix the two. Simultaneously issued as a separate monograph: H. Bruns, *Das Eikonal*, S. Hirzel, Leipzig, 1895. No DOI. This is the work the eikonal equation is named after. 1895, pp. 321–436.

[264] P. Curie. "Propriétés magnétiques des corps à diverses températures". In: *Annales de Chimie et de Physique* 5 (1895). 7th series; Curie's doctoral thesis., pp. 289–405.

[265] D. J. Korteweg and G. de Vries. "On the change of form of long waves advancing in a rectangular canal, and on a new type of long stationary waves". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 39.240 (1895). The KdV equation., pp. 422–443. DOI: 10.1080/14786449508620739.

[266] A. A. Michelson. "Détermination expérimentale de la valeur du mètre en longueurs d'ondes lumineuses". In: *Travaux et Mémoires du Bureau International des Poids et Mesures*. Vol. 11. BIPM Travaux et Mémoires tome 11, 1895. The title page reads 'par M. Albert-A. Michelson; mémoire traduit de l'anglais par M. J.-René Benoît' — Michelson is the sole named author and Benoît the translator, although the etalon work was carried out jointly with Benoît at the BIPM, which is why the chapter says 'Michelson and Benoit's determination'. Record Benoît as translator in a note rather

than as a second author. This is the source of the 1 m = 1553163.5 red-cadmium wavelengths figure quoted in 10-exp-wave-optics.tex. No DOI; digitised on Gallica (ark:/12148/bpt6k9693613c), a GREEN access route. 1895, pp. 1–85.

[267] S. Newcomb. *The Elements of the Four Inner Planets and the Fundamental Constants of Astronomy*. Washington, DC. Newcomb's re-reduction of the inner-planet observations with improved planetary masses; this is the work that moved Le Verrier's 38 arcsec/century Mercury residual to the modern 43 (Newcomb's own value was 41.24 +/- 2.09). No DOI (1895 government monograph). Full text is on the Internet Archive (elementsoffourin00newcrich and cihm_16774), so it can be declared "access": "open" with that URL rather than grading RED. Cited at the Newcomb sentence in sec:clt-mercury. U.S. Government Printing Office, 1895.

[268] O. Reynolds. "On the dynamical theory of incompressible viscous fluids and the determination of the criterion". In: *Philosophical Transactions of the Royal Society of London. (A.)* 186.186 (1895). Introduces the Reynolds decomposition and Reynolds stresses., pp. 123–164. DOI: 10.1098/rsta.1895.0004.

[269] W. C. Roentgen. "Ueber eine neue Art von Strahlen (Vorlaeufige Mittheilung)". In: *Sitzungsberichte der Physikalisch-Medicinischen Gesellschaft zu Wuerzburg*. Key transliterates the umlaut as in the existing Roemer:1676 and Goedel:1931 entries. Surname Röntgen; title Ueber = Über, Vorlaeufige = Vorläufige; venue Würzburg. 1895, pp. 132–141.

[270] K. Weierstrass. *Über das sogenannte Dirichlet'sche Princip*. Paper read to the Berlin Academy on 14 July 1870; first printed in the collected works (1895). Best entered as @incollection in Mathematische Werke, Band 2. 1895.

[271] H. Becquerel. "Sur les radiations emises par phosphorescence". In: *Comptes Rendus Hebdomadaires des Seances de l'Academie des Sciences*. Vol. 122. 1896, pp. 420–421.

[272] W. Wien. "Ueber die Energievertheilung im Emissionsspectrum eines schwarzen Körpers". In: *Annalen der Physik* 294.8 (1896). Wien's distribution law, falsified at long wavelength by Lummer:1899 and Rubens:1900., pp. 662–669. DOI: 10.1002/andp.18962940803.

[273] E. Zermelo. "Ueber einen Satz der Dynamik und die mechanische Wärmetheorie". In: *Annalen der Physik* 293.3 (1896). Not a genuine collision: the two claimed works are one paper under two volume numberings – Wiedemann's Annalen der Physik und Chemie vol. 57 is Wiley's continuous Annalen der Physik vol. 293, same pages. Crossref issue 3, January 1896. The 1896 printing sets the title in the old orthography ('Ueber'); modernised to 'Über' per house rule. Zermelo's recurrence objection to the H-theorem; same author as Zermelo:1908., pp. 485–494. DOI: 10.1002/andp.18962930314.

[274] Archimedes. *The Works of Archimedes*. Ed. by T. L. Heath. Edited and translated by Thomas L. Heath; the editor satisfies the author requirement. Cited for On Floating Bodies (buoyancy, Book I, Props. 5-7); primary text is 3rd century BC. Cambridge University Press, 1897.

[275] J. Larmor. "On the theory of the magnetic influence on spectra; and on the radiation from moving ions". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 44.271 (1897). Series 5, issue 271 (December 1897). This is the paper containing the Larmor radiated-power formula (radiation from moving ions), which is what the citing sentence in 07-electrodynamics/08-radiation-scattering.tex needs. Not to be confused with Larmor's 'A dynamical theory of the electric and luminiferous medium, Part III', Phil. Trans. R. Soc. A 190 (1897) 205-300, which is

sometimes cited for the same result. Crossref confirms title/volume/pages against the DOI., pp. 503–512. DOI: 10.1080/14786449708621095.

[276] J. J. Thomson. “Cathode Rays”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 44.269 (1897). Discovery of the electron. No collision with Thomson:1927 (G. P. Thomson), which is a different year., pp. 293–316. DOI: 10.1080/14786449708621070.

[277] P. Zeeman. “On the influence of magnetism on the nature of the light emitted by a substance”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 43.262 (1897). A shorter announcement appeared in Nature 55 (1897) 347., pp. 226–239. DOI: 10.1080/14786449708620985.

[278] P. Curie and M. Curie. “Sur une substance nouvelle radio-active, contenue dans la pechblende”. In: *Comptes Rendus Hebdomadaires des Seances de l’Academie des Sciences*. Vol. 127. 1898, pp. 175–178.

[279] P. Curie, M. Curie, and G. Bémont. “Sur une nouvelle substance fortement radio-active, contenue dans la pechblende”. In: *Comptes Rendus Hebdomadaires des Seances de l’Academie des Sciences*. Vol. 127. The radium paper (December 1898). The companion key Curie:1898 is the July polonium paper; the two are distinct discoveries in the same journal volume. 1898, pp. 1215–1217.

[280] J. Dewar. “Preliminary note on the liquefaction of hydrogen and helium”. In: *Proceedings of the Royal Society of London* 63.389-400 (1898), pp. 256–258. DOI: 10.1098/rspl.1898.0031.

[281] A. Liénard. “Champ électrique et magnétique produit par une charge électrique concentrée en un point et animée d’un mouvement quelconque”. In: *L’Éclairage Électrique* 16 (1898). Published in three instalments, nos. 27, 28 and 29 of tome 16 (July-September 1898). No DOI; the journal is digitised by CNAM (cnum.cnam.fr, P91.16) which is the access route to declare. Pages must be given as the three ranges — a single range would misreport the source., pp. 5–14, 53–59, 106–112.

[282] O. Lummer and F. Kurlbaum. “Der elektrisch gegluehte absolut schwarze Koerper und seine Temperaturmessung”. In: *Verhandlungen der Physikalischen Gesellschaft zu Berlin*. Vol. 17. The Reichsanstalt cavity radiator. Published title puts ’absolut schwarze’ in quotation marks. The Berlin society’s Verhandlungen restarted numbering as the Deutsche Physikalische Gesellschaft series vol. 1 in 1899. 1898, pp. 106–111.

[283] J. W. GIBBS. “Fourier’s Series”. In: *Nature* 59.1539 (1899). Letter correcting his 1898 letter (Nature 59, 200); this is where the overshoot value is stated., pp. 606–606. DOI: 10.1038/059606a0.

[284] O. Lummer and E. Pringsheim. “Die Vertheilung der Energie im Spectrum des schwarzen Koerpers”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 1. First clear deviations from Wien’s law. 1899, pp. 23–41.

[285] M. Planck. “Über irreversible Strahlungsvorgänge”. In: *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften zu Berlin*. Academy proceedings: the series carries no volume number. Introduces the natural units built from h, c and G. No DOI. 1899, pp. 440–480.

[286] L. Rayleigh. “On the transmission of light through an atmosphere containing small particles in suspension, and on the origin of the blue of the sky”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 47.287 (1899). Crossref-verified. Philosophical Magazine series 5. This is the later paper the chapter cites for the demonstration that the air molecules themselves suffice, so the blue of

the sky needs no dust. Crossref deposits this title with no roman-numeral prefix., pp. 375–384. DOI: 10.1080/14786449908621276.

[287] E. Rutherford. “Uranium radiation and the electrical conduction produced by it”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 47.284 (1899), pp. 109–163. DOI: 10.1080/14786449908621245.

[288] H. Bénard. “Étude expérimentale des courants de convection dans une nappe liquide. — Régime permanent : tourbillons cellulaires”. In: *Journal de Physique Théorique et Appliquée* 9.1 (1900). Two instalments in volume 11. The cellular-convection experiments., pp. 513–524. DOI: 10.1051/jphystap:019000090051300.

[289] P. Drude. “Zur Elektronentheorie der Metalle”. In: *Annalen der Physik* 306.3 (1900), pp. 566–613. DOI: 10.1002/andp.19003060312.

[290] P. Drude. “Zur Elektronentheorie der Metalle; II. Teil. Galvanomagnetische und thermomagnetische Effecte”. In: *Annalen der Physik* 308.11 (1900), pp. 369–402. DOI: 10.1002/andp.19003081102.

[291] D. Hilbert. “Mathematische Probleme”. In: *Nachrichten von der Königlichen Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-physikalische Klasse*. The twenty-three problems. The Göttinger Nachrichten carry no volume numbers. English translation by M. W. Newson, Bulletin of the AMS 8 (1902), 437–479. 1900, pp. 253–297.

[292] O. Lummer and E. Pringsheim. “Über die Strahlung des schwarzen Körpers für lange Wellen”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 2. The 1900 continuation of Lummer:1899, extending the measurement to about 18 um and to source temperatures up to 1772 C. Same series as the existing Lummer:1899 entry (Verhandlungen der Deutschen Physikalischen Gesellschaft, vol. 2 for 1900), so @inproceedings with booktitle, matching the house treatment of Lummer:1898/1899. No DOI exists. NOTE on encoding: the two neighbouring entries in references.bib transliterate umlauts (Koerper, gegluehte); if that local convention is kept, this title becomes ’Ueber die Strahlung des schwarzen Koerpers fuer lange Wellen’ – but the published title is the Unicode form given here and pdflatex+T1 handles it. Placed only where the chapter claims the push to long wavelength AND high temperature; deliberately NOT added to the phenomenon, whose ’8 um / 300-1650 K’ numbers are the 1899 measurement, not this one. 1900, pp. 163–180.

[293] R. D. Oldham. “On the propagation of earthquake motion to great distances”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 194.252-261 (1900). Identification of P, S and surface-wave phases in distant seismograms., pp. 135–174. DOI: 10.1098/rsta.1900.0015.

[294] M. Planck. “Ueber eine Verbesserung der Wienschen Spectralgleichung”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 2. Suffix ’a’: the interpolation of 19 October 1900. Distinct from Planck:1900b, the quantum derivation of 14 December 1900, in the same volume. 1900, pp. 202–204.

[295] M. Planck. “Zur Theorie des Gesetzes der Energieverteilung im Normalspectrum”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 2. Suffix ’b’: read 14 December 1900, the combinatorial derivation introducing energy elements h*nu and the relation S = k log W. 1900, pp. 237–245.

[296] L. Rayleigh. “Remarks upon the law of complete radiation”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 49.301 (1900). Published under the title ’Lord Rayleigh’; the paper states the nu^2 T form and inserts an exponential cut-off by hand. Rayleigh’s numerical factor was later corrected by Jeans:1905., pp. 539–540. DOI: 10.1080/14786440009463878.

[297] H. Rubens and F. Kurlbaum. “Ueber die Emission langwelliger Waermestrahlen durch den schwarzen Koerper bei verschiedenen Temperaturen”. In: *Sitzungsberichte der Koeniglich Preussischen Akademie der Wissenschaften zu Berlin*. Residual-ray measurements at 24 and 51.2 micrometres; communicated to Planck on 7 October 1900, the immediate cause of Planck:1900a. An expanded version appeared in Annalen der Physik 309 (1901) 649–666. 1900, pp. 929–941.

[298] I. Bendixson. “Sur les courbes définies par des équations différentielles”. In: *Acta Mathematica* 24.0 (1901). The Poincaré-Bendixson theorem in its general form., pp. 1–88. DOI: 10.1007/bf02403068.

[299] P. Lebedew. “Untersuchungen über die Druckkräfte des Lichtes”. In: *Annalen der Physik* 311.11 (1901). Keyed Lebedew (the published spelling) rather than the modern transliteration Lebedev, per the Surname:YYYY convention. Wiley volume 311 = series 4, vol. 6, confirmed against Crossref. A duplicate key Lebedev:1901 was merged here. Umlauts: ueber = über, Druckkraefte = Druckkräfte., pp. 433–458. DOI: 10.1002/andp.19013111102.

[300] M. Planck. “Ueber das Gesetz der Energieverteilung im Normalspectrum”. In: *Annalen der Physik* 309.3 (1901). DOI supplied by the task prompt. Whole-series vol. 309 = 4th series vol. 4., pp. 553–563. DOI: 10.1002/andp.19013090310.

[301] E. Wiechert. “Elektrodynamische Elementargesetze”. In: *Annalen der Physik* 309.4 (1901). DATING TRAP, of the Kretschmann kind but sharper: the text first appeared in 1900 in the Lorentz jubilee volume — "Recueil de travaux offerts par les auteurs a H. A. Lorentz", Archives Neerlandaises des Sciences Exactes et Naturelles, 2nd series, vol. 5 (Nijhoff, The Hague, 1900), pp. 549-573 — which is the year the citing author used and the year the key records. That 1900 printing has no DOI. The same paper was republished in Annalen der Physik 309(4), 667-689 (1901), and only that version has a resolvable DOI (fetched and title-checked: "Elektrodynamische Elementargesetze", author Wiechert). Recommendation: keep the citekey Wiechert:1900 (it is fixed by the citation in 08-radiation-scattering.tex), give the entry the Annalen 1901 fields plus DOI so the reader can actually retrieve it, and record the 1900 Festschrift first appearance in the note field — do NOT put the 1901 DOI on 1900 Archives Neerlandaises fields, and do not invent a DOI for the 1900 printing., pp. 667–689. DOI: 10.1002/andp.19013090403.

[302] L. Bianchi. “Sui simboli a quattro indici e sulla curvatura di Riemann”. In: *Rendiconti della Reale Accademia Nazionale dei Lincei*. Vol. 11. Series 5, vol. 11. Attribution is customary: the identities were known earlier to Voss (1880) and in Ricci’s school; the citing chapter says so explicitly. 1902, pp. 3–7.

[303] H. L. Callendar. “Continuous electrical calorimetry”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 199.312-320 (1902). Companion paper by H. T. Barnes on the heat capacity of water in the same volume, pp. 149–263., pp. 55–148. DOI: 10.1098/rsta.1902.0013.

[304] J. W. Gibbs. *Elementary Principles in Statistical Mechanics, Developed with Especial Reference to the Rational Foundation of Thermodynamics*. New York: Charles Scribner’s Sons, 1902.

[305] J. Hadamard. “Sur les problèmes aux dérivées partielles et leur signification physique”. In: *Princeton University Bulletin* 13 (1902). The well-posedness definition., pp. 49–52.

[306] J. H. Jeans. “The Stability of a Spherical Nebula”. In: *Philosophical Transactions of the Royal Society of London A* 199 (1902). Metadata confirmed against Crossref., pp. 1–53. DOI: 10.1098/rsta.1902.0012.

[307] W. M. Kutta. “Auftriebskräfte in strömenden Flüssigkeiten”. In: *Illustrierte Aeronautische Mitteilungen* 6 (1902). Thin-aerofoil lift computation; the Kutta half of Kutta-Joukowski., pp. 133–135.

[308] P. Lenard. “Ueber die lichtelektrische Wirkung”. In: *Annalen der Physik* 313.5 (1902). Establishes that the maximum electron energy depends on frequency and not on intensity, and that there is a threshold frequency., pp. 149–198. DOI: 10.1002/andp.19023130510.

[309] H. Poincaré. *La Science et l’Hypothèse*. Source of the conventionalist thesis: parts of a physical theory are stipulations rather than measured facts. English translation: Science and Hypothesis, Walter Scott, London (1905). Paris: Ernest Flammarion, 1902.

[310] L. Fejér. “Untersuchungen über Fouriersche Reihen”. In: *Mathematische Annalen* 58.1-2 (1903), pp. 51–69. DOI: 10.1007/bf01447779.

[311] E. F. Nichols and G. F. Hull. “The Pressure due to Radiation”. In: *The Astrophysical Journal* 17 (1903). The independent and more accurate measurement of radiation pressure. A companion pair of papers appeared the same year in Physical Review (Series I) 17, 26–50 and 91–104., p. 315. DOI: 10.1086/141035.

[312] E. Rutherford and F. Soddy. “Radioactive Change”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 5.29 (1903), pp. 576–591. DOI: 10.1080/14786440309462960.

[313] M. Abraham. “Zur Theorie der Strahlung und des Strahlungsdruckes”. In: *Annalen der Physik* 319.7 (1904). Cited for the Abraham–Lorentz radiation-reaction force. Volume 319 is the continuous Annalen count; contemporary citations give ’Band 14’ (4th series), so a source saying Ann. Phys. 14, 236 (1904) is the same paper. Crossref-verified., pp. 236–287. DOI: 10.1002/andp.19043190703.

[314] D. Hilbert. “Über das Dirichletsche Prinzip”. In: *Mathematische Annalen* 59.1-2 (1904). The rehabilitation of the Dirichlet principle; an earlier short version appeared in Jahresbericht der DMV 8 (1900)., pp. 161–186. DOI: 10.1007/bf01444753.

[315] L. Prandtl. “Über Flüssigkeitsbewegung bei sehr kleiner Reibung”. In: *Verhandlungen des dritten Internationalen Mathematiker-Kongresses in Heidelberg 1904*. Delivered at the Heidelberg ICM in August 1904; the Verhandlungen volume was printed in 1905. Universally cited as 1904 and keyed so here (no DOI to arbitrate); record the dating in the entry note. The boundary-layer paper. 1904, pp. 484–491.

[316] J. Thomson. “On the structure of the atom: an investigation of the stability and periods of oscillation of a number of corpuscles arranged at equal intervals around the circumference of a circle; with application of the results to the theory of atomic structure”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 7.39 (1904). The ’plum pudding’ model, cited as a genuine falsifiable dynamical model rather than as a straw man., pp. 237–265. DOI: 10.1080/14786440409463107.

[317] C. G. Barkla. “Polarised röntgen radiation”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 204.372-386 (1905). The double-scattering experiment showing X-rays are transverse. Crossref prefixes the title with the article number, "XIII. Polarised röntgen radiation", and lowercases it; the volume as printed reads "Polarised Röntgen Radiation". Verified against the Crossref record for the DOI (volume 204, pages 467-479, 1905)., pp. 467–479. DOI: 10.1098/rsta.1905.0013.

[318] A. Einstein. “Über die von der molekularkinetischen Theorie der Wärme geforderte Bewegung von in ruhenden Flüssigkeiten suspendierten Teilchen”. In: *Annalen der Physik* 322.8 (1905). Ser. 4, vol. 17, issue 8; received 11 May 1905. The Brownian-motion paper. Takes the next free suffix d, since a/b are the relativity and mass–energy papers and c is claimed for the light-quantum paper by a directive in the photoelectric chapter., pp. 549–560. DOI: 10.1002/andp.19053220806.

[319] A. Einstein. “Über einen die Erzeugung und Verwandlung des Lichtes betreffenden heuristischen Gesichtspunkt”. In: *Annalen der Physik* 322.6 (1905). Ser. 4, vol. 17, issue 6; received 18 March 1905. The light-quantum (photoelectric) paper. Suffix c because Einstein:1905a/b are the relativity and mass–energy papers; the Brownian-motion paper is Einstein:1905d. A prior version of this entry duplicated the Brownian-motion metadata under this key while the photon chapter cited it for the light quantum – wrong work under a right key, caught by a reader on the bibliography page. Metadata confirmed against Crossref., pp. 132–148. DOI: 10.1002/andp.19053220607.

[320] A. Einstein. “Ist die Trägheit eines Körpers von seinem Energieinhalt abhängig?” In: *Annalen der Physik* 323.13 (1905). Ser. 4, vol. 18. Received 27 September 1905. The mass–energy paper; the equation never appears as $E = mc^2$, but as a mass change L/V^2, quoted numerically as $L/(9 \times 10^{20})$ with energy in erg and mass in gram, pp. 639–641. DOI: 10.1002/andp.19053231314.

[321] A. Einstein. “Zur Elektrodynamik bewegter Körper”. In: *Annalen der Physik* 322.10 (1905). Ser. 4, vol. 17. Received 30 June 1905. The founding paper of special relativity; Einstein writes V for the speed of light throughout, pp. 891–921. DOI: 10.1002/andp.19053221004.

[322] J. Jeans. “On the partition of energy between matter and Æther”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 10.55 (1905). Published title spells the second noun with the ligature ’Aether’ (AE ligature)., pp. 91–98. DOI: 10.1080/14786440509463348.

[323] P. Langevin. “Magnétisme et théorie des électrons”. In: *Annales de Chimie et de Physique* 5 (1905). 8th series., pp. 70–127.

[324] W. Sutherland. “A dynamical theory of diffusion for non-electrolytes and the molecular mass of albumin”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 9.54 (1905). Not a genuine collision: both candidates are this one paper, one carrying the Phil. Mag. running article number ’LXXV.’ before the title. Series 6, issue 54. Title given in the form the DOI record prints it, without the running number., pp. 781–785. DOI: 10.1080/14786440509463331.

[325] P. Duhem. *La Théorie physique: son objet, sa structure*. The holism thesis later generalized by Quine: an experiment tests a hypothesis only together with its auxiliaries. Second, enlarged edition 1914; English translation The Aim and Structure of Physical Theory, trans. P. P. Wiener, Princeton University Press (1954). Paris: Chevalier et Rivière, 1906.

[326] A. Einstein. “Zur Theorie der Brownschen Bewegung”. In: *Annalen der Physik* 324.2 (1906). The second Brownian paper; contains the rotational diffusion result, pp. 371–381. DOI: 10.1002/andp.19063240208.

[327] T. Lyman. “The Spectrum of Hydrogen in the Region of Extremely Short Wave-Length”. In: *Memoirs of the American Academy of Arts and Sciences* 13.3 (1906), p. 125. DOI: 10.2307/25058084.

[328] W. Nernst. “Über die Berechnung chemischer Gleichgewichte aus thermischen Messungen”. In: *Nachrichten von der Königlichen Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-physikalische Klasse*. Academy proceedings, year-based issues, no volume number; the heat theorem (third law). 1906, pp. 1–40.

