Treatise of Physics

An evidence-based account of theoretical, mathematical, and experimental physics

Nicolas Gonzalez

Written with the assistance of Claude (Opus 5, Fable 5);
see *A note on method* in the preface.

August 25, 2026

Preface

To be human is to change. Physics is the description of change; even the acquisition of knowledge is itself a change. And yet beneath all of it Nature keeps a set of regularities — rules — that allow us to reproduce everything empirical that she is telling us. That set of rules, taken whole, is the entire framework of Theoretical, Mathematical, and Experimental Physics.

This treatise attempts a single, connected account of physics restricted to what has actually been observed in Nature. Its three threads — theoretical, mathematical, and experimental physics — are kept deliberately interwoven: every theoretical claim is anchored to the experiments that force it, every experiment is presented in full phenomenological detail, and every observed phenomenon carries its mathematical derivation, either in place or in Appendix A.

Speculative programs without experimental support — string theory, supersymmetry, supergravity, and their relatives — are outside the scope of this work, however mathematically compelling. High-energy physics up to the Standard Model, being among the best-tested science ever produced, is treated in full. The frontier of what is observed but not understood is stated honestly in the closing part.

Two working rules govern the text throughout. First, SI units are used axiomatically in every branch. Second, the mathematics is developed in the generality it deserves — in particular, geometric and group-theoretic chapters are written for general dimension $D = p + q$ with signature (p, q) — while the physics is always instantiated in the observed $3 + 1$ dimensions.

Derivations not yet written are never silently omitted: they are marked as pending, and collected in the List of Pending Derivations.

A note on method

Much of this text was drafted with the assistance of large language models — Anthropic's Claude, in the Opus 5 and Fable 5 versions. The division of labour was this: I set the scope, the editorial rules and the structure, directed the work chapter by chapter, and decided what the book would and would not claim; the models translated and ported the older Spanish sources, drafted prose and derivations to those rules, and wrote most of the checking apparatus described below. They are named on the title page as what they were, an instrument. They are not authors, and could not be: an author answers for the work, and a language model cannot. Every error here is mine.

That apparatus is worth describing, because it is what the honesty of a book this size actually rests on. The sources are checked mechanically before every commit: that each citation key resolves to a real entry, that each entry's DOI resolves to the work claimed for it, that no equation silently loses a unit, that nothing reaches the reader as raw markup, and that the logical skeleton of the book — which statement rests on which, which derivation discharges which claim — is a machine-readable database whose two representations are proved equivalent. Where a result is quoted rather than proved, a remark headed *What is*

quoted here says so and names the missing theorem.

None of that is peer review, and it should not be mistaken for it. A derivation drafted by a model and checked by a program can still be wrong in ways neither notices; a citation can resolve perfectly and support nothing. What the machinery buys is that the book's gaps are visible rather than hidden — the pending derivations are listed, the quoted inputs are named, and the claims that no experiment tests are marked as such. A reader who distrusts a particular argument is meant to be able to find its foundations and check them. That is the standard this book sets for itself, and the reason to prefer a stated gap to a confident sentence.

Editorial Conventions

The four rules below govern how this treatise is written, read once here and applied silently everywhere after. They are rules of editorial *policy*, not of notation; for what the symbols themselves mean, see the single canonical reference, Appendix E.

Units

> **Axiom (SI).** All physical quantities in this treatise are expressed in the International System of Units (SI), in every branch of physics.

Numerical values are typeset with their units, e.g. the standard acceleration of free fall $g_0 = 9.806\,65\,\mathrm{m/s^2}$. Natural or Gaussian units appear only inside clearly flagged remarks, always with the conversion back to SI stated. The SI base units and the defining constants of the 2019 revision are collected in Appendix B.

Proofs of observed phenomena

Every observed phenomenon stated in this treatise (environment *Phenomenon*) carries its mathematical derivation: short derivations follow the statement directly; long derivations live in Appendix A and are linked from the statement. A derivation not yet written is marked visibly as pending — never omitted.

Experiments

Experiments are presented in dedicated boxes with a fixed structure: apparatus, procedure, observations and data (with uncertainties, in SI), interpretation, and primary references. The List of Experiments in the front matter indexes all of them.

Notation

Every symbol, macro, and index convention used in this treatise — vector notation, the differential d, index-letter conventions for general dimension $D = p + q$, the full macro-to-meaning dictionary — is collected in one place, Appendix E, rather than restated piecemeal through the front matter.

List of Pending Derivations xcix

I Foundations 1

1 Epistemology and the Scientific Method 3
- 1.1 What physics is . . . 3
- 1.2 Physics, mathematics, and philosophy . . . 3
- 1.3 Why this treatise follows analytic philosophy . . . 4
  - 1.3.1 The choice cannot be avoided . . . 4
  - 1.3.2 What the commitment amounts to . . . 4
  - 1.3.3 Why this tradition and not another . . . 5
  - 1.3.4 What the alternatives would cost . . . 6
  - 1.3.5 The price of the choice . . . 6
  - 1.3.6 How the choice shows on the page . . . 7
- 1.4 The scientific method as used in this treatise . . . 7
- 1.5 Primitive notions . . . 8
- 1.6 How this treatise is organized . . . 9

2 Measurement, SI Units, and the Theory of Errors 11
- 2.1 Measurement . . . 11
- 2.2 The International System of Units . . . 11
  - 2.2.1 Dimensional analysis . . . 11
- 2.3 The theory of errors . . . 12
  - 2.3.1 Repeated measurements . . . 12
  - 2.3.2 Propagation of uncertainty . . . 13
  - 2.3.3 Combining and fitting data . . . 14
  - 2.3.4 Reporting . . . 14
- 2.4 A worked example: timing a pendulum . . . 14

II Mathematical Methods 15

3 Logic, Sets, and Maps 17
- 3.1 Logic . . . 17
  - 3.1.1 Propositions . . . 17

3.1.2 Logical operators . . . 18
3.1.3 Implications and logical equivalences . . . 21
3.1.4 Predicates and quantifiers . . . 23
3.1.5 Methods of proof . . . 24
3.2 Sets . . . 25
3.2.1 Sets . . . 25
3.2.2 Numbers . . . 26
3.2.3 Operations with sets . . . 28
3.2.4 Cardinality . . . 30
3.3 Maps . . . 31
3.3.1 Maps . . . 31
3.4 Equivalence classes . . . 34
3.4.1 Equivalence relations . . . 34
3.4.2 Quotient space . . . 35
3.5 The infinite . . . 36
3.5.1 Equipotence and countability . . . 36
3.5.2 The diagonal argument . . . 37
3.5.3 The continuum hypothesis . . . 38
3.6 The crisis of foundations . . . 39
3.6.1 Russell's paradox . . . 39
3.6.2 The Zermelo–Fraenkel axioms . . . 40
3.6.3 The axiom of choice . . . 41
3.6.4 Three answers to the crisis . . . 41
3.7 The analytical perspective . . . 42
3.7.1 The linguistic turn . . . 42
3.7.2 Logical positivism and its collapse . . . 43
3.7.3 The position this treatise takes . . . 44
3.8 Formal systems and incompleteness . . . 44
3.8.1 Formal systems . . . 45
3.8.2 Completeness — what logic does deliver . . . 46
3.8.3 Arithmetization . . . 46
3.8.4 The first incompleteness theorem . . . 47
3.8.5 The second incompleteness theorem . . . 48
3.8.6 What the theorems do not say . . . 48
3.9 Computability and decidability . . . 49
3.9.1 Turing machines . . . 50
3.9.2 The halting problem . . . 51
3.9.3 The Entscheidungsproblem answered . . . 52
3.9.4 Where decision procedures do exist . . . 52
3.9.5 Undecidability inside physics . . . 53
3.10 Can mathematics be built without contradictions? . . . 54
3.10.1 What Hilbert asked for . . . 54
3.10.2 What survived: relative consistency . . . 54
3.10.3 The honest answer . . . 55
3.10.4 How much of this reaches physics . . . 55

4 Algebraic Structures **57**
4.1 Binary operations and algebraic structures . . . 57
4.1.1 Binary operations . . . 57
4.1.2 Maps between algebraic structures . . . 60
4.1.3 Kernel and image . . . 61
4.2 Simple algebraic structures . . . 62

4.2.1 Semigroups, monoids, and groups . . . 62
4.2.2 Basic properties of groups . . . 64
4.3 Composite algebraic structures . . . 65
4.3.1 Axioms for composite algebraic structures . . . 65
4.3.2 Composite algebraic structures . . . 66
4.4 Group theory: further definitions . . . 68
4.4.1 Groups . . . 68
4.4.2 Cayley tables . . . 69
4.5 Basic groups . . . 70
4.5.1 The first finite groups . . . 70
4.5.2 The group $\mathbb{Z}$ . . . 71
4.6 Functions on groups . . . 74
4.6.1 Homomorphisms . . . 75
4.6.2 Properties of homomorphisms . . . 76
4.7 The symmetric group . . . 77
4.7.1 The symmetric group . . . 77
4.7.2 The permutation group . . . 78
4.8 Decompositions of a group . . . 81
4.8.1 Conjugacy classes . . . 81
4.8.2 Cosets . . . 83
4.8.3 The quotient group . . . 85
4.9 Direct products . . . 87
4.9.1 Direct product . . . 87
4.9.2 Semidirect product . . . 90

5 Linear Algebra and Representation Theory 95
5.1 Preliminary formulas from elementary algebra . . . 95
5.1.1 Factorials and the binomial theorem . . . 95
5.1.2 Trigonometric formulas . . . 95
5.1.3 The sine and cosine theorems . . . 96
5.1.4 Cramer's rule . . . 96
5.1.5 Derivations of the elementary identities . . . 96
5.1.6 The derivative of a determinant . . . 100
5.2 Vector spaces . . . 101
5.2.1 Vector spaces . . . 101
5.2.2 Bases . . . 104
5.3 Inner product, norm, and metric . . . 106
5.3.1 Inner product . . . 106
5.3.2 Orthogonal bases . . . 111
5.3.3 Vector algebra in three dimensions . . . 113
5.4 Linear transformations . . . 116
5.4.1 Linear transformations . . . 116
5.4.2 The vector space of linear transformations . . . 121
5.4.3 Morphisms of vector spaces . . . 124
5.5 The dual space . . . 127
5.5.1 The dual space . . . 127
5.5.2 Pullback and pushforward . . . 131
5.6 Eigenvectors, eigenvalues, and decompositions . . . 133
5.6.1 Eigenvectors and eigenvalues . . . 133
5.6.2 Decomposition of vector spaces . . . 147
5.6.3 Bilinear transformations . . . 151
5.7 Algebras . . . 157

5.7.1 Algebras . . . 157
5.7.2 The algebra of linear transformations . . . 158
5.7.3 Lie algebras . . . 159
5.7.4 Derivations . . . 160
5.8 Representations of groups . . . 161
5.8.1 The classical groups . . . 161
5.8.2 Representations . . . 168
5.8.3 Irreducible representations . . . 169
5.9 Representations of finite groups . . . 171
5.9.1 Complete reducibility of a unitary representation . . . 171
5.9.2 Every representation of a finite group is unitary . . . 173
5.9.3 The regular representation . . . 176
5.9.4 Direct-sum and direct-product representations . . . 178
5.10 Properties of irreducible representations . . . 178
5.10.1 Fundamental theorems of representations . . . 178
5.10.2 Orthonormality relations . . . 181
5.10.3 Decomposition into irreducible representations . . . 183
5.11 Representations of algebras . . . 187
5.11.1 Basic properties of the representations . . . 187

6 Topological and Metric Spaces 193
6.1 Topological spaces . . . 193
6.1.1 Basic definitions . . . 193
6.1.2 Continuity . . . 194
6.1.3 Compactness . . . 194
6.1.4 Connectedness . . . 195
6.1.5 The winding number . . . 196
6.2 Metric spaces . . . 198
6.2.1 The metric . . . 198
6.2.2 Convergence and completeness . . . 199
6.2.3 Continuity in metric terms . . . 199
6.2.4 Compactness in metric spaces . . . 200
6.3 The topology of $\mathbb{R}^N$ . . . 201
6.3.1 Vectors in $\mathbb{R}^N$ . . . 201

7 Real Analysis 203
7.1 The real numbers . . . 203
7.2 Sequences . . . 203
7.3 Real functions . . . 204
7.4 Limits . . . 205
7.4.1 One-sided limits . . . 206
7.4.2 Infinite limits and limits at infinity . . . 206
7.5 Continuity . . . 207
7.6 The derivative . . . 208
7.6.1 Geometric interpretation of the derivative . . . 208
7.6.2 The derivative function . . . 208
7.6.3 Rules of differentiation . . . 213
7.6.4 The mean value theorems . . . 214
7.7 The Riemann integral . . . 216
7.8 The fundamental theorem of calculus . . . 216
7.9 Series . . . 217
7.9.1 The numbers e and π . . . 219

7.10 Multivariable calculus . . . 225
7.10.1 Planes in $\mathbb{R}^3$ . . . 225
7.10.2 Differentiable functions . . . 225
7.10.3 Taylor expansion in several variables . . . 228
7.10.4 Differentiation under the integral sign . . . 230
7.10.5 The implicit function theorem . . . 232
7.11 Vector analysis . . . 236
7.11.1 The nabla operator . . . 236
7.11.2 Identities of the nabla calculus . . . 236
7.11.3 The integral theorems . . . 239
7.11.4 Conservative fields . . . 243
7.11.5 The Helmholtz decomposition . . . 244
7.12 Sets of measure zero and Hausdorff dimension . . . 245
7.13 Functional calculus . . . 247
7.14 The Dirac delta . . . 248

8 Complex Analysis 249
8.1 The complex field . . . 249
8.2 Holomorphic functions . . . 250
8.3 Contour integrals . . . 251
8.4 Cauchy's integral theorem . . . 251
8.5 The Cauchy integral formula . . . 253
8.6 Laurent series and singularities . . . 255
8.7 The residue theorem . . . 255

9 Ordinary Differential Equations and Sturm–Liouville Theory 257
9.1 Ordinary differential equations . . . 257
9.1.1 Order, linearity, homogeneity . . . 258
9.1.2 Existence and uniqueness . . . 258
9.1.3 The solution space and the Wronskian . . . 262
9.1.4 Elementary first-order equations . . . 263
9.2 Linear systems with constant coefficients . . . 264
9.2.1 The matrix exponential . . . 264
9.2.2 The shape of the solutions . . . 266
9.2.3 Planar systems: classification of the equilibrium . . . 268
9.2.4 Equilibria of a nonlinear system . . . 269
9.2.5 Planar flows and closed orbits . . . 270
9.3 Linear systems with periodic coefficients . . . 271
9.3.1 The monodromy matrix . . . 271
9.3.2 Hill's equation and the tongues of instability . . . 273
9.3.3 The Mathieu equation . . . 274
9.4 Orthonormal systems of functions . . . 275
9.4.1 Orthonormality . . . 275
9.4.2 Expansion in series of orthonormal functions . . . 275
9.4.3 Expansion of a product . . . 276
9.4.4 Parseval relation . . . 277
9.5 The Sturm–Liouville operator . . . 278
9.5.1 Self-adjointness and orthogonality . . . 278
9.6 The semiclassical approximation . . . 279
9.6.1 The equation and its Sturm–Liouville data . . . 280
9.6.2 The expansion in powers of $\hbar$ . . . 280
9.6.3 Where the approximation is valid, and where it is not . . . 283

9.6.4 Connection across a simple turning point . . . 284
9.6.5 Turning points of higher order . . . 287
9.6.6 Barrier penetration and the Gamow factor . . . 288
9.6.7 Bohr–Sommerfeld quantisation and the Maslov index . . . 290
9.6.8 Worked example: a charged particle against a Coulomb barrier . . . 291
9.6.9 The radial equation . . . 292
9.6.10 The Langer substitution . . . 293
9.6.11 Boundary layers and matched asymptotic expansions . . . 294
9.7 The one-dimensional Helmholtz equation . . . 296
9.7.1 Sturm–Liouville data . . . 296
9.7.2 Homogeneous solution . . . 296
9.7.3 Orthonormality . . . 297
9.7.4 Fourier series . . . 297
9.7.5 The Fourier transform . . . 298
9.8 The Bessel equation . . . 299
9.8.1 Sturm–Liouville data . . . 299
9.8.2 General solution . . . 299
9.8.3 Recurrence relations . . . 300
9.8.4 Orthogonality . . . 301
9.8.5 Generating function . . . 301
9.8.6 The Fourier–Bessel series . . . 302
9.8.7 The zeros . . . 302
9.8.8 The modified Bessel functions . . . 304
9.9 The Legendre equation and spherical harmonics . . . 305
9.9.1 The Legendre equation . . . 305
9.9.2 The associated Legendre equation . . . 308
9.9.3 Spherical harmonics . . . 311
9.10 The Hermite equation . . . 312
9.10.1 Sturm–Liouville data . . . 312
9.10.2 Solutions and generating function . . . 312
9.10.3 Orthogonality and Hermite series . . . 313
9.11 The Laguerre equation . . . 314
9.11.1 Sturm–Liouville data . . . 314
9.11.2 Solutions and generating function . . . 314
9.11.3 Orthogonality and Laguerre series . . . 315
9.12 Elliptic integrals and the Jacobi elliptic functions . . . 316
9.12.1 The three normal forms . . . 316
9.12.2 The Jacobi elliptic functions . . . 318
9.12.3 Quadratures that reduce to elliptic integrals . . . 319
9.13 The Laplace transform . . . 321
9.14 Summary of the classical families . . . 322