[329] H. Poincaré. “Sur la dynamique de l’électron”. In: *Rendiconti del Circolo Matematico di Palermo* 21.1 (1906). Submitted July 1905 and universally cited as 1905; the volume is dated 1906, which fixes the key. Introduces the Lorentz group as a group and the invariant $x^2 + y^2 + z^2 - c^2t^2$, pp. 129–176. DOI: 10.1007/BF03013466.

[330] K. Schwarzschild. “Über das Gleichgewicht der Sonnenatmosphäre”. In: *Nachrichten von der Königlichen Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-physikalische Klasse*. Vol. 1906. Karl Schwarzschild; radiative equilibrium and the convective stability criterion; no DOI. 1906, pp. 41–53.

[331] M. von Smoluchowski. “Zur kinetischen Theorie der Brownschen Molekularbewegung und der Suspensionen”. In: *Annalen der Physik* 326.14 (1906), pp. 756–780. DOI: 10.1002/andp.19063261405.

[332] J. J. Thomson. *Conduction of Electricity through Gases*. Second edition, 1906 (first edition 1903) – the edition is load-bearing: the scattering calculation giving sigma_T = (8 pi/3) r_e^2, which is what both citations in ch. 08-radiation-scattering rest on, is in the second edition, so the entry must carry edition = 2. No DOI. The later two-volume rewrite with G. P. Thomson (1928, 1933) is a different work. Public-domain scans exist (Internet Archive, conductionofele00thomuoft), which is a declarable access route. Cambridge University Press, 1906.

[333] A. Einstein. “Die Plancksche Theorie der Strahlung und die Theorie der spezifischen Wärme”. In: *Annalen der Physik* 327.1 (1907). Series 4, volume 22 = continuous volume 327, issue 1. The DOI string encodes 1906 (Wiley numbered it from the volume’s opening), but Crossref records published-print 1907 for the issue, which is also the customary citation — verified against the Crossref record, title, volume, issue and pages all matching. Introduces the quantized-oscillator model of the specific heats of solids., pp. 180–190. DOI: 10.1002/andp.19063270110.

[334] A. Einstein. “Über das Relativitätsprinzip und die aus demselben gezogenen Folgerungen”. In: *Jahrbuch der Radioaktivität und Elektronik* 4 (1907). Review article whose section V gives the first statement of the equivalence principle and of the gravitational redshift. The volume is dated 1907 and the issue appeared in early 1908; the customary citation is 1907. Corrections printed as Berichtigungen, Jahrbuch der Radioaktivität und Elektronik 5 (1908), 98–99. No DOI exists., pp. 411–462.

[335] E. Fischer. “Sur la convergence en moyenne”. In: *Comptes Rendus de l’Académie des Sciences (Paris)*. Vol. 144. The Riesz–Fischer theorem (completeness of L2). 1907, pp. 1022–1024.

[336] F. Riesz. “Sur une espèce de géométrie analytique des systèmes de fonctions sommables”. In: *Comptes Rendus de l’Académie des Sciences (Paris)*. Vol. 144. The L2 representation theorem. Riesz published several C.R. notes in 1907; if another is ever cited, suffix then. Fréchet’s simultaneous note customarily shares credit. 1907, pp. 1409–1411.

[337] H. J. Round. “A Note on Carborundum”. In: *Electrical World* 49 (1907), p. 309.

[338] E. Schmidt. “Zur Theorie der linearen und nichtlinearen Integralgleichungen”. In: *Mathematische Annalen* 63.4 (1907). The orthogonalization procedure and the expansion theorem for compact kernels., pp. 433–476. DOI: 10.1007/bf01449770.

[339] P. Weiss. “L’hypothèse du champ moléculaire et la propriété ferromagnétique”. In: *Journal de Physique Théorique et Appliquée* 6.1 (1907), pp. 661–690. DOI: 10.1051/jphystap:019070060066100.

[340] C. G. Barkla and C. A. Sadler. “Homogeneous secondary Röntgen radiations”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 16.94 (1908). Series 6, issue 94 (October 1908). Discovery of homogeneous radiation characteristic of the radiating element. Crossref prefixes the title with the article number "XLVIII."; dropped here as in the existing Moseley entries., pp. 550–584. DOI: 10.1080/14786441008636537.

[341] H. Blasius. “Grenzschichten in Flüssigkeiten mit kleiner Reibung”. In: *Zeitschrift für Mathematik und Physik* 56 (1908). The flat-plate boundary-layer similarity solution., pp. 1–37.

[342] G. E. Hale. “On the Probable Existence of a Magnetic Field in Sun-Spots”. In: *The Astrophysical Journal* 28 (1908). The founding observation of astrophysical magnetism, as the citing sentence says. Crossref confirms title, ApJ vol. 28, first page 315, year 1908; the article runs to p. 343., p. 315. DOI: 10.1086/141602.

[343] H. Kamerlingh Onnes. “The Liquefaction of Helium”. In: *Science* 28.714 (1908). Leiden Communication no. 108; also Proceedings KNAW Amsterdam 11, 168 (1908)., pp. 316–316. DOI: 10.1126/science.28.714.316.a.

[344] P. Langevin. “Sur la théorie du mouvement brownien”. In: *Comptes Rendus de l’Académie des Sciences (Paris)*. Vol. 146. 1908, pp. 530–533.

[345] G. Mie. “Beiträge zur Optik trüber Medien, speziell kolloidaler Metallösungen”. In: *Annalen der Physik* 330.3 (1908). Wiley’s continuous volume numbering is 330, issue 3; the original title page reads 4. Folge, Band 25. Cite volume 330 (that is what the DOI and Crossref carry) and record ’ser. 4, vol. 25’ in a note if desired., pp. 377–445. DOI: 10.1002/andp.19083300302.

[346] H. Minkowski. “Die Grundgleichungen für die elektromagnetischen Vorgänge in bewegten Körpern”. In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-Physikalische Klasse*. Academy Nachrichten: NO volume number – the series is dated by year only. Presented in the session of 21 December 1907 and therefore cited as 1907 by some sources; printed in the 1908 Nachrichten, which fixes the key. This is the Minkowski electromagnetic energy–momentum tensor paper the citing sentence needs (Minkowski vs Abraham momentum), distinct from the existing bib entry Minkowski:1909 (’Raum und Zeit’). The Gesellschaft was styled ’Königliche’ on the 1908 title page; the form given here is the one universally used and matches EUDML. Reprinted in Math. Ann. 68 (1910) 472–525, DOI 10.1007/BF01455871 – do NOT attach that DOI to the 1908 Nachrichten entry. No DOI exists for the Nachrichten printing. 1908, pp. 53–111.

[347] F. Paschen. “Zur Kenntnis ultraroter Linienspektra. I. (Normalwellenlängen bis 27000 Å.-E.)” In: *Annalen der Physik* 332.13 (1908). The infrared hydrogen series. Title contains the Angstrom symbol and an umlaut: Normalwellenlängen bis 27000 ångström-Einheiten., pp. 537–570. DOI: 10.1002/andp.19083321303.

[348] W. Ritz. “On a New Law of Series Spectra”. In: *The Astrophysical Journal* 28 (1908). The combination principle. A German version, Ueber ein neues Gesetz der Serienspektren, appeared in Physikalische Zeitschrift 9 (1908) 521–529., p. 237. DOI: 10.1086/141591.

[349] M. v. Smoluchowski. “Molekular-kinetische Theorie der Opaleszenz von Gasen im kritischen Zustande, sowie einiger verwandter Erscheinungen”. In: *Annalen der Physik* 330.2 (1908), pp. 205–226. DOI: 10.1002/andp.19083300203.

[350] E. Zermelo. “Untersuchungen über die Grundlagen der Mengenlehre. I”. In: *Mathematische Annalen* 65.2 (1908), pp. 261–281. DOI: 10.1007/BF01449999.

[351] M. Abraham. “Zur Elektrodynamik bewegter Körper”. In: *Rendiconti del Circolo Matematico di Palermo* 28.1 (1909). The origin of the Abraham momentum in the Abraham–Minkowski controversy. Same title as Einstein’s 1905 paper – do not confuse them. Crossref-verified., pp. 1–28. DOI: 10.1007/BF03018208.

[352] C. Barkla and C. Sadler. “The absorption of Röntgen rays”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 17.101 (1909). Series 6, issue 101 (May 1909). Mass absorption coefficients of the characteristic radiations through the periodic table, and the excitation threshold. Crossref prefixes the title with the article number "LXIX."., pp. 739–760. DOI: 10.1080/14786440508636650.

[353] C. Carathéodory. “Untersuchungen über die Grundlagen der Thermodynamik”. In: *Mathematische Annalen* 67.3 (1909), pp. 355–386. DOI: 10.1007/bf01450409.

[354] H. Geiger and E. Marsden. “On a diffuse reflection of the alpha-particles”. In: *Proceedings of the Royal Society of London A* 82 (1909). Published title uses the Greek letter: On a Diffuse Reflection of the α-Particles., pp. 495–500.

[355] M. Knudsen. “Die Gesetze der Molekularströmung und der inneren Reibungsströmung der Gase durch Röhren”. In: *Annalen der Physik* 333.1 (1909). Wiley continuous numbering; customary citation vol. 28 (series 4)., pp. 75–130. DOI: 10.1002/andp.19093330106.

[356] H. A. Lorentz. *The Theory of Electrons and Its Applications to the Phenomena of Light and Radiant Heat*. First edition, Leipzig: B. G. Teubner; New York: G. E. Stechert & Co., 1909. Subtitle: ’A Course of Lectures Delivered in Columbia University, New York, in March and April 1906’. A second edition appeared in 1916 — the electron-theory programme the chapters cite is in both, but the key’s year fixes the 1909 first edition. No DOI. Full scans are on the Internet Archive (archive.org/details/theoryofelectron00loreuoft), which is a GREEN access route. B. G. Teubner, 1909.

[357] H. Minkowski. “Raum und Zeit”. In: *Physikalische Zeitschrift* 10.3 (1909). Address delivered at the 80th Assembly of German Natural Scientists and Physicians, Cologne, 21 September 1908, and customarily cited as 1908; printed in the issue of 1 February 1909, which fixes the key. No DOI exists: Physikalische Zeitschrift was never registered, pp. 104–111.

[358] J. Perrin. “Mouvement brownien et réalité moléculaire”. In: *Annales de Chimie et de Physique* 18 (1909). 8th series., pp. 5–114.

[359] W. Ritz. “Über eine neue Methode zur Lösung gewisser Variationsprobleme der mathematischen Physik”. In: *crll* 135.135 (1909), pp. 1–61. DOI: 10.1515/crll.1909.135.1.

[360] G. I. Taylor. “Interference fringes with feeble light”. In: *Proceedings of the Cambridge Philosophical Society* 15 (1909). No DOI – Cambridge’s back-file DOIs for this series do not reach 1909, and the Crossref hits under this title are later reprints (Concepts of Quantum Optics, 1983, pp. 91-92, doi 10.1016/b978-0-08-029160-4.50015-4). Do not use the reprint DOI for the 1909 entry. The journal was renamed ’Mathematical Proceedings of the Cambridge Philosophical Society’ only in 1975, so the 1909 venue name is the shorter one., pp. 114–115.

[361] A. Einstein. “Theorie der Opaleszenz von homogenen Flüssigkeiten und Flüssigkeitsgemischen in der Nähe des kritischen Zustandes”. In: *Annalen der Physik* 338.16 (1910), pp. 1275–1298. DOI: 10.1002/andp.19103381612.

[362] N. Joukowski. “Über die Konturen der Tragflächen der Drachenflieger”. In: *Zeitschrift für Flugtechnik und Motorluftschiffahrt* 1 (1910). Name also transliterated Zhukovsky. The circulation lift theorem was first published in Russian in 1906 (’O prisoedinennykh vikhryakh’, Trudy Otdeleniya Fizicheskikh Nauk); this German paper is the accessible primary and the chapter notes the 1906 origin., pp. 281–284.

[363] M. Plancherel and M. Leffler. “Contribution À LÉtude de la reprÉsentation D’une fonction arbitraire par des intÉgrales dÉfinies”. In: *Rendiconti del Circolo Matematico di Palermo* 30.1 (1910), pp. 289–335. DOI: 10.1007/bf03014877.

[364] W. Voigt. *Lehrbuch der Kristallphysik (mit Ausschluss der Kristalloptik)*. Anisotropic elasticity, the 21 constants, Voigt notation; experimental resolution of the rari-constant vs multi-constant (Cauchy relations) controversy. Leipzig: B. G. Teubner, 1910.

[365] A. N. Whitehead and B. Russell. *Principia Mathematica*. Vol. 1. Volumes II and III followed in 1912 and 1913; second edition 1925–1927. Cambridge: Cambridge University Press, 1910.

[382] P. Debye. “Zur Theorie der spezifischen Wärmen”. In: *Annalen der Physik* 344.14 (1912). Ser. 4, vol. 39, issue 14; Wiley numbering 344. The T^3 law and the Debye temperature. Printed as ’P. Debye’., pp. 789–839. DOI: 10.1002/andp.19123441404.

[383] P. Debye. “Einige Resultate einer kinetischen Theorie der Isolatoren”. In: *Physikalische Zeitschrift* 13 (1912). Vorläufige Mitteilung, Heft 3. Orientation polarization of permanent molecular dipoles and the temperature dependence of the static dielectric constant. NOT one of the two supplied candidates — both of those were the specific-heats paper — but the electrodynamics-of-matter chapter plainly cites Debye 1912 for polar molecules, so this work is supplied. Physikalische Zeitschrift is not in Crossref; no DOI exists, which is acceptable for pre-1990 work., pp. 97–100.

[384] G. Eiffel. “Sur la résistance des sphères dans l’air en mouvement”. In: *Comptes Rendus des Séances de l’Académie des Sciences*. Vol. 155. Discovery of the drag crisis of the sphere. 1912, pp. 1597–1599.

[385] W. Friedrich, P. Knipping, and M. Laue. “Interferenz-Erscheinungen bei Roentgenstrahlen”. In: *Sitzungsberichte der Koeniglich Bayerischen Akademie der Wissenschaften zu Muenchen*. First X-ray diffraction by a crystal, keyed by the first listed author. Umlauts: Röntgenstrahlen, Königlich, München. 1912, pp. 303–322.

[386] E. Grüneisen. “Theorie des festen Zustandes einatomiger Elemente”. In: *Annalen der Physik* 344.12 (1912), pp. 257–306. DOI: 10.1002/andp.19123441202.

[387] V. F. Hess. “Über Beobachtungen der durchdringenden Strahlung bei sieben Freiballonfahrten”. In: *Physikalische Zeitschrift* 13 (1912). Discovery of cosmic rays; no DOI exists for Physikalische Zeitschrift of this period., pp. 1084–1091.

[388] D. Hilbert. *Grundzüge einer allgemeinen Theorie der linearen Integralgleichungen*. Collects the six Göttinger Nachrichten communications of 1904–1910; origin of the word ’spectrum’ and of l2. Leipzig and Berlin: B. G. Teubner, 1912.

[389] M. von Laue. “Eine quantitative Prüfung der Theorie für die Interferenzerscheinungen bei Röntgenstrahlen”. In: *Sitzungsberichte der Mathematisch-Physikalischen Classe der Königlich-Bayerischen Akademie der Wissenschaften zu München*. 1912, pp. 363–373.

[390] H. S. Leavitt and E. C. Pickering. “Periods of 25 Variable Stars in the Small Magellanic Cloud”. In: *Harvard College Observatory Circular* 173 (1912). Observatory circular signed by Pickering, reporting Leavitt’s work; commonly cited under Leavitt. No DOI., pp. 1–3.

[391] F. Paschen and E. Back. “Normale und anomale Zeemaneffekte”. In: *Annalen der Physik* 344.15 (1912). The systematic study of the anomalous Zeeman patterns and of their collapse in strong fields (the Paschen-Back effect)., pp. 897–932. DOI: 10.1002/andp.19123441502.

[392] G. A. Schott. *Electromagnetic Radiation and the Mechanical Reactions Arising from It, being an Adams Prize Essay in the University of Cambridge*. No DOI (1912 monograph). This is the classical calculation of radiation from a charge on a circular orbit, decades before synchrotron light was seen – exactly what sec:rad-synchrotron cites it for. Public domain and scanned on the Internet Archive (electromagneticr00schouoft), which is a declarable open access route for the availability grade. Cambridge University Press, 1912.

[393] H. Tetrode. “Die chemische Konstante der Gase und das elementare Wirkungsquantum”. In: *Annalen der Physik* 343.7 (1912). Contains the comparison with mercury-vapour data, pp. 434–442. DOI: 10.1002/andp.19123430708.

[394] C. T. R. Wilson. “On an expansion apparatus for making visible the tracks of ionising particles in gases and some results obtained by its use”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 87.595 (1912). C. T. R. Wilson; distinct from Kenneth G. Wilson of Wilson:1969, pp. 277–292. DOI: 10.1098/rspa.1912.0081.

[395] N. Bohr. “On the constitution of atoms and molecules”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 26.151 (1913). Part I – the one that derives the Balmer formula and R_infinity from hbar, m and e, which is the claim in the citing sentence. Series 6, vol. 26, issue 151. Crossref records the title with the Phil. Mag. article-number prefix (’I. On the constitution of atoms and molecules’), so a strict string comparison against the DOI will differ by that prefix

and by capitalisation only. Parts II (26, 476–502, DOI 10.1080/14786441308634993) and III (26, 857–875, DOI 10.1080/14786441308635031) are separate works – keep them as Bohr:1913b/c if ever cited., pp. 1–25. DOI: 10.1080/14786441308634955.

[396] N. Bohr. "On the constitution of atoms and molecules". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 26.155 (1913). Part I of the trilogy; suffix a/b/c distinguishes the three 1913 instalments., pp. 857–875. DOI: 10.1080/14786441308635031.

[397] N. Bohr. "On the constitution of atoms and molecules. Part II. Systems containing only a single nucleus". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science, Series 6* 26 (1913), pp. 476–502.

[398] N. Bohr. "On the constitution of atoms and molecules. Part III. Systems containing several nuclei". In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science, Series 6* 26 (1913), pp. 857–875.

[399] W. L. Bragg. "The Diffraction of Short Electromagnetic Waves by a Crystal". In: *Proceedings of the Cambridge Philosophical Society* 17 (1913). Read 11 November 1912, published in the 1913 volume. The paper in which n lambda = 2 d sin theta first appears, recasting Laue's conditions as reflection from lattice planes. No DOI: the Cambridge Philosophical Society proceedings of this period are not registered., pp. 43–57.

[400] W. H. Bragg and W. L. Bragg. "The reflection of X-rays by crystals". In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 88.605 (1913). The two-author paper describing the X-ray (ionization) spectrometer and the reflection measurements made with it. DOI verified against Crossref, which titles the container "Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character"., pp. 428–438. DOI: 10.1098/rspa.1913.0040.

[401] L. E. J. Brouwer. "Intuitionism and Formalism". In: *Bulletin of the American Mathematical Society* 20.2 (1913). Translated by Arnold Dresden from the inaugural address at the University of Amsterdam, 14 October 1912, pp. 81–96. DOI: 10.1090/S0002-9904-1913-02440-6.

[402] P. Debye. "Über die Intensitätsverteilung in den mit Röntgenstrahlen erzeugten Interferenzbildern". In: *Verhandlungen der Deutschen Physikalischen Gesellschaft.* Vol. 15. 1913, pp. 678–689.

[403] A. Eucken. "Über das Wärmeleitvermögen, die spezifische Wärme und die innere Reibung der Gase". In: *Physikalische Zeitschrift* 14 (1913). NO DOI given deliberately: Physikalische Zeitschrift (ceased 1945) is not in Crossref, so any DOI here would be invented. Volume 14 is the 1913 volume, so the issue year and the customary year agree. Volume/page range corroborated across four independent citing-literature searches, all giving 'Physik. Z. 14 (1913) 324-332'; note that several modern reference lists mis-expand the abbreviation as 'Z. Phys. 14:324', which is impossible (Zeitschrift für Physik began in 1920) – the venue is Physikalische Zeitschrift. This is the paper that established the Eucken factor kappa*m/(eta*c_V) = (9*gamma-5)/4, equal to 5/2 for a monatomic gas. Being pre-1990 the validator will not demand a DOI, but with no DOI and no stored copy it will grade RED on availability: it needs a docs/library/manifest.json entry, honestly 'access': 'offline' naming volume 14, pages 324-332, unless a verified open scan URL is found (I did not verify one, so I am not asserting it)., pp. 324–332.

[404] H. Geiger and E. Marsden. “The laws of deflexion of a particles through large angles”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 25.148 (1913). Published title uses the Greek letter: The Laws of Deflexion of α Particles through Large Angles., pp. 604–623. DOI: 10.1080/14786440408634197.

[405] W. Kolhörster. “Messungen der durchdringenden Strahlung im Freiballon in größeren Höhen”. In: *Physikalische Zeitschrift* 14 (1913), pp. 1153–1156.

[406] A. Lo Surdo. “Sul fenomeno analogo a quello di Zeeman nel campo elettrico”. In: *Rendiconti della Reale Accademia dei Lincei, Classe di scienze fisiche, matematiche e naturali*. Vol. 22. Series 5, vol. 22; presented at the session of 21 December 1913. This is the priority note that establishes the independent discovery the chapter claims, so it is the right work for the key. No DOI. A fuller version with the same title appeared as Il Nuovo Cimento 7 (1914) 335-337, DOI 10.1007/BF02958602 — that DOI belongs to the Nuovo Cimento record and must NOT be attached to the Rendiconti entry; mention it in a note (or add a separate LoSurdo:1914 entry) so the reader has a retrievable route. 1913, pp. 664–666.

[407] R. A. Millikan. “On the Elementary Electrical Charge and the Avogadro Constant”. In: *Physical Review* 2 (1913). Physical Review Series II, vol. 2, issue 2, 1 August 1913. Crossref prints the author family name as ’Millikan.’ with a stray period; the correct form is Millikan., pp. 109–143.

[408] H. Moseley. “The high-frequency spectra of the elements”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 26.156 (1913), pp. 1024–1034. DOI: 10.1080/14786441308635052.

[409] J. Perrin. *Les Atomes*. Paris: Félix Alcan, 1913.

[410] G. Sagnac. “L’éther lumineux démontré par l’effet du vent relatif d’éther dans un interféromètre en rotation uniforme”. In: *Comptes rendus hebdomadaires des séances de l’Académie des Sciences*. Vol. 157. No DOI. Comptes rendus tome 157, séance of 27 October 1913 (issue no. 17) – Comptes rendus does carry tome numbers, so 157 is real and not invented. This first note announces the effect. The chapter also promises ’the measured fringe shift versus rotation rate’, which is in Sagnac’s companion note in the SAME tome: ’Sur la preuve de la réalité de l’éther lumineux par l’expérience de l’interférographe tournant’, C. R. Acad. Sci. 157, 1410-1413 (1913). If the measurement is to be cited, that second note is the source and deserves its own key (Sagnac:1913b). 1913, pp. 708–710.

[411] A. VAN DER BROEK. “Intra-atomic Charge”. In: *Nature* 92.2300 (1913). Issue 2300. The hypothesis that the nuclear charge equals the serial number of the element, which Moseley then tested. Crossref’s deposited metadata misspells the author as "A. Van der Broek"; Nature printed "A. van den Broek" — an instance of the corrupt-Crossref-metadata trap in CLAUDE.md, so take the name from the journal and the DOI/volume/pages from Crossref. Key follows the existing vonLaue:1912 convention for particled surnames. Do not confuse with his other 1913 Nature note, "Intra-atomic Charge and the Structure of the Atom", 92, 476-478, doi 10.1038/092476b0., pp. 372–373. DOI: 10.1038/092372c0.

[412] L. Brillouin. “Über die Fortpflanzung des Lichtes in dispergierenden Medien”. In: *Annalen der Physik* 349.10 (1914). TRAP: Sommerfeld’s companion paper in the very same issue carries the IDENTICAL title and is DOI 10.1002/andp.19143491002, pp. 177-202. Brillouin’s is the SECOND of the pair, pp. 203-240, DOI ...1003 – both Crossref-confirmed. Annalen vol. 349 = 4th series vol. 44; issue 10. The citing chapter cites Sommerfeld:1914 and Brillouin:1914 together, so getting the two the right way round matters., pp. 203–240. DOI: 10.1002/andp.19143491003.

[413] E. Buckingham. “On Physically Similar Systems; Illustrations of the Use of Dimensional Equations”. In: *Physical Review* 4.4 (1914). The Π theorem. Priority is contested: the general statement was published by Vaschy (1892) and, apparently independently, by Federman and Riabouchinsky (both 1911), and Buckingham himself later ceded priority to Riabouchinsky. Note also that Buckingham defines k as the size of a maximal independent set of quantities, i.e. the rank of the dimensional matrix, not the number of base dimensions, pp. 345–376. DOI: 10.1103/PhysRev.4.345.

[414] J. Chadwick. “Intensitatsverteilung im magnetischen Spektrum der beta-Strahlen von Radium B+C”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 16. No DOI; first demonstration that the beta spectrum is continuous. 1914, pp. 383–391.

[415] A. D. Fokker. “Die mittlere Energie rotierender elektrischer Dipole im Strahlungsfeld”. In: *Annalen der Physik* 348.5 (1914), pp. 810–820. DOI: 10.1002/andp.19143480507.

[416] J. Franck and G. Hertz. “Ueber die Erregung der Quecksilberresonanzlinie 253,6 Mikromikrometer durch Elektronenstoesse”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 16. Suffix ’b’; the companion paper reporting the 253.6 nm resonance line excited by electron impact. Published title writes the wavelength as 253,6 mu-mu (micromicrons), i.e. 253.6 nm in SI. Umlaut/eszett: Elektronenstoße. 1914, pp. 512–517.

[417] J. Franck and G. Hertz. “Ueber Zusammenstoesse zwischen Elektronen und den Molekuelen des Quecksilberdampfes und die Ionisierungsspannung desselben”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 16. Suffix ’a’ because a second Franck-Hertz paper of 1914 is cited as Franck:1914b. Society proceedings, not a journal article. The title itself carries the authors’ misreading of the 4.9 V threshold as an ionization potential, corrected in Bohr:1915. Umlauts and eszett: Zusammenstöße, Molekülen. 1914, pp. 457–467.

[418] H. Moseley. “The high-frequency spectra of the elements. Part II”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 27.160 (1914), pp. 703–713. DOI: 10.1080/14786440408635141.

[419] L. S. Ornstein and F. Zernike. “Accidental deviations of density and opalescence at the critical point of a single substance”. In: *Proceedings of the Royal Netherlands Academy of Arts and Sciences*. Vol. 17. 1914, pp. 793–806.

[420] H. N. Russell. “Relations Between the Spectra and other Characteristics of the Stars ast;” in: *Nature* 93.2322 (1914). No DOI, pp. 227–230. DOI: 10.1038/093227b0.

[421] A. Sommerfeld. “Über die Fortpflanzung des Lichtes in dispergierenden Medien”. In: *Annalen der Physik* 349.10 (1914). Crossref-verified. Brillouin’s companion paper cited in the same sentence carries the IDENTICAL title and immediately follows it in the same volume: Brillouin, L., Ann. Phys. 349, 203-240 (1914), doi 10.1002/andp.19143491003 – if Brillouin:1914 is also orphaned, that is the entry, and the two must be distinguished by author and pages, not by title. Wiley volume 349 = Band 44., pp. 177–202. DOI: 10.1002/andp.19143491002.

[422] J. Stark. “Beobachtungen über den Effekt des elektrischen Feldes auf Spektrallinien. I. Quereffekt”. In: *Annalen der Physik* 348.7 (1914). The discovery was announced in the Sitzungsberichte of the Berlin Academy in November 1913; this Annalen paper of 1914 is the full account, and the entry is keyed by its publication year per the treatise convention., pp. 965–982. DOI: 10.1002/andp.19143480702.

[423] W. S. Adams. “THE SPECTRUM OF THE COMPANION OF SIRIUS”. In: *Publications of the Astronomical Society of the Pacific* 27.161 (1915). First spectrum of a white dwarf, pp. 236–236. DOI: 10.1086/122440.

[424] S. J. Barnett. “Magnetization by Rotation”. In: *Physical Review* 6.4 (1915), pp. 239–270. DOI: 10.1103/PhysRev.6.239.

[425] N. Bohr. “On the Quantum theory of radiation and the structure of the atom”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 30.177 (1915). Contains the correction of Franck and Hertz’s reading of their own 4.9 V threshold as an ionization rather than an excitation potential., pp. 394–415. DOI: 10.1080/14786440908635413.

[426] A. Einstein and W. J. de Haas. “Experimenteller Nachweis der Ampèreschen Molekularströme”. In: *Verhandlungen der Deutschen Physikalischen Gesellschaft*. Vol. 17. First measurement of the gyromagnetic ratio of iron (the Einstein–de Haas effect). Also issued in English by the KNAW (Amsterdam) proceedings. Keyed with suffix c, not a, because Einstein:1915a (perihelion) and Einstein:1915b (field equations) are the two November 1915 Sitzungsberichte papers already cited throughout Part V; renumbering them would have rewritten correct references. The volume number 17 is the genuine Jahrgang of the series, not an invented field. No DOI exists. 1915, pp. 152–170.

[427] A. Einstein. “Die Feldgleichungen der Gravitation”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Academy proceedings, series has NO volume number – @inproceedings. The final field equations, presented 25 November 1915. 1915, pp. 844–847.

[428] A. Einstein. “Erklärung der Perihelbewegung des Merkur aus der allgemeinen Relativitätstheorie”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Academy proceedings, series has NO volume number – @inproceedings with booktitle, never invent a volume. Suffix a/b: two November 1915 Sitzungsberichte papers; a = perihelion (18 Nov), b = field equations (25 Nov). Also contains the full 1.7 arcsec light deflection. 1915, pp. 831–839.

[429] A. Einstein. “Zur allgemeinen Relativitätstheorie”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Academy proceedings, series has NO volume number. Presented 4 November 1915. Suffix d: a = perihelion, b = field equations, c = Einstein–de Haas; cite by content, never by letter. 1915, pp. 778–786.

[430] A. Einstein. “Zur allgemeinen Relativitätstheorie (Nachtrag)”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Academy proceedings, series has NO volume number. Presented 11 November 1915; the Nachtrag to Einstein:1915d. 1915, pp. 799–801.

[431] D. Hilbert. “Die Grundlagen der Physik. (Erste Mitteilung.)” In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-physikalische Klasse*. Communicated 20 November 1915; the issue was printed in 1916 but the Nachrichten volume and customary citation year are 1915. Proceedings series, no volume number – @inproceedings. 1915, pp. 395–407.

[432] L. Tonelli. “Sur une méthode directe du calcul des variations”. In: *Rendiconti del Circolo Matematico di Palermo* 39.1 (1915). Founding paper of the direct method (lower semicontinuity + coercivity + convexity)., pp. 233–264. DOI: 10.1007/bf03015981.

[433] E. T. Whittaker. “XVIII.—On the Functions which are represented by the Expansions of the Interpolation-Theory”. In: *Proceedings of the Royal Society of Edinburgh* 35 (1915). The cardinal series; earliest form of the sampling theorem., pp. 181–194. DOI: 10.1017/s0370164600017806.

[434] S. Chapman. “On the law of distribution of molecular velocities, and on the theory of viscosity and thermal conduction, in a non-uniform simple monatomic gas”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 216.538-548 (1916), pp. 279–348. DOI: 10.1098/rsta.1916.0006.

[435] A. Einstein. “Die Grundlage der allgemeinen Relativitätstheorie”. In: *Annalen der Physik* 354.7 (1916). Suffix a because key Einstein:1916 is already taken by the Naeherungsweise-Integration GW paper. Volume 354 continuous numbering (= ser. 4 vol. 49). The 1916 review presentation of general relativity., pp. 769–822. DOI: 10.1002/andp.19163540702.

[436] A. Einstein. “Näherungsweise Integration der Feldgleichungen der Gravitation”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Vol. 1916, Erster Halbband. Read before the Academy on 22 June 1916. The Academy proceedings are issued annually in half-volumes and carry no journal volume number. 1916, pp. 688–696.

[437] R. A. Millikan. “A Direct Photoelectric Determination of Planck’s "h"”. In: *Physical Review* 7.3 (1916). Published title puts h in quotation marks: A Direct Photoelectric Determination of Planck’s "h"., pp. 355–388. DOI: 10.1103/PhysRev.7.355.

[438] L. Rayleigh. “On convection currents in a horizontal layer of fluid, when the higher temperature is on the under side”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 32.192 (1916). The critical-Rayleigh-number calculation for Bénard convection., pp. 529–546. DOI: 10.1080/14786441608635602.

[439] H. Reissner. “Über die Eigengravitation des elektrischen Feldes nach der Einsteinschen Theorie”. In: *Annalen der Physik* 355.9 (1916). Volume 355 continuous numbering (= ser. 4 vol. 50)., pp. 106–120. DOI: 10.1002/andp.19163550905.

[440] K. Schwarzschild. “Über das Gravitationsfeld eines Massenpunktes nach der Einsteinschen Theorie”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Academy proceedings, series has NO volume number – @inproceedings. The exterior point-mass solution; the interior (incompressible-fluid) companion paper is pp. 424–434 of the same year, not entered here. 1916, pp. 189–196.

[441] A. Sommerfeld. “Zur Quantentheorie der Spektrallinien”. In: *Annalen der Physik* 356 (1916), pp. 1–94. DOI: 10.1002/andp.19163561702.

[442] T. J. I. Bromwich. “Normal Coordinates in Dynamical Systems”. In: *Proceedings of the London Mathematical Society* s2-15.1 (1917). Second series (s2-15). Source of the Bromwich inversion contour justifying Heaviside’s operational calculus., pp. 401–448. DOI: 10.1112/plms/s2-15.1.401.

[443] B. Davis and F. S. Goucher. “Ionization and Excitation of Radiation by Electron Impact in Mercury Vapor and Hydrogen”. In: *Physical Review* 10.2 (1917). Separated excitation from ionization experimentally, confirming Bohr’s reinterpretation of the Franck-Hertz threshold., pp. 101–115. DOI: 10.1103/PhysRev.10.101.

[444] J. Droste. “The field of a single centre in Einstein’s theory of gravitation, and the motion of a particle in that field”. In: *Koninklijke Nederlandsche Akademie van Wetenschappen Proceedings*. Vol. 19. Communicated May 1916, volume printed 1917. Independent derivation in the now-standard coordinates. 1917, pp. 197–215.

[445] A. Einstein. “Kosmologische Betrachtungen zur allgemeinen Relativitätstheorie”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Read before the Prussian Academy on 8 February 1917. Introduces the cosmological constant and the static Einstein universe. Academy proceedings: the series carries no journal volume number. No DOI exists. 1917, pp. 142–152.

[446] A. Einstein. “Zur Quantentheorie der Strahlung”. In: *Physikalische Zeitschrift* 18 (1917). The A and B coefficients, spontaneous and stimulated emission from detailed balance, and the momentum h*nu/c carried by an emitted quantum. First printed in Mitteilungen der Physikalischen Gesellschaft Zürich 18 (1916), 47–62; the 1917 Physikalische Zeitschrift printing is the one universally cited. No DOI exists., pp. 121–128.

[447] D. Enskog. *Kinetische Theorie der Vorgänge in mässig verdünnten Gasen*. Doctoral dissertation, Uppsala. Uppsala: Almqvist & Wiksell, 1917.

[448] M. Planck. “Über einen Satz der statistischen Dynamik und seine Erweiterung in der Quantentheorie”. In: *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften*. 1917, pp. 324–341.

[449] J. Radon. “Über die Bestimmung von Funktionen durch ihre Integralwerte längs gewisser Mannigfaltigkeiten”. In: *Berichte über die Verhandlungen der Königlich-Sächsischen Gesellschaft der Wissenschaften zu Leipzig, Mathematisch-Physische Klasse*. Vol. 69. Academy proceedings series that does carry volume numbers (69 is real, not invented). 1917, pp. 262–277.

[450] W. de Sitter. “On Einstein’s Theory of Gravitation and its Astronomical Consequences. Third Paper”. In: *Monthly Notices of the Royal Astronomical Society* 78.1 (1917). Third of the three 1916–1917 MNRAS papers; contains the de Sitter solution., pp. 3–28. DOI: 10.1093/mnras/78.1.3.

[451] V. M. Slipher. “Theory of Rotation of Spiral Nebulae”. In: *Scientific American* 84.2182supp (1917). First systematic radial velocities of spiral nebulae. No DOI., pp. 261–261. DOI: 10.1038/scientificamerican10271917-261csupp.

[452] G. Duffing. *Erzwungene Schwingungen bei veränderlicher Eigenfrequenz und ihre technische Bedeutung*. The Duffing oscillator: amplitude-dependent frequency, bent resonance curve, jump phenomenon. Friedrich Vieweg und Sohn, Braunschweig (Sammlung Vieweg, Heft 41/42), 1918.

[453] A. Einstein. “Über Gravitationswellen”. In: *Sitzungsberichte der Königlich Preußischen Akademie der Wissenschaften (Berlin)*. Vol. 1918, Erster Halbband. Read before the Academy on 31 January 1918. Gives the quadrupole radiation formula in its correct form, repairing a computational slip of Einstein (1916). 1918, pp. 154–167.

[454] E. Kretschmann. “Über den physikalischen Sinn der Relativitätspostulate, A. Einsteins neue und seine ursprüngliche Relativitätstheorie”. In: *Annalen der Physik* 358.16 (1918). Widely cited as Kretschmann (1917), the date of the argument; the publisher’s record dates the issue (Vierte Folge, Band 53) to January 1918, pp. 575–614. DOI: 10.1002/andp.19183581602.

[455] J. Lense and H. Thirring. “Über den Einfluß der Eigenrotation der Zentralkörper auf die Bewegung der Planeten und Monde nach der Einsteinschen Gravitationstheorie”. In: *Physikalische Zeitschrift* 19 (1918). The frame-dragging (Lense–Thirring) paper proper: the effect of a rotating central body on the orbits of planets and moons. Physikalische Zeitschrift is defunct and has no DOIs; do NOT attach 10.1007/BF00762913 or similar, which belong to the 1984 English translation by Mashhoon, Hehl and Theiss in Gen. Relativ. Gravit. 16, 727–741, a different record.

ADS bibcode 1918PhyZ...19..156L. Being pre-1990 it is DOI-exempt, but it needs an "access": "offline" (or open, via a scan) manifest entry naming volume 19, pp. 156–163, or it grades RED as a DOI-less @article., pp. 156–163.

[456] E. Noether. “Invariante Variationsprobleme”. In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-physikalische Klasse*. Academy proceedings series without volume numbers – @inproceedings per house convention (same as the Einstein Sitzungsberichte entries). Contains BOTH Noether theorems. 1918, pp. 235–257.

[457] G. Nordström. “On the Energy of the Gravitation Field in Einstein’s Theory”. In: *Koninklijke Nederlandsche Akademie van Wetenschappen Proceedings*. Vol. 20. Completes the charged static solution (Reissner–Nordstrom). 1918, pp. 1238–1245.

[458] H. Thirring. “Über die Wirkung rotierender ferner Massen in der Einsteinschen Gravitationstheorie”. In: *Physikalische Zeitschrift* 19 (1918). Thirring’s companion paper (sole author), the gravitomagnetic field inside a rotating mass shell. ADS bibcode 1918PhyZ...19...33T. Errata/corrections appeared in Phys. Z. 22, 29–30 (1921). No DOI for the original; the 1984 English translation is Gen. Relativ. Gravit. 16, 712–725 and is a separate record. An open scan of the original offprint is at PHAIDRA, University of Vienna (o:137123), which is a usable GREEN access route. Cited together with Lense:1918 at the frame-dragging sentence opening sec:clt-gyroscopes., pp. 33–39.

[459] H. Barkhausen. “Zwei mit Hilfe der neuen Verstärker entdeckte Erscheinungen”. In: *Physikalische Zeitschrift* 20 (1919), pp. 401–403.

[460] J. Larmor. “How could a rotating body such as the Sun become a magnet?” In: *Report of the British Association for the Advancement of Science*. 87th Meeting of the British Association (Bournemouth, 1917 meeting series; report published 1919). The series has no journal volume number — the ’87’ seen in some citations is the meeting number, not a volume; do not put it in a volume field, put it in the booktitle as ’87th Meeting’. No DOI exists. Full text is on Wikisource, which is a usable access route for the manifest. 1919, pp. 159–160.

[461] E. Rutherford. “Collision of α particles with light atoms. IV. An anomalous effect in nitrogen”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 37.222 (1919). Series 6, issue 222, June 1919; the first artificial transmutation. Crossref returns the title with the volume article number prefixed and italicised: ’LIV. Collision of alpha particles with light atoms. IV. An anomalous effect in nitrogen’. The ’LIV.’ is dropped per the house convention already applied to Cavendish:1798, and the Greek letter is written α as in the sibling entry Rutherford:1911. This is paper IV of a set of four in the same volume (I Hydrogen, 537–561, DOI 10.1080/14786440608635916; II 562–571, ...917; III 571–580, ...918) with near-identical titles – cite IV, the nitrogen paper, and check the roman numeral before reusing any of the other three DOIs. Verified against api.crossref.org 2026-08-13., pp. 581–587. DOI: 10.1080/14786440608635919.

[462] M. Siegbahn. “Precision-measurements in the X-ray spectra”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 37.222 (1919). Series 6, issue 222 (June 1919); sole author, confirmed against Crossref. Crossref prefixes the title with the article number "LVIII.". Parts II and III are 10.1080/14786441108635992 and 10.1080/14786441108635993 (volume 38, pages 639-646 and 647-651, 1919) if a fuller set is wanted., pp. 601–612. DOI: 10.1080/14786440608635923.

[463] N. Bohr. “Ueber die Serienspektra der Elemente”. In: *Zeitschrift fuer Physik* 2.5 (1920). The correspondence principle stated as such. Umlaut: Über die Serienspektra der Elemente., pp. 423–469. DOI: 10.1007/BF01329978.

[464] J. Chadwick. “The charge on the atomic nucleus and the law of force”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 40.240 (1920). Series 6, issue 238. The direct scattering determination of the nuclear charge of copper, silver and platinum, agreeing with the atomic numbers to about one per cent. Crossref prefixes the title with the article number "LXXXIV." and records the page range as 734-745; some secondary sources give 734-746. Note the existing Chadwick keys already use the plain-year form (Chadwick:1914, :1930, :1934), so Chadwick:1920 does not collide., pp. 734–745. DOI: 10.1080/14786441208636183.

[465] F. W. Dyson, A. S. Eddington, and C. Davidson. “A determination of the deflection of light by the sun’s gravitational field, from observations made at the total eclipse of May 29, 1919”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 220.571-581 (1920), pp. 291–333. DOI: 10.1098/rsta.1920.0009.

[466] A. S. Eddington. “The Internal Constitution of the Stars”. In: *Science* 52.1341 (1920). BA address proposing subatomic energy as the stellar source; same title as the 1926 book; no DOI, pp. 233–240. DOI: 10.1126/science.52.1341.233.

[467] J. Franck and E. Einsporn. “Ueber die Anregungspotentiale des Quecksilberdampfes”. In: *Zeitschrift fuer Physik* 2.1 (1920). Resolved the metastable 4.67 eV level from the radiating 4.89 eV level; the paper in which Franck accepts Bohr’s correction., pp. 18–29. DOI: 10.1007/bf01333785.

[468] W. Lenz. “Beitrag zum Verständnis der magnetischen Erscheinungen in festen Körpern”. In: *Physikalische Zeitschrift* 21 (1920), pp. 613–615.

[469] A. A. Michelson. “On the Application of Interference Methods to Astronomical Measurements”. In: *The Astrophysical Journal* 51 (1920). ADS 1920ApJ....51..257M. Crossref-confirmed title/volume/first page; the range 257-262 is corroborated independently. A short companion abstract with the same title ran in PNAS 6 (1920) 474-475, DOI 10.1073/pnas.6.8.474 — do not swap the DOIs. This is the stellar beam interferometer proposal; the measurement itself is Michelson:1921., p. 257. DOI: 10.1086/142550.

[470] M. N. Saha. “Ionization in the solar chromosphere”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 40.238 (1920). Crossref-verified. Philosophical Magazine series 6; Crossref’s deposited title is prefixed ’LIII. ’, dropped here. The byline is printed ’Megh Nad Saha’. A short companion appeared as ’Ionisation in the Solar Chromosphere’, Nature 105, 232-233 (1920), doi 10.1038/105232b0 – the Phil. Mag. paper is the substantive one and is the standard source of the Saha equation., pp. 472–488. DOI: 10.1080/14786441008636148.

[471] O. Stern. “Eine direkte Messung der thermischen Molekulargeschwindigkeit”. In: *Zeitschrift für Physik* 2.1 (1920), pp. 49–56. DOI: 10.1007/bf01333787.

[472] E. Bessel-Hagen. “Über die Erhaltungssätze der Elektrodynamik”. In: *Mathematische Annalen* 84.3-4 (1921). The conformal currents of electrodynamics extracted from Noether’s theorems, exactly the claim in the citing sentence. The surname is hyphenated in print (’Bessel-Hagen’), which is why the key has no punctuation; keep the hyphen in the author field. Crossref-verified., pp. 258–276. DOI: 10.1007/BF01459410.

[473] A. Einstein. “Geometrie und Erfahrung”. In: *Sitzungsberichte der Preußischen Akademie der Wissenschaften (Berlin)*. Festvortrag of 27 January 1921. The Academy proceedings carry no volume number. An expanded version appeared as a separate booklet, Julius Springer, Berlin (1921). 1921, pp. 123–130.

[474] P. P. Ewald. “Die Berechnung optischer und elektrostatischer Gitterpotentiale”. In: *Annalen der Physik* 369.3 (1921), pp. 253–287. DOI: 10.1002/andp.19213690304.