10 Partial Differential Equations **323**
10.1 Definitions . . . 323
10.1.1 Classification and characteristics . . . 324
10.1.2 Well-posedness in the sense of Hadamard . . . 330
10.1.3 The equations of physics . . . 331
10.2 From partial to ordinary differential equations . . . 332
10.2.1 Separable coordinate systems . . . 333
10.2.2 Eigenfunction expansions . . . 334
10.2.3 Integral-transform methods . . . 335
10.3 Green's functions . . . 336

10.3.1 The Green's function of a boundary-value problem . . . 336
10.3.2 Causal Green's functions and Duhamel's principle . . . 338
10.4 The canonical equations and their fundamental solutions . . . 339
10.4.1 The wave equation . . . 339
10.4.2 The heat equation . . . 342
10.4.3 The Laplace and Poisson equations . . . 343
10.4.4 The Helmholtz decomposition . . . 344
10.5 Maximum principles . . . 345
10.5.1 Elliptic maximum principles . . . 345
10.5.2 Parabolic maximum principles . . . 347
10.6 Weak solutions . . . 347
10.6.1 Distributional solutions and Sobolev spaces . . . 347
10.6.2 Variational formulation . . . 348
10.6.3 Shocks and conservation laws . . . 350

11 Probability and Statistics **355**
11.1 Discrete statistics . . . 355
11.1.1 Definitions . . . 355
11.2 Continuous statistics . . . 361
11.2.1 Definitions . . . 361
11.2.2 Measure spaces, null sets and "almost every" . . . 364
11.2.3 Invariant measures and the ergodic theorem . . . 366
11.3 Characteristic functions and the central limit theorem . . . 367
11.3.1 Characteristic functions . . . 367
11.3.2 The central limit theorem . . . 369
11.4 Estimation . . . 371
11.4.1 The likelihood function . . . 373
11.4.2 Score and Fisher information . . . 374
11.4.3 The Cramér–Rao bound . . . 376
11.4.4 Consistency and asymptotic normality . . . 378
11.4.5 Nuisance parameters and the profile likelihood . . . 381
11.5 Hypothesis testing . . . 382
11.5.1 Tests, size, power and p-values . . . 382
11.5.2 The Neyman–Pearson lemma . . . 383
11.5.3 The chi-squared distribution . . . 384
11.5.4 The likelihood-ratio statistic and Wilks' theorem . . . 386
11.5.5 Significance . . . 389
11.6 The look-elsewhere effect . . . 390
11.6.1 Local and global p-values . . . 390
11.6.2 Upcrossings . . . 391
11.6.3 A worked example: a bump search over a mass window . . . 394

12 Hilbert Spaces **397**
12.1 Definitions . . . 397
12.2 Orthonormal bases and separability . . . 400
12.2.1 Orthogonality and projections . . . 400
12.2.2 Gram–Schmidt orthogonalization . . . 403
12.2.3 Fourier expansion, Bessel and Parseval . . . 404
12.3 Bounded operators and duality . . . 406
12.3.1 Bounded operators and their adjoints . . . 406
12.3.2 The Riesz representation theorem . . . 410
12.4 Self-adjointness and the spectral theorem . . . 411

12.4.1 Spectrum and resolvent . . . 411
12.4.2 The spectral theorem . . . 414
12.4.3 Stone's theorem . . . 416
12.5 Unbounded operators and domains . . . 418
12.5.1 Closed operators and domains . . . 418
12.5.2 Symmetric versus self-adjoint: deficiency indices . . . 420
12.6 Direct sums, tensor products and rigged spaces . . . 423
12.6.1 Direct sums and orthogonal decompositions . . . 423
12.6.2 Tensor products . . . 425
12.6.3 Rigged Hilbert spaces . . . 427
12.7 The canonical commutation relations in Weyl form . . . 429

13 Differentiable Manifolds, Tensors, and Curvature 433
13.1 Index conventions and the symmetry ladder . . . 433
13.2 Tensors under orthogonal transformations . . . 434
13.2.1 Orthogonal coordinate transformations . . . 434
13.2.2 Algebra of Cartesian tensors . . . 438
13.3 The theory of curves and surfaces in $\mathbb{R}^3$ . . . 441
13.3.1 Theory of curves . . . 441
13.3.2 Theory of surfaces . . . 445
13.3.3 Curvatures of a surface . . . 451
13.4 Differentiable manifolds . . . 462
13.4.1 Charts, atlases, and differentiable structure . . . 462
13.4.2 Euclidean space . . . 474
13.4.3 Curves in Euclidean space . . . 477
13.5 Tensor analysis on manifolds . . . 483
13.5.1 Vectors, covectors, and tensors on a manifold . . . 483
13.5.2 Tensors under general coordinate transformations . . . 488
13.5.3 Tensor densities . . . 492
13.6 Differential forms: k-forms and k-vectors . . . 495
13.6.1 k-forms and k-vectors . . . 495
13.6.2 The basis of the cotangent space . . . 496
13.6.3 The wedge product . . . 497
13.6.4 The exterior derivative . . . 498
13.6.5 Closed and exact forms . . . 499
13.6.6 The volume form . . . 502
13.6.7 The Hodge dual . . . 502
13.7 The metric tensor . . . 503
13.7.1 Isometries . . . 504
13.8 Vielbein and local frames . . . 504
13.9 Flows, the Lie derivative, and Killing vectors . . . 505
13.9.1 Distributions and the Frobenius theorem . . . 508
13.9.2 Killing vectors . . . 512
13.10 Connections, parallel transport, and torsion . . . 514
13.10.1 The spin connection . . . 516
13.11 Curvature . . . 516
13.12 The Cartan formalism . . . 517
13.13 Maximally symmetric spaces and the symmetry ladder . . . 519
13.13.1 The conformal group . . . 522
13.13.2 The observed case . . . 523

14 Lie Groups, Lie Algebras, and Fibre Bundles **525**
14.1 Lie groups . . . 525
14.1.1 Definition and generators . . . 525
14.2 Representations of Lie groups . . . 534
14.2.1 The group SO(2, ℝ) . . . 534
14.2.2 The groups SO(3), SU(2) and SU(3) . . . 537
14.3 The Lie algebra associated with a Lie group . . . 552
14.3.1 Translations in D dimensions . . . 552
14.3.2 The algebra $\mathfrak{so}(p,q)$ . . . 552
14.4 Central extensions . . . 563
14.4.1 Extensions and cocycles . . . 563
14.4.2 The instances that occur in physics . . . 565
14.5 Contraction of Lie algebras . . . 566
14.5.1 The Inönü–Wigner limit . . . 566
14.5.2 The classification of kinematical algebras . . . 569
14.6 Fibre bundles . . . 571
14.6.1 Bundles, sections and principal bundles . . . 572
14.6.2 Connection and curvature . . . 573
14.7 Invariant polynomials . . . 575
14.8 The Chern–Weil theorem and transgression forms . . . 578
14.8.1 Chern–Simons forms . . . 581
14.8.2 Characteristic classes . . . 582
14.8.3 The transgression of an $\mathfrak{so}(p,q)$ connection . . . 583

15 Expansions of Lie Algebras **585**
15.1 The tensor product construction . . . 586
15.2 Ideals, the radical, and the Killing form . . . 587
15.3 The Takiff tower . . . 590
15.4 Gradings and resonant subalgebras . . . 591
15.4.1 The gradings of the anti-de Sitter algebra . . . 592
15.5 Contraction as a degeneration of A . . . 593
15.5.1 The curvature parameter lives in A . . . 594
15.5.2 The (anti-)de Sitter radius and the cosmological constant . . . 595
15.6 Central charges as the top level of an expansion . . . 597
15.7 The Bacry–Lévy-Leblond cube as a lattice of algebras . . . 601
15.7.1 The kinematical generators are a Klein grading . . . 601
15.7.2 Resonance for a graded group . . . 601
15.7.3 The algebra with three structure constants . . . 602
15.7.4 The cube . . . 602
15.8 Invariant forms and why the extension is needed . . . 605
15.9 Relation to the published expansion methods . . . 609
15.10 The construction in 3+1 dimensions . . . 610
15.11 Positive functionals and the Gram form . . . 611

16 Calculus of Variations **615**
16.1 The classical problems . . . 615
16.1.1 The brachistochrone . . . 615
16.1.2 The catenary and the isoperimetric problem . . . 616
16.1.3 Minimal surfaces and soap films . . . 618
16.2 Functionals and the first variation . . . 619
16.2.1 Function spaces and functionals . . . 619
16.2.2 The fundamental lemma . . . 621

16.2.3 The Euler–Lagrange equation . . . 622
16.2.4 First integrals and natural boundary conditions . . . 624
16.2.5 Several functions, several variables, higher derivatives . . . 626
16.3 Constrained variation . . . 628
16.3.1 Lagrange multipliers . . . 628
16.3.2 Isoperimetric constraints . . . 629
16.3.3 Holonomic and nonholonomic constraints . . . 630
16.4 The second variation . . . 631
16.4.1 The Legendre condition . . . 631
16.4.2 The Jacobi equation and conjugate points . . . 632
16.4.3 Strong variations and the Weierstrass condition . . . 634
16.4.4 Fields of extremals and sufficiency . . . 635
16.5 Direct methods and existence . . . 638
16.5.1 The Dirichlet principle and its failure . . . 638
16.5.2 Tonelli's existence theory . . . 639
16.5.3 The Rayleigh–Ritz method . . . 641
16.5.4 The Plateau problem . . . 644
16.6 Symmetry and conservation: Noether's theorems . . . 644
16.6.1 Noether's first theorem . . . 645
16.6.2 Noether's second theorem . . . 648
16.7 The variational principles of physics . . . 649
16.7.1 Hamilton's principle . . . 649
16.7.2 Maupertuis' principle . . . 650
16.7.3 Fermat's principle . . . 651
16.7.4 Field actions . . . 653

17 Fourier Analysis and Integral Transforms 655
17.1 Fourier series . . . 655
17.1.1 Trigonometric expansion of periodic functions . . . 655
17.1.2 Convergence: from Dirichlet to Carleson . . . 658
17.1.3 The Gibbs phenomenon and summability . . . 665
17.1.4 Series in several variables . . . 667
17.2 The Fourier transform . . . 668
17.2.1 Definition and inversion . . . 668
17.2.2 Parseval and Plancherel . . . 671
17.2.3 Tempered distributions . . . 673
17.2.4 The uncertainty principle . . . 675
17.2.5 Poisson summation . . . 676
17.3 Convolution and correlation . . . 677
17.3.1 The convolution theorem . . . 677
17.3.2 Correlation and the Wiener–Khinchin theorem . . . 679
17.4 The Laplace transform . . . 682
17.4.1 Definition, convergence and inversion . . . 682
17.4.2 Initial-value problems and the operational calculus . . . 685
17.5 Sampling and the discrete transform . . . 687
17.5.1 The sampling theorem . . . 687
17.5.2 The discrete Fourier transform and the FFT . . . 689
17.6 Other integral transforms . . . 691
17.6.1 Hankel and Mellin transforms . . . 691
17.6.2 Multiplicative convolution and the moments . . . 693
17.6.3 The Radon transform . . . 695

III Classical Mechanics **699**

18 Kinematics **701**
18.1 Foundations . . . 701
18.1.1 Fundamental concepts . . . 701
18.1.2 Frames of reference . . . 703
18.1.3 Kinematics of a particle . . . 703
18.1.4 The itinerary equation for constant acceleration . . . 705
18.2 Galilean relativity . . . 706
18.2.1 Newton's postulates of absolute space and time . . . 706
18.2.2 Galileo's principle of relativity . . . 707
18.2.3 Galilean transformations . . . 708
18.2.4 Transformation of velocities and accelerations . . . 710
18.3 Circular motion . . . 711
18.3.1 The angular description . . . 712
18.3.2 Uniform circular motion . . . 712
18.3.3 Non-uniform circular motion . . . 713
18.3.4 The intrinsic decomposition of the acceleration . . . 714
18.3.5 Magnitudes . . . 714

19 Newtonian Dynamics **717**
19.1 Inertia and mass . . . 717
19.2 Newton's laws and the Newtonian formulation: translation . . . 718
19.2.1 Linear momentum and Newton's first law . . . 718
19.2.2 Force and Newton's second law . . . 719
19.3 Newton's laws and the Newtonian formulation: rotation . . . 722
19.3.1 Angular momentum . . . 722
19.3.2 Torque . . . 724
19.4 Energy . . . 726
19.4.1 Kinetic energy . . . 726
19.4.2 Potential energy and conservative forces . . . 726
19.4.3 Energy . . . 727
19.4.4 The law of conservation of energy . . . 727
19.4.5 Work . . . 728
19.4.6 The work–energy theorem . . . 730
19.5 Systems of particles . . . 731
19.5.1 Inertia and mass of a system . . . 731
19.5.2 Internal dynamics of the system . . . 734
19.5.3 Translational Newton laws for systems of particles . . . 736
19.5.4 Rotational Newton laws for systems of particles . . . 738
19.5.5 Conservation laws . . . 742

20 Experiment: Free Fall and Projectile Motion **747**
20.1 Historical context: the Aristotelian expectation and its collapse . . . 747
20.2 The observed phenomenon and its derivation . . . 748
20.3 Galileo's Inclined Planes (1604–1638) . . . 750
20.3.1 Apparatus . . . 750
20.3.2 Procedure . . . 750
20.3.3 Observations and data . . . 750
20.3.4 Interpretation . . . 751
20.3.5 Primary references . . . 751
20.4 Absolute Ballistic Gravimetry (1995–present) . . . 751

20.4.1 Apparatus . . . 751
20.4.2 Procedure . . . 751
20.4.3 Observations and data . . . 752
20.4.4 Interpretation . . . 752
20.4.5 Primary references . . . 752
20.5 Deviations and the domain of validity . . . 752
20.6 From Galileo's ratios to the equivalence principle . . . 757

21 Lagrangian Mechanics **759**
21.1 Generalized coordinates . . . 759
21.1.1 Constraints . . . 759
21.1.2 Degrees of freedom . . . 760
21.1.3 Generalized coordinates . . . 760
21.1.4 Constraint forces and active forces . . . 761
21.2 Virtual work . . . 761
21.2.1 Virtual displacements . . . 761
21.2.2 The constraint-force hypothesis . . . 761
21.2.3 Virtual work and its principle . . . 762
21.3 d'Alembert's principle . . . 763
21.4 The Euler–Lagrange equations . . . 763
21.4.1 Lagrange equations of the first kind . . . 763
21.4.2 Lagrange multipliers as constraint forces . . . 764
21.4.3 Lagrange equations of the second kind . . . 767
21.4.4 The Lagrangian . . . 769
21.4.5 Cyclic coordinates . . . 770
21.4.6 The energy of a Lagrangian system . . . 770
21.5 Hamilton's principle . . . 773
21.5.1 The action . . . 773
21.5.2 Hamilton's principle . . . 773
21.6 Nonholonomic constraints . . . 774
21.6.1 Pfaffian constraints . . . 775
21.6.2 The d'Alembert–Chetaev prescription . . . 775
21.6.3 Why the vakonomic prescription is not the observed one . . . 776
21.7 General coordinate transformations . . . 778
21.7.1 Point transformations . . . 778
21.7.2 Covariance of the Euler–Lagrange equations . . . 779
21.7.3 The kinetic metric and the geodesic form . . . 780
21.7.4 Inertial forces are connection coefficients . . . 781
21.8 The universality of general covariance . . . 782
21.8.1 Flat spacetime in arbitrary coordinates . . . 782
21.8.2 What general relativity adds . . . 784

22 Hamiltonian Mechanics **789**
22.1 From the Lagrangian to the Hamiltonian . . . 789
22.1.1 The Legendre transformation of the Lagrangian . . . 789
22.1.2 Hamilton's equations . . . 790
22.1.3 The Hamiltonian and the energy . . . 792
22.2 Canonical transformations . . . 793
22.2.1 Definition and transformation conditions . . . 793
22.2.2 Generating functions . . . 794
22.2.3 Derivation of the transformation conditions . . . 795
22.3 Invariant integrals . . . 797

22.3.1 The Lagrange bracket . . . 798
22.3.2 The Poisson bracket . . . 800
22.4 Motion in phase space . . . 802
22.5 Symplectic formulation . . . 804
22.5.1 Symplectic form of the transformation condition . . . 805
22.6 Beyond the canonical formalism . . . 805
22.6.1 Hamilton–Jacobi theory . . . 805
22.6.2 Symplectic geometry . . . 805
22.6.3 Symmetries . . . 806

23 Hamilton–Jacobi Theory and the Optical–Mechanical Analogy 807
23.1 The Hamilton–Jacobi equation . . . 807
23.1.1 The transformation to constant coordinates . . . 807
23.1.2 Jacobi's theorem . . . 808
23.1.3 Time-independent systems and the characteristic function . . . 810
23.2 Complete integrals and separation of variables . . . 811
23.2.1 Conditions for separability . . . 812
23.2.2 Worked separations . . . 815
23.3 Action–angle variables and integrable systems . . . 817
23.3.1 Adiabatic invariance . . . 819
23.3.2 The old quantum theory . . . 821
23.4 The optical–mechanical analogy . . . 821
23.4.1 The eikonal limit of wave optics . . . 821
23.4.2 The dictionary . . . 823
23.4.3 Where the analogy is not an analogy . . . 824
23.5 From Hamilton–Jacobi to the Schrödinger equation . . . 825
23.5.1 The semiclassical expansion . . . 826
23.5.2 Caustics . . . 827

24 Symplectic Geometry of Phase Space 833
24.1 Symplectic vector spaces . . . 833
24.2 Symplectic manifolds . . . 835
24.3 Hamiltonian vector fields and the flow . . . 837
24.4 Invariants of the flow . . . 840
24.4.1 Integral invariants . . . 841
24.4.2 Symplectic capacity and non-squeezing . . . 843
24.5 Poisson manifolds . . . 847
24.6 Symmetry, momentum maps, and reduction . . . 849
24.7 Geometric quantization . . . 852
24.7.1 Prequantization . . . 852
24.7.2 Polarization . . . 853
24.7.3 Bohr–Sommerfeld from holonomy . . . 854
24.8 What the symplectic view buys . . . 855

25 The Poisson Algebra and the Canonical Bridge to Quantum Mechanics 857
25.1 The Poisson algebra of observables . . . 857
25.2 Generators, symmetries, and constants of motion . . . 859
25.2.1 Mass as a central charge . . . 863
25.2.2 The generators as a bridge . . . 864
25.3 The first-order formalism . . . 865
25.3.1 The Faddeev–Jackiw form . . . 866
25.4 Canonical quantization: the correspondence rule . . . 868

25.5 The obstruction: what the correspondence cannot be . . . 872
25.5.1 Ordering . . . 874
25.5.2 Deformation quantization and the Moyal bracket . . . 877
25.5.3 Phase-space quantum mechanics . . . 877
25.6 What carries over to field theory . . . 881

26 Constrained Hamiltonian Systems: the Dirac–Bergmann Formalism 883
26.1 Singular Lagrangians and primary constraints . . . 884
26.2 The Dirac–Bergmann consistency algorithm . . . 885
26.3 First- and second-class constraints . . . 887
26.4 The Dirac bracket . . . 889
26.5 Gauge fixing and the reduced phase space . . . 892
26.6 Worked systems . . . 894
26.6.1 The relativistic free particle . . . 895
26.6.2 The electromagnetic field . . . 896
26.6.3 The massive vector field . . . 897
26.6.4 Yang–Mills fields . . . 898
26.6.5 General relativity . . . 900
26.7 Quantizing a constrained system . . . 903
26.7.1 Reduced-phase-space quantization . . . 904
26.7.2 Weak imposition: the Gupta–Bleuler construction . . . 905
26.7.3 BRST . . . 906
26.8 Constraints in field theory . . . 907

27 Central Forces and Statics 909
27.1 Statics . . . 909
27.1.1 The centre of gravity . . . 911
27.1.2 Equilibrium as a stationary potential energy . . . 912
27.2 Central forces . . . 913
27.2.1 Areal velocity . . . 914
27.2.2 Conservation laws of central motion . . . 915
27.2.3 The Binet equation . . . 916
27.3 The equivalent one-dimensional problem . . . 917
27.3.1 Energy of the system . . . 917
27.3.2 Effective potential . . . 918
27.3.3 Turning points . . . 918
27.3.4 The radial quadrature . . . 919
27.4 The two-body problem and Kepler orbits . . . 920
27.4.1 Reduction to one body . . . 920
27.4.2 The orbit of an inverse-square attraction . . . 921
27.4.3 Kepler's third law . . . 923
27.4.4 The Laplace–Runge–Lenz vector . . . 925
27.4.5 Closure, and what its failure measures . . . 926
27.5 The virial theorem . . . 927
27.6 Where the claims of this chapter are tested . . . 928

28 Oscillations and Mechanical Waves 929
28.1 The harmonic oscillator . . . 930
28.1.1 Free oscillations . . . 930
28.1.2 The pendulum . . . 931
28.1.3 Universality of the harmonic approximation . . . 933
28.2 Damped and driven oscillations . . . 934

28.2.1 Linear damping . . . 934
28.2.2 The driven oscillator and resonance . . . 936
28.2.3 Parametric resonance . . . 938
28.3 Coupled oscillators and normal modes . . . 940
28.3.1 Two coupled oscillators and beats . . . 940
28.3.2 Small oscillations about equilibrium . . . 941
28.3.3 The loaded string and the continuum limit . . . 944
28.4 The vibrating string and the wave equation . . . 945
28.4.1 d'Alembert's equation and its general solution . . . 945
28.4.2 Superposition and the vibrating-string controversy . . . 946
28.4.3 Standing waves . . . 947
28.4.4 Fourier decomposition . . . 948
28.5 Sound . . . 949
28.5.1 The acoustic wave equation . . . 949
28.5.2 Acoustic phenomena . . . 951
28.6 Dispersion . . . 953
28.6.1 Phase and group velocity . . . 953
28.6.2 Energy transport and impedance . . . 954
28.7 Anharmonicity: a first look . . . 956
28.7.1 The anharmonic oscillator . . . 956
28.7.2 Secular terms and the Lindstedt–Poincaré method . . . 959

29 Rigid Bodies and Rotating Frames 961
29.1 Rigid-body kinematics . . . 961
29.1.1 Angular velocity and Euler's theorem . . . 961
29.1.2 Euler angles . . . 963
29.2 The inertia tensor . . . 964
29.2.1 Definition and principal axes . . . 964
29.2.2 Computing moments of inertia . . . 966
29.3 Euler's equations and free rotation . . . 968
29.3.1 Euler's equations . . . 968
29.3.2 The free symmetric top . . . 969
29.3.3 Stability of rotation about the principal axes . . . 971
29.3.4 Free nutation of the Earth: the Chandler wobble . . . 972
29.4 The heavy top . . . 974
29.4.1 The Lagrange top . . . 974
29.4.2 Integrable cases and the Kovalevskaya top . . . 978
29.4.3 Gyroscopes . . . 979
29.4.4 Precession of the equinoxes and astronomical nutation . . . 981
29.5 Motion in rotating frames . . . 984
29.5.1 The transport theorem and the fictitious forces . . . 984
29.5.2 Absolute rotation: Newton's bucket and Mach's critique . . . 984
29.5.3 Terrestrial evidence of the Earth's rotation . . . 985
29.5.4 The Foucault pendulum . . . 988

30 Continuum Mechanics and Elasticity 991
30.1 The continuum hypothesis . . . 991
30.2 Deformation: the strain tensor . . . 993
30.2.1 Displacement and linear strain . . . 993
30.2.2 Finite strain and compatibility . . . 994
30.3 Stress: the Cauchy tensor . . . 997
30.3.1 Traction and the existence of the stress tensor . . . 997

30.3.2 Momentum balance . . . 998
30.4 Linear elasticity: Hooke's law and the moduli . . . 999
30.4.1 Hooke's law . . . 999
30.4.2 The elastic moduli and their measurement . . . 1001
30.4.3 Anisotropic elasticity . . . 1005
30.5 Elastodynamics and elastic waves . . . 1006
30.5.1 The Navier–Cauchy equations . . . 1006
30.5.2 P and S waves . . . 1007
30.5.3 Surface waves and the seismological evidence . . . 1009
30.6 Rods, beams and plates . . . 1011
30.6.1 The elastica and Euler buckling . . . 1012
30.6.2 Euler–Bernoulli beam theory . . . 1014
30.6.3 Torsion . . . 1015
30.6.4 Plates and shells . . . 1016
30.7 Static problems and contact . . . 1018
30.8 The limits of elasticity . . . 1020

31 Fluid Dynamics **1025**
31.1 Kinematics of flow . . . 1025
31.1.1 The continuum hypothesis and the two descriptions . . . 1025
31.1.2 The continuity equation . . . 1028
31.2 Hydrostatics . . . 1029
31.3 Ideal flow: the Euler equations . . . 1031
31.3.1 The Euler equations . . . 1031
31.3.2 Bernoulli's theorem . . . 1032
31.3.3 Potential flow and the d'Alembert paradox . . . 1034
31.4 Viscous flow: the Navier–Stokes equations . . . 1035
31.4.1 Viscosity . . . 1035
31.4.2 The Navier–Stokes equations . . . 1036
31.4.3 Exact solutions: Couette and Poiseuille flow . . . 1038
31.4.4 Stokes flow . . . 1040
31.4.5 Existence and smoothness: an open problem . . . 1041
31.5 Dynamical similarity . . . 1042
31.5.1 The Reynolds number . . . 1042
31.5.2 Drag laws . . . 1045
31.6 Vorticity . . . 1046
31.6.1 Vortex lines and Helmholtz's theorems . . . 1046
31.6.2 Kelvin's circulation theorem . . . 1048
31.7 Lift and the boundary layer . . . 1049
31.7.1 The Kutta–Joukowski theorem . . . 1049
31.7.2 The Prandtl boundary layer . . . 1051
31.8 Instability and transition . . . 1052
31.8.1 Shear and buoyancy instabilities . . . 1052
31.8.2 Rayleigh–Bénard convection and Taylor–Couette flow . . . 1055
31.9 Turbulence . . . 1057
31.9.1 The Reynolds decomposition and the closure problem . . . 1057
31.9.2 The energy cascade and Kolmogorov's 1941 theory . . . 1058
31.10 Compressible flow . . . 1060
31.10.1 Sound . . . 1060
31.10.2 Shock waves . . . 1061
31.11 Surface waves and solitary waves . . . 1062

32 Nonlinear Dynamics and Chaos **1065**
32.1 Flows in phase space . . . 1066
32.1.1 Dynamical systems, flows and maps . . . 1066
32.1.2 Fixed points and Lyapunov stability . . . 1067
32.1.3 Bifurcations . . . 1070
32.2 Limit cycles . . . 1072
32.2.1 The Poincaré–Bendixson theorem . . . 1072
32.2.2 Relaxation oscillations: van der Pol . . . 1073
32.3 Poincaré sections and discrete dynamics . . . 1076
32.3.1 The return map . . . 1076
32.3.2 The Smale horseshoe and symbolic dynamics . . . 1077
32.4 Hamiltonian chaos . . . 1078
32.4.1 The three-body problem . . . 1078
32.4.2 The KAM theorem . . . 1079
32.4.3 Resonance overlap and the standard map . . . 1080
32.4.4 Numerical discovery: Hénon–Heiles . . . 1082
32.4.5 Chaos in the solar system . . . 1083
32.5 Strange attractors . . . 1086
32.5.1 The Lorenz system . . . 1086
32.5.2 Strange attractors and the Ruelle–Takens proposal . . . 1088
32.5.3 Sensitive dependence and Lyapunov exponents . . . 1089
32.5.4 Fractal dimension . . . 1092
32.6 Universal routes to chaos . . . 1093
32.6.1 The logistic map . . . 1093
32.6.2 Feigenbaum universality . . . 1094
32.6.3 Quasiperiodicity and intermittency . . . 1097
32.7 Experimental chaos . . . 1099
32.7.1 Rayleigh–Bénard convection . . . 1099
32.7.2 Taylor–Couette flow . . . 1100
32.7.3 Circuits and driven oscillators . . . 1101

33 Experiment: The Cavendish Torsion Balance **1103**
33.1 Historical context and the prediction under test . . . 1103
33.1.1 Universal gravitation without a constant . . . 1104
33.1.2 The Schiehallion experiment . . . 1105
33.1.3 Michell's apparatus . . . 1106
33.2 Torsion pendulum theory . . . 1106
33.2.1 The torsion pendulum . . . 1106
33.2.2 From deflection to attraction . . . 1107
33.2.3 Systematics of the method . . . 1109
33.3 Apparatus . . . 1110
33.4 Procedure . . . 1110
33.5 Observations and data . . . 1112
33.6 Interpretation . . . 1113
33.7 Modern determinations and their discrepancies . . . 1115
33.7.1 Classic redeterminations . . . 1115
33.7.2 Modern torsion-balance measurements . . . 1115
33.7.3 Beyond torsion . . . 1116
33.7.4 The discrepancy, honestly stated . . . 1116
33.8 Primary references . . . 1119

34 Experiment: The Pendulum **1121**
34.1 Galileo and Huygens: the isochronous pendulum (1602–1673) 1121
34.1.1 Apparatus 1121
34.1.2 Procedure 1122
34.1.3 Observations and data 1122
34.1.4 Interpretation 1124
34.1.5 Primary references 1125
34.2 Coulomb: the torsion pendulum (1784) 1125
34.2.1 Apparatus 1125
34.2.2 Procedure 1125
34.2.3 Observations and data 1125
34.2.4 Interpretation 1128
34.2.5 Primary references 1130
34.3 Kater: the reversible pendulum (1818) 1130
34.3.1 Apparatus 1130
34.3.2 Procedure 1131
34.3.3 Observations and data 1131
34.3.4 Interpretation 1133
34.3.5 Primary references 1134
34.4 The seconds pendulum and the metre 1134
34.5 Foucault: the pendulum at the Panthéon (1851) 1135
34.5.1 Apparatus 1135
34.5.2 Procedure 1135
34.5.3 Observations and data 1135
34.5.4 Interpretation 1140
34.5.5 Primary references 1140
34.6 The pendulum as the first precision instrument 1140

35 Experiment: Waves and Acoustics **1143**
35.1 Mersenne: the laws of the vibrating string (1636) 1143
35.1.1 Apparatus 1143
35.1.2 Procedure 1144
35.1.3 Observations and data 1144
35.1.4 Interpretation 1145
35.1.5 Primary references 1145

37.5.1 Apparatus . . . 1186
37.5.2 Procedure . . . 1186
37.5.3 Observations and data . . . 1186
37.5.4 Interpretation . . . 1187
37.5.5 Primary references . . . 1187
37.6 The muon lifetime . . . 1187
37.7 What the experiments establish . . . 1187

38 Lorentz Transformations **1189**
38.1 The postulates . . . 1189
38.2 Lorentz boosts . . . 1190
38.2.1 The one-dimensional boost . . . 1190
38.2.2 Minkowski space . . . 1191
38.2.3 The general boost . . . 1194
38.3 Spacetime diagrams . . . 1194
38.4 Consequences of the postulates . . . 1196
38.4.1 Relativity of simultaneity . . . 1196
38.4.2 Time dilation . . . 1197
38.4.3 Length contraction . . . 1198
38.5 Composition of velocities . . . 1199
38.5.1 Rapidity . . . 1200
38.6 General Lorentz transformations . . . 1201
38.6.1 Boosts composed with rotations . . . 1201
38.6.2 Directions normal to the relative velocity . . . 1203

39 Minkowski Space and Its Symmetries **1205**
39.1 Conserved quantities . . . 1205
39.2 The Lorentz group . . . 1205
39.2.1 Foundations . . . 1205
39.2.2 The proper Lorentz group . . . 1207
39.2.3 The improper Lorentz group . . . 1207
39.2.4 The orthochronous Lorentz group . . . 1207
39.2.5 The antichronous Lorentz group . . . 1208

39.2.6 The four components . . . 1208
39.2.7 The algebra of the proper Lorentz group . . . 1209
39.3 The Poincaré group . . . 1210
39.3.1 Foundations . . . 1210
39.3.2 The algebra of the Poincaré group . . . 1211

40 Relativistic Dynamics **1213**
40.1 Four-vectors . . . 1213
40.2 Four-momentum and mass–energy . . . 1214
40.3 The relativistic force law . . . 1215
40.4 Massless particles . . . 1215
40.5 Collisions . . . 1216
40.6 The twin paradox . . . 1217
40.7 Covariant electrodynamics in one line . . . 1217