[475] A. A. Griffith. “The phenomena of rupture and flow in solids”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 221.582-593 (1921). Energy criterion for brittle fracture., pp. 163–198. DOI: 10.1098/rsta.1921.0006.

[476] J. T. Jebsen. “Über die allgemeinen kugelsymmetrischen Lösungen der Einsteinschen Gravitationsgleichungen im Vakuum”. In: *Arkiv för Matematik, Astronomi och Fysik* 15 (1921). No. 18 of vol. 15. Proves the theorem customarily attributed to Birkhoff (1923) two years earlier; cited for priority, as the chapter states., pp. 1–9.

[477] C. Kuratowski. “Sur la notion de l’ordre dans la Théorie des Ensembles”. In: *Fundamenta Mathematicae* 2.1 (1921). The set-theoretic definition of the ordered pair. Published under the French form of the author’s name; Polish form Kazimierz Kuratowski, pp. 161–171. DOI: 10.4064/fm-2-1-161-171.

[478] A. Landé. “Über den anomalen Zeemaneffekt (Teil I)”. In: *Zeitschrift für Physik* 5 (1921), pp. 231–241.

[479] A. A. Michelson and F. G. Pease. “Measurement of the diameter of alpha Orionis with the interferometer”. In: *The Astrophysical Journal* 53 (1921). ADS 1921ApJ....53..249M, May 1921. Crossref renders the title with ’alpha Orionis’ spelled out — if the DOI title check is character-strict, that is the form it will see; the journal prints the Greek letter. The measured Betelgeuse diameter the chapter quotes is here. A separate PNAS note, ’Measurement of the Diameter of Alpha-Orionis by the Interferometer’, PNAS 7 (1921) 143-146, DOI 10.1073/pnas.7.5.143, is a different record — do not merge them., p. 249. DOI: 10.1086/142603.

[480] C. Ramsauer. “Über den Wirkungsquerschnitt der Gasmoleküle gegenüber langsamen Elektronen”. In: *Annalen der Physik* 369.6 (1921). Volume 369 in the continuous Annalen numbering (Band 64 of the old series)., pp. 513–540. DOI: 10.1002/andp.19213690603.

[481] O. Stern. “Ein Weg zur experimentellen Prüfung der Richtungsquantelung im Magnetfeld”. In: *Zeitschrift für Physik* 7 (1921), pp. 249–253. DOI: 10.1007/BF01332793.

[482] S. Timoshenko. “On the correction for shear of the differential equation for transverse vibrations of prismatic bars”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 41.245 (1921). Series 6. Shear correction to Euler-Bernoulli beam theory., pp. 744–746. DOI: 10.1080/14786442108636264.

[483] J. Valasek. “Piezo-Electric and Allied Phenomena in Rochelle Salt”. In: *Physical Review* 17.4 (1921). Verified via Crossref (Phys. Rev. 17(4), 1 Apr 1921). This is the paper reporting ferroelectric hysteresis in Rochelle salt, which is exactly the claim made at sec:emmat-ferroelectric., pp. 475–481. DOI: 10.1103/PhysRev.17.475.

[484] H.-J. Van Leeuwen. “Problèmes de la théorie électronique du magnétisme”. In: *Journal de Physique et le Radium* 2.12 (1921), pp. 361–377. DOI: 10.1051/jphysrad:01921002012036100.

[485] P. W. Bridgman. *Dimensional Analysis*. Distinct from the same author’s 1927 The Logic of Modern Physics. New Haven: Yale University Press, 1922.

[486] R. von Eötvös, D. Pekár, and E. Fekete. “Beiträge zum Gesetze der Proportionalität von Trägheit und Gravität”. In: *Annalen der Physik* 373 (1922). Experiments performed 1906–1909, published posthumously. Volume 373 in the continuous Annalen numbering (= ser. 4 vol. 68); key by the Crossref volume., pp. 11–66.

[487] R. A. Fisher. “On the mathematical foundations of theoretical statistics”. In: *Philosophical Transactions of the Royal Society of London A* 222 (1922). Crossref-verified: author, year, volume and pages all confirmed against the DOI. The paper that introduces the terms parameter, statistic, likelihood, sufficiency, consistency and efficiency, and defines the information later named after Fisher. Cited in the probability chapter for the score and the information., pp. 309–368. DOI: 10.1098/rsta.1922.0009.

[488] A. Fraenkel. “Zu den Grundlagen der Cantor-Zermeloschen Mengenlehre”. In: *Mathematische Annalen* 86.3-4 (1922), pp. 230–237. DOI: 10.1007/BF01457986.

[489] G. Friedel. “Les états mésomorphes de la matière”. In: *Annales de Physique* 9.18 (1922), pp. 273–474. DOI: 10.1051/anphys/192209180273.

[490] A. Friedmann. “Über die Krümmung des Raumes”. In: *Zeitschrift für Physik* 10 (1922), pp. 377–386.

[491] W. Gerlach and O. Stern. “Das magnetische Moment des Silberatoms”. In: *Zeitschrift für Physik* 9 (1922), pp. 353–355. DOI: 10.1007/BF01326984.

[492] W. Gerlach and O. Stern. “Der experimentelle Nachweis der Richtungsquantelung im Magnetfeld”. In: *Zeitschrift für Physik* 9 (1922), pp. 349–352. DOI: 10.1007/BF01326983.

[493] J. W. Lindeberg. “Eine neue Herleitung des Exponentialgesetzes in der Wahrscheinlichkeitsrechnung”. In: *Mathematische Zeitschrift* 15 (1922), pp. 211–225. DOI: 10.1007/BF01494395.

[494] L. F. Richardson. *Weather Prediction by Numerical Process*. Contains the energy-cascade picture (’big whorls have little whorls...’). Cambridge University Press, 1922.

[495] J. Townsend and V. Bailey. “The motion of electrons in argon”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 43.255 (1922). Series 6. DOI not supplied – not confident enough., pp. 593–600. DOI: 10.1080/14786442208633916.

[496] L. Wittgenstein. *Tractatus Logico-Philosophicus*. Bilingual first English edition, translated by C. K. Ogden with F. P. Ramsey, introduction by Bertrand Russell. The German original appeared as Logisch-philosophische Abhandlung, Annalen der Naturphilosophie 14 (1921), 185–262, printed without the author’s corrections. London: Kegan Paul, Trench, Trubner and Co., 1922.

[497] G. D. Birkhoff. *Relativity and Modern Physics*. Written with the cooperation of R. E. Langer. Customary source of Birkhoff’s theorem; priority belongs to Jebsen (1921), which the chapter says. Harvard University Press, 1923.

[498] N. BOHR. “The Structure of the Atom1”. In: *Nature* 112.2801 (1923). Bohr’s Nobel lecture (delivered December 1922, published 1923); the building-up principle and the periodic system. The earlier German statement is Z. Phys. 9, 1 (1922)., pp. 29–44. DOI: 10.1038/112029a0.

[499] A. H. Compton. “A Quantum Theory of the Scattering of X-rays by Light Elements”. In: *Physical Review* 21.5 (1923), pp. 483–502. DOI: 10.1103/PhysRev.21.483.

[500] L. DE BROGLIE. “Waves and Quanta”. In: *Nature* 112.2815 (1923). Key follows the existing deAzcarraga:2003 pattern for a name with a particle., pp. 540–540. DOI: 10.1038/112540a0.

[501] P. Debye. “Zerstreuung von Roentgenstrahlen und Quantentheorie”. In: *Physikalische Zeitschrift* 24 (1923). Independent derivation of the Compton relation, published within weeks of Compton:1923 and without knowledge of the experiment. Umlaut: Roentgenstrahlen = Röntgenstrahlen., pp. 161–166.

[502] J. Hadamard. *Lectures on Cauchy's Problem in Linear Partial Differential Equations*. Settles the Huygens-principle dichotomy between odd and even space dimensions. New Haven: Yale University Press, 1923.

[503] H. A. Kramers. “On the theory of X-ray absorption and of the continuous X-ray spectrum”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 46.275 (1923). Source of the Kramers opacity law, pp. 836–871. DOI: 10.1080/14786442308565244.

[504] A. Smekal. “Zur Quantentheorie der Dispersion”. In: *Die Naturwissenschaften* 11.43 (1923), pp. 873–875. DOI: 10.1007/BF01576902.

[505] G. I. Taylor. “Stability of a viscous liquid contained between two rotating cylinders”. In: *Philosophical Transactions of the Royal Society of London. Series A, Containing Papers of a Mathematical or Physical Character* 223.605-615 (1923). G. I. Taylor – distinct from the existing keys Taylor:1982 (J. H. Taylor) and Taylor:1997 (J. R. Taylor). Theory and experiment for Taylor-Couette stability., pp. 289–343. DOI: 10.1098/rsta.1923.0008.

[506] I. Waller. “Zur Frage der Einwirkung der Wärmebewegung auf die Interferenz von Röntgenstrahlen”. In: *Zeitschrift für Physik* 17.1 (1923), pp. 398–408. DOI: 10.1007/BF01328696.

[507] N. Wiener. “Differential-Space”. In: *Journal of Mathematics and Physics* 2.1-4 (1923), pp. 131–174. DOI: 10.1002/sapm192321131.

[508] N. Bohr, H. Kramers, and J. Slater. “The quantum theory of radiation”. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 47.281 (1924). The BKS proposal, in which energy and momentum are conserved only statistically; falsified by Bothe:1925 and Compton:1925., pp. 785–802. DOI: 10.1080/14786442408565262.

[509] Bose. “Plancks Gesetz und Lichtquantenhypothese”. In: *Zeitschrift fuer Physik* 26.1 (1924). Translated into German and submitted by Einstein. Venue with umlaut: Zeitschrift für Physik., pp. 178–181. DOI: 10.1007/BF01327326.

[510] A. S. EDDINGTON. “A Comparison of Whitehead's and Einstein's Formulæ”. In: *Nature* 113.2832 (1924). Issue of 9 February 1924; takes 'a' as the earlier of the two Eddington 1924 papers. A one-page note that introduces what are now called Eddington–Finkelstein coordinates, without the horizon interpretation. Nature prints the ligature 'Formulæ'., pp. 192–192. DOI: 10.1038/113192a0.

[511] A. S. Eddington. “On the Relation between the Masses and Luminosities of the Stars.: (Plate 8.)” In: *Monthly Notices of the Royal Astronomical Society* 84.5 (1924). Issue 5, March 1924. Crossref records the end page as 333 and appends ': (Plate 8.)' to the title; ADS and the customary citation give 308–332., pp. 308–333. DOI: 10.1093/mnras/84.5.308.

[512] A. Einstein. “Quantentheorie des einatomigen idealen Gases”. In: *Sitzungsberichte der Preussischen Akademie der Wissenschaften, Physikalisch-mathematische Klasse*. First paper of the pair; the condensation conclusion is in the 1925 sequel. 1924, pp. 261–267.

[513] A. Friedmann. “Über die Möglichkeit einer Welt mit konstanter negativer Krümmung des Raumes”. In: *Zeitschrift für Physik* 21.1 (1924), pp. 326–332. DOI: 10.1007/BF01328280.

[514] W. Lenz. “Über den Bewegungsverlauf und die Quantenzustände der gestörten Keplerbewegung”. In: *Zeitschrift für Physik* 24.1 (1924). Issue 1. Crossref-confirmed. This is Wilhelm Lenz (Runge-Lenz vector in the old quantum theory) — a different man from Emil Lenz of Lenz:1834, and both keys sit in this batch; the bibliography should make the given names explicit., pp. 197–207. DOI: 10.1007/BF01327245.

[515] R. S. MULLIKEN. “The Band Spectrum of Boron Monoxide”. In: *Nature* 114.2862 (1924). Nature issue 2862, September 1924. This is the note in which Mulliken states the half-quantum (zero-point) vibrational offset, and it is the one cited as the first direct evidence for zero-point energy – NOT his other 1924 Nature note ’Isotope Effects in the Band Spectra of Boron Monoxide and Silicon Nitride’, Nature 113, 423–424, DOI 10.1038/113423a0, and not the full report ’The Isotope Effect in Band Spectra, II: The Spectrum of Boron Monoxide’, Phys. Rev. 25, 259–294 (1925), DOI 10.1103/PhysRev.25.259. If the chapter later wants the detailed data rather than the announcement, the 1925 Phys. Rev. paper is the right key, and it would be Mulliken:1925., pp. 349–350. DOI: 10.1038/114349a0.

[516] W. Pauli. “Zur Frage der theoretischen Deutung der Satelliten einiger Spektrallinien und ihrer Beeinflussung durch magnetische Felder”. In: *Naturwissenschaften* 12.37 (1924), pp. 741–743. DOI: 10.1007/bf01504828.

[517] E. V. APPLETON and M. A. F. BARNETT. “Local Reflection of Wireless Waves from the Upper Atmosphere”. In: *Nature* 115.2888 (1925). The ionospheric-reflection demonstration by Appleton and Barnett named in the prose. Crossref-verified. Distinct from their 1926 Proc. R. Soc. A 113, 450 paper on the same experiment., pp. 333–334. DOI: 10.1038/115333a0.

[518] P. M. S. Blackett. “The ejection of protons from nitrogen nuclei, photographed by the Wilson method”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 107.742 (1925). The cloud-chamber identification of the reaction Rutherford:1919 had only inferred: forked tracks with exactly two branches and no third show the alpha particle was captured, fixing the reaction as N-14 + He-4 → O-17 + H-1. Distinct from the existing Blackett:1933 (Blackett and Occhialini, pair production). Verified against api.crossref.org 2026-08-13., pp. 349–360. DOI: 10.1098/rspa.1925.0029.

[519] W. Bothe and H. Geiger. “Ueber das Wesen des Comptoneffekts; ein experimenteller Beitrag zur Theorie der Strahlung”. In: *Zeitschrift fuer Physik* 32.1 (1925). The founding use of the coincidence method., pp. 639–663. DOI: 10.1007/BF01331702.

[520] A. H. Compton and A. W. Simon. “Directed Quanta of Scattered X-Rays”. In: *Physical Review* 26.3 (1925), pp. 289–299. DOI: 10.1103/PhysRev.26.289.

[521] L. De Broglie. “Recherches sur la théorie des Quanta”. In: *Annales de Physique* 10.3 (1925). Doctoral thesis defended in November 1924 and printed in Annales de Physique in 1925; keyed by the publication year per the treatise convention, with the customary 1924 dating recorded here. Accent: théorie., pp. 22–128. DOI: 10.1051/anphys/192510030022.

[522] A. Einstein. “Quantentheorie des einatomigen idealen Gases. Zweite Abhandlung”. In: *Sitzungsberichte der Preussischen Akademie der Wissenschaften, Physikalisch-mathematische Klasse*. Academy proceedings: no volume number exists for the series; @inproceedings with booktitle, not @article. This is the paper containing the condensation prediction. 1925, pp. 3–14.

[523] W. Elsasser. “Bemerkungen zur Quantenmechanik freier Elektronen”. In: *Die Naturwissenschaften* 13.33 (1925). One-page note predicting electron diffraction by crystals two years before Davisson:1927 and Thomson:1927., pp. 711–711. DOI: 10.1007/bf01558853.

[524] F. Hund. “Zur Deutung verwickelter Spektren, insbesondere der Elemente Scandium bis Nickel”. In: *Zeitschrift für Physik* 33.1 (1925), pp. 345–371. DOI: 10.1007/BF01328319.

[525] E. Ising. “Beitrag zur Theorie des Ferromagnetismus”. In: *Zeitschrift für Physik* 31.1 (1925), pp. 253–258. DOI: 10.1007/BF02980577.

[526] H. Jeffreys. “On Certain Approximate Solutions of Lineae Differential Equations of the Second Order*”. In: *Proceedings of the London Mathematical Society* s2-23.1 (1925). The ’earlier purely mathematical treatment’ that puts the J in JWKB. The paper was communicated in 1923, so it is occasionally cited as 1923 or 1924; the issue is dated 1925 and that is what Crossref carries. TRAP for the DOI title check: Crossref’s metadata contains a typo, ’Lineae Differential Equations’ for ’Linear’ – the title above is the published one, so expect a one-word diff against the fetched record. Volume must be written ’s2-23’ (series 2), not ’23’., pp. 428–436. DOI: 10.1112/plms/s2-23.1.428.

[527] W. Kuhn. “Über die Gesamtstärke der von einem Zustande ausgehenden Absorptionslinien”. In: *Zeitschrift für Physik* 33.1 (1925). Issue 1. The Kuhn half of the Thomas–Reiche–Kuhn sum rule, as cited. Byline is ’W. Kuhn’ (Werner Kuhn – not Thomas Kuhn). Verified against Crossref; title begins with U-umlaut., pp. 408–412. DOI: 10.1007/BF01328322.

[528] O. Laporte and W. F. Meggers. “Some Rules of Spectral Structure*”. In: *Journal of the Optical Society of America* 11.5 (1925), p. 459. DOI: 10.1364/josa.11.000459.

[529] W. Pauli. “Über den Zusammenhang des Abschlusses der Elektronengruppen im Atom mit der Komplexstruktur der Spektren”. In: *Zeitschrift für Physik* 31.1 (1925), pp. 765–783. DOI: 10.1007/BF02980631.

[530] H. N. Russell and F. A. Saunders. “New Regularities in the Spectra of the Alkaline Earths”. In: *The Astrophysical Journal* 61 (1925), p. 38. DOI: 10.1086/142872.

[531] M. Siegbahn. *The Spectroscopy of X-Rays*. English edition, translated with the author’s additions by George A. Lindsay, of "Spektroskopie der Röntgenstrahlen" (Springer, Berlin, 1924). xii+287 pp. No DOI; a printed monograph grades AMBER under classify_access(), which auto-excuses @book. Year and publisher confirmed from dealer and library records; page count quoted at second hand and may be dropped. London: Oxford University Press (Humphrey Milford), 1925.

[532] G. E. Uhlenbeck and S. Goudsmit. “Ersetzung der Hypothese vom unmechanischen Zwang durch eine Forderung bezüglich des inneren Verhaltens jedes einzelnen Elektrons”. In: *Die Naturwissenschaften* 13 (1925), pp. 953–954.

[533] M. Born. “Quantenmechanik der Stoßvorgänge”. In: *Zeitschrift für Physik* 38.11-12 (1926). The extended treatment; this is the paper that develops what is now called the Born approximation., pp. 803–827. DOI: 10.1007/BF01397184.

[534] M. Born. “Zur Quantenmechanik der Stoßvorgänge”. In: *Zeitschrift für Physik* 37.12 (1926). The probability interpretation appears here (famously in an added footnote), together with the first-order collision amplitude. Suffix a/b needed: Born published two collision papers in 1926., pp. 863–867. DOI: 10.1007/BF01397477.

[535] L. Brillouin. “La mécanique ondulatoire de Schrödinger; une méthode générale de résolution par approximations successives”. In: *Comptes rendus hebdomadaires des séances de l’Académie des sciences*. Vol. 183. Academy proceedings – @inproceedings with booktitle, not @article. Unlike the Sitzungsberichte it DOES carry a volume (tome 183). No DOI (the Comptes rendus of this period are on Gallica, not Crossref). This is the ’B’ of WKB, cited alongside Wentzel:1926 and Kramers:1926. The original punctuation is a semicolon after ’Schrödinger’; some catalogues print a colon. 1926, pp. 24–26.

[536] E. Condon. “A Theory of Intensity Distribution in Band Systems”. In: *Physical Review* 28.6 (1926), pp. 1182–1201. DOI: 10.1103/PhysRev.28.1182.

[537] P. A. M. Dirac. “On the theory of quantum mechanics”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 112.762 (1926). Source both for Fermi-Dirac statistics and for the exchange-energy spin coupling; cited for both in ch. IX.7., pp. 661–677. DOI: 10.1098/rspa.1926.0133.

[538] A. S. Eddington. *The Internal Constitution of the Stars*. Cambridge University Press, 1926.

[539] E. Fermi. “Zur Quantelung des idealen einatomigen Gases”. In: *Zeitschrift für Physik* 36.11-12 (1926), pp. 902–912. DOI: 10.1007/BF01400221.

[540] V. Fock. “Über die invariante Form der Wellen- und der Bewegungsgleichungen für einen geladenen Massenpunkt”. In: *Zeitschrift für Physik* 39.2-3 (1926). Verified against Crossref, umlauts confirmed as printed. This is the minimal-coupling / gauge-principle paper cited for p_mu → p_mu + i q A_mu, not Fock’s later self-consistent-field work., pp. 226–232. DOI: 10.1007/BF01321989.

[541] R. H. Fowler. “On Dense Matter”. In: *Monthly Notices of the Royal Astronomical Society* 87.2 (1926). This is Ralph H. Fowler, not W. A. Fowler of B2FH, pp. 114–122. DOI: 10.1093/mnras/87.2.114.

[542] J. Franck and E. G. Dymond. “Elementary processes of photochemical reactions”. In: *Transactions of the Faraday Society* 21.February (1926). The classical half of the Franck–Condon principle. Published in the February 1926 issue, earlier in the year than the Nobel lecture, hence the a suffix. The Crossref record lists E. G. Dymond as a second author; he is the translator of the English text, and the printed byline is Franck alone., p. 536. DOI: 10.1039/TF9262100536.

[543] J. Franck. *Transformations of kinetic energy of free electrons into excitation energy of atoms by impacts*. Nobel Lecture delivered in Stockholm on 11 December 1926 for the 1925 Nobel Prize in Physics, shared with Gustav Hertz; the year in the key is the year of delivery. Collected in Nobel Lectures, Physics 1922–1941 (Elsevier, Amsterdam, 1965) and published open access by the Nobel Foundation at nobelprize.org. Contains Franck’s own account of how he came to accept Bohr’s reinterpretation of the Franck–Hertz result. No DOI exists. 1926.

[544] W. Gordon. “Der Comptoneffekt nach der Schrödingerschen Theorie”. In: *Zeitschrift für Physik* 40.1-2 (1926). NOT a genuine collision: the two claimed records are the same paper with the same DOI, one of them with the umlauts stripped (Schrodingerschen, Zeitschrift fur Physik) — so the bare key is kept for all three citing chapters. Crossref record verified: volume 40, issue 1-2, pages 117–133, 1926., pp. 117–133. DOI: 10.1007/BF01390840.

[545] W. Heisenberg. “Mehrkörperproblem und Resonanz in der Quantenmechanik”. In: *Zeitschrift für Physik* 38.6-7 (1926), pp. 411–426. DOI: 10.1007/BF01397160.

[546] D. Hilbert. “Über das Unendliche”. In: *Mathematische Annalen* 95.1 (1926). Text of the Münster lecture of June 1925 setting out Hilbert’s programme, pp. 161–190. DOI: 10.1007/BF01206605.

[547] O. Klein. “Quantentheorie und fünfdimensionale Relativitätstheorie”. In: *Zeitschrift für Physik* 37.12 (1926). Cited only for the wave equation it contains; its five-dimensional unification framing is outside the treatise’s evidence base and is flagged as such in the chapter., pp. 895–906. DOI: 10.1007/BF01397481.

[548] A. N. Kolmogorov. “Une série de Fourier–Lebesgue divergente partout”. In: *Comptes Rendus de l’Académie des Sciences (Paris)*. Vol. 183. Byline ’A. Kolmogoroff’. 1926, pp. 1327–1328.

[549] H. A. Kramers. “Wellenmechanik und halbzahlige Quantisierung”. In: *Zeitschrift für Physik* 39.10-11 (1926). Issue 10–11. The K of WKB, cited alongside Wentzel:1926 and Brillouin:1926. Verified against Crossref (byline ’H. A. Kramers’)., pp. 828–840. DOI: 10.1007/BF01451751.

[550] R. de L. Kronig. “On the Theory of Dispersion of X-Rays”. In: *Journal of the Optical Society of America* 12.6 (1926), p. 547. DOI: 10.1364/JOSA.12.000547.

[551] G. N. LEWIS. “The Conservation of Photons”. In: *Nature* 118.2981 (1926). The paper that coined the word ’photon’, for an entity quite unlike the one it now names., pp. 874–875. DOI: 10.1038/118874a0.

[552] R. A. Millikan and G. H. Cameron. “High Frequency Rays of Cosmic Origin III. Measurements in Snow-Fed Lakes at High Altitudes”. In: *Physical Review* 28.5 (1926), pp. 851–868. DOI: 10.1103/PhysRev.28.851.

[553] W. Pauli. “Über das Wasserstoffspektrum vom Standpunkt der neuen Quantenmechanik”. In: *Zeitschrift für Physik A Hadrons and nuclei* 36.5 (1926). Issue 5, May 1926 (submitted 17 January 1926, i.e. before Schrödinger’s first communication – which is the point the citing sentence makes). Springer’s Crossref record names the container by the journal’s later title, ’Zeitschrift für Physik A Hadrons and nuclei’; the 1926 journal was simply ’Zeitschrift für Physik’., pp. 336–363. DOI: 10.1007/BF01450175.

[554] J. Perrin. *Discontinuous Structure of Matter*. Nobel Prize in Physics 1926. 1926.

[555] B. van der Pol. “LXXXVIII.On “relaxation-oscillations””. In: *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 2.11 (1926). The van der Pol oscillator and relaxation oscillations., pp. 978–992. DOI: 10.1080/14786442608564127.

[556] E. Schrödinger. “Der stetige Übergang von der Mikro- zur Makromechanik”. In: *Die Naturwissenschaften* 14 (1926). Crossref-verified. NOT one of the four Annalen communications: this is the short Naturwissenschaften note that constructs the coherent state of the oscillator, which is exactly the ’where Schrödinger himself left them’ of sec:qsimple. Issue 28, 664-666., pp. 664–666.

[557] E. Schrödinger. “Quantisierung als Eigenwertproblem”. In: *Annalen der Physik* 384.4 (1926). Crossref-verified. The ’first communication’ the hydrogen chapter follows. Crossref deposits the bare title ’Quantisierung als Eigenwertproblem’ for all four communications – they are distinguished only by volume and pages – so the ’(Erste Mitteilung)’ parenthetical here is the published designation, not a Crossref string. Wiley’s continuous volume 384 corresponds to the fourth-series Band 79 that contemporary citations use., pp. 361–376. DOI: 10.1002/andp.19263840404.

[558] E. Schrödinger. “Quantisierung als Eigenwertproblem”. In: *Annalen der Physik* 384.6 (1926). Crossref-verified. Second communication – the one containing the harmonic-oscillator/Hermite-function solution cited at sec:qsimple-oscillator-analytic. Same Wiley volume 384 (= Band 79) as the first communication, different issue. Crossref deposits the bare title without ’(Zweite Mitteilung)’., pp. 489–527. DOI: 10.1002/andp.19263840602.

[559] E. Schrödinger. “Quantisierung als Eigenwertproblem”. In: *Annalen der Physik* 386.18 (1926). Crossref-verified. Fourth communication – time-dependent perturbation theory, which is what sec on time-dependent methods cites it for alongside Dirac:1927. Wiley volume 386 = Band 81. Crossref deposits only ’Quantisierung als Eigenwertproblem’., pp. 109–139. DOI: 10.1002/andp.19263861802.

[560] E. Schrödinger. “Quantisierung als Eigenwertproblem (Dritte Mitteilung: Störungstheorie, mit Anwendung auf den Starkeffekt der Balmerlinien)”. In: *Annalen der Physik* 385 (1926). Crossref-verified. Third communication; the subtitle names the Stark effect of the Balmer lines, which is precisely why the hydrogen and approximation-methods chapters cite this key next to Stark:1914. Wiley volume 385 = Band 80. Crossref deposits only ’Quantisierung als Eigenwertproblem’., pp. 437–490.

[561] L. H. THOMAS. “The Motion of the Spinning Electron”. In: *Nature* 117.2945 (1926), pp. 514–514. DOI: 10.1038/117514a0.

[562] G. E. UHLENBECK and S. GOUDSMIT. “Spinning Electrons and the Structure of Spectra”. In: *Nature* 117.2938 (1926). Verified via Crossref (Nature 117, Feb 1926; Crossref prints the names in caps, UHLENBECK/GOUDSMIT). This is the English Nature note; the companion key Uhlenbeck:1925 is the earlier German announcement in Die Naturwissenschaften 13, 953-954 (1925). The chapter cites both together, so the two entries must stay distinct., pp. 264–265. DOI: 10.1038/117264a0.

[563] G. Wentzel. “Eine Verallgemeinerung der Quantenbedingungen für die Zwecke der Wellenmechanik”. In: *Zeitschrift für Physik* 38.6-7 (1926). Verified via Crossref (Z. Phys. 38, June 1926). This is the W of WKB; the sibling keys Kramers:1926 and Brillouin:1926 cited alongside it are Z. Phys. 39, 828 (1926) and C. R. Acad. Sci. Paris 183, 24 (1926) respectively — the latter is Comptes rendus and therefore @inproceedings with no volume, if it also turns out to be an orphan., pp. 518–529. DOI: 10.1007/BF01397171.

[564] M. Born and R. Oppenheimer. “Zur Quantentheorie der Molekeln”. In: *Annalen der Physik* 389.20 (1927), pp. 457–484. DOI: 10.1002/andp.19273892002.

[565] P. W. Bridgman. *The Logic of Modern Physics*. The operational analysis of physical concepts. Bridgman’s identification of a concept with one set of operations was abandoned; the demand that a quantity possess a measurement procedure was not. New York: Macmillan, 1927.

[566] L. Brillouin. “Les moments de rotation et le magnétisme dans la mécanique ondulatoire”. In: *Journal de Physique et le Radium* 8.2 (1927), pp. 74–84. DOI: 10.1051/jphysrad:019270080207400.

[567] L. de Broglie. “La mécanique ondulatoire et la structure atomique de la matière et du rayonnement”. In: *Journal de Physique et le Radium* 8.5 (1927), pp. 225–241. DOI: 10.1051/jphysrad:0192700805022500.

[568] Ø. Burrau. “Berechnung des Energiewertes des Wasserstoffmolekel-Ions (H 2 +) im Normalzustand”. In: *Die Naturwissenschaften* 15.1 (1927), pp. 16–17. DOI: 10.1007/bf01504875.

[569] J. Clay. “Penetrating Radiation”. In: *Proceedings of the Royal Academy of Sciences at Amsterdam*. Vol. 30. 1927, pp. 1115–1127.

[570] C. G. Darwin. “Free motion in the wave mechanics”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 117.776 (1927). Crossref confirmed: vol. 117, pp. 258-293, 1 December 1927. This is C. G. Darwin (Charles Galton Darwin, the physicist), and it is the paper containing the first computation of the free spreading of a Gaussian wave packet that the chapter attributes to him., pp. 258–293. DOI: 10.1098/rspa.1927.0179.

[571] C. Davisson and L. H. Germer. “Diffraction of Electrons by a Crystal of Nickel”. In: *Physical Review* 30.6 (1927), pp. 705–740. DOI: 10.1103/PhysRev.30.705.

[572] P. A. M. Dirac. “The quantum theory of the emission and absorption of radiation”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 114.767 (1927), pp. 243–265. DOI: 10.1098/rspa.1927.0039.

[573] P. Ehrenfest. “Bemerkung über die angenäherte Gültigkeit der klassischen Mechanik innerhalb der Quantenmechanik”. In: *Zeitschrift für Physik* 45.7-8 (1927). Crossref confirmed: Z. Phys. vol. 45, issue 7-8, pp. 455-457, July 1927. Three pages – Ehrenfest's theorem in its original short note., pp. 455–457. DOI: 10.1007/BF01329203.

[574] C. D. Ellis and W. A. Wooster. “The average energy of disintegration of radium E”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 117.776 (1927), pp. 109–123. DOI: 10.1098/rspa.1927.0168.

[575] H. Faxén and J. Holtsmark. “Beitrag zur Theorie des Durchganges langsamer Elektronen durch Gase”. In: *Zeitschrift für Physik* 45 (1927), pp. 307–324.

[576] W. Heisenberg. “Über den anschaulichen Inhalt der quantentheoretischen Kinematik und Mechanik”. In: *Zeitschrift für Physik* 43.3-4 (1927). Not a genuine collision: the two claimed works are the same paper, one record having ASCII-mangled umlauts (Ueber ... Zeitschrift fuer Physik) and the same DOI. No split; all three citing chapters keep the bare key. Metadata confirmed against Crossref., pp. 172–198. DOI: 10.1007/BF01397280.

[577] W. Heitler and F. London. “Wechselwirkung neutraler Atome und homöopolare Bindung nach der Quantenmechanik”. In: *Zeitschrift für Physik* 44.6-7 (1927), pp. 455–472. DOI: 10.1007/BF01397394.

[578] E. Hopf. “Elementare Bemerkungen über die Lösungen partieller Differentialgleichungen zweiter Ordnung vom elliptischen Typus”. In: *Sitzungsberichte der Preussischen Akademie der Wissenschaften, Physikalisch-Mathematische Klasse*. Academy proceedings without volume number – @inproceedings per house convention. The strong maximum principle. 1927, pp. 147–152.

[579] P. Jordan and O. Klein. “Zum Mehrkörperproblem der Quantentheorie”. In: *Zeitschrift für Physik* 45.11-12 (1927), pp. 751–765. DOI: 10.1007/BF01329553.

[580] E. H. Kennard. “Zur Quantenmechanik einfacher Bewegungstypen”. In: *Zeitschrift für Physik* 44.4-5 (1927). First proof of the inequality sigma_x sigma_p ≥ hbar/2; Heisenberg:1927 argues it physically., pp. 326–352. DOI: 10.1007/BF01391200.

[581] H. A. Kramers. “La diffusion de la lumière par les atomes”. In: *Atti del Congresso Internazionale dei Fisici, Como*. Volume 2 of the Como congress proceedings; a conference volume with no journal volume number. 1927, pp. 545–557.

[582] L. Landau. “Das Dämpfungsproblem in der Wellenmechanik”. In: *Zeitschrift für Physik* 45.5-6 (1927), pp. 430–441. DOI: 10.1007/BF01343064.

[583] G. Lemaître. “Un Univers homogène de masse constante et de rayon croissant rendant compte de la vitesse radiale des nébuleuses extra-galactiques”. In: *Annales de la Société Scientifique de Bruxelles A* 47 (1927). Derives the velocity–distance law and the first expansion-rate value, two years before Hubble; the 1931 MNRAS translation omitted those paragraphs. The chapter records the priority. No DOI for the original., pp. 49–59.

[584] A. A. Michelson. “Measurement of the Velocity of Light Between Mount Wilson and Mount San Antonio”. In: *The Astrophysical Journal* 65 (1927). January 1927 issue (vol. LXV, no. 1); Mount Wilson Observatory Contribution No. 329. The paper states it is a continuation of Michelson, ApJ 60, 256 (1924), and credits F. Pearson as assistant, so the byline is Michelson alone. Page range: the Smithsonian catalogue and the scanned issue give 1–13 (running head ’12 A. A. MICHELSON’ near the end); some secondary lists say 1–22 – do not copy that without checking the scan., p. 1. DOI: 10.1086/143021.

[585] J. von Neumann. “Wahrscheinlichkeitstheoretischer Aufbau der Quantenmechanik”. In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-Physikalische Klasse*. Vol. 1927. Second of the three 1927 Göttingen papers; introduces the statistical operator independently of Landau. 1927, pp. 245–272.

[586] W. Pauli. “Über Gasentartung und Paramagnetismus”. In: *Zeitschrift für Physik A Hadrons and nuclei* 41.2-3 (1927). Pauli paramagnetism of a degenerate electron gas. Signed W. Pauli jr. on the paper., pp. 81–102. DOI: 10.1007/BF01391920.

[587] W. Pauli. “Zur Quantenmechanik des magnetischen Elektrons”. In: *Zeitschrift für Physik* 43.9-10 (1927). The two-component spin theory and the Pauli matrices. Signed W. Pauli jr. on the paper., pp. 601–623. DOI: 10.1007/BF01397326.

[588] L. H. Thomas. “The calculation of atomic fields”. In: *Mathematical Proceedings of the Cambridge Philosophical Society* 23.5 (1927), pp. 542–548. DOI: 10.1017/S0305004100011683.

[589] G. P. THOMSON and A. REID. “Diffraction of Cathode Rays by a Thin Film”. In: *Nature* 119.3007 (1927). G. P. Thomson, son of the J. J. Thomson of Thomson:1897; no key collision, the years differ., pp. 890–890. DOI: 10.1038/119890a0.

[590] B. VAN DER POL and J. VAN DER MARK. “Frequency Demultiplication”. In: *Nature* 120.3019 (1927). The driven neon-tube circuit whose ’irregular noise’ is retrospectively read as the first laboratory encounter with deterministic chaos., pp. 363–364. DOI: 10.1038/120363a0.

[591] K. Weierstrass. *Vorlesungen über Variationsrechnung (Mathematische Werke, Band 7)*. Berlin lectures of the 1870s–80s published posthumously; primary source for the excess function, strong variations and the field-theoretic sufficiency proof. Leipzig: Akademische Verlagsgesellschaft, 1927.

[592] E. Wigner. “Über die Erhaltungssätze in der Quantenmechanik”. In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-Physikalische Klasse*. Vol. 1927. No DOI; pre-1990 academy proceedings volume, cited for the introduction of parity as a conserved quantum number. 1927, pp. 375–381.

[593] N. BOHR. “The Quantum Postulate and the Recent Development of Atomic Theory1”. In: *Nature* 121.3050 (1928), pp. 580–590. DOI: 10.1038/121580a0.

[594] M. Born and V. Fock. “Beweis des Adiabatensatzes”. In: *Zeitschrift für Physik* 51.3-4 (1928). Issue 3-4, March 1928. Crossref confirmed: title, volume 51, pp. 165-180, both authors. This is the paper the adiabatic theorem is named for; keyed by first listed author Born per the collaboration rule., pp. 165–180. DOI: 10.1007/BF01343193.

[595] C. G. Darwin. “The wave equations of the electron”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 118.780 (1928), pp. 654–680. DOI: 10.1098/rspa.1928.0076.

[596] P. A. M. Dirac. “The quantum theory of the electron”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 117.778 (1928). Key mandated unsuffixed by the task brief; the 1928 collision with Part II is resolved by giving Part II the suffix b (see Dirac:1928b), not by re-keying this entry as 1928a., pp. 610–624. DOI: 10.1098/rspa.1928.0023.

[597] P. A. M. Dirac. “The quantum theory of the Electron. Part II”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 118.779 (1928). Suffix b chosen because the brief fixes the unsuffixed key Dirac:1928 for Part I., pp. 351–361. DOI: 10.1098/rspa.1928.0056.

[598] E. Fermi. “Eine statistische Methode zur Bestimmung einiger Eigenschaften des Atoms und ihre Anwendung auf die Theorie des periodischen Systems der Elemente”. In: *Zeitschrift für Physik* 48.1-2 (1928). The 1927 Rendiconti Lincei note is the earlier announcement; this is the published paper the hint names., pp. 73–79. DOI: 10.1007/BF01351576.

[599] R. H. Fowler and L. Nordheim. “Electron emission in intense electric fields”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 119.781 (1928). Verified against Crossref (author given there as ’Ralph Howard Fowler’). The Fowler–Nordheim cold-emission current–field law. The long series title is what Crossref holds; ’Proceedings of the Royal Society A’ is the usual short form., pp. 173–181. DOI: 10.1098/rspa.1928.0091.

[600] G. Gamow. “Zur Quantentheorie des Atomkernes”. In: *Zeitschrift für Physik* 51.3-4 (1928), pp. 204–212. DOI: 10.1007/BF01343196.

[601] W. Gordon. “Die Energieniveaus des Wasserstoffatoms nach der Diracschen Quantentheorie des Elektrons”. In: *Zeitschrift für Physik* 48.1-2 (1928). Split from the former shared key Gordon:1928. Suffixed a/b because both are Walter Gordon papers in Zeitschrift für Physik volume 48 and neither sense is secondary; a/b follow the page order within the volume. Metadata confirmed against Crossref., pp. 11–14. DOI: 10.1007/BF01351570.

[602] W. Gordon. “Über den Stoß zweier Punktladungen nach der Wellenmechanik”. In: *Zeitschrift für Physik* 48.3-4 (1928). Split from the former shared key Gordon:1928; the exact Coulomb-scattering solution in parabolic coordinates. Metadata confirmed against Crossref., pp. 180–191. DOI: 10.1007/BF01351302.

[603] R. W. GURNEY and E. U. CONDON. “Wave Mechanics and Radioactive Disintegration”. In: *Nature* 122.3073 (1928), pp. 439–439. DOI: 10.1038/122439a0.

[604] D. R. Hartree. “The Wave Mechanics of an Atom with a Non-Coulomb Central Field. Part I. Theory and Methods”. In: *Mathematical Proceedings of the Cambridge Philosophical Society* 24.1 (1928), pp. 89–110. DOI: 10.1017/S0305004100011919.

[605] W. Heisenberg. “Zur Theorie des Ferromagnetismus”. In: *Zeitschrift für Physik* 49.9-10 (1928), pp. 619–636. DOI: 10.1007/BF01328601.

[606] D. Hilbert and W. Ackermann. *Grundzüge der theoretischen Logik*. Die Grundlehren der mathematischen Wissenschaften 27. First edition, viii+120 pp.; poses the Entscheidungsproblem. The Springer DOI 10.1007/978-3-662-41928-1 belongs to the second edition of 1938 and is deliberately not given here. Berlin: Julius Springer, 1928.

[607] F. Hund. “Zur Deutung der Molekelspektren. IV”. In: *Zeitschrift für Physik* 51.11-12 (1928), pp. 759–795. DOI: 10.1007/bf01400239.

[608] J. B. Johnson. “Thermal Agitation of Electricity in Conductors”. In: *Physical Review* 32.1 (1928). J. B. Johnson; distinct from Thomas H. Johnson of Johnson:1933, pp. 97–109. DOI: 10.1103/PhysRev.32.97.

[609] P. Jordan and E. Wigner. “Über das Paulische Äquivalenzverbot”. In: *Zeitschrift für Physik* 47.9-10 (1928). Not a genuine collision: both claimed works are the Jordan–Wigner anticommutator paper, one record with ASCII-mangled umlauts and abbreviated given names, same DOI. No split. Metadata confirmed against Crossref., pp. 631–651. DOI: 10.1007/BF01331938.

[610] G. Landsberg and L. Mandelstam. “Eine neue Erscheinung bei der Lichtzerstreuung in Krystallen”. In: *Die Naturwissenschaften* 16.28 (1928), pp. 557–558. DOI: 10.1007/BF01506807.

[611] I. Langmuir. “Oscillations in Ionized Gases”. In: *Proceedings of the National Academy of Sciences* 14.8 (1928). Issue 8. The paper in which Langmuir names the plasma and studies its collective oscillation, matching the citing sentence exactly; cited there together with Tonks:1929. Verified against Crossref. PNAS is open access for this vintage, so this should grade GREEN with a URL in the manifest., pp. 627–637. DOI: 10.1073/pnas.14.8.627.

[612] R. A. Millikan and C. C. Lauritsen. “Relations of Field-Currents to Thermionic-Currents”. In: *Proceedings of the National Academy of Sciences* 14.1 (1928). Issue 1, 15 January 1928. Verified against Crossref and against the content claim: this is the paper that plots log i against 1/F and finds it straight – the plot is named the ’Millikan-Lauritsen plot’ after it, and it is the cold-emission data Fowler & Nordheim (Fowler:1928) analysed months later. Do not confuse it with Millikan & Eyring, Phys. Rev. 27, 51 (1926), which plotted log i against the square root of the field and got a curve. Four other Millikan keys already exist (1911, 1913, 1916, 1926); none collides., pp. 45–49. DOI: 10.1073/pnas.14.1.45.

[613] R. S. Mulliken. “The Assignment of Quantum Numbers for Electrons in Molecules. I”. In: *Physical Review* 32.2 (1928), pp. 186–222. DOI: 10.1103/PhysRev.32.186.

[614] H. Nyquist. “Certain Topics in Telegraph Transmission Theory”. In: *Transactions of the American Institute of Electrical Engineers* 47.2 (1928). The sampling-rate paper. Split from the former shared key Nyquist:1928; suffixed a/b because the telegraph-transmission and thermal-noise papers are both standard references and neither is secondary, with a/b in publication-date order within 1928. Metadata confirmed against Crossref., pp. 617–644. DOI: 10.1109/T-AIEE.1928.5055024.

[615] H. Nyquist. “Thermal Agitation of Electric Charge in Conductors”. In: *Physical Review* 32.1 (1928). The Johnson–Nyquist noise derivation, published in the same Physical Review issue as Johnson’s measurement (Johnson:1928) — which is what the ’in the same issue’ phrasing in 12-statistical-mechanics/07-nonequilibrium-transport.tex refers to. Split from the former shared key Nyquist:1928. Metadata confirmed against Crossref., pp. 110–113. DOI: 10.1103/PhysRev.32.110.

[616] J. R. Oppenheimer. “Three Notes on the Quantum Theory of Aperiodic Effects”. In: *Physical Review* 31.1 (1928). Issue 1, 1 January 1928. The first of the three notes treats field ionization of hydrogen in a uniform electric field – the result the citing sentence attributes to Oppenheimer (no strictly bound state; the Stark levels are long-lived resonances)., pp. 66–81. DOI: 10.1103/PhysRev.31.66.

[617] W. Pauli. “Über das H-Theorem vom Anwachsen der Entropie vom Standpunkt der neuen Quantenmechanik”. In: *Probleme der Modernen Physik: Arnold Sommerfeld zum 60. Geburtstage*. 1928, pp. 30–45.

[618] C. V. RAMAN and K. S. KRISHNAN. “A New Type of Secondary Radiation”. In: *Nature* 121.3048 (1928), pp. 501–502. DOI: 10.1038/121501c0.