41 Experiment: Time Dilation and Relativistic Kinematics **1219**
41.1 Ives and Stilwell: the moving atomic clock (1938) . . . 1219
41.1.1 Apparatus . . . 1219
41.1.2 Procedure . . . 1219
41.1.3 Observations and data . . . 1219
41.1.4 Interpretation . . . 1220
41.1.5 Primary references . . . 1220
41.2 Rossi and Hall: muon survival with altitude (1941) . . . 1220
41.2.1 Apparatus . . . 1220
41.2.2 Procedure . . . 1220
41.2.3 Observations and data . . . 1221
41.2.4 Interpretation . . . 1221
41.2.5 Primary references . . . 1221
41.3 Frisch and Smith: Mount Washington to sea level (1963) . . . 1221
41.3.1 Apparatus . . . 1221
41.3.2 Procedure . . . 1221
41.3.3 Observations and data . . . 1222
41.3.4 Interpretation . . . 1222
41.3.5 Primary references . . . 1222

41.6.5 Primary references . . . 1224

41.7 Summary of the evidence . . . 1224

V General Relativity and Cosmology 1227

42 The Equivalence Principle and Classical Tests 1229
42.1 The universality of free fall . . . 1229
42.1.1 From Galileo to Newton . . . 1229
42.1.2 The Eötvös torsion balance . . . 1230
42.1.3 Modern limits . . . 1230
42.2 The equivalence principle in three strengths . . . 1231
42.2.1 Weak, Einstein and strong forms . . . 1231
42.2.2 Lunar laser ranging . . . 1232
42.3 Gravitational redshift . . . 1234
42.3.1 The prediction . . . 1234
42.3.2 Pound–Rebka and Pound–Snider . . . 1234
42.3.3 Clocks on rockets and in orbit . . . 1235
42.4 The perihelion of Mercury . . . 1236
42.4.1 Le Verrier's anomaly . . . 1236
42.4.2 Einstein's 1915 computation . . . 1237
42.5 The deflection of light . . . 1237
42.5.1 Half and full values . . . 1237
42.5.2 The 1919 eclipse expeditions . . . 1238
42.5.3 Radio interferometry and gravitational lensing . . . 1239
42.6 The Shapiro time delay . . . 1239
42.6.1 Radar ranging to the inner planets . . . 1239
42.6.2 Viking and Cassini . . . 1239
42.7 Relativity in the Global Positioning System . . . 1240
42.8 Beyond the classical tests . . . 1241

43 Geometric Formulation of Gravity 1243
43.1 Geodesics as the trajectories of free fall . . . 1243
43.2 Curvature and tidal forces . . . 1244
43.3 The Einstein–Hilbert action . . . 1244

44 The Einstein Field Equations 1247
44.1 The route to the field equations . . . 1247
44.1.1 Requirements on a relativistic theory of gravity . . . 1247
44.1.2 The November 1915 papers . . . 1248
44.1.3 The Hilbert action . . . 1249
44.2 The stress–energy tensor . . . 1253
44.2.1 Matter models . . . 1253
44.2.2 Conservation and Noether's theorem . . . 1255
44.3 The Bianchi identities . . . 1256
44.4 The Newtonian correspondence . . . 1257
44.4.1 Geodesics and the potential . . . 1257
44.4.2 Fixing the coupling constant . . . 1258
44.5 The linearized theory . . . 1258
44.6 The cosmological constant . . . 1259
44.7 Lovelock's uniqueness theorem . . . 1260
44.8 Energy conditions . . . 1261
44.9 The initial-value problem . . . 1263

44.9.1 Constraints and evolution . . . 1263
44.9.2 Well-posedness . . . 1265
44.10 Exact solutions: an overview . . . 1266

45 Schwarzschild Geometry and Black Holes 1269
45.1 The Schwarzschild solution . . . 1269
45.1.1 Derivation and the 1916 paper . . . 1269
45.1.2 Birkhoff's theorem . . . 1271
45.2 Geodesics and orbits . . . 1272
45.2.1 The effective potential . . . 1272
45.2.2 Circular orbits, the ISCO and the photon sphere . . . 1274
45.2.3 Null geodesics: deflection and delay . . . 1275
45.3 The horizon . . . 1277
45.3.1 Coordinate and curvature singularities . . . 1277
45.3.2 The Kruskal–Szekeres extension . . . 1278
45.4 Gravitational collapse . . . 1279
45.4.1 Oppenheimer–Snyder collapse . . . 1279
45.4.2 The singularity theorems . . . 1281
45.4.3 Cosmic censorship . . . 1282
45.5 Rotating and charged black holes . . . 1282
45.5.1 The Kerr solution . . . 1282
45.5.2 Charge: Reissner–Nordström and Kerr–Newman . . . 1285
45.5.3 The no-hair theorems . . . 1286
45.6 Black-hole mechanics . . . 1287
45.6.1 The four laws . . . 1287
45.6.2 Hawking radiation: prediction without observation . . . 1289
45.7 The shadow . . . 1291

46 Gravitational-Wave Theory 1293
46.1 Linearized gravity and the wave equation . . . 1293
46.2 Transverse-traceless gauge and the two polarizations . . . 1293
46.3 The quadrupole formula . . . 1294
46.4 Beyond linear order . . . 1295

47 Experiment: Gravitational Waves 1297
47.1 The Hulse–Taylor Binary Pulsar (PSR B1913+16) (1974–2016) . . . 1297
47.1.1 Apparatus . . . 1297
47.1.2 Procedure . . . 1297
47.1.3 Observations and data . . . 1297
47.1.4 Interpretation . . . 1298
47.1.5 Primary references . . . 1299
47.2 Direct detection: the instrument . . . 1299
47.3 GW150914 (2015) . . . 1299
47.3.1 Apparatus . . . 1299
47.3.2 Procedure . . . 1300
47.3.3 Observations and data . . . 1300
47.3.4 Interpretation . . . 1300
47.3.5 Primary references . . . 1300
47.4 The multimessenger outlook . . . 1301

48 Evidence-Based Cosmology **1303**
48.1 The expanding universe . . . 1303
48.1.1 Nebular redshifts . . . 1303
48.1.2 The distance ladder . . . 1304
48.1.3 The Hubble–Lemaître law . . . 1304
48.2 The FLRW geometry . . . 1305
48.2.1 Homogeneity, isotropy and the metric . . . 1305
48.2.2 The Friedmann equations . . . 1307
48.2.3 Distances and horizons . . . 1308
48.3 The thermal history . . . 1310
48.3.1 Radiation, matter and Λ eras . . . 1310
48.3.2 Big-Bang nucleosynthesis . . . 1311
48.3.3 The prediction of the relic radiation . . . 1313
48.4 The cosmic microwave background . . . 1313
48.4.1 Discovery . . . 1313
48.4.2 Anisotropies . . . 1314
48.5 Large-scale structure . . . 1315
48.5.1 Growth of perturbations . . . 1315
48.5.2 Baryon acoustic oscillations . . . 1317
48.5.3 Evidence for dark matter . . . 1318
48.6 The accelerating universe . . . 1319
48.6.1 Type Ia supernovae . . . 1319
48.6.2 The cosmological constant as dark energy . . . 1320
48.7 The ΛCDM parametrization . . . 1321
48.7.1 Six numbers . . . 1321
48.7.2 The Hubble tension . . . 1321
48.8 Inflation: the evidence status . . . 1323
48.8.1 The proposal . . . 1323
48.8.2 Measured and unmeasured . . . 1324

49 Compact Stars and Relativistic Astrophysics **1325**
49.1 White dwarfs . . . 1325
49.1.1 The observational puzzle: Sirius B . . . 1325
49.1.2 Electron degeneracy pressure . . . 1326
49.1.3 The Chandrasekhar mass limit . . . 1329
49.1.4 White-dwarf cooling and ages . . . 1330
49.2 Neutron stars . . . 1331
49.2.1 The Baade–Zwicky hypothesis . . . 1331
49.2.2 The Tolman–Oppenheimer–Volkoff equations . . . 1332
49.2.3 Birth: core collapse and supernova neutrinos . . . 1334
49.2.4 The dense-matter equation of state . . . 1335
49.3 Pulsars . . . 1336
49.3.1 Discovery and identification . . . 1336
49.3.2 The pulsar population . . . 1338
49.3.3 Binary pulsars: precision gravity . . . 1338
49.4 Maximum masses and radii . . . 1339
49.4.1 Bounds on the maximum mass . . . 1339
49.4.2 Radius measurements: X-ray pulse-profile modelling . . . 1340
49.4.3 Tidal deformability: GW170817 . . . 1340
49.5 The black-hole endpoint . . . 1342

50 Experiment: Black-Hole Observations **1343**
50.1 Historical context and the prediction under test . . . 1343
50.1.1 From invisible companions to relativistic collapse . . . 1343
50.1.2 What general relativity predicts . . . 1344
50.2 Apparatus . . . 1344
50.2.1 X-ray observatories . . . 1344
50.2.2 Adaptive optics and interferometry on the Galactic Centre . . . 1345
50.2.3 The Event Horizon Telescope . . . 1345
50.3 Procedure . . . 1346
50.4 Observations and data . . . 1346
50.4.1 Cygnus X-1 and the X-ray binaries . . . 1346
50.4.2 Sgr A*: stellar orbits . . . 1348
50.4.3 Event-horizon-scale imaging . . . 1350
50.4.4 Black-hole masses from gravitational waves . . . 1352

VI Classical Thermodynamics **1413**

54 Classical Thermodynamics **1415**
54.1 Systems, equilibrium and temperature . . . 1415
54.1.1 State variables and equilibrium . . . 1415
54.1.2 The zeroth law and empirical temperature . . . 1415
54.1.3 Thermometry and the kelvin . . . 1416
54.2 Equations of state . . . 1416
54.2.1 The gas laws . . . 1416
54.2.2 The ideal-gas equation of state . . . 1416
54.3 The first law . . . 1417
54.3.1 Work, heat and internal energy . . . 1417
54.3.2 Heat capacities . . . 1418
54.3.3 Processes and cycles . . . 1418
54.4 The second law . . . 1418
54.4.1 Carnot's theorem . . . 1418
54.4.2 The Clausius and Kelvin statements . . . 1418
54.4.3 Thermodynamic temperature and the Carnot efficiency . . . 1419
54.4.4 Entropy and the Clausius inequality . . . 1419
54.4.5 Carathéodory's axiomatics . . . 1420
54.5 Thermodynamic potentials . . . 1420
54.5.1 Legendre transforms and the four potentials . . . 1420
54.5.2 Maxwell relations . . . 1420
54.5.3 Extremum principles, stability and the chemical potential . . . 1420
54.6 Phase equilibria . . . 1420
54.6.1 Coexistence and the Clausius–Clapeyron equation . . . 1420
54.6.2 The Gibbs phase rule . . . 1420
54.6.3 Real gases: van der Waals and the critical point . . . 1420
54.6.4 The Joule–Thomson effect . . . 1421
54.7 The third law . . . 1421
54.8 The bridge to the molecular theory . . . 1422

55 Kinetic Theory of Gases **1423**
55.1 The kinetic hypothesis . . . 1423
55.1.1 From Bernoulli to Clausius . . . 1423
55.1.2 Pressure from molecular impacts . . . 1423
55.1.3 The mean free path . . . 1423
55.2 The Maxwell velocity distribution . . . 1424
55.2.1 Maxwell's derivation . . . 1424
55.2.2 Molecular-beam verification . . . 1424
55.3 Equipartition and specific heats . . . 1425
55.3.1 The equipartition theorem . . . 1425
55.3.2 Specific heats and the classical failure . . . 1425
55.4 The Boltzmann equation . . . 1426
55.4.1 The transport equation . . . 1426
55.4.2 The H-theorem . . . 1426
55.4.3 Reversibility and recurrence . . . 1426
55.4.4 The Maxwell–Boltzmann distribution . . . 1426
55.5 Transport phenomena . . . 1426
55.5.1 Viscosity . . . 1426
55.5.2 Heat conduction . . . 1427
55.5.3 Diffusion . . . 1427

55.5.4 Chapman–Enskog and the road to hydrodynamics . . . 1427
55.6 Effusion and rarefied gases . . . 1428
55.6.1 Graham's law of effusion . . . 1428
55.6.2 The Knudsen regime . . . 1428
55.7 Molecular reality and Avogadro's constant . . . 1428
55.7.1 Loschmidt's count . . . 1428
55.7.2 From estimates to an exact constant . . . 1429

56 Experiment: The Mechanical Equivalent of Heat 1431
56.1 Historical context: heat as substance or motion . . . 1431
56.1.1 Rumford's cannon-boring observations . . . 1431
56.1.2 Mayer's inference . . . 1432
56.1.3 Joule's programme, 1843–1849 . . . 1432
56.2 The claim under test . . . 1432
56.3 Apparatus . . . 1433
56.4 Procedure . . . 1433
56.5 Observations . . . 1433
56.6 Interpretation . . . 1434
56.7 The Joule–Thomson companion experiments . . . 1434
56.8 Modern repetitions and precision . . . 1435

57 Experiment: The Kinetic Theory Tested 1437
57.1 Stern: the direct measurement of molecular speeds (1920) . . . 1437
57.1.1 Apparatus . . . 1437
57.1.2 Procedure . . . 1438
57.1.3 Observations and data . . . 1438
57.1.4 Interpretation . . . 1438
57.1.5 Primary references . . . 1438
57.2 Miller and Kusch: the shape of the distribution (1955) . . . 1439
57.2.1 Apparatus . . . 1439
57.2.2 Procedure . . . 1439
57.2.3 Observations and data . . . 1439
57.2.4 Interpretation . . . 1440
57.2.5 Primary references . . . 1440
57.3 Maxwell: the viscosity of air and its density (1866) . . . 1441
57.3.1 Apparatus . . . 1441
57.3.2 Procedure . . . 1441
57.3.3 Observations and data . . . 1441
57.3.4 Interpretation . . . 1441
57.3.5 Primary references . . . 1442
57.4 Graham: diffusion, effusion and the transport coefficients (1833–1846) . . . 1443
57.4.1 Apparatus . . . 1443
57.4.2 Procedure . . . 1443
57.4.3 Observations and data . . . 1443
57.4.4 Interpretation . . . 1443
57.4.5 Primary references . . . 1444

VII Classical Field Theory and Electrodynamics 1455

58 Electrostatics 1457
58.1 The electrostatic field . . . 1457
58.1.1 Fundamentals . . . 1457
58.1.2 Geometry of the field . . . 1460
58.2 Methods for obtaining the potential . . . 1461
58.2.1 Boundary conditions . . . 1461
58.2.2 The method of images . . . 1462
58.2.3 The Poisson equation . . . 1464
58.2.4 Green functions . . . 1465
58.2.5 Multipole expansion . . . 1465
58.3 Electrostatic potential energy . . . 1465
58.4 Charge distributions in external fields . . . 1465
58.4.1 Potential energy of a charge distribution in an external field . . . 1465
58.4.2 Force on a charge distribution in an external field . . . 1465
58.4.3 Torque on a charge distribution in an external field . . . 1465
58.4.4 The ideal dipole . . . 1465
58.5 Electrostatics in macroscopic media . . . 1466

59 Magnetostatics 1467
59.1 Steady currents . . . 1467
59.1.1 Current density and charge conservation . . . 1467
59.1.2 The SI unit of current . . . 1467
59.2 The discovery of electromagnetism . . . 1467
59.2.1 Magnetism before 1820 . . . 1467
59.2.2 Ørsted's experiment . . . 1468
59.2.3 The Biot–Savart law . . . 1469
59.2.4 Ampère's electrodynamics . . . 1469
59.3 The field equations of magnetostatics . . . 1470
59.3.1 Gauss's law for the magnetic field . . . 1470
59.3.2 Ampère's circuital law . . . 1470
59.3.3 Boundary conditions . . . 1470
59.4 The vector potential . . . 1470
59.4.1 Existence and gauge freedom . . . 1470
59.4.2 The Biot–Savart law as the general solution . . . 1471
59.4.3 Multipole expansion and the magnetic dipole . . . 1471

59.4.4 Force and torque on a dipole . . . 1471
59.5 Magnetostatics in matter . . . 1471
59.5.1 Magnetization and bound currents . . . 1471
59.5.2 The auxiliary field $\boldsymbol{H}$ . . . 1472
59.5.3 Permanent magnets and boundary-value problems . . . 1472
59.6 Magnetic monopoles: the empirical status . . . 1472
59.6.1 The Dirac quantization argument . . . 1472
59.6.2 Searches and the null record . . . 1472

60 The Maxwell Equations 1473
60.1 Electromagnetic induction . . . 1473
60.1.1 Faraday's discovery . . . 1473
60.1.2 Lenz's law . . . 1474
60.1.3 The Maxwell–Faraday equation . . . 1474
60.2 The displacement current and the complete system . . . 1474
60.2.1 The inconsistency of the static circuital law . . . 1474
60.2.2 Maxwell's dynamical theory . . . 1474
60.2.3 The Heaviside vector form . . . 1475
60.3 Potentials and gauge freedom . . . 1475
60.3.1 Scalar and vector potentials . . . 1475
60.3.2 Gauge transformations . . . 1475
60.4 Conservation laws . . . 1475
60.4.1 Charge conservation . . . 1475
60.4.2 Poynting's theorem . . . 1476
60.4.3 The stress tensor and field momentum . . . 1476
60.5 The electromagnetic wave prediction . . . 1477
60.5.1 The wave equation and the speed c . . . 1477
60.5.2 Hertz's confirmation . . . 1477
60.6 Structure of the theory . . . 1478
60.6.1 Relativity of the field decomposition . . . 1478
60.6.2 Duality and the absence of magnetic charge . . . 1478
60.6.3 Limits and the domain of validity . . . 1478

61 Electromagnetic Waves and Optics 1479
61.1 Plane electromagnetic waves . . . 1479
61.1.1 Monochromatic plane waves . . . 1479
61.1.2 Energy and momentum transport . . . 1479
61.2 The speed of light . . . 1479
61.2.1 Astronomical determinations . . . 1479
61.2.2 Terrestrial measurements . . . 1480
61.2.3 From measured constant to defined constant . . . 1481
61.3 Reflection and refraction . . . 1481
61.3.1 Snell's law and Fermat's principle . . . 1481
61.3.2 The Fresnel equations . . . 1482
61.4 Polarization . . . 1482
61.4.1 Discovery and phenomenology . . . 1482
61.4.2 Mathematical description . . . 1483
61.4.3 Birefringence and wave plates . . . 1483
61.5 Interference . . . 1483
61.5.1 Young's double slit . . . 1483
61.5.2 Thin films and interferometers . . . 1484
61.5.3 Coherence . . . 1484

61.6 Diffraction . . . 1484
61.6.1 Fresnel diffraction and the Arago spot . . . 1484
61.6.2 Fraunhofer diffraction and gratings . . . 1484
61.6.3 Kirchhoff's scalar theory . . . 1485
61.7 Geometrical optics . . . 1485
61.7.1 The eikonal limit . . . 1485
61.7.2 Images and instruments . . . 1485
61.8 Dispersion . . . 1485
61.8.1 The prism and the solar spectrum . . . 1485
61.8.2 The rainbow . . . 1486
61.8.3 Phase velocity, group velocity, and media . . . 1486

62 Electrodynamics in Matter 1487
62.1 From microscopic to macroscopic fields . . . 1487
62.1.1 Bound charges and the polarization field . . . 1487
62.1.2 Bound currents and the magnetization field . . . 1487
62.1.3 Constitutive relations and boundary conditions . . . 1487
62.2 Dielectrics . . . 1488
62.2.1 Polarizability and local fields . . . 1488
62.2.2 Polar molecules and relaxation . . . 1488
62.2.3 Piezo- and ferroelectricity . . . 1488
62.3 Conduction . . . 1488
62.3.1 Ohm's law . . . 1488
62.3.2 The Drude model and the Hall effect . . . 1489
62.3.3 The skin effect . . . 1489
62.4 Magnetic materials . . . 1489
62.4.1 Dia-, para- and ferromagnetism . . . 1489
62.4.2 Langevin theory and the Curie–Weiss law . . . 1490
62.4.3 The Bohr–van Leeuwen theorem . . . 1491
62.4.4 Superconductors: deferred . . . 1491
62.5 Dispersion and causality . . . 1491
62.5.1 The Lorentz oscillator model . . . 1491
62.5.2 The Kramers–Kronig relations . . . 1492
62.5.3 Signal velocity and the front . . . 1492
62.6 Free-carrier response and plasmas . . . 1492
62.6.1 Plasma frequency and transparency . . . 1492
62.7 Magneto- and electro-optics . . . 1493

63 Experiments: Electromagnetism 1495
63.1 The predictions under test . . . 1495
63.2 Coulomb: the torsion balance (1785) . . . 1495
63.2.1 Apparatus and procedure . . . 1495
63.2.2 Observations . . . 1496
63.2.3 Interpretation . . . 1496
63.3 Cavendish: the concentric spheres . . . 1496
63.4 Galvanic circuits: Ohm and Kirchhoff . . . 1496
63.5 Ørsted: the current and the needle (1820) . . . 1497
63.6 Ampère: the force between currents (1820) . . . 1497
63.7 Faraday: electromagnetic induction (1831–1832) . . . 1497
63.7.1 Apparatus and procedure . . . 1497
63.7.2 Observations . . . 1497
63.7.3 Interpretation . . . 1498

63.8 Weber and Kohlrausch: the ratio of the units (1856) . . . 1498
63.8.1 Convection currents: Rowland (1876) . . . 1498
63.9 Hertz: electromagnetic waves (1888) . . . 1499
63.9.1 Apparatus and procedure . . . 1499
63.9.2 Observations . . . 1499
63.9.3 Interpretation . . . 1500
63.10 Millikan: the quantization of charge (1911–1913) . . . 1500
63.10.1 Apparatus and procedure . . . 1500
63.10.2 Observations . . . 1500
63.10.3 Interpretation . . . 1501
63.11 Modern repetitions and precision . . . 1501
63.11.1 The Coulomb exponent . . . 1501
63.11.2 Photon-mass bounds . . . 1501
63.11.3 Charge quantization today . . . 1501

64 Generalized Classical Field Theory 1503
64.1 Fields as dynamical systems . . . 1503
64.1.1 From many degrees of freedom to a continuum . . . 1503
64.1.2 The action functional and the Lagrangian density . . . 1504
64.1.3 Functional derivatives . . . 1504
64.2 The Euler–Lagrange field equations . . . 1504
64.2.1 Variation, boundary terms and natural conditions . . . 1504
64.2.2 The real scalar field: the Klein–Gordon equation . . . 1504
64.2.3 The complex scalar field and internal symmetry . . . 1504
64.3 Symmetries and conservation laws . . . 1504
64.3.1 Noether's first theorem . . . 1504
64.3.2 Poincaré invariance and the ten charges . . . 1505
64.3.3 Internal symmetry and electric charge . . . 1505
64.3.4 Noether's second theorem and local symmetries . . . 1505
64.4 The energy–momentum tensor . . . 1505
64.4.1 The canonical tensor and its defects . . . 1505
64.4.2 The Belinfante–Rosenfeld improvement . . . 1505
64.4.3 The Hilbert tensor and the gravitational source . . . 1505
64.4.4 What is actually measured . . . 1506
64.5 The electromagnetic field as a Lagrangian system . . . 1506
64.5.1 The free-field Lagrangian . . . 1506
64.5.2 Minimal coupling and the gauge principle . . . 1506
64.5.3 Gauge invariance and charge conservation . . . 1506
64.5.4 The electromagnetic energy–momentum tensor . . . 1506
64.5.5 The non-abelian generalization . . . 1506
64.6 Massive vector fields: the Proca theory . . . 1507
64.6.1 The Proca equation . . . 1507
64.6.2 The photon mass as a measured quantity . . . 1507
64.7 Hamiltonian field theory . . . 1507
64.7.1 Momentum density and the Hamiltonian . . . 1507
64.7.2 Poisson brackets for fields . . . 1507
64.7.3 Singular Lagrangians and constraints . . . 1507
64.7.4 Covariant Hamiltonian formulations . . . 1507
64.8 From classical fields to quanta . . . 1508

65 Radiation and Scattering of Electromagnetic Waves **1509**
65.1 Fields of a charge in arbitrary motion . . . 1509
65.1.1 Retarded potentials . . . 1509
65.1.2 The Liénard–Wiechert potentials . . . 1510
65.1.3 The velocity and acceleration fields . . . 1510
65.2 Radiated power . . . 1510
65.2.1 The Larmor formula . . . 1510
65.2.2 The relativistic generalization . . . 1511
65.2.3 Angular distribution and beaming . . . 1511
65.3 Multipole radiation . . . 1511
65.3.1 Electric dipole radiation . . . 1511
65.3.2 Magnetic dipole and electric quadrupole . . . 1512
65.3.3 The multipole expansion of the radiation field . . . 1512
65.4 Antennas . . . 1512
65.4.1 Radiation resistance . . . 1512
65.4.2 Arrays, directivity and reciprocity . . . 1512
65.5 Radiation reaction . . . 1512
65.5.1 The Abraham–Lorentz force . . . 1512
65.5.2 The Lorentz–Abraham–Dirac equation . . . 1512
65.5.3 Runaways, pre-acceleration and the domain of validity . . . 1513
65.5.4 The Landau–Lifshitz reduction of order . . . 1513
65.5.5 Radiation reaction observed . . . 1513
65.6 Scattering . . . 1513
65.6.1 Thomson scattering . . . 1513
65.6.2 Rayleigh scattering and the colour of the sky . . . 1514
65.6.3 Mie scattering . . . 1515
65.6.4 Where the classical account fails: Compton scattering . . . 1515
65.7 Radiation from relativistic charges and in matter . . . 1516
65.7.1 Synchrotron radiation . . . 1516
65.7.2 Bremsstrahlung . . . 1516
65.7.3 Cherenkov radiation . . . 1516
65.7.4 Transition radiation . . . 1517

66 Plasmas and Magnetohydrodynamics **1519**
66.1 The plasma state . . . 1519
66.1.1 Ionization equilibrium . . . 1519
66.1.2 Debye screening and the plasma parameter . . . 1519
66.1.3 Quasi-neutrality and the plasma frequency . . . 1520
66.1.4 Where plasmas are found . . . 1520
66.2 Waves in a plasma . . . 1521
66.2.1 Langmuir waves . . . 1521
66.2.2 Electromagnetic waves and the cutoff . . . 1522
66.2.3 Magnetized waves and ion-acoustic waves . . . 1522
66.3 Kinetic theory and Landau damping . . . 1522
66.3.1 The Vlasov equation . . . 1522
66.3.2 Landau damping . . . 1523
66.3.3 The observation . . . 1523
66.3.4 Collisions and transport . . . 1523
66.4 Single-particle motion . . . 1524
66.4.1 Gyration and the guiding centre . . . 1524
66.4.2 Drifts . . . 1524
66.4.3 Adiabatic invariants and magnetic mirrors . . . 1524

66.4.4 Fermi acceleration . . . 1525
66.5 Magnetohydrodynamics . . . 1525
66.5.1 The MHD equations and their validity . . . 1525
66.5.2 Flux freezing and the magnetic Reynolds number . . . 1525
66.5.3 Alfvén and magnetosonic waves . . . 1525
66.5.4 Equilibria and the pinch . . . 1526
66.6 Magnetic reconnection . . . 1526
66.6.1 The Sweet–Parker layer . . . 1526
66.6.2 Petschek and fast reconnection . . . 1526
66.6.3 Reconnection observed . . . 1526
66.7 Instabilities and turbulence . . . 1527
66.7.1 Ideal MHD instabilities . . . 1527
66.7.2 Microinstabilities and turbulence . . . 1527
66.8 Fusion and confinement . . . 1527
66.8.1 The Lawson criterion . . . 1527
66.8.2 Magnetic confinement . . . 1528
66.8.3 Inertial confinement and ignition . . . 1528
66.9 Space and astrophysical plasmas . . . 1528
66.9.1 The solar wind . . . 1528
66.9.2 The magnetosphere . . . 1529
66.9.3 The dynamo . . . 1529

67 Experiment: Wave Optics 1531
67.1 The predictions under test . . . 1531
67.1.1 Two accounts of light . . . 1531
67.1.2 What separates them . . . 1532
67.2 Young: the double slit (1801–1804) . . . 1532
67.2.1 Apparatus and procedure . . . 1532
67.2.2 Observations . . . 1532
67.2.3 Interpretation . . . 1533
67.3 Fresnel and the Poisson–Arago spot (1818–1819) . . . 1533
67.3.1 Apparatus and procedure . . . 1533
67.3.2 Observations . . . 1533
67.3.3 Interpretation . . . 1533
67.4 The Fresnel–Arago laws and transversality . . . 1533
67.4.1 Apparatus and procedure . . . 1533
67.4.2 Observations . . . 1534
67.4.3 Interpretation . . . 1534
67.5 Diffraction gratings and wavelength metrology . . . 1535
67.5.1 Fraunhofer's gratings . . . 1535
67.5.2 Rowland's ruling engine and concave grating . . . 1535
67.5.3 Resolving power measured . . . 1535
67.5.4 The same experiment with X-rays . . . 1536
67.6 Interferometry . . . 1536
67.6.1 The Michelson interferometer . . . 1536
67.6.2 The metre in wavelengths of light . . . 1536
67.6.3 Light in a moving medium . . . 1537
67.6.4 Rotation: the Sagnac effect . . . 1537
67.7 Stellar interferometry . . . 1538
67.7.1 Michelson's beam interferometer . . . 1538
67.7.2 Intensity interferometry . . . 1538
67.8 Gabor: holography and the recording of phase (1948, 1962) . . . 1538

67.8.1 Apparatus . . . 1539
67.8.2 Procedure . . . 1539
67.8.3 Observations and data . . . 1540
67.8.4 Interpretation . . . 1544
67.8.5 Primary references . . . 1544
67.9 Modern repetitions and precision . . . 1545
67.9.1 One photon at a time . . . 1545
67.9.2 Matter-wave double slits . . . 1545
67.9.3 Beyond the diffraction limit . . . 1545
67.9.4 Interferometers as detectors . . . 1545

VIII The Transition to Quantum Physics 1547

68 Black-Body Radiation and Planck's Hypothesis 1549
68.1 Cavity radiation and Kirchhoff's theorem . . . 1549
68.1.1 Emissive and absorptive power . . . 1549
68.1.2 The cavity as a thermodynamic system . . . 1550
68.2 What classical thermodynamics could settle . . . 1550
68.2.1 The Stefan–Boltzmann law . . . 1550
68.2.2 Wien's displacement law . . . 1551
68.2.3 Wien's distribution law . . . 1552
68.3 The classical field theory and its failure . . . 1552
68.3.1 Counting the modes of a cavity . . . 1552
68.3.2 The Rayleigh–Jeans law . . . 1552
68.3.3 The ultraviolet catastrophe . . . 1552
68.4 The measurements that decided the matter . . . 1553
68.4.1 Realizing a black body . . . 1553
68.4.2 Lummer–Pringsheim and the failure of Wien's law . . . 1553
68.4.3 Rubens–Kurlbaum in the far infrared . . . 1553
68.5 Planck's law . . . 1553
68.5.1 The interpolation of October 1900 . . . 1553
68.5.2 The combinatorial derivation of December 1900 . . . 1554
68.5.3 The 1901 Annalen paper . . . 1555
68.5.4 Limits, moments and consistency . . . 1555
68.6 What exactly was quantized . . . 1555
68.6.1 Energy elements . . . 1555
68.6.2 The reception, 1900–1911 . . . 1555
68.7 Out of the cavity: specific heats . . . 1555
68.7.1 The Einstein solid . . . 1555
68.7.2 Debye's improvement and the phonon . . . 1556
68.8 The statistics behind the law . . . 1556
68.8.1 Bose's derivation . . . 1556
68.8.2 Detailed balance and the Einstein coefficients . . . 1556
68.9 Black bodies in nature . . . 1556
68.9.1 The cosmic microwave background . . . 1556
68.9.2 Stellar spectra and radiation thermometry . . . 1557

69 The Photon: Photoelectric and Compton Effects **1559**
69.1 The photoelectric effect . . . 1559
69.1.1 Discovery: Hertz and Hallwachs . . . 1559
69.1.2 Lenard's measurements and the classical impasse . . . 1560
69.2 The light-quantum hypothesis . . . 1560
69.2.1 Einstein's heuristic viewpoint of 1905 . . . 1560
69.2.2 The photoelectric equation and the work function . . . 1561
69.2.3 Millikan's verification . . . 1561
69.2.4 What the photoelectric effect does not prove . . . 1561
69.3 Momentum and angular momentum of light . . . 1562
69.3.1 Radiation pressure . . . 1562
69.3.2 Angular momentum of light . . . 1562
69.4 Compton scattering . . . 1563
69.4.1 The 1923 experiment . . . 1563
69.4.2 Kinematics and the Compton wavelength . . . 1564
69.4.3 Debye's independent derivation . . . 1564
69.4.4 The Klein–Nishina cross-section . . . 1564
69.5 Coincidence: the last classical alternative . . . 1564
69.5.1 The Bohr–Kramers–Slater proposal . . . 1564
69.5.2 Bothe–Geiger coincidences . . . 1565
69.5.3 Compton–Simon cloud-chamber pairs . . . 1565
69.6 The photon as a countable object . . . 1565
69.6.1 Anticorrelation at a beam splitter . . . 1565
69.6.2 Counting photons . . . 1566
69.7 Creation and annihilation of quanta . . . 1566
69.7.1 Pair production and annihilation . . . 1566
69.7.2 The photon in quantum electrodynamics . . . 1566