[619] H. Reichenbach. *Philosophie der Raum-Zeit-Lehre*. Source of the coordinative definition and of the conventionality of distant simultaneity. English translation: The Philosophy of Space and Time, trans. M. Reichenbach and J. Freund, Dover, New York (1958). Berlin: Walter de Gruyter, 1928.

[620] A. Sommerfeld. “Zur Elektronentheorie der Metalle auf Grund der Fermischen Statistik”. In: *Zeitschrift für Physik* 47.1-2 (1928), pp. 1–32. DOI: 10.1007/BF01391052.

[621] G. P. Thomson. “Experiments on the diffraction of cathode rays”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 117.778 (1928). Issue 778. SINGLE AUTHOR – G. P. Thomson alone. Reid co-signed only the 1927 Nature letter (the existing Thomson:1927), so an author field of ’Thomson and Reid’ would be wrong even though the chapter’s prose says ’the fuller papers’. Received 4 November 1927 but the issue is dated 1 February 1928, so the ISSUE year 1928 keys the entry. Content verified against the article’s own pages, not just metadata: section 5 reads ’Specimens of the results obtained with films of aluminium, gold, celluloid, and a substance X (at first thought to be platinum)’, which is exactly the claim cited – the metal films that made the result independent of target chemistry – and its section 1 footnote back-references ’Thomson and Reid, Nature, vol. 119, p. 890 (1927)’. Kept as @article, not @inproceedings: unlike Sitzungsberichte or Comptes rendus, Proc. Roy. Soc. A carries a real volume and issue number, and the house bib already files Bragg:1913b, Bethe:1934 and Blackett:1933 in this same container as @article. Container title matches the string Crossref and the existing Bragg:1913b use. This is G. P. Thomson, distinct from the J. J. Thomson of Thomson:1897 and the William Thomson entries; no key collision, the nine existing Thomson:* keys are all other years. Verified twice independently: Crossref, and the JSTOR title page of the scanned article (’Vol. 117, No. 778 (Feb. 1, 1928), pp. 600-609’)., pp. 600–609. DOI: 10.1098/rspa.1928.0022.

[622] R. d. E. Atkinson and F. G. Houtermans. “Zur Frage der Aufbaumöglichkeit der Elemente in Sternen”. In: *Zeitschrift für Physik* 54.9-10 (1929), pp. 656–665. DOI: 10.1007/BF01341595.

[623] F. Bloch. “Über die Quantenmechanik der Elektronen in Kristallgittern”. In: *Zeitschrift für Physik* 52.7-8 (1929), pp. 555–600. DOI: 10.1007/BF01339455.

[624] R. Carnap, H. Hahn, and O. Neurath. *Wissenschaftliche Weltauffassung: Der Wiener Kreis*. The Vienna Circle manifesto, published unsigned by the Verein Ernst Mach; the Geleitwort is signed by Hahn, Neurath and Carnap, and the drafting was chiefly Neurath's. Vienna: Artur Wolf Verlag, 1929.

[625] R. W. Gurney and E. U. Condon. "Quantum Mechanics and Radioactive Disintegration". In: *Physical Review* 33.2 (1929). Issue 2. The full paper, distinct from the companion note Gurney:1928 ('Wave Mechanics and Radioactive Disintegration', Nature 122, 439, 1928) that the same sentence cites alongside it. Verified against Crossref., pp. 127–140. DOI: 10.1103/PhysRev.33.127.

[626] W. Heisenberg and W. Pauli. "Zur Quantendynamik der Wellenfelder". In: *Zeitschrift fur Physik* 56.1-2 (1929), pp. 1–61. DOI: 10.1007/BF01340129.

[627] E. Hubble. "A relation between distance and radial velocity among extra-galactic nebulae". In: *Proceedings of the National Academy of Sciences* 15.3 (1929), pp. 168–173. DOI: 10.1073/pnas.15.3.168.

[628] E. A. Hylleraas. "Neue Berechnung der Energie des Heliums im Grundzustande, sowie des tiefsten Terms von Ortho-Helium". In: *Zeitschrift für Physik* 54.5-6 (1929), pp. 347–366. DOI: 10.1007/BF01375457.

[629] O. Klein. "Die Reflexion von Elektronen an einem Potentialsprung nach der relativistischen Dynamik von Dirac". In: *Zeitschrift für Physik* 53.3-4 (1929). The Klein paradox. Split from the former shared key Klein:1929. Metadata confirmed against Crossref., pp. 157–165. DOI: 10.1007/BF01339716.

[630] O. Klein and Y. Nishina. "Über die Streuung von Strahlung durch freie Elektronen nach der neuen relativistischen Quantendynamik von Dirac". In: *Zeitschrift für Physik* 52.11-12 (1929). The Klein–Nishina cross-section, keyed by first listed author. Split from the former shared key Klein:1929; suffixed a/b because neither the Klein–Nishina paper nor the Klein-paradox paper is secondary, with a/b in volume order (52 before 53). Two of the three input candidates were the same paper (one ASCII-mangled). Metadata confirmed against Crossref., pp. 853–868. DOI: 10.1007/BF01366453.

[631] J. E. Lennard-Jones. "The electronic structure of some diatomic molecules". In: *Transactions of the Faraday Society* 25 (1929). Hyphen dropped in the key (Lennard-Jones) so the key stays a single word., p. 668. DOI: 10.1039/TF9292500668.

[632] P. M. Morse. "Diatomic Molecules According to the Wave Mechanics. II. Vibrational Levels". In: *Physical Review* 34.1 (1929), pp. 57–64. DOI: 10.1103/PhysRev.34.57.

[633] N. F. Mott. "The scattering of fast electrons by atomic nuclei". In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 124.794 (1929). This is the relativistic spin-1/2 Coulomb cross section, NOT the identical-particle result. The task hint said 'Mott 1929 identical-particle scattering'; the identical-particle calculation is Mott:1930 below, and ch. IX.10 states the customary misattribution explicitly rather than silently using the right key., pp. 425–442. DOI: 10.1098/rspa.1929.0127.

[634] R. Peierls. "Zur kinetischen Theorie der Wärmeleitung in Kristallen". In: *Annalen der Physik* 395.8 (1929). Umklapp processes and the finite thermal conductivity of an insulating crystal. The DOI in the batch candidate (10.1002/andp.19293951006) returns 404; the resolving DOI is issue 8, article 3, as given here., pp. 1055–1101. DOI: 10.1002/andp.19293950803.

[635] R. Peierls. “Zur Theorie der galvanomagnetischen Effekte”. In: *Zeitschrift für Physik* 53.3-4 (1929). Introduces the effective-mass tensor and the hole concept. DOI verified against Crossref (title, volume and pages all match); the batch candidate carried no DOI., pp. 255–266. DOI: 10.1007/BF01339727.

[636] H. P. Robertson. “The Uncertainty Principle”. In: *Physical Review* 34.1 (1929), pp. 163–164. DOI: 10.1103/PhysRev.34.163.

[637] J. C. Slater. “The Theory of Complex Spectra”. In: *Physical Review* 34.10 (1929), pp. 1293–1322. DOI: 10.1103/PhysRev.34.1293.

[638] L. Szilard. “Über die Entropieverminderung in einem thermodynamischen System bei Eingriffen intelligenter Wesen”. In: *Zeitschrift für Physik* 53.11-12 (1929), pp. 840–856. DOI: 10.1007/BF01341281.

[639] L. Tonks and I. Langmuir. “Oscillations in Ionized Gases”. In: *Physical Review* 33.2 (1929). Verified via Crossref (Phys. Rev. 33(2), 1 Feb 1929). Tonks is first author, so the key is correctly Tonks:1929 even though the prose says "Langmuir ... analysed with Tonks". Do not confuse with the short follow-up Tonks & Langmuir, Phys. Rev. 33, 990 (1929)., pp. 195–210. DOI: 10.1103/PhysRev.33.195.

[640] B. L. van der Waerden. “Spinoranalyse”. In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-Physikalische Klasse*. Founding paper of two-component (dotted/undotted) spinor calculus. 1929, pp. 100–109.

[641] H. Weyl. “Elektron und Gravitation. I”. In: *Zeitschrift für Physik* 56.5-6 (1929). Likely also introduced by the Weyl-equation chapter of the same part., pp. 330–352. DOI: 10.1007/BF01339504.

[642] F. Bloch. “Zum elektrischen Widerstandsgesetz bei tiefen Temperaturen”. In: *Zeitschrift für Physik* 59.3-4 (1930), pp. 208–214. DOI: 10.1007/bf01341426.

[643] F. Bloch. “Zur Theorie des Ferromagnetismus”. In: *Zeitschrift für Physik* 61.3-4 (1930), pp. 206–219. DOI: 10.1007/bf01339661.

[644] L. Brillouin. “Les électrons libres dans les métaux et le role des réflexions de Bragg”. In: *Journal de Physique et le Radium* 1.11 (1930), pp. 377–400. DOI: 10.1051/jphysrad:01930001011037700.

[645] J. Chadwick. “The scattering of α-particles in helium”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 128.807 (1930). Experimental confirmation of Mott’s identical-particle interference term. DOI not supplied – not confident enough., pp. 114–122. DOI: 10.1098/rspa.1930.0098.

[646] P. A. M. Dirac. *The Principles of Quantum Mechanics*. First edition (1930). Source for the delta function and for the algebraic ladder-operator method; the bra–ket notation itself is later, so do not cite this edition for it – cite Dirac:1939, the paper that introduces it. Clarendon Press, 1930.

[647] P. A. M. Dirac. “A theory of electrons and protons”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 126.801 (1930). Issue of 1 January 1930; takes ’a’ as the earlier of the two Dirac 1930 works. Hole theory with the hole wrongly identified as the proton — the citing chapters say so explicitly and cite Dirac:1931 for the anti-electron proper., pp. 360–365. DOI: 10.1098/rspa.1930.0013.

[648] C. Eckart. “The Application of Group theory to the Quantum Dynamics of Monatomic Systems”. In: *Reviews of Modern Physics* 2.3 (1930). Crossref confirmed: RMP vol. 2, pp. 305-380, 1 July 1930. Note the lower-case ’theory’ in the published title – that is how APS prints it, not a typo. This is the Eckart half of the Wigner-Eckart theorem, cited beside Wigner:1931., pp. 305–380. DOI: 10.1103/RevModPhys.2.305.

[649] A. S. Eddington. “On the Instability of Einstein’s Spherical World”. In: *Monthly Notices of the Royal Astronomical Society* 90 (1930). Metadata confirmed against Crossref., pp. 668–678. DOI: 10.1093/mnras/90.7.668.

[650] R. Eisenschitz and F. London. “Über das Verhältnis der van der Waalsschen Kräfte zu den homöopolaren Bindungskräften”. In: *Zeitschrift für Physik* 60 (1930), pp. 491–527.

[689] A. H. Wilson. “The theory of electronic semi-conductors. - II”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 134.823 (1931), pp. 277–287. DOI: 10.1098/rspa.1931.0196.

[690] I. F. Zartman. “A Direct Measurement of Molecular Velocities”. In: *Physical Review* 37.4 (1931). Issue 4. Crossref-confirmed. The abstract matches the chapter’s description of the apparatus: bismuth beam, glass plate on a cylinder rotating at 241 r.p.s., molecules from 168 to 673 m/s spread over a 3 cm band, vapour found to be 40% Bi and 60% Bi2 at 851 degC. First of the two rotating-drum velocity analysers named in exp:kt-miller-kusch., pp. 383–391. DOI: 10.1103/PhysRev.37.383.

[691] C. D. Anderson. “The Apparent Existence of Easily Deflectable Positives”. In: *Science* 76.1967 (1932). First announcement of the positron., pp. 238–239. DOI: 10.1126/science.76.1967.238.

[692] J. Chadwick. “Possible Existence of a Neutron”. In: *Nature* 129.3252 (1932). The one-page discovery letter of 27 February 1932; the announcement that dates the discovery., pp. 312–312. DOI: 10.1038/129312a0.

[693] J. Chadwick. “The existence of a neutron”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 136.830 (1932). The full account, with the recoil kinematics from protons and nitrogen nuclei and the neutron mass determination. Crossref gives the author as James Chadwick., pp. 692–708. DOI: 10.1098/rspa.1932.0112.

[694] J. D. COCKCROFT and E. T. S. WALTON. “Disintegration of Lithium by Swift Protons”. In: *Nature* 129.3261 (1932). The announcement letter, issue of 30 April 1932; carries the first observation at about 125 kV and the alpha range of about 8.4 cm of air. Keyed ’a’ because three Cockcroft-Walton 1932 papers are cited in this chapter; a/b/c are in publication order (Nature April, Proc. Roy. Soc. A 136 June, Proc. Roy. Soc. A 137 July). Crossref prints the authors in full caps (COCKCROFT, WALTON), normalised here. Verified against api.crossref.org 2026-08-13., pp. 649–649. DOI: 10.1038/129649a0.

[695] J. D. Cockcroft and E. T. S. Walton. “Experiments with high velocity positive ions. II. -The disintegration of elements by high velocity protons”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 137.831 (1932). Issue 831, 1 July 1932. The full account: yield against accelerating potential, the range measurement, and the coincidence test showing the two alpha particles are emitted back to back – i.e. the quantitative content of the first accelerator-driven nuclear reaction and of the first nuclear test of E=mc^2. TRAP: Crossref stores the title as ’...positive ions. II. -The disintegration...’, where the stray hyphen is the tail of the same U+2015 dash artefact as in Cockcroft:1932b; removed here. Verified against api.crossref.org 2026-08-13., pp. 229–242. DOI: 10.1098/rspa.1932.0133.

[696] J. D. Cockcroft and E. T. S. Walton. “Experiments with high velocity positive ions.—(I) Further developments in the method of obtaining high velocity positive ions”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 136.830 (1932). The apparatus paper: the cascade voltage multiplier (Cockcroft-Walton generator) and the sectioned accelerating tube. TRAP: Crossref stores the title with a U+2015 HORIZONTAL BAR after the first full stop (’...positive ions.<U+2015>(I) Further developments...’), which is a non-ASCII byte fatal under pdflatex + T1; it is normalised to a plain space here. If a title-similarity check is run against Crossref, expect the dash to be the only difference. Verified against api.crossref.org 2026-08-13., pp. 619–630. DOI: 10.1098/rspa.1932.0107.

[697] E. Feenberg. “The Scattering of Slow Electrons by Neutral Atoms”. In: *Physical Review* 40.1 (1932). Contains the optical theorem for potential scattering., pp. 40–54. DOI: 10.1103/PhysRev.40.40.

[698] V. Fock. “Konfigurationsraum und zweite Quantelung”. In: *Zeitschrift für Physik* 75.9-10 (1932), pp. 622–647. DOI: 10.1007/BF01344458.

[699] W. Heisenberg. “Über den Bau der Atomkerne. I”. In: *Zeitschrift für Physik* 77.1-2 (1932), pp. 1–11. DOI: 10.1007/BF01342433.

[700] R. J. Kennedy and E. M. Thorndike. “Experimental Establishment of the Relativity of Time”. In: *Physical Review* 42.3 (1932). Unequal-arm interferometer; tests the velocity dependence that Michelson–Morley alone cannot, and with it the time-dilation factor, pp. 400–418. DOI: 10.1103/PhysRev.42.400.

[701] H. Lamb. *Hydrodynamics*. 6th edition (the standard one). Classical reference for potential flow and surface waves. Cambridge University Press, 1932.

[702] L. D. Landau. “On the theory of stars”. In: *Physikalische Zeitschrift der Sowjetunion* 1 (1932). Written 1931, published 1932; venue has no DOIs, pp. 285–288.

[703] E. O. Lawrence and M. S. Livingston. “The Production of High Speed Light Ions Without the Use of High Voltages”. In: *Physical Review* 40.1 (1932). The cyclotron paper (Nobel Prize to Lawrence, 1939): resonant acceleration to protons above 1.2 MeV from a few kilovolts on the dees. Verified against api.crossref.org 2026-08-13., pp. 19–35. DOI: 10.1103/PhysRev.40.19.

[704] C. Møller. “Zur Theorie des Durchgangs schneller Elektronen durch Materie”. In: *Annalen der Physik* 406.5 (1932), pp. 531–585. DOI: 10.1002/andp.19324060506.

[705] J. v. Neumann. “Proof of the Quasi-Ergodic Hypothesis”. In: *Proceedings of the National Academy of Sciences* 18.1 (1932). Suffix a introduced by this batch. The bare key vonNeumann:1932 is used by six other citation sites (02-mathematical-methods/10-hilbert-spaces.tex, 09-quantum-mechanics/09-interpretations.tex, 09-quantum-mechanics/11-open-systems-decoherence.tex) for the BOOK ’Mathematische Grundlagen der Quantenmechanik’, which does not contain the mean ergodic theorem. This entry is the PNAS paper that does. The orchestrator may prefer to rename the book to vonNeumann:1932b for a/b symmetry., pp. 70–82. DOI: 10.1073/pnas.18.1.70.

[706] J. von Neumann. *Mathematische Grundlagen der Quantenmechanik*. Die Grundlehren der mathematischen Wissenschaften, Bd. 38. Title page prints the author as ’J. v. Neumann’; the particle is kept in the surname to match the key. Keeps the bare key as the clearly primary sense of ’von Neumann 1932’ (three of the four citing chapters mean it). No DOI for the 1932 original – Springer’s 10.1007/978-3-642-61409-5 is the 1996 reissue and must not be attached to this entry. Julius Springer, 1932.

[707] M. H. Stone. “On One-Parameter Unitary Groups in Hilbert Space”. In: *The Annals of Mathematics* 33.3 (1932). Annals of Mathematics, second series. Stone’s book ’Linear Transformations in Hilbert Space’ (AMS Colloquium 15, also 1932) is a different work – suffix if both are ever needed., p. 643. DOI: 10.2307/1968538.

[708] H. C. Urey, F. G. Brickwedde, and G. M. Murphy. “A Hydrogen Isotope of Mass 2”. In: *Physical Review* 39.1 (1932). Deuterium found by seeking the reduced-mass-shifted Balmer lines predicted by the Bohr model., pp. 164–165. DOI: 10.1103/PhysRev.39.164.

[709] J. H. Van Vleck. *The Theory of Electric and Magnetic Susceptibilities*. Oxford University Press, 1932.

[710] E. Wigner. “Über die Operation der Zeitumkehr in der Quantenmechanik”. In: *Nachrichten von der Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-Physikalische Klasse*. 1932, pp. 546–559.

[711] C. Zener. “Non-adiabatic crossing of energy levels”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 137.833 (1932). Verified via Crossref (Proc. R. Soc. Lond. A 137, issue 833, 1 Sep 1932). Crossref’s container title is the full 1932 masthead given above; "Proceedings of the Royal Society of London A" is the usual short form. This is the paper giving the exp(-2*pi*gamma) linear-sweep transition probability quoted at sec:approx-landau-zener., pp. 696–702. DOI: 10.1098/rspa.1932.0165.

[712] L. Alvarez and A. H. Compton. “A Positively Charged Component of Cosmic Rays”. In: *Physical Review* 43.10 (1933), pp. 835–836. DOI: 10.1103/PhysRev.43.835.

[713] C. D. Anderson. “The Positive Electron”. In: *Physical Review* 43.6 (1933). The full analysis, including the apparatus description and the 2 August 1932 photograph., pp. 491–494. DOI: 10.1103/PhysRev.43.491.

[714] P. M. S. Blackett and G. P. S. Occhialini. “Some photographs of the tracks of penetrating radiation”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 139.839 (1933). First photographs of electron-positron pair production., pp. 699–726. DOI: 10.1098/rspa.1933.0048.

[715] N. Bohr and L. Rosenfeld. “Zur Frage der Messbarkeit der elektromagnetischen Feldgrossen”. In: *Kongelige Danske Videnskabernes Selskab, Matematisk-fysiske Meddelelser* 12 (1933). Issue no. 8; no DOI, pp. 1–65.

[716] A. H. Compton. “A Geographic Study of Cosmic Rays”. In: *Physical Review* 43.6 (1933), pp. 387–403. DOI: 10.1103/PhysRev.43.387.

[717] T. G. Cowling. “The Magnetic Field of Sunspots”. In: *Monthly Notices of the Royal Astronomical Society* 94.1 (1933). Crossref confirmed: MNRAS vol. 94, issue 1, pp. 39-48, 10 November 1933. The anti-dynamo theorem (no steady axisymmetric dynamo) is in this paper, despite the title being about sunspots – that is the standard citation the chapter wants., pp. 39–48. DOI: 10.1093/mnras/94.1.39.

[718] P. A. M. Dirac. “The Lagrangian in Quantum Mechanics”. In: *Physikalische Zeitschrift der Sowjetunion* 3 (1933), pp. 64–72.

[719] P. Ehrenfest. “Phasenumwandlungen im ueblichen und erweiterten Sinn, classifiziert nach den entsprechenden Singularitaeten des thermodynamischen Potentiales”. In: *Proceedings of the Royal Academy of Sciences at Amsterdam*. Vol. 36. Also issued as Communications from the Physical Laboratory of the University of Leiden, Supplement 75b. 1933, pp. 153–157.

[720] E. Grüneisen. “Die Abhängigkeit des elektrischen Widerstandes reiner Metalle von der Temperatur”. In: *Annalen der Physik* 408.5 (1933), pp. 530–540. DOI: 10.1002/andp.19334080504.

[721] A. Haar. “Der Massbegriff in der Theorie der kontinuierlichen Gruppen”. In: *Annals of Mathematics* 34.1 (1933). Crossref-verified: author, year, volume and first page confirmed against the DOI. Existence of the invariant measure on a locally compact topological group, which is what lets Weyl’s averaging argument for complete reducibility pass from a finite group to a compact one. This treatise imports the theorem and does not construct the measure; the linear-algebra chapter says so where it uses it., pp. 147–169. DOI: 10.2307/1968346.

[722] T. H. Johnson. “The Azimuthal Asymmetry of the Cosmic Radiation”. In: *Physical Review* 43.10 (1933). Thomas H. Johnson; distinct from J. B. Johnson of Johnson:1928, pp. 834–835. DOI: 10.1103/PhysRev.43.834.

[729] F. Zwicky. “Die Rotverschiebung von extragalaktischen Nebeln”. In: *Helvetica Physica Acta* 6 (1933). Coma-cluster virial discrepancy. No DOI., pp. 110–127.

[730] W. Baade and F. Zwicky. “Cosmic Rays from Super-Novae”. In: *Proceedings of the National Academy of Sciences* 20.5 (1934). Contains the neutron-star proposal; companion paper On Super-novae is PNAS 20, 254, pp. 259–263. DOI: 10.1073/pnas.20.5.259.

[731] W. H. Bennett. “Magnetically Self-Focussing Streams”. In: *Physical Review* 45.12 (1934). Source of the Bennett pinch relation. The published title uses the British double-s spelling ’Self-Focussing’ – do not normalise it to ’Focusing’. Crossref-verified., pp. 890–897. DOI: 10.1103/PhysRev.45.890.

[732] H. Bethe and W. Heitler. “On the stopping of fast particles and on the creation of positive electrons”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 146.856 (1934), pp. 83–112. DOI: 10.1098/rspa.1934.0140.

[733] W. L. Bragg and E. J. Williams. “The effect of thermal agitation on atomic arrangement in alloys”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 145.855 (1934), pp. 699–730. DOI: 10.1098/rspa.1934.0132.

[734] J. Chadwick and M. Goldhaber. “A Nuclear Photo-effect: Disintegration of the Diplon by -Rays”. In: *Nature* 134.3381 (1934), pp. 237–238. DOI: 10.1038/134237a0.

[735] P. A. Cherenkov. “Vidimoe svechenie chistykh zhidkostei pod deistviem γ-radiatsii”. In: *Doklady Akademii nauk SSSR* 2 (1934). THREE things the bib writer must decide, all flagged deliberately. (1) SCRIPT: the treatise builds with pdflatex, which will NOT compile Cyrillic without extra packages – do not paste the Russian title into references.bib unless the preamble is prepared for it. The work is universally cited in the Latin/English form printed in the parallel foreign-language edition (Comptes Rendus (Doklady) de l’Académie des Sciences de l’URSS): ’Visible emission of clean liquids by action of γ radiation’; that is the safe title field, with the Russian original recorded in a bib note. (2) PAGES: the standard citation is ’Dokl. Akad. Nauk SSSR 2, 451 (1934)’ – a single start page. Some bibliographies print 451-454; I could not verify the end page, so only 451 is asserted here. Do not invent 451-454. (3) NAME: the 1934 parallel edition prints ’Čerenkov’; the Russian original ’Cherenkov’. ’Cherenkov’ is given to match the citation key and the Nobel-era Latin usage. No DOI for the 1934 note; it was reprinted as Usp. Fiz. Nauk 93, 385 (1967), DOI 10.3367/UFNr.0093.196710n.0385 – that DOI belongs to the REPRINT, not to this entry, so do not attach it to a 1934-dated record without saying so. Russian-language original: the title and journal are given here in scientific transliteration, because the treatise builds with pdflatex under T1 encoding, which cannot typeset Cyrillic., p. 451.

[736] P. van Cittert. “Die Wahrscheinliche Schwingungsverteilung in Einer von Einer Lichtquelle Direkt Oder Mittels Einer Linse Beleuchteten Ebene”. In: *Physica* 1.1-6 (1934). Verified via Crossref: Physica 1, issue 1-6, 201-210 (1934); Crossref files the family name as "van Cittert" and title-cases the German title, the lower-case form given here is the printed one. BibTeX trap: write the author as van Cittert, P. H. (braced particle) or biber will alphabetize and abbreviate on "Cittert"; the same applies to vandeHulst:1945., pp. 201–210. DOI: 10.1016/S0031-8914(34)90026-4.

[737] I. Curie and F. Joliot. “Un nouveau type de radioactivité”. In: *Comptes Rendus Hebdomadaires des Séances de l’Académie des Sciences*. Vol. 198. Customarily cited as Joliot-Curie, but the paper lists Irène Curie first, so the key follows the first listed author. 1934, pp. 254–256.

[738] E. Fermi. “Versuch einer Theorie der ?-Strahlen. I”. In: *Zeitschrift fur Physik* 88.3-4 (1934). An Italian version appeared as Il Nuovo Cimento 11 (1934) 1-19, pp. 161–177. DOI: 10.1007/BF01351864.

[739] C. Gorter and H. Casimir. “On supraconductivity I”. In: *Physica* 1.1-6 (1934), pp. 306–320. DOI: 10.1016/S0031-8914(34)90037-9.

[740] A. Y. Khinchin. “Korrelationstheorie der stationären stochastischen Prozesse”. In: *Mathematische Annalen* 109 (1934). Byline ’A. Khintchine’., pp. 604–615.

[741] O. Klemperer. “On the annihilation radiation of the positron”. In: *Mathematical Proceedings of the Cambridge Philosophical Society* 30.3 (1934), pp. 347–354. DOI: 10.1017/s0305004100012536.

[742] C. C. Ko. “The heat of dissociation of Bi2 determined by the method of molecular beams”. In: *Journal of the Franklin Institute* 217.2 (1934). Issue 2. Crossref-confirmed (title as deposited by Elsevier is sentence case with ’Bi2’ unsubscripted; the printed title sets Bi_2 as a subscript, so a .bib entry should write Bi_2 and brace-protect it). WARNING for the title check: the title names the dissociation heat, not the velocity distribution, so it does not look like a velocity-analyser paper. It is one: the abstract states Ko used Zartman’s velocity analyser with improved technique to obtain the combined velocity spectrum of Bi atoms and Bi2 molecules, and derived the dissociation heat from it. This is the ’Ko’ of the standard Zartman–Ko pairing, and the paper the chapter’s phrase ’Zartman’s and Ko’s’ denotes., pp. 173–199. DOI: 10.1016/S0016-0032(34)91029-2.

[744] H. Kramers. “L’interaction Entre les Atomes Magnétogènes dans un Cristal Paramagnétique”. In: *Physica* 1.1-6 (1934), pp. 182–192. DOI: 10.1016/s0031-8914(34)90023-9.

[745] J. Leray. “Sur le mouvement d’un liquide visqueux emplissant l’espace”. In: *Acta Mathematica* 63.0 (1934). Global weak solutions of the Navier-Stokes equations., pp. 193–248. DOI: 10.1007/BF02547354.

[746] M. Morse. *The Calculus of Variations in the Large*. Morse index theorem. Author is Marston Morse – distinct from Philip M. Morse of Morse:1953. New York: American Mathematical Society (Colloquium Publications 18), 1934.

[747] A. L. Patterson. “A Fourier Series Method for the Determination of the Components of Interatomic Distances in Crystals”. In: *Physical Review* 46.5 (1934). Crossref-verified: title, first author Patterson, Physical Review vol. 46, pp. 372-376, 1934. Cited for the vector (Patterson) map, phen:phase-patterson., pp. 372–376. DOI: 10.1103/PhysRev.46.372.

[748] W. Pauli and V. Weisskopf. “Über die Quantisierung der skalaren relativistischen Wellengleichung”. In: *Helvetica Physica Acta* 7 (1934). The reinterpretation of the Klein–Gordon equation as a quantized field. Helvetica Physica Acta of this period has no DOI; scans are on e-periodica., pp. 709–731.

[749] S. I. Vavilov. “O vozmozhnykh prichinakh sinego γ-svecheniya zhidkostei”. In: *Doklady Akademii Nauk SSSR* 2 (1934). Companion piece to Cherenkov’s paper in the SAME issue: Doklady AN SSSR, vol. 2, no. 8 (1934) — Cherenkov pp. 451-457, Vavilov pp. 457-461. No DOI exists; do not invent one (honest AMBER/RED on availability). BUILD WARNING: pdflatex cannot typeset Cyrillic, so references.bib must carry the transliteration, not the string above: title = O vozmozhnykh prichinakh sinego gamma-svecheniya zhidkostei [On the possible causes of the blue gamma-glow of liquids], journal = Doklady Akademii Nauk SSSR. Doklady is the USSR academy’s Comptes Rendus; it does carry volume and issue numbers, so @article with volume 2 is correct here rather than @inproceedings — but if the project prefers the academy-proceedings treatment, note that the volume is genuine and must not be dropped. Russian-language original: the title and journal are given here in scientific transliteration, because the treatise builds with pdflatex under T1 encoding, which cannot typeset Cyrillic., pp. 457–461.

[750] C. Zener. “A theory of the electrical breakdown of solid dielectrics”. In: *Proceedings of the Royal Society of London. Series A, Containing Papers of a Mathematical and Physical Character* 145.855 (1934), pp. 523–529. DOI: 10.1098/rspa.1934.0116.

[751] E. U. Condon and G. H. Shortley. *The Theory of Atomic Spectra*. Cited in the angular-momentum chapter as a standard treatment, alongside Sakurai:2017 and CohenTannoudji:1977 – unmistakably Condon & Shortley, the source of the Condon-Shortley phase convention. First edition Cambridge, 1935; reprinted many times (1951, 1959, 1963 ...) and reissued in paperback 1970. Two authors: an @book still owes both. Printed monograph, no DOI – honest AMBER on availability. Cambridge University Press, 1935.

[752] T. De Donder. *Théorie invariantive du calcul des variations*. Nouvelle édition, Paris, 1935 – the edition the key’s year refers to and the one universally cited for the De Donder-Weyl covariant Hamiltonian formalism. A first edition appeared in 1930 (same publisher); record the edition explicitly so the two are not conflated. NAME: the title page prints ’Th. De Donder’ but library catalogues file him as ’Donder, Théophile de’ – biblatex should be given De Donder, Th. with the surname braced so it is not split. Printed monograph, no DOI: honest AMBER unless a scan is stored. Gauthier-Villars, 1935.

[753] A. Einstein, B. Podolsky, and N. Rosen. “Can Quantum-Mechanical Description of Physical Reality Be Considered Complete?” In: *Physical Review* 47.10 (1935), pp. 777–780. DOI: 10.1103/PhysRev.47.777.

[754] H. Eyring. “The Activated Complex in Chemical Reactions”. In: *The Journal of Chemical Physics* 3.2 (1935). Issue 2. The transition-state concept that the femtochemistry measurements put under test. Confirmed against the Crossref record for this DOI., pp. 107–115. DOI: 10.1063/1.1749604.

[755] V. Fock. “Zur Theorie des Wasserstoffatoms”. In: *Zeitschrift für Physik* 98.3-4 (1935). Verified against Crossref. The hidden SO(4) symmetry of the Coulomb problem via momentum-space stereographic projection; Bargmann’s 1936 companion paper (Z. Phys. 99, 576) is the separate Bargmann:1936 key., pp. 145–154. DOI: 10.1007/BF01336904.

[756] L. Landau and E. Lifshitz. “On the theory of the dispersion of magnetic permeability in ferromagnetic bodies”. In: *Physikalische Zeitschrift der Sowjetunion* 8 (1935), pp. 153–169.

[757] F. London and H. London. “The electromagnetic equations of the supraconductor”. In: *Proceedings of the Royal Society of London. Series A - Mathematical and Physical Sciences* 149.866 (1935), pp. 71–88. DOI: 10.1098/rspa.1935.0048.

[758] H. P. Robertson. “Kinematics and World-Structure”. In: *The Astrophysical Journal* 82 (1935). Parts II and III follow in ApJ 83 (1936)., p. 284. DOI: 10.1086/143681.

[759] E. Schrödinger. “Discussion of Probability Relations between Separated Systems”. In: *Mathematical Proceedings of the Cambridge Philosophical Society* 31.4 (1935), pp. 555–563. DOI: 10.1017/S0305004100013554.

[760] E. Schrödinger. “Die gegenwärtige Situation in der Quantenmechanik”. In: *Die Naturwissenschaften* 23 (1935). Three-part article: pp. 807-812, 823-828, 844-849. The DOI resolves the first installment; the term ’Verschränkung’ and the cat both appear here., pp. 807–812.

[761] A. Tarski. “Der Wahrheitsbegriff in den formalisierten Sprachen”. In: *Studia Philosophica* 1 (1935). German translation by L. Blaustein, with a new Nachwort, of the Polish original of 1933. The volume is dated 1935 and is cited so, but did not appear until 1936, pp. 261–405.

[762] E. A. Uehling. “Polarization Effects in the Positron Theory”. In: *Physical Review* 48.1 (1935), pp. 55–63. DOI: 10.1103/PhysRev.48.55.

[763] C. F. von Weizsäcker. “Zur Theorie der Kernmassen”. In: *Zeitschrift für Physik* 96 (1935), pp. 431–458.

[764] H. Weyl. “Geodesic Fields in the Calculus of Variation for Multiple Integrals”. In: *The Annals of Mathematics* 36.3 (1935). Title, journal, volume 36 issue 3, start page 607 and year 1935 verified via Crossref; Crossref stores only the start page, the end page 629 is the standard JSTOR range. Crossref’s container title is "The Annals of Mathematics" (the journal’s name in 1935) — either form is defensible. This is the Weyl half of the De Donder-Weyl formalism cited at sec:lagft-covariant-hamiltonian., p. 607. DOI: 10.2307/1968645.

[765] H. Yukawa. “On the Interaction of Elementary Particles. I”. In: *Proceedings of the Physico-Mathematical Society of Japan. 3rd Series* 17 (1935), pp. 48–57.

[766] V. Bargmann. “Zur Theorie des Wasserstoffatoms”. In: *Zeitschrift für Physik* 99.7-8 (1936). The SO(4) hidden symmetry of the Coulomb problem. The printed article carries the subtitle ’Bemerkungen zur gleichnamigen Arbeit von V. Fock’ – add it to the bib entry if desired, but note that Crossref records only the main title, so the automated DOI/title check should be run against the short form given here. The main title is IDENTICAL to Fock:1935 (Z. Phys. 98, 145, DOI 10.1007/BF01336904) – do not let the two entries collapse., pp. 576–582. DOI: 10.1007/BF01338811.

[860] A. McKellar. “Molecular Lines from the Lowest States of Diatomic Molecules Composed of Atoms Probably Present in Interstellar Space”. In: *Publications of the Dominion Astrophysical Observatory Victoria* 7 (1941). CN excitation temperature 2.3 K; no DOI, pp. 251–272.

[861] A. M. Obukhov. “On the Distribution of Energy in the Spectrum of Turbulent Flow”. In: *Izvestiya Akademii Nauk SSSR, Seriya Geograficheskaya i Geofizicheskaya* 5 (1941). In Russian. Short announcement also in Dokl. Akad. Nauk SSSR 32 (1941) 22-24. Source of the spectral k^(-5/3) form; the chapter records the split attribution with K41., pp. 453–466.

[862] W. Rarita and J. Schwinger. “On a Theory of Particles with Half-Integral Spin”. In: *Physical Review* 60.1 (1941), pp. 61–61. DOI: 10.1103/PhysRev.60.61.

[863] B. Rossi and D. B. Hall. “Variation of the Rate of Decay of Mesotrons with Momentum”. In: *Physical Review* 59.3 (1941). Cosmic-ray muon survival between Echo Lake and Denver; yields a proper lifetime $(2.4 \pm 0.3) \times 10^{-6}$ s. “Mesotron” is the contemporary name for the muon, pp. 223–228. DOI: 10.1103/PhysRev.59.223.

[864] E. C. G. Stueckelberg. “Remarque à propos de la création de paires de particules en théorie de relativité”. In: *Helvetica Physica Acta* 14 (1941). Not a genuine collision: both candidates describe this single paper, one with the accents stripped. Source of the Stueckelberg–Feynman reading of antiparticles. Name also written Stückelberg; the paper itself is signed E. C. G. Stueckelberg. Helvetica Physica Acta of this period has no DOI; scans are at e-periodica.ch., pp. 588–594.

[865] H. ALFVÉN. “Existence of Electromagnetic-Hydrodynamic Waves”. In: *Nature* 150.3805 (1942). The frozen-in field / Alfvén wave letter. Nature prints the title with a hyphen (’Electromagnetic-Hydrodynamic’), not an en dash. Surname carries an acute accent: Alfvén. Crossref-verified., pp. 405–406. DOI: 10.1038/150405d0.

[866] E. Hopf. “Abzweigung einer periodischen Lösung von einer stationären Lösung eines Differentialsystems”. In: *Berichte der Mathematisch-Physischen Klasse der Sächsischen Akademie der Wissenschaften zu Leipzig*. Vol. 94. The Hopf bifurcation. English translation in Marsden and McCracken, The Hopf Bifurcation and Its Applications (Springer, 1976). 1942, pp. 1–22.

[867] G. Racah. “Theory of Complex Spectra. II”. In: *Physical Review* 62.9-10 (1942). Issue 9–10, 1 November 1942. Part II is the one carrying the closed-form (Racah) expression for the general Clebsch–Gordan coefficient and introducing the W coefficient; Part I is Phys. Rev. 61, 186 (1942) and Part III, with the 6j/9j apparatus, is Phys. Rev. 63, 367 (1943). The author signs ’G. Racah’; forename Giulio (Hebrew: Yoel)., pp. 438–462. DOI: 10.1103/PhysRev.62.438.

[868] M. Schönberg and S. Chandrasekhar. “On the Evolution of the Main-Sequence Stars”. In: *The Astrophysical Journal* 96 (1942), p. 161. DOI: 10.1086/144444.

[869] S. Chandrasekhar. “Stochastic Problems in Physics and Astronomy”. In: *Reviews of Modern Physics* 15.1 (1943), pp. 1–89. DOI: 10.1103/RevModPhys.15.1.

[870] M. Fréchet. “Sur l’extension de certaines évaluations statistiques au cas de petits échantillons”. In: *Revue de l’Institut International de Statistique* 11.3/4 (1943). Crossref-verified. The earliest of the three independent statements of the information inequality, ahead of Rao:1945 and of Cramer’s 1946 book; the treatise keeps the customary name Cramer-Rao and records the priority here. Crossref lists the author twice, once accented and once not, which is a deposit artefact and not two people., pp. 182–205. DOI: 10.2307/1401114.

[871] I. Gelfand and M. Neumark. “On the imbedding of normed rings into the ring of operators in Hilbert space”. In: *Matematicheskii Sbornik* 12(54) (1943), pp. 197–213.

[872] W. Heisenberg. “Die "beobachtbaren Größen" in der Theorie der Elementarteilchen”. In: *Zeitschrift für Physik* 120.7-10 (1943), pp. 513–538. DOI: 10.1007/BF01329800.

[873] G. Racah. “Theory of Complex Spectra. III”. In: *Physical Review* 63.9-10 (1943). Crossref-verified. Third instalment of the series; this is the paper that introduces the coefficient for the recoupling of four angular momenta (the modern 9j symbol). Its companion Racah:1942, cited in the same sentence, is ’Theory of Complex Spectra. II’, Phys. Rev. 62, 438-462 (1942), doi 10.1103/PhysRev.62.438, where the W (6j) coefficient appears., pp. 367–382. DOI: 10.1103/PhysRev.63.367.

[874] R. L. Goodstein. “On the restricted ordinal theorem”. In: *The Journal of Symbolic Logic* 9.2 (1944). Proves what is now called Goodstein’s theorem; its unprovability in PA is Kirby–Paris 1982, pp. 33–41. DOI: 10.2307/2268019.

[875] L. Onsager. “Crystal Statistics. I. A Two-Dimensional Model with an Order-Disorder Transition”. In: *Physical Review* 65.3-4 (1944), pp. 117–149. DOI: 10.1103/PhysRev.65.117.

[876] V. Peshkov. “Second sound in helium II”. In: *Journal of Physics USSR* 8 (1944). No DOI., p. 381.

[877] S. O. Rice. “Mathematical analysis of random noise”. In: *Bell System Technical Journal* 23.3 (1944). Crossref-verified. Parts I (Shot Effect) and II (Power Spectra and Correlation Functions). This instalment does NOT contain the level-crossing formula: the expected number of upcrossings of a stationary process is Part III, sec. 3.3, in the companion Rice:1945. Cite Rice:1945 for the crossing count., pp. 282–332. DOI: 10.1002/j.1538-7305.1944.tb00874.x.

[878] H. B. G. Casimir. “On Onsager’s Principle of Microscopic Reversibility”. In: *Reviews of Modern Physics* 17.2-3 (1945), pp. 343–350. DOI: 10.1103/RevModPhys.17.343.

[879] E. A. Guggenheim. “The Principle of Corresponding States”. In: *The Journal of Chemical Physics* 13.7 (1945), pp. 253–261. DOI: 10.1063/1.1724033.

[880] H. C. van de Hulst. “Radiogolven uit het wereldruim. II. Herkomst der radiogolven”. In: *Nederlandsch Tijdschrift voor Natuurkunde* 11 (1945). The wartime 21 cm prediction: presented to the Nederlandsche Astronomen Club, Leiden, 15 April 1944, published in the December 1945 issue (jaargang XI, no. 12). It is part II of a two-part article; part I, "Ontvangst der radiogolven", pp. 201-210, is by C. J. Bakker, which is why some catalogues cite the whole as Bakker & van de Hulst, Ned. Tijdschr. Natuurkd. 11, 201-221 (1945). Only pp. 210-221 are van de Hulst’s and only those contain the cited prediction. TITLE VARIANT: the Dictionary of Scientific Biography bibliography prints the series title as "Radiostraling uit het wereldruim"; the radio-astronomy literature and the Dutch sources agree on "Radiogolven", which is also the form consistent with both part titles, so that is what I give. No DOI exists (do not invent one); the retrievable access route for a reader is the English translation, paper 34 in W. T. Sullivan III (ed.), Classics in Radio Astronomy (Reidel, Dordrecht, 1982), pp. 302-316 — worth recording in the bib note or the library manifest, since the Dutch original is otherwise unverifiable., pp. 210–221.

[881] C. Møller. “General Properties of the Characteristic Matrix in the Theory of Elementary Particles. I”. In: *Det Kongelige Danske Videnskabernes Selskab, Matematisk-fysiske Meddelelser* 23 (1945). Issue no. 1 of volume 23. Danish academy communications; unlikely to be in Crossref, no DOI supplied., pp. 1–48.

[882] C. R. Rao. “Information and the accuracy attainable in the estimation of statistical parameters”. In: *Bulletin of the Calcutta Mathematical Society* 37 (1945). The information inequality, independently obtained by Frechet:1943 and by Cramer in 1946; the treatise states it as the Cramer-Rao bound and records the joint attribution. The 1945 original is not deposited with Crossref (the Bulletin of the Calcutta Mathematical Society has no DOIs for that period), so no DOI is given here rather than an invented one. It is reprinted, with an introduction by P. K. Pathak, in Breakthroughs in Statistics vol. I, Springer Series in Statistics (1992), pp. 235–247, doi 10.1007/978-1-4612-0919-5_16, which is the practical route to the text and was verified against the API., pp. 81–91.

[883] S. O. Rice. “Mathematical analysis of random noise”. In: *Bell System Technical Journal* 24.1 (1945). Crossref-verified (resolved record read: Rice, S. O., Bell System Technical Journal 24(1) 46–156, 1945). Parts III (Statistical Properties of Random Noise Currents) and IV of the paper begun in Rice:1944. Section 3.3 carries the level-crossing formula for the expected number of zeros and upcrossings per second, which is what fixes how the trials factor of the look-elsewhere effect scales with the threshold., pp. 46–156. DOI: 10.1002/j.1538-7305.1945.tb00453.x.

[884] J. A. Wheeler and R. P. Feynman. “Interaction with the Absorber as the Mechanism of Radiation”. In: *Reviews of Modern Physics* 17.2-3 (1945). Verified via Crossref (Rev. Mod. Phys. 17(2-3), Apr 1945). This is the absorber-theory paper the prose names. The 1949 sequel, "Classical Electrodynamics in Terms of Direct Interparticle Action", Rev. Mod. Phys. 21, 425 (1949), is a different work and would need its own key., pp. 157–181. DOI: 10.1103/RevModPhys.17.157.

[885] E. Zavoisky. “Spin-magnetic resonance in paramagnetics”. In: *Journal of Physics USSR* 9 (1945), pp. 211–216.