70 Atomic Models and Spectra **1567**
70.1 Spectra before any model . . . 1567
70.1.1 The Fraunhofer lines . . . 1567
70.1.2 Spectral analysis . . . 1568
70.1.3 Balmer's formula . . . 1568
70.1.4 The Rydberg formula and the combination principle . . . 1568
70.2 The constituents of the atom . . . 1569
70.2.1 The electron . . . 1569
70.2.2 Thomson's model and its failure . . . 1569
70.3 The nuclear atom . . . 1569
70.3.1 Large-angle alpha scattering . . . 1569
70.3.2 Rutherford's scattering formula . . . 1570
70.3.3 Why the classical nuclear atom cannot exist . . . 1570
70.4 The Bohr model . . . 1571
70.4.1 The 1913 trilogy . . . 1571
70.4.2 What the model gets right . . . 1571
70.4.3 Reduced mass and the isotope shift . . . 1572
70.4.4 Where the model fails . . . 1573
70.5 The old quantum theory . . . 1573
70.5.1 Sommerfeld's elliptic orbits and the fine structure . . . 1573
70.5.2 The correspondence principle . . . 1573
70.5.3 Space quantization . . . 1574
70.6 X-ray spectra and the atomic number . . . 1574
70.6.1 X-rays and their wavelengths . . . 1574

70.6.2 Moseley's law . . . 1574
70.7 Atoms in external fields . . . 1575
70.7.1 The Zeeman effect . . . 1575
70.7.2 The anomalous Zeeman effect . . . 1575
70.7.3 The Stark effect . . . 1576
70.8 Levels made visible . . . 1576

71 Matter Waves **1577**
71.1 The de Broglie hypothesis . . . 1577
71.1.1 The relation . . . 1577
71.1.2 Phase waves and the Bohr condition . . . 1578
71.1.3 The optical–mechanical analogy completed . . . 1578
71.2 Electron diffraction . . . 1578
71.2.1 Elsasser's prediction . . . 1578
71.2.2 Davisson and Germer . . . 1578
71.2.3 Thomson's transmission experiment . . . 1579
71.3 Interference of atoms and molecules . . . 1579
71.3.1 Helium beams: Estermann and Stern . . . 1579
71.3.2 The electron double slit . . . 1580
71.3.3 Building the pattern one particle at a time . . . 1580
71.4 Neutron interferometry . . . 1580
71.4.1 The perfect-crystal interferometer . . . 1580
71.4.2 Gravitationally induced phase . . . 1581
71.4.3 Rotation by a full turn changes the sign . . . 1581
71.4.4 Bound states of a neutron in the Earth's field . . . 1582
71.5 How large can an interfering object be? . . . 1582
71.5.1 Fullerenes . . . 1582
71.5.2 The present limits . . . 1583
71.6 Wave packets . . . 1583
71.6.1 Superposition and localization . . . 1583
71.6.2 Phase velocity, group velocity and spreading . . . 1583
71.6.3 Bandwidth and the uncertainty relation . . . 1584
71.7 From a wavelength to a wave equation . . . 1584
71.7.1 What the hypothesis does not supply . . . 1584
71.7.2 Matter waves as instruments . . . 1584

72 Experiment: Franck–Hertz **1585**
72.1 Historical context and the prediction under test . . . 1585
72.1.1 What the Bohr postulates predict for a collision . . . 1585
72.1.2 What was known in 1913 . . . 1586
72.2 Apparatus . . . 1586
72.2.1 The tube . . . 1586
72.2.2 Electrical arrangement and the systematics it controls . . . 1586
72.3 Procedure . . . 1586
72.4 Observations . . . 1586
72.4.1 The current–voltage curve . . . 1586
72.4.2 The emission line at 253.7 nanometres . . . 1587
72.4.3 Uncertainties and the dataset . . . 1588
72.5 Interpretation . . . 1588
72.5.1 Discrete energy transfer . . . 1588
72.5.2 What the authors concluded, and why it was wrong . . . 1588
72.5.3 Bohr's correction and its experimental confirmation . . . 1589

72.6 Modern repetitions and precision . . . 1589
72.6.1 The neon variant . . . 1589
72.6.2 Fine structure of the mercury curve . . . 1589
72.6.3 Present-day level energies . . . 1590
72.7 What the experiment settles . . . 1590

73 Experiment: The Blackbody Spectrum Measured 1591
73.1 Stefan: the fourth power, from Tyndall's data (1879) . . . 1591
73.1.1 Apparatus . . . 1592
73.1.2 Procedure . . . 1592
73.1.3 Observations and data . . . 1592
73.1.4 Interpretation . . . 1593
73.1.5 Primary references . . . 1593
73.2 Lummer and Kurlbaum: a black body one can build (1898) . . . 1593
73.2.1 Apparatus . . . 1593
73.2.2 Procedure . . . 1594
73.2.3 Observations and data . . . 1594
73.2.4 Interpretation . . . 1595
73.2.5 Primary references . . . 1595
73.3 Lummer and Pringsheim: Wien's law breaks (1899) . . . 1595
73.3.1 Apparatus . . . 1595
73.3.2 Procedure . . . 1595
73.3.3 Observations and data . . . 1596
73.3.4 Interpretation . . . 1597
73.3.5 Primary references . . . 1597
73.4 Rubens and Kurlbaum: residual rays in the far infrared (1900) . . . 1597
73.4.1 Apparatus . . . 1597
73.4.2 Procedure . . . 1597
73.4.3 Observations and data . . . 1598
73.4.4 Interpretation . . . 1599
73.4.5 Primary references . . . 1599
73.5 Radiometric realization of the kelvin (2019) . . . 1599
73.5.1 Apparatus . . . 1600
73.5.2 Procedure . . . 1600
73.5.3 Observations and data . . . 1600
73.5.4 Interpretation . . . 1601
73.5.5 Primary references . . . 1601
73.6 What the measurements settle . . . 1601

74 Experiment: The Photoelectric Effect and Compton Scattering 1603
74.1 Hertz and Hallwachs: ultraviolet light discharges a metal (1887–1888) . . . 1603
74.1.1 Apparatus . . . 1604
74.1.2 Procedure . . . 1604
74.1.3 Observations and data . . . 1604
74.1.4 Interpretation . . . 1605
74.1.5 Primary references . . . 1605
74.2 Lenard: the energy of the electrons ignores the intensity (1902) . . . 1605
74.2.1 Apparatus . . . 1605
74.2.2 Procedure . . . 1606
74.2.3 Observations and data . . . 1606
74.2.4 Interpretation . . . 1607
74.2.5 Primary references . . . 1607

74.3 Millikan: the slope of the line is h/e (1916) . . . 1607
74.3.1 Apparatus . . . 1608
74.3.2 Procedure . . . 1608
74.3.3 Observations and data . . . 1608
74.3.4 Interpretation . . . 1610
74.3.5 Primary references . . . 1610
74.4 Compton: the wavelength of scattered X-rays changes (1923) . . . 1610
74.4.1 Apparatus . . . 1610
74.4.2 Procedure . . . 1610
74.4.3 Observations and data . . . 1611
74.4.4 Interpretation . . . 1612
74.4.5 Primary references . . . 1612
74.5 Bothe and Geiger: the two products appear together (1925) . . . 1612
74.5.1 Apparatus . . . 1612
74.5.2 Procedure . . . 1613
74.5.3 Observations and data . . . 1613
74.5.4 Interpretation . . . 1614
74.5.5 Primary references . . . 1615
74.6 Grangier, Roger and Aspect: a single quantum is not split (1986) . . . 1615
74.6.1 Apparatus . . . 1615
74.6.2 Procedure . . . 1615
74.6.3 Observations and data . . . 1615
74.6.4 Interpretation . . . 1617
74.6.5 Primary references . . . 1617
74.7 What the measurements settle . . . 1617

75 Experiment: Matter Waves Observed 1619
75.1 Davisson and Germer: electron diffraction by a crystal (1927) . . . 1620
75.1.1 Apparatus . . . 1620
75.1.2 Procedure . . . 1620
75.1.3 Observations and data . . . 1620
75.1.4 Interpretation . . . 1621
75.1.5 Primary references . . . 1621
75.2 Thomson and Reid: transmission rings from thin films (1927) . . . 1622
75.2.1 Apparatus . . . 1622
75.2.2 Procedure . . . 1622
75.2.3 Observations and data . . . 1622
75.2.4 Interpretation . . . 1623
75.2.5 Primary references . . . 1623
75.3 Estermann and Stern: helium and hydrogen diffracted (1930) . . . 1623
75.3.1 Apparatus . . . 1623
75.3.2 Procedure . . . 1624
75.3.3 Observations and data . . . 1624
75.3.4 Interpretation . . . 1625
75.3.5 Primary references . . . 1625
75.4 The electron double slit, one electron at a time (1961–1989) . . . 1625
75.4.1 Apparatus . . . 1625
75.4.2 Procedure . . . 1626
75.4.3 Observations and data . . . 1626
75.4.4 Interpretation . . . 1627
75.4.5 Primary references . . . 1627
75.5 Colella, Overhauser and Werner: gravity shifts a phase (1975) . . . 1627

75.5.1 Apparatus . . . 1627
75.5.2 Procedure . . . 1628
75.5.3 Observations and data . . . 1628
75.5.4 Interpretation . . . 1629
75.5.5 Primary references . . . 1629

IX Quantum Mechanics **1649**

77 The Postulates of Quantum Mechanics **1651**
77.1 The conventional postulates . . . 1651
77.1.1 The state postulate . . . 1651
77.1.2 The observable postulate . . . 1651
77.1.3 The measurement postulate . . . 1652
77.1.4 The probability postulate: the Born rule . . . 1652
77.1.5 The collapse postulate . . . 1652
77.1.6 The time-evolution postulate . . . 1652
77.1.7 The composite-system postulate . . . 1653
77.2 Density-matrix postulates . . . 1653
77.3 On Planck's constant . . . 1653
77.4 Pictures of time evolution . . . 1653
77.4.1 The Schrödinger picture . . . 1653
77.4.2 The Heisenberg picture . . . 1653
77.5 Canonical quantization rules . . . 1653
77.5.1 From the Poisson bracket to the commutator . . . 1653
77.5.2 Linear momentum as a differential operator . . . 1653
77.6 The Heisenberg uncertainty principle . . . 1654
77.6.1 Mean value of an observable . . . 1654
77.6.2 Uncertainty . . . 1654
77.6.3 The generalized uncertainty principle . . . 1654

78 Elementary Quantum Systems **1655**
78.1 The free particle . . . 1655
78.1.1 Plane waves and the continuum . . . 1655
78.1.2 Wave packets, group velocity and spreading . . . 1655
78.1.3 Ehrenfest's theorem . . . 1655
78.2 Potential wells . . . 1656
78.2.1 The infinite square well . . . 1656
78.2.2 The finite square well . . . 1656
78.2.3 The delta potential . . . 1656
78.2.4 The linear potential: the quantum bouncer . . . 1657
78.3 Tunnelling . . . 1657
78.3.1 Steps, barriers and the tunnel effect . . . 1657
78.3.2 Alpha decay . . . 1658
78.3.3 Field emission and the scanning tunnelling microscope . . . 1658
78.4 The harmonic oscillator . . . 1659
78.4.1 Analytic solution . . . 1659
78.4.2 Ladder operators . . . 1659
78.4.3 Zero-point energy . . . 1659
78.4.4 Coherent states . . . 1660
78.5 Periodic potentials: a preview . . . 1660

79 Angular Momentum and Spin **1661**
79.1 The angular-momentum algebra . . . 1661
79.1.1 Rotations and their generators . . . 1661
79.1.2 The spectrum from the algebra alone . . . 1662
79.1.3 Representation matrices and Euler angles . . . 1662
79.1.4 SU(2), SO(3) and the double cover . . . 1662
79.2 Orbital angular momentum . . . 1663

79.2.1 Spherical harmonics . . . 1663
79.2.2 Central potentials and the radial reduction . . . 1663
79.2.3 Rotational spectra of molecules . . . 1663
79.2.4 Parity and selection rules . . . 1664
79.3 Spin . . . 1664
79.3.1 The evidence for an intrinsic angular momentum . . . 1664
79.3.2 Pauli matrices and spinors . . . 1665
79.3.3 Magnetic moments and the g factor . . . 1665
79.3.4 Thomas precession . . . 1665
79.3.5 Spin beyond one half . . . 1666
79.4 Addition of angular momenta . . . 1666
79.4.1 The coupling problem and the Clebsch–Gordan series . . . 1666
79.4.2 Clebsch–Gordan coefficients . . . 1667
79.4.3 Two spins one half: singlet and triplet . . . 1667
79.4.4 $3j$, $6j$ and $9j$ symbols . . . 1667
79.5 Tensor operators and the Wigner–Eckart theorem . . . 1667
79.5.1 Spherical tensor operators . . . 1667
79.5.2 The Wigner–Eckart theorem . . . 1667
79.5.3 What the theorem buys . . . 1667
79.6 Spin dynamics and magnetic resonance . . . 1668
79.6.1 Larmor precession . . . 1668
79.6.2 Rabi's resonance method . . . 1668
79.6.3 Nuclear magnetic resonance . . . 1669
79.6.4 Spin as the elementary two-state system . . . 1669

80 Experiment: Stern–Gerlach 1671
80.1 Historical context, 1921–1922 . . . 1671
80.2 Stern–Gerlach (1921–1922) . . . 1672
80.2.1 Apparatus . . . 1672
80.2.2 Procedure . . . 1673
80.2.3 Observations and data . . . 1673
80.2.4 Interpretation . . . 1674
80.2.5 Primary references . . . 1674
80.3 The phenomenon: space quantization . . . 1674
80.4 Sequential Stern–Gerlach experiments . . . 1675
80.5 Legacy . . . 1675

81 The Hydrogen Atom 1677
81.1 The spectrum before the theory . . . 1677
81.1.1 Balmer's formula and the Rydberg constant . . . 1677
81.1.2 What the old quantum theory got right . . . 1679
81.2 The exact solution . . . 1679
81.2.1 Two bodies, one Coulomb potential . . . 1679
81.2.2 The radial equation and its quantization . . . 1679
81.2.3 Eigenfunctions, orbitals and expectation values . . . 1680
81.2.4 Levels, degeneracy and scales . . . 1680
81.3 Degeneracy and the hidden symmetry . . . 1680
81.3.1 The Runge–Lenz vector and the algebraic solution . . . 1680
81.3.2 SO(4) and Fock's construction . . . 1680
81.4 Fine and hyperfine structure . . . 1681
81.4.1 Relativistic corrections and spin–orbit coupling . . . 1681
81.4.2 The Lamb shift . . . 1681

81.4.3 Hyperfine structure . . . 1681
81.4.4 Hydrogen in external fields . . . 1682
81.5 The 21-centimetre line . . . 1682
81.5.1 A prediction made before the instrument existed . . . 1682
81.5.2 Detection . . . 1682
81.5.3 What the line measures . . . 1682
81.6 Precision hydrogen and the constants . . . 1683
81.6.1 The Rydberg constant and optical frequency metrology . . . 1683
81.6.2 The proton radius . . . 1683
81.6.3 Antihydrogen and the tests it carries . . . 1684
81.7 Hydrogen-like systems . . . 1684
81.7.1 One electron, other cores . . . 1684
81.7.2 Exotic atoms . . . 1684

82 Approximation Methods 1685
82.1 Stationary perturbation theory . . . 1685
82.1.1 The Rayleigh–Schrödinger series . . . 1685
82.1.2 Degenerate and near-degenerate levels . . . 1686
82.1.3 Does the series converge? Usually not . . . 1686
82.2 Perturbation theory at work . . . 1686
82.2.1 The Stark effect . . . 1686
82.2.2 The Zeeman effect . . . 1686
82.2.3 Fine structure, hyperfine structure and isotope shifts . . . 1686
82.2.4 The Hellmann–Feynman and virial theorems . . . 1687
82.3 The variational method . . . 1687
82.3.1 The Rayleigh–Ritz principle . . . 1687
82.3.2 Helium . . . 1687
82.3.3 Self-consistent fields . . . 1687
82.4 The semiclassical approximation . . . 1687
82.4.1 The WKB expansion . . . 1687
82.4.2 Turning points and connection formulae . . . 1688
82.4.3 Semiclassical quantization . . . 1688
82.4.4 Barrier penetration . . . 1688
82.5 Time-dependent perturbation theory . . . 1688
82.5.1 Variation of constants and the interaction picture . . . 1688
82.5.2 Fermi's golden rule . . . 1688
82.5.3 Periodic perturbations and the two-level check . . . 1688
82.5.4 The Born approximation . . . 1689
82.6 Adiabatic and sudden limits . . . 1689
82.6.1 The adiabatic theorem . . . 1689
82.6.2 Berry's geometric phase . . . 1689
82.6.3 Landau–Zener transitions . . . 1689
82.6.4 The sudden approximation . . . 1689
82.6.5 Born–Oppenheimer separation . . . 1690