[886] E. L. Andronikashvili. “A direct observation of two kinds of motion in helium II”. In: *Journal of Physics USSR* 10 (1946). Russian original Zh. Eksp. Teor. Fiz. 16, 780 (1946); no DOI., pp. 201–206.

[887] F. Bloch, W. W. Hansen, and M. Packard. “Nuclear Induction”. In: *Physical Review* 69.3-4 (1946), pp. 127–127. DOI: 10.1103/PhysRev.69.127.

[888] R. H. Dicke. “The Measurement of Thermal Radiation at Microwave Frequencies”. In: *Review of Scientific Instruments* 17.7 (1946). The Dicke switched radiometer, pp. 268–275. DOI: 10.1063/1.1770483.

[889] A. S. Eddington. *Fundamental Theory*. Published posthumously. The attempted derivation of $1/\alpha$ as an exact integer, revised from 136 to 137 as measurements moved, is the standard cautionary tale against numerology. Cambridge: Cambridge University Press, 1946.

[890] V. L. Ginzburg and I. M. Frank. “Izluchenie ravnomerno dvizhushchegosya elektrona, voznikayushchee pri ego perekhode iz odnoi sredy v druguyu”. In: *Zhurnal eksperimentalnoi i teoreticheskoi fiziki* 16 (1946). The transition-radiation prediction. TWO THINGS THE BIB WRITER MUST KNOW. (1) The treatise builds with pdflatex, which cannot typeset Cyrillic – use the transliteration ’Izluchenie ravnomerno dvizhushchegosya elektrona, voznikayushchee pri ego perekhode iz odnoi sredy v druguyu’, venue ’Zhurnal Eksperimental’noi i Teoreticheskoi Fiziki (ZhETF)’, and put the Cyrillic in a note if wanted. (2) An English-language version was published FIRST: Ginzburg and Frank, ’Radiation of a uniformly moving electron due to its transition from one medium into another’, J. Phys. (USSR) 9, 353-362 (1945) – that is the retrievable one and the better entry if the chapter is willing to carry the 1945 dating; keeping the key Ginzburg:1946 while citing the 1945 English printing would misreport the year, so pick one and say so in the note. Pages: only the opening page 15 is attested by the sources I checked; the range is often quoted as 15-28 but I did not confirm it, so no range is given here. No DOI. Russian-language original: the title and journal are given here in scientific transliteration, because the treatise builds with pdflatex under T1 encoding, which cannot typeset Cyrillic., p. 15.

[891] L. D. Landau. “On the vibration of the electronic plasma”. In: *Journal of Physics (USSR)* 10 (1946). The collisionless (Landau) damping paper cited in the plasma chapter. Published in English in the Soviet Academy’s Journal of Physics (USSR), vol. 10 no. 1; the Russian original is Zh. Eksp. Teor. Fiz. 16, 574 (1946). Title variants exist in the literature (’On the vibrations of the electronic plasma’, used by the 1967 UFN reprint and by mathnet); the form above is the one carried by the J. Phys. USSR printing and by the ter Haar Collected Papers reprint (Pergamon, 1965, pp. 445–460). No DOI exists; the ter Haar volume or the UFN reprint is the practical access route for a reader., pp. 25–34.

[892] E. M. Lifshitz. “On the gravitational stability of the expanding universe”. In: *Journal of Physics (USSR)* 10 (1946). Pre-DOI original; access route recorded in the library manifest (Golden Oldie republication, Gen. Rel. Grav. 49, 18 (2017))., pp. 116–129.

[893] E. M. Purcell. “Spontaneous Emission Probabilities at Radio Frequencies”. In: *Physical Review* 69 (1946). Meeting abstract B10, printed under ’Proceedings of the American Physical Society’; the origin of the Purcell factor. No DOI of its own: the only DOI covering it, 10.1103/PhysRev.69.674.2, is titled ’Proceedings of the American Physical Society’ and would not match this title, so it is deliberately omitted., p. 681.

[894] E. M. Purcell, H. C. Torrey, and R. V. Pound. “Resonance Absorption by Nuclear Magnetic Moments in a Solid”. In: *Physical Review* 69.1-2 (1946). NMR detected by absorption in bulk paraffin; the counterpart of Bloch’s induction method., pp. 37–38. DOI: 10.1103/PhysRev.69.37.

[895] S. Tomonaga. “On a Relativistically Invariant Formulation of the Quantum Theory of Wave Fields*”. In: *Progress of Theoretical Physics* 1.2 (1946), pp. 27–42. DOI: 10.1143/PTP.1.27.

[896] J. Bardeen. “Surface States and Rectification at a Metal Semi-Conductor Contact”. In: *Physical Review* 71.10 (1947), pp. 717–727. DOI: 10.1103/PhysRev.71.717.

[897] H. A. Bethe. “The Electromagnetic Shift of Energy Levels”. In: *Physical Review* 72.4 (1947), pp. 339–341. DOI: 10.1103/PhysRev.72.339.

[898] N. N. Bogoliubov. “On the theory of superfluidity”. In: *Journal of Physics (USSR)* 11 (1947), pp. 23–32.

[899] M. Conversi, E. Pancini, and O. Piccioni. “On the Disintegration of Negative Mesons”. In: *Physical Review* 71.3 (1947), pp. 209–210. DOI: 10.1103/PhysRev.71.209.

[900] F. R. Elder, A. M. Gurewitsch, R. V. Langmuir, and H. C. Pollock. “Radiation from Electrons in a Synchrotron”. In: *Physical Review* 71.11 (1947). Crossref confirmed: Phys. Rev. vol. 71, pp. 829-830, 1 June 1947, all four authors. The DOI’s trailing ’.5’ is REAL – it disambiguates the fifth Letter to the Editor beginning on p. 829; 10.1103/PhysRev.71.829 alone does not resolve to this paper. Do not ’clean’ it. First observation of synchrotron radiation; cited in the chapter beside Schott:1912., pp. 829–830. DOI: 10.1103/PhysRev.71.829.5.

[901] W. E. Lamb and R. C. Retherford. “Fine Structure of the Hydrogen Atom by a Microwave Method”. In: *Physical Review* 72.3 (1947), pp. 241–243. DOI: 10.1103/PhysRev.72.241.

[902] C. M. G. LATTES, H. MUIRHEAD, G. P. S. OCCHIALINI, and C. F. POWELL. “PROCESSES INVOLVING CHARGED MESONS”. In: *Nature* 159.4047 (1947), pp. 694–697. DOI: 10.1038/159694a0.

[903] G. D. Rochester and C. C. Butler. “Evidence for the Existence of New Unstable Elementary Particles”. In: *Nature* 160 (1947), pp. 855–857.

[904] I. E. Segal. “Postulates for General Quantum Mechanics”. In: *The Annals of Mathematics* 48.4 (1947), p. 930. DOI: 10.2307/1969387.

[905] R. A. Alpher, H. Bethe, and G. Gamow. “The Origin of Chemical Elements”. In: *Physical Review* 73.7 (1948). The alpha-beta-gamma paper. Suffix a/b: two 1948 works by first author Alpher; b is the Alpher–Herman Nature CMB prediction., pp. 803–804. DOI: 10.1103/PhysRev.73.803.

[906] R. A. ALPHER and R. HERMAN. “Evolution of the Universe”. In: *Nature* 162.4124 (1948). Prediction of the relic radiation at a few kelvin. See suffix note on Alpher:1948a., pp. 774–775. DOI: 10.1038/162774b0.

[907] J. Bardeen and W. H. Brattain. “The Transistor, A Semi-Conductor Triode”. In: *Physical Review* 74.2 (1948), pp. 230–231. DOI: 10.1103/PhysRev.74.230.

[908] V. Bargmann and E. P. Wigner. “Group Theoretical Discussion of Relativistic Wave Equations”. In: *Proceedings of the National Academy of Sciences* 34.5 (1948), pp. 211–223. DOI: 10.1073/pnas.34.5.211.

[909] H. B. G. Casimir. “On the attraction between two perfectly conducting plates”. In: *Proceedings of the Koninklijke Nederlandse Akademie van Wetenschappen*. Vol. 51. Academy proceedings (Series B, Physical Sciences), issued in numbered volumes, so volume 51 is printed and not invented; no DOI exists for it. Treated as @article because it is a numbered periodical with volume and pages. 1948, pp. 793–795.

[910] H. B. G. Casimir and D. Polder. “The Influence of Retardation on the London-van der Waals Forces”. In: *Physical Review* 73.4 (1948). Retarded dispersion forces: Rˆ-7 between two atoms, zˆ-4 between an atom and a conducting wall., pp. 360–372. DOI: 10.1103/PhysRev.73.360.

[911] R. P. Feynman. “Space-Time Approach to Non-Relativistic Quantum Mechanics”. In: *Reviews of Modern Physics* 20.2 (1948), pp. 367–387. DOI: 10.1103/RevModPhys.20.367.

[912] H. M. Foley and P. Kusch. “On the Intrinsic Moment of the Electron”. In: *Physical Review* 73.4 (1948). The earlier of the two 1948 papers (received February 1948); the customary single citation Kusch–Foley 1948 refers to the later Phys. Rev. 74, 250., pp. 412–412. DOI: 10.1103/PhysRev.73.412.

[913] D. GABOR. “A New Microscopic Principle”. In: *Nature* 161.4098 (1948). Crossref-verified. Crossref records the title as ’A New Microscopic Principle’; the paper is very widely cited as ’A new microscope principle’, so the customary form is wrong and the Crossref form is used. Nobel Prize in Physics 1971. Cited for the holography contrast in the interpretation., pp. 777–778. DOI: 10.1038/161777a0.

[914] G. Gamow. “The Origin of Elements and the Separation of Galaxies”. In: *Physical Review* 74 (1948). Letter; the DOI carries the .2 suffix because the page is shared. Metadata confirmed against Crossref., pp. 505–506. DOI: 10.1103/PhysRev.74.505.2.

[915] C. G. Hempel and P. Oppenheim. “Studies in the Logic of Explanation”. In: *Philosophy of Science* 15.2 (1948). The deductive-nomological account of explanation: the explanandum is derived from laws together with stated initial conditions, pp. 135–175. DOI: 10.1086/286983.

[916] P. Kusch and H. M. Foley. “The Magnetic Moment of the Electron”. In: *Physical Review* 74.3 (1948), pp. 250–263. DOI: 10.1103/PhysRev.74.250.

[917] L. D. Landau. “On the angular momentum of a system of two photons”. In: *Doklady Akademii Nauk SSSR* 60 (1948), pp. 207–209.

[918] M. L. Néel. “Propriétés magnétiques des ferrites ; ferrimagnétisme et antiferromagnétisme”. In: *Annales de Physique* 12.3 (1948). DOI not verified; omitted deliberately, pp. 137–198. DOI: 10.1051/anphys/194812030137.

[919] J. Schwinger. “On Quantum-Electrodynamics and the Magnetic Moment of the Electron”. In: *Physical Review* 73.4 (1948), pp. 416–417. DOI: 10.1103/PhysRev.73.416.

[920] J. Schwinger. “Quantum Electrodynamics. I. A Covariant Formulation”. In: *Physical Review* 74.10 (1948), pp. 1439–1461. DOI: 10.1103/PhysRev.74.1439.

[921] C. E. Shannon. “A Mathematical Theory of Communication”. In: *Bell System Technical Journal* 27.3 (1948), pp. 379–423. DOI: 10.1002/j.1538-7305.1948.tb01338.x.

[922] E. P. Wigner. “On the Behavior of Cross Sections Near Thresholds”. In: *Physical Review* 73.9 (1948), pp. 1002–1009. DOI: 10.1103/PhysRev.73.1002.

[923] E. O. Wollan and C. G. Shull. “The Diffraction of Neutrons by Crystalline Powders”. In: *Physical Review* 73.8 (1948). Issue 8. Crossref-verified. The Oak Ridge graphite-reactor powder-diffractometer method paper (monochromating crystal, Soller collimators, BF3 counter on a rotating arm) that the Apparatus subsection of exp:nscat-shull-mno describes; added to the existing cite group there (line 158). Wollan is first author here, Shull second, so the key is correctly Wollan:YYYY and does not collide with Shull:1949/Shull:1951., pp. 830–841. DOI: 10.1103/PhysRev.73.830.

[924] H. A. Bethe. “Theory of the Effective Range in Nuclear Scattering”. In: *Physical Review* 76.1 (1949), pp. 38–50. DOI: 10.1103/PhysRev.76.38.

[925] D. Bohm and E. P. Gross. “Theory of Plasma Oscillations. A. Origin of Medium-Like Behavior”. In: *Physical Review* 75.12 (1949). The Bohm–Gross dispersion relation cited in the chapter is in part A. Part B (’Excitation and Damping of Oscillations’, Phys. Rev. 75, 1864–1876, DOI 10.1103/PhysRev.75.1864) is a separate entry – if the damping discussion is ever cited, it needs key Bohm:1949b. Crossref-verified., pp. 1851–1864. DOI: 10.1103/PhysRev.75.1851.

[926] D. Crowfoot, C. W. Bunn, B. W. Rogers-Low, and A. Turner-Jones. “The X-Ray Crystallographic Investigation of the Structure of Penicillin”. In: *Chemistry of Penicillin*. Book chapter – the correct biblatex type is @incollection (the schema here has no such option; do NOT enter as @inproceedings without a booktitle). booktitle = The Chemistry of Penicillin, editors H. T. Clarke, J. R. Johnson and R. Robinson, Princeton University Press 1949, pp. 310-366. Crossref prints the title with its chapter numeral, ’XI. The X-Ray Crystallographic Investigation of the Structure of Penicillin’; a JSTOR record of the same chapter carries DOI 10.2307/j.ctt183px0j.14. Dorothy Crowfoot is Dorothy Crowfoot Hodgkin, publishing under her maiden name. 1949, pp. 310–366. DOI: 10.1515/9781400874910-012.

[927] F. J. Dyson. “The Radiation Theories of Tomonaga, Schwinger, and Feynman”. In: *Physical Review* 75.3 (1949). Crossref confirmed: Phys. Rev. vol. 75, pp. 486-502, 1 February 1949. This is the paper that introduces the time-ordered expansion now called the Dyson series, which is what the citing sentence claims, so it is the right one of the two 1949 Dyson papers. The companion – ’The S Matrix in Quantum Electrodynamics’, Phys. Rev. 75, 1736-1755 (1949), DOI 10.1103/PhysRev.75.1736 – is sometimes cited for the same material; if the QED chapter later needs it, key it Dyson:1949b and leave this one unsuffixed., pp. 486–502. DOI: 10.1103/PhysRev.75.486.

[928] F. J. Dyson. “TheSMatrix in Quantum Electrodynamics”. In: *Physical Review* 75.11 (1949), pp. 1736–1755. DOI: 10.1103/PhysRev.75.1736.

[929] E. Fermi. “On the Origin of the Cosmic Radiation”. In: *Physical Review* 75.8 (1949), pp. 1169–1174. DOI: 10.1103/PhysRev.75.1169.

[930] R. P. Feynman. “Space-Time Approach to Quantum Electrodynamics”. In: *Physical Review* 76.6 (1949), pp. 769–789. DOI: 10.1103/PhysRev.76.769.

[931] R. P. Feynman. “The Theory of Positrons”. In: *Physical Review* 76.6 (1949). Suffix a/b needed: two Feynman papers of 1949 are cited., pp. 749–759. DOI: 10.1103/PhysRev.76.749.

[932] D. Gabor. “Microscopy by reconstructed wave-fronts”. In: *Proceedings of the Royal Society of London. Series A. Mathematical and Physical Sciences* 197.1051 (1949). Issue 1051. The full theory plus the in-line mercury-arc experiments, including the reconstruction of the transparency bearing the names Huygens, Young and Fresnel, and the electron-microscope aberration-correction programme that motivated the work., pp. 454–487. DOI: 10.1098/rspa.1949.0075.

[933] O. Haxel, J. H. D. Jensen, and H. E. Suess. “On the "Magic Numbers" in Nuclear Structure”. In: *Physical Review* 75.11 (1949), pp. 1766–1766. DOI: 10.1103/physrev.75.1766.2.

[934] L. van Hove. “Quelques Propriétés Générales De L’intégrale De Configuration D’un Système De Particules Avec Interaction”. In: *Physica* 15.11-12 (1949), pp. 951–961. DOI: 10.1016/0031-8914(49)90059-2.

[935] M. Kac. “On distributions of certain Wiener functionals”. In: *Transactions of the American Mathematical Society* 65.1 (1949), pp. 1–13. DOI: 10.1090/S0002-9947-1949-0027960-X.

[937] N. M. Kroll and W. E. Lamb. “On the Self-Energy of a Bound Electron”. In: *Physical Review* 75.3 (1949), pp. 388–398. DOI: 10.1103/PhysRev.75.388.

[938] N. Levinson. “On the uniqueness of the potential in a Schrödinger equation for a given asymptotic phase”. In: *Kongelige Danske Videnskabernes Selskab, Matematisk-Fysiske Meddelelser* 25 (1949). Issue no. 9 of volume 25. Danish academy communications; no DOI supplied., pp. 1–29.

[939] S. Lundquist. “Experimental Investigations of Magneto-Hydrodynamic Waves”. In: *Physical Review* 76.12 (1949). Issue 12. Crossref-confirmed. The liquid-mercury Alfven-wave experiment the plasma chapter cites., pp. 1805–1809. DOI: 10.1103/PhysRev.76.1805.

[940] M. G. Mayer. “On Closed Shells in Nuclei. II”. In: *Physical Review* 75.12 (1949), pp. 1969–1970. DOI: 10.1103/PhysRev.75.1969.

[941] N. F. Mott. “The Basis of the Electron Theory of Metals, with Special Reference to the Transition Metals”. In: *Proceedings of the Physical Society. Section A* 62.7 (1949), pp. 416–422. DOI: 10.1088/0370-1298/62/7/303.

[942] T. D. Newton and E. P. Wigner. “Localized States for Elementary Systems”. In: *Reviews of Modern Physics* 21.3 (1949), pp. 400–406. DOI: 10.1103/RevModPhys.21.400.

[943] L. Onsager. “Statistical hydrodynamics”. In: *Il Nuovo Cimento* 6.S2 (1949). Supplement 2 to volume 6. Contains the remark that circulation in superfluid helium is quantized in units of h/m; the two 1949 Onsager papers are split a/b because neither sense is secondary., pp. 279–287. DOI: 10.1007/BF02780991.

[944] L. Onsager. “THE EFFECTS OF SHAPE ON THE INTERACTION OF COLLOIDAL PARTICLES”. In: *Annals of the New York Academy of Sciences* 51.4 (1949). Origin of the purely entropic, excluded-volume isotropic–nematic transition for hard rods., pp. 627–659. DOI: 10.1111/j.1749-6632.1949.tb27296.x.

[945] W. Pauli and F. Villars. “On the Invariant Regularization in Relativistic Quantum Theory”. In: *Reviews of Modern Physics* 21.3 (1949), pp. 434–444. DOI: 10.1103/RevModPhys.21.434.

[946] G. L. Pearson and J. Bardeen. “Electrical Properties of Pure Silicon and Silicon Alloys Containing Boron and Phosphorus”. In: *Physical Review* 75.5 (1949), pp. 865–883. DOI: 10.1103/PhysRev.75.865.

[947] C. Shannon. “Communication in the Presence of Noise”. In: *Proceedings of the IRE* 37.1 (1949), pp. 10–21. DOI: 10.1109/JRPROC.1949.232969.

[948] W. Shockley. “The Theory ofp-nJunctions in Semiconductors andp-nJunction Transistors”. In: *Bell System Technical Journal* 28.3 (1949), pp. 435–489. DOI: 10.1002/j.1538-7305.1949.tb03645.x.

[949] C. G. Shull and J. S. Smart. “Detection of Antiferromagnetism by Neutron Diffraction”. In: *Physical Review* 76.8 (1949), pp. 1256–1257. DOI: 10.1103/physrev.76.1256.2.

[950] A. Wald. “Note on the consistency of the maximum likelihood estimate”. In: *The Annals of Mathematical Statistics* 20.4 (1949). Crossref-verified. Consistency of the maximum-likelihood estimator under conditions weaker than the classical ones. DISTINGUISH from Wald:1984 and Wald:1994, which are Robert M. Wald’s General Relativity and Quantum Field Theory in Curved Spacetime: a different Wald entirely., pp. 595–601. DOI: 10.1214/aoms/1177729952.

[951] H. Alfvén. *Cosmical Electrodynamics*. Cited as a standard plasma monograph alongside Spitzer:1962. First edition, Oxford, 1950, in the International Series of Monographs on Physics. A much-revised 2nd edition (1963) is co-authored with C.-G. Fälthammar – if the 2nd edition is ever meant, the author list and year both change, so keep this entry pinned to the 1950 first edition. Printed monograph: expect an AMBER availability grade. Clarendon Press, 1950.

[952] P. W. Anderson. “Antiferromagnetism. Theory of Superexchange Interaction”. In: *Physical Review* 79.2 (1950), pp. 350–356. DOI: 10.1103/PhysRev.79.350.

[953] K. Bleuler. “Eine neue Methode zur Behandlung der longitudinalen und skalaren Photonen”. In: *Helvetica Physica Acta* 23 (1950). No DOI; Helvetica Physica Acta is not indexed by Crossref for this period, pp. 567–586.

[954] E. Fermi. *Nuclear Physics: A Course Given by Enrico Fermi at the University of Chicago*. Lecture notes from Fermi’s 1949 Chicago course; this is where the transition-rate formula is christened ’Golden Rule No. 2’. A revised edition appeared in 1950/1951 – the citing prose only needs the naming, so the 1950 first printing is correct for the key. No DOI. notes compiled by Orear, Jay and Rosenfeld, A. H. and Schluter, R. A. Chicago: University of Chicago Press, 1950.

[955] L. L. Foldy and S. A. Wouthuysen. “On the Dirac Theory of Spin 1/2 Particles and Its Non-Relativistic Limit”. In: *Physical Review* 78.1 (1950), pp. 29–36. DOI: 10.1103/PhysRev.78.29.

[956] H. Fröhlich. “Theory of the Superconducting State. I. The Ground State at the Absolute Zero of Temperature”. In: *Physical Review* 79.5 (1950), pp. 845–856. DOI: 10.1103/PhysRev.79.845.

[1303] S. I. Braginskii. “Transport Processes in a Plasma”. In: *Reviews of Plasma Physics, Volume 1*. NOT a proceedings paper – it is a chapter in an edited volume, so the right biblatex type is @incollection: booktitle = Reviews of Plasma Physics, volume = 1, editor = Leontovich, M. A., publisher = Consultants Bureau, address = New York, pages = 205–311. 'inproceedings' is only the closest kind the schema offers. Authorised English translation from the Russian by H. Lashinsky; the Russian original is 'Yavleniya perenosa v plazme' in *Voprosy teorii plazmy*, vyp. 1 (Gosatomizdat, Moskva, 1963) – I do not have its page range, so do not state one. No DOI exists; ADS bibcode 1965RvPP....1..205B. This is the source of the standard anisotropic transport-coefficient tables cited in the plasma chapter. 1965, pp. 205–311.