83 Identical Particles 1691
83.1 Indistinguishability and the exchange operator . . . 1691
83.1.1 What indistinguishability asserts . . . 1691
83.1.2 The permutation group on the Hilbert space . . . 1692
83.1.3 The exchange operator and its eigenvalues . . . 1692
83.1.4 The symmetrization postulate . . . 1692
83.2 Bosons and fermions . . . 1692

83.2.1 Bose–Einstein statistics . . . 1692
83.2.2 Fermi–Dirac statistics and the exclusion principle . . . 1692
83.2.3 Parastatistics, and why nature does not use it . . . 1693
83.2.4 Exchange in an effectively two-dimensional system . . . 1693
83.3 Constructing many-particle states . . . 1693
83.3.1 Slater determinants and permanents . . . 1693
83.3.2 Occupation numbers and second quantization . . . 1693
83.3.3 The self-consistent field . . . 1694
83.4 The exchange interaction . . . 1694
83.4.1 Exchange energy has no classical analogue . . . 1694
83.4.2 Helium: ortho and para . . . 1694
83.4.3 From exchange to magnetic order . . . 1695
83.5 The spin–statistics connection . . . 1695
83.5.1 Statement of the theorem . . . 1695
83.5.2 Experimental tests of the symmetrization postulate . . . 1695
83.6 Two-particle interference . . . 1696
83.6.1 The Hong–Ou–Mandel dip . . . 1696
83.6.2 Intensity correlations and the fermionic counterpart . . . 1697
83.7 Consequences for bulk matter . . . 1698
83.7.1 Stability of matter . . . 1698
83.7.2 Degeneracy pressure . . . 1698

84 Entanglement and Bell Tests 1699
84.1 Entangled states . . . 1699
84.1.1 Tensor products and separability . . . 1699
84.1.2 The Schmidt decomposition . . . 1700
84.1.3 Reduced states, purification and steering . . . 1700
84.2 The EPR argument and the replies . . . 1700
84.2.1 Einstein, Podolsky and Rosen . . . 1700
84.2.2 Verschränkung, the cat, and the amplification argument . . . 1700
84.2.3 Bohm's spin version . . . 1700
84.3 Bell's theorem . . . 1701
84.3.1 Local hidden variables and the 1964 inequality . . . 1701
84.3.2 CHSH: the form that is actually measured . . . 1701
84.3.3 The quantum bound . . . 1702
84.3.4 GHZ: contradiction without inequalities . . . 1703
84.3.5 What a violation excludes — and what it does not . . . 1703
84.4 What entanglement may not do . . . 1703
84.4.1 No-signalling . . . 1703
84.4.2 No-cloning . . . 1704
84.4.3 Monogamy . . . 1704
84.5 Quantifying entanglement . . . 1705
84.5.1 Separability criteria . . . 1705
84.5.2 Entropy of entanglement . . . 1705
84.5.3 Mixed-state measures . . . 1705
84.6 Entanglement as a resource . . . 1705
84.6.1 Teleportation and entanglement swapping . . . 1705
84.6.2 Device-independent protocols . . . 1706
84.7 The experimental record . . . 1706

85 Interpretations (Evidence-Anchored) 1707
85.1 The measurement problem . . . 1707
85.1.1 The Born rule . . . 1707
85.1.2 The von Neumann chain . . . 1708
85.1.3 Three problems, stated separately . . . 1708
85.2 What experiment has already settled . . . 1708
85.2.1 Gleason's theorem . . . 1708
85.2.2 Contextuality . . . 1708
85.2.3 Bell and Leggett–Garg constraints . . . 1708
85.2.4 PBR and the status of the quantum state . . . 1709
85.2.5 Decoherence . . . 1709
85.3 The interpretive programmes . . . 1709
85.3.1 Copenhagen and complementarity . . . 1709
85.3.2 Pilot-wave theory . . . 1709
85.3.3 Everett's relative states . . . 1709
85.3.4 Consistent histories . . . 1710
85.3.5 Epistemic and relational accounts . . . 1710
85.4 Dynamical collapse: interpretation made testable . . . 1710
85.4.1 GRW and continuous spontaneous localization . . . 1710
85.4.2 Gravitationally induced collapse . . . 1710
85.4.3 The experimental bounds . . . 1711
85.5 Adjacent experiments that constrain the discussion . . . 1711
85.5.1 Delayed choice and quantum erasure . . . 1711
85.5.2 Weak measurement . . . 1711
85.6 The ledger . . . 1711

86 Scattering Theory 1713
86.1 What a scattering experiment measures . . . 1713
86.1.1 Cross sections . . . 1713
86.1.2 Kinematics, frames and flux . . . 1713
86.1.3 The scattering amplitude . . . 1714
86.2 The stationary formulation . . . 1714
86.2.1 Asymptotic conditions and scattering states . . . 1714
86.2.2 Green functions and the Lippmann–Schwinger equation . . . 1714
86.2.3 The Born series and the Born approximation . . . 1714
86.3 Partial waves and phase shifts . . . 1714
86.3.1 The partial-wave expansion . . . 1714
86.3.2 Unitarity and the optical theorem . . . 1715
86.3.3 Low energy: scattering length and effective range . . . 1715
86.3.4 Levinson's theorem . . . 1716
86.4 The S-matrix . . . 1716
86.4.1 The S operator and its symmetries . . . 1716
86.4.2 Analyticity, poles and dispersion relations . . . 1716
86.5 Resonances . . . 1716
86.5.1 The Breit–Wigner form . . . 1716
86.5.2 Time delay . . . 1717
86.5.3 Fano profiles and Feshbach resonances . . . 1717
86.6 Coulomb scattering . . . 1717
86.6.1 Rutherford, classically and quantum mechanically . . . 1717
86.6.2 Identical particles: Mott scattering . . . 1719
86.7 Observed effects the formalism must reproduce . . . 1719
86.7.1 The Ramsauer–Townsend effect . . . 1719

86.7.2 Threshold behaviour . . . 1720
86.7.3 High energy: the eikonal and Glauber regime . . . 1721

87 Open Quantum Systems and Decoherence 1723
87.1 States of an open system . . . 1723
87.1.1 The density operator . . . 1723
87.1.2 Reduced states and the partial trace . . . 1724
87.1.3 Proper and improper mixtures . . . 1724
87.1.4 Entropy and mixedness . . . 1724
87.2 Quantum channels . . . 1724
87.2.1 Complete positivity . . . 1724
87.2.2 The Kraus representation . . . 1724
87.2.3 The standard channels . . . 1724
87.2.4 Process tomography . . . 1725
87.3 Master equations . . . 1725
87.3.1 Projection-operator derivations . . . 1725
87.3.2 The Lindblad–Gorini–Kossakowski–Sudarshan generator . . . 1725
87.3.3 Quantum Brownian motion . . . 1725
87.3.4 Unravellings and quantum trajectories . . . 1725
87.3.5 Beyond Markov . . . 1726
87.4 Decoherence . . . 1726
87.4.1 Environment-induced superselection . . . 1726
87.4.2 Pointer states . . . 1726
87.4.3 Decoherence rates . . . 1727
87.4.4 Quantum Darwinism . . . 1727
87.4.5 Thermalization of an isolated system . . . 1727
87.4.6 What decoherence does not settle . . . 1728
87.5 Decoherence observed . . . 1728
87.5.1 Cavity quantum electrodynamics . . . 1728
87.5.2 Engineered reservoirs in ion traps . . . 1729
87.5.3 Matter-wave interferometry . . . 1729
87.5.4 Solid-state qubits . . . 1730
87.6 The quantum Zeno effect . . . 1730
87.6.1 The Misra–Sudarshan theorem . . . 1730
87.6.2 Observations . . . 1730
87.7 Fighting decoherence . . . 1731
87.7.1 Decoherence-free subspaces . . . 1731
87.7.2 Dynamical decoupling . . . 1731
87.7.3 Quantum error correction . . . 1732

88 Atoms and Molecules 1733
88.1 The many-electron problem . . . 1733
88.1.1 The Coulomb Hamiltonian . . . 1733
88.1.2 Antisymmetry and Slater determinants . . . 1733
88.1.3 Helium: exchange and the ortho–para splitting . . . 1734
88.2 Self-consistent field theory . . . 1734
88.2.1 The Hartree method . . . 1734
88.2.2 Hartree–Fock . . . 1735
88.2.3 Correlation energy . . . 1735
88.2.4 Density functional theory . . . 1735
88.3 The Thomas–Fermi model . . . 1735
88.4 The periodic table . . . 1736

88.4.1 The building-up principle . . . 1736
88.4.2 The Madelung rule and its exceptions . . . 1736
88.4.3 Periodic trends and their evidence . . . 1737
88.5 Angular-momentum coupling . . . 1737
88.5.1 LS coupling and atomic terms . . . 1737
88.5.2 Hund's rules . . . 1737
88.5.3 jj coupling and the intermediate regime . . . 1737
88.5.4 Atoms in external fields . . . 1737
88.5.5 Hyperfine structure . . . 1737
88.6 The Born–Oppenheimer separation . . . 1738
88.6.1 The adiabatic approximation . . . 1738
88.6.2 Where the surface fails . . . 1738
88.7 The chemical bond . . . 1739
88.7.1 The one-electron bond . . . 1739
88.7.2 Valence bond theory . . . 1739
88.7.3 Molecular orbitals and LCAO . . . 1739
88.7.4 What the two pictures agree on . . . 1740
88.8 Molecular spectra . . . 1740
88.8.1 Rotational spectra . . . 1740
88.8.2 Vibrational spectra . . . 1741
88.8.3 Electronic transitions . . . 1741
88.8.4 Raman scattering . . . 1741
88.9 Intermolecular forces . . . 1742
88.9.1 London dispersion . . . 1742
88.9.2 Retardation and the Casimir–Polder force . . . 1743
88.9.3 Weakly bound dimers . . . 1743

89 Experiment: Bell Tests 1745
89.1 Historical context and the prediction under test . . . 1745
89.1.1 From EPR to a testable inequality . . . 1745
89.1.2 CHSH: the inequality that is measured . . . 1746
89.1.3 The three loopholes . . . 1746
89.1.4 The first tests . . . 1746
89.2 Apparatus . . . 1747
89.2.1 Atomic cascade sources . . . 1747
89.2.2 Parametric down-conversion . . . 1747
89.2.3 Detectors . . . 1747
89.2.4 Entangled matter systems . . . 1747
89.2.5 Setting generators . . . 1747
89.3 Procedure . . . 1748
89.4 Observations . . . 1748
89.5 Interpretation . . . 1749
89.5.1 What the violations exclude . . . 1749
89.5.2 What remains open . . . 1749
89.5.3 Why a violation is not fragile . . . 1750
89.5.4 The 2022 Nobel citation . . . 1750
89.6 Modern repetitions and precision . . . 1750
89.6.1 Closing the locality loophole . . . 1750
89.6.2 Closing the detection loophole . . . 1751
89.6.3 The loophole-free experiments . . . 1751
89.6.4 Pushing back the setting choice . . . 1751
89.6.5 Other platforms and longer baselines . . . 1751

89.6.6 From test to instrument . . . 1752

90 Experiment: Precision Spectroscopy and Atomic Clocks 1753
90.1 Historical context and the prediction under test . . . 1753
90.1.1 The degeneracy the Dirac equation predicts . . . 1753
90.1.2 The Lamb shift . . . 1754
90.1.3 What a frequency measures . . . 1754
90.2 Apparatus . . . 1755
90.2.1 Resonance methods . . . 1755
90.2.2 Doppler-free laser spectroscopy . . . 1755
90.2.3 Cooling and trapping . . . 1756
90.2.4 Stable lasers and optical cavities . . . 1756
90.2.5 The frequency comb . . . 1756
90.3 Procedure . . . 1757
90.4 Observations . . . 1758
90.5 Interpretation . . . 1758
90.5.1 Tests of quantum electrodynamics . . . 1758
90.5.2 The proton-radius puzzle . . . 1758
90.5.3 Constants, and whether they are constant . . . 1758
90.5.4 Relativity measured with clocks . . . 1759
90.6 Modern repetitions and precision . . . 1760
90.6.1 Optical clocks . . . 1760
90.6.2 Redefining the second . . . 1760
90.6.3 Two-electron and exotic atoms . . . 1760
90.6.4 Antihydrogen . . . 1760
90.6.5 Toward a nuclear clock . . . 1760

91 Experiment: Quantum Tunnelling Observed 1763
91.1 The prediction under test . . . 1763
91.2 Alpha decay and the Geiger–Nuttall relation (1911, 1928) . . . 1764
91.2.1 Apparatus . . . 1764
91.2.2 Procedure . . . 1764
91.2.3 Observations and data . . . 1765
91.2.4 Interpretation . . . 1767
91.2.5 Primary references . . . 1767
91.3 Fowler and Nordheim: cold field emission from metals (1928) . . . 1767
91.3.1 Apparatus . . . 1767
91.3.2 Procedure . . . 1768
91.3.3 Observations and data . . . 1768
91.3.4 Interpretation . . . 1769
91.3.5 Primary references . . . 1769
91.4 Esaki: the tunnel diode and negative differential resistance (1958) . . . 1769
91.4.1 Apparatus . . . 1769
91.4.2 Procedure . . . 1769
91.4.3 Observations and data . . . 1770
91.4.4 Interpretation . . . 1771
91.4.5 Primary references . . . 1771

91.7 Summary of the evidence . . . 1775

X Relativistic Quantum Mechanics 1777

92 The Klein–Gordon Equation 1779
92.1 The equation . . . 1779
92.1.1 Schrödinger's discarded first attempt . . . 1779
92.1.2 Klein, Gordon, and the equation itself . . . 1780
92.1.3 The mass shell and the Poincaré Casimir . . . 1780
92.1.4 Lorentz covariance and the scalar transformation law . . . 1780
92.2 Negative energies and the indefinite density . . . 1780
92.2.1 Both branches of the dispersion relation . . . 1781
92.2.2 The conserved current and why its density changes sign . . . 1781
92.2.3 The two problems are one problem . . . 1781
92.3 Minimal coupling and the charged scalar . . . 1781
92.3.1 The covariant derivative and gauge invariance . . . 1781
92.3.2 The current as charge, not probability . . . 1782
92.3.3 The Compton effect after Gordon . . . 1782
92.3.4 Exact solutions in external fields . . . 1782
92.4 The Feshbach–Villars form and the nonrelativistic limit . . . 1783
92.4.1 The two-component representation . . . 1783
92.4.2 Recovery of the Schrödinger equation . . . 1783
92.4.3 Relativistic corrections . . . 1783
92.5 Propagation, causality and the propagator . . . 1783
92.5.1 Green functions of the Klein–Gordon operator . . . 1783
92.5.2 The Feynman prescription . . . 1783
92.5.3 Localization and its limits . . . 1783
92.5.4 The Yukawa potential . . . 1784
92.6 Pauli–Weisskopf: the equation is a field . . . 1784
92.6.1 Quantization of the scalar field . . . 1784
92.6.2 Bose statistics and microcausality . . . 1784
92.6.3 What survives of the one-particle reading . . . 1785
92.7 The observed spin-0 sector . . . 1785
92.7.1 Pions and the light pseudoscalars . . . 1785
92.7.2 Pionic and kaonic atoms . . . 1785
92.7.3 The Higgs boson . . . 1786

93 The Dirac Equation 1787
93.1 Construction of the equation . . . 1787
93.1.1 Dirac's requirement: first order in time . . . 1787
93.1.2 The Clifford algebra of the gamma matrices . . . 1788
93.1.3 Representations and the choice of basis . . . 1788
93.1.4 The conserved positive-definite current . . . 1788
93.2 Lorentz covariance and the spinor . . . 1788

93.2.1 The spinor transformation law . . . 1788
93.2.2 Bilinear covariants . . . 1789
93.2.3 Plane-wave solutions and spin projectors . . . 1789
93.3 Spin as a consequence, not an assumption . . . 1789
93.3.1 Orbital angular momentum is not conserved . . . 1789
93.3.2 The gyromagnetic ratio $g = 2$ . . . 1790
93.3.3 The Pauli equation as the nonrelativistic limit . . . 1790
93.4 The hydrogen atom solved exactly . . . 1791
93.4.1 The Dirac–Coulomb spectrum . . . 1791
93.4.2 Fine structure: spin–orbit, Darwin and mass terms . . . 1791
93.4.3 Where the exact spectrum fails: the Lamb shift . . . 1791
93.5 Negative energies, holes and the positron . . . 1792
93.5.1 Hole theory . . . 1792
93.5.2 The prediction of the anti-electron . . . 1792
93.5.3 The Stueckelberg–Feynman reading . . . 1793
93.5.4 Charge conjugation and the Majorana alternative . . . 1793
93.6 Phenomena of the one-particle theory . . . 1793
93.6.1 Zitterbewegung . . . 1793
93.6.2 The Klein paradox . . . 1793
93.6.3 Thomas precession and spin transport . . . 1794
93.7 The systematic nonrelativistic expansion . . . 1794
93.7.1 The Foldy–Wouthuysen transformation . . . 1794
93.7.2 The corrections order by order . . . 1794
93.8 The massless limit and the boundary of the theory . . . 1794
93.8.1 Weyl spinors and chirality . . . 1794
93.8.2 Where relativistic quantum mechanics ends . . . 1794

94 Particles as Poincaré Representations 1795
94.1 Symmetries act unitarily: Wigner's theorem . . . 1795
94.2 The unitary generators of the Poincaré group . . . 1796
94.3 The universal cover $\mathrm{SL}(2,\mathbb{C})$ . . . 1798
94.4 The invariants: mass and spin . . . 1799
94.5 Orbits, little groups, and induced representations . . . 1800
94.6 Massive particles: spin . . . 1803
94.7 Massless particles: helicity . . . 1804
94.8 The particle dictionary . . . 1805

95 Experiment: The Positron 1807
95.1 Historical context and the prediction under test . . . 1807
95.1.1 Dirac's hole theory as a falsifiable prediction . . . 1807
95.1.2 Cosmic rays as the available source . . . 1808
95.1.3 What else the track could have been . . . 1808
95.2 Apparatus . . . 1808
95.2.1 The cloud chamber . . . 1808
95.2.2 The magnet . . . 1808
95.2.3 The lead plate . . . 1808
95.3 Procedure . . . 1808
95.3.1 Expansion, triggering and photography . . . 1808
95.3.2 Track reconstruction and momentum from curvature . . . 1809
95.4 Observations . . . 1809
95.4.1 The photograph of 2 August 1932 . . . 1809
95.4.2 The tabulated quantities . . . 1810

95.4.3 Uncertainties and systematics . . . 1810
95.5 Interpretation . . . 1810
95.5.1 Identification with Dirac's anti-electron . . . 1810
95.5.2 Independent confirmation and pair production . . . 1810
95.5.3 Annihilation radiation . . . 1811
95.5.4 The muon: the same apparatus, a different particle . . . 1811
95.6 Modern repetitions and precision . . . 1812
95.6.1 Positronium . . . 1812
95.6.2 The antiproton and antihydrogen . . . 1812
95.6.3 Precision comparisons of positron and electron . . . 1812
95.6.4 Applied annihilation: positron emission tomography . . . 1813

96 The Weyl Equation and Neutrinos 1815
96.1 The two-component equation . . . 1815
96.1.1 Weyl's equation . . . 1815
96.1.2 Two-component spinors and $\mathrm{SL}(2,\mathbb{C})$ . . . 1815
96.1.3 Chirality and helicity . . . 1816
96.1.4 Relation to the Dirac equation . . . 1816
96.1.5 Discrete symmetries of a Weyl field . . . 1816
96.2 The neutrino hypothesis . . . 1816
96.2.1 The continuous beta spectrum . . . 1816
96.2.2 Pauli's 1930 letter . . . 1817
96.2.3 Fermi's theory of beta decay . . . 1817
96.2.4 Detection: Reines and Cowan . . . 1817
96.2.5 How many neutrinos . . . 1817
96.3 Parity and the reinstatement of the equation . . . 1818
96.3.1 Parity as an assumed symmetry . . . 1818
96.3.2 The measurements . . . 1818
96.3.3 Maximal violation . . . 1818
96.4 The two-component theory of the neutrino . . . 1818
96.4.1 Landau, Lee–Yang and Salam . . . 1818
96.4.2 The measured helicity . . . 1819
96.4.3 The V–A current . . . 1819
96.5 Chirality in the Standard Model . . . 1820
96.5.1 Left-handed doublets, right-handed singlets . . . 1820
96.5.2 The chiral anomaly . . . 1820
96.5.3 Chiral fermions on a lattice . . . 1820
96.6 Mass, and where the massless picture fails . . . 1820
96.6.1 Dirac and Majorana mass terms . . . 1820
96.6.2 Oscillations as the evidence for mass . . . 1820
96.6.3 Absolute mass bounds . . . 1821
96.6.4 Where the mass could come from . . . 1822
96.7 The Majorana question . . . 1822
96.7.1 Majorana's symmetric theory . . . 1822
96.7.2 Neutrinoless double beta decay . . . 1822
96.7.3 Null results and present status . . . 1822
96.8 Weyl fermions as an observed phenomenon . . . 1823

97 Higher-Spin Wave Equations **1825**
97.1 The classification problem . . . 1825
97.1.1 From representations to field equations . . . 1825
97.1.2 What a wave equation must deliver . . . 1826
97.2 Spin 1: the Proca field . . . 1826
97.2.1 The Proca equation . . . 1826
97.2.2 The Duffin–Kemmer form . . . 1826
97.2.3 Stueckelberg's restoration of gauge invariance . . . 1826
97.2.4 Massive vectors in Nature . . . 1826
97.3 Spin 3/2: the Rarita–Schwinger field . . . 1826
97.3.1 The equation and its constraints . . . 1826
97.3.2 The Velo–Zwanziger causality problem . . . 1827
97.3.3 The $\Delta(1232)$ resonance . . . 1827
97.4 Spin 2: the Fierz–Pauli field . . . 1827
97.4.1 The Fierz–Pauli Lagrangian . . . 1827
97.4.2 The vDVZ discontinuity . . . 1827
97.4.3 The Boulware–Deser ghost and the Vainshtein radius . . . 1827
97.4.4 The massless graviton and its evidence . . . 1827
97.5 General spin . . . 1828
97.5.1 Massive fields of arbitrary spin . . . 1828
97.5.2 Massless fields of arbitrary spin . . . 1828
97.5.3 Coupling obstructions . . . 1828
97.6 No-go theorems . . . 1828
97.6.1 Soft theorems and Weinberg's low-energy argument . . . 1828
97.6.2 Weinberg–Witten . . . 1828
97.6.3 Coleman–Mandula . . . 1828
97.7 Experimental status . . . 1829
97.7.1 The observed spectrum . . . 1829
97.7.2 Programmes without evidence . . . 1829

98 Experiment: Neutrino Helicity **1831**
98.1 Historical context and the prediction under test . . . 1831
98.1.1 From parity violation to the two-component neutrino . . . 1831
98.1.2 Why direct neutrino polarimetry is impossible . . . 1831
98.1.3 The chosen decay scheme . . . 1832
98.2 Apparatus . . . 1833
98.2.1 The source . . . 1833
98.2.2 The analysing magnet . . . 1833
98.2.3 Resonant scatterer and detector . . . 1833
98.3 Procedure . . . 1833
98.3.1 Selecting the recoil-aligned photons . . . 1833
98.3.2 Field reversal and counting . . . 1833
98.4 Observations . . . 1833
98.4.1 The counting asymmetry . . . 1833
98.4.2 Systematic checks . . . 1834
98.5 Interpretation . . . 1834
98.5.1 The neutrino is left-handed . . . 1834
98.5.2 Consequences for V–A . . . 1835
98.5.3 What the result does not say . . . 1835
98.6 Modern repetitions and precision . . . 1835
98.6.1 Chirality tests in leptonic decays . . . 1835
98.6.2 Parity violation in electron scattering and atoms . . . 1835

98.6.3 Limits on right-handed currents . . . 1836

XI Quantum Field Theory and the Standard Model 1837

99 Canonical Quantization of Fields 1839
99.1 Why fields . . . 1840
99.1.1 Failure of the single-particle relativistic theories . . . 1840
99.1.2 Field as a mechanical system with continuously many degrees of freedom 1843
99.1.3 The historical sequence . . . 1845
99.2 The free real scalar field . . . 1845
99.2.1 Canonical commutation relations . . . 1845
99.2.2 Mode expansion, creation and annihilation operators . . . 1848
99.2.3 Fock space . . . 1851
99.2.4 Normal ordering and the vacuum energy . . . 1852
99.3 The complex scalar field and antiparticles . . . 1853
99.3.1 Global phase symmetry and conserved charge . . . 1853
99.3.2 Two species of quantum: particle and antiparticle . . . 1855
99.3.3 Charge conjugation . . . 1856
99.4 Noether charges and the Poincaré algebra . . . 1857
99.4.1 Noether's theorem in field form . . . 1857
99.4.2 The Poincaré algebra and the labels of a particle . . . 1858
99.5 Fermions and gauge fields . . . 1859
99.5.1 The Dirac field and anticommutation . . . 1859
99.5.2 The electromagnetic field and gauge redundancy . . . 1862
99.5.3 Massive vector fields and the general spin case . . . 1864
99.6 Propagators . . . 1865
99.6.1 Time ordering and the Feynman propagator . . . 1865
99.6.2 The family of Green functions . . . 1868
99.6.3 Wick's theorem . . . 1870
99.7 Causality and spin–statistics . . . 1871
99.7.1 Microcausality . . . 1871
99.7.2 The spin–statistics theorem . . . 1873
99.7.3 Measurability of the field operators . . . 1875
99.8 Vacuum energy made observable: the Casimir effect . . . 1876
99.8.1 The prediction . . . 1876
99.8.2 Measurements . . . 1878
99.9 Limits of the canonical approach . . . 1879
99.9.1 Haag's theorem . . . 1879
99.9.2 What comes next . . . 1880

100 Quantum Electrodynamics and Renormalization 1883
100.1 The QED Lagrangian . . . 1883
100.1.1 Conventions, and the SI dimension of everything . . . 1883
100.1.2 Local phase invariance and minimal coupling . . . 1885
100.1.3 Gauge fixing and the photon propagator . . . 1887
100.1.4 Discrete symmetries and Furry's theorem . . . 1888
100.2 Perturbation theory and its three formalisms . . . 1889
100.2.1 Tomonaga–Schwinger covariant formulation . . . 1889
100.2.2 Feynman's space-time approach and the diagrams . . . 1890
100.2.3 Dyson's S-matrix and the equivalence of the formalisms . . . 1892
100.3 Tree-level QED . . . 1893

100.3.1 Elementary processes . . . 1893
100.3.2 From amplitudes to observables . . . 1895
100.4 One loop: where the infinities are . . . 1898
100.4.1 Vacuum polarization . . . 1900
100.4.2 Electron self-energy and mass renormalization . . . 1903
100.4.3 The vertex correction and the anomalous magnetic moment . . . 1905
100.4.4 Regularization . . . 1907
100.5 Renormalization . . . 1908
100.5.1 Counterterms and renormalization constants . . . 1908
100.5.2 The Ward–Takahashi identity . . . 1909
100.5.3 All orders: the BPHZ theorem . . . 1910
100.5.4 Scheme dependence and the meaning of a renormalized parameter . . . 1911
100.6 Infrared structure . . . 1912
100.6.1 Soft photons and the Bloch–Nordsieck mechanism . . . 1912
100.6.2 Mass singularities . . . 1914
100.7 The running coupling . . . 1914
100.7.1 Gell-Mann–Low and the beta function . . . 1914
100.7.2 Measured running of α . . . 1916
100.7.3 The Landau pole, stated honestly . . . 1916
100.8 Precision tests . . . 1917
100.8.1 The Lamb shift . . . 1917
100.8.2 The electron anomalous magnetic moment . . . 1919
100.8.3 Light-by-light scattering . . . 1920
100.8.4 Bound-state QED and the fine-structure constant . . . 1922

101 Weak Interactions **1925**
101.1 The beta-decay crisis . . . 1925
101.1.1 The continuous spectrum . . . 1925
101.1.2 Pauli's neutrino . . . 1927
101.1.3 Detection . . . 1928
101.2 Fermi's theory . . . 1930
101.2.1 The four-fermion interaction . . . 1930
101.2.2 Allowed transitions: Fermi and Gamow–Teller . . . 1933
101.2.3 The Kurie plot and the neutrino mass . . . 1936
101.3 Parity violation . . . 1938
101.3.1 The tau–theta puzzle and the Lee–Yang question . . . 1938
101.3.2 Observation . . . 1939
101.3.3 Neutrino helicity . . . 1941
101.4 The $V - A$ interaction . . . 1944
101.4.1 Chirality and the left-handed current . . . 1944
101.4.2 Conserved vector current and universality . . . 1946
101.4.3 Muon decay and the Fermi constant . . . 1949
101.5 Strangeness-changing currents . . . 1955
101.5.1 The strangeness deficit and the Cabibbo rotation . . . 1955
101.5.2 Selection rules . . . 1956
101.5.3 The GIM mechanism . . . 1957
101.5.4 Three generations: the CKM matrix . . . 1958
101.6 Neutral currents and the intermediate bosons . . . 1960
101.6.1 The intermediate vector boson hypothesis . . . 1960
101.6.2 Gargamelle and the weak neutral current . . . 1963
101.6.3 Discovery of the W and Z . . . 1965
101.6.4 Precision electroweak measurements . . . 1966

101.7 Why Fermi theory had to be replaced . . . 1968
101.7.1 Unitarity violation . . . 1968
101.7.2 Non-renormalizability and the effective-theory reading . . . 1969

102 Quantum Chromodynamics 1973
102.1 Hadron spectroscopy and the quark hypothesis . . . 1973
102.1.1 The eightfold way . . . 1973
102.1.2 The Ω^- prediction and its confirmation . . . 1975
102.1.3 Quarks . . . 1976
102.2 Colour . . . 1978
102.2.1 The statistics paradox . . . 1978
102.2.2 Counting the colours . . . 1979
102.3 The QCD Lagrangian . . . 1981
102.3.1 Yang–Mills theory . . . 1981
102.3.2 Gauge fixing, ghosts and the Slavnov–Taylor identities . . . 1983
102.3.3 The Lagrangian and its parameters . . . 1985
102.4 Asymptotic freedom . . . 1987
102.4.1 The sign of the beta function . . . 1987
102.4.2 The measured running of α_s . . . 1991
102.5 Deep inelastic scattering and the parton model . . . 1993
102.5.1 Bjorken scaling and partons . . . 1993
102.5.2 Scaling violation and the DGLAP equations . . . 1995
102.5.3 Factorization and parton distributions . . . 1998
102.6 Jets and the gluon . . . 1999
102.6.1 Two-jet events and the quark spin . . . 1999
102.6.2 Three-jet events: the gluon . . . 2000
102.7 Confinement . . . 2001
102.7.1 Lattice gauge theory . . . 2001
102.7.2 The static potential and hadron masses . . . 2002
102.7.3 No free quark has ever been observed . . . 2004
102.8 Chiral symmetry and its breaking . . . 2005
102.8.1 The chiral limit . . . 2005
102.8.2 Dynamical symmetry breaking . . . 2006
102.8.3 The pion as a pseudo-Goldstone boson . . . 2007
102.9 QCD under extreme conditions . . . 2008
102.10 The strong CP problem . . . 2010

103 Flavour Physics and Neutrinos 2013
103.1 The discovery of new quantum numbers . . . 2014
103.1.1 V particles . . . 2014
103.1.2 Strangeness . . . 2015
103.2 Quark mixing . . . 2016
103.2.1 The Cabibbo angle . . . 2016
103.2.2 GIM and the prediction of charm . . . 2017
103.2.3 The November revolution . . . 2019
103.3 Three generations . . . 2020
103.3.1 Kobayashi and Maskawa . . . 2020
103.3.2 The tau lepton . . . 2021
103.3.3 The bottom quark . . . 2022
103.3.4 The top quark . . . 2023
103.3.5 How many generations . . . 2024
103.4 The CKM matrix . . . 2025

103.4.1 Structure and parametrization . . . 2025
103.4.2 Measured magnitudes . . . 2028
103.4.3 Unitarity triangle . . . 2028
103.5 Neutral meson mixing and CP violation . . . 2030
103.5.1 Neutral kaon mixing . . . 2030
103.5.2 Discovery of CP violation . . . 2032
103.5.3 B mixing and the B factories . . . 2033
103.5.4 Charm and the present picture . . . 2036
103.5.5 What CP violation cannot yet explain . . . 2036
103.6 Lepton flavour and neutrino mixing . . . 2037
103.6.1 The PMNS matrix . . . 2037
103.6.2 Oscillation in vacuum . . . 2039
103.6.3 Matter effects . . . 2042
103.6.4 The evidence . . . 2045
103.6.5 Measured parameters and what is still unknown . . . 2046
103.7 Neutrino mass . . . 2047
103.7.1 Direct kinematic limits . . . 2047
103.7.2 Neutrinoless double beta decay . . . 2048
103.7.3 Cosmological bounds . . . 2050
103.7.4 Dirac or Majorana: an open question . . . 2051
103.8 Open questions in flavour . . . 2052

104 Electroweak Unification and the Higgs Boson 2055
104.1 Conventions carried into this chapter . . . 2055
104.2 From Fermi's theory to a gauge theory . . . 2056
104.2.1 The four-fermion interaction and its breakdown . . . 2056
104.2.2 Yang–Mills fields and the mass problem . . . 2058
104.2.3 Glashow's $\mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ . . . 2060
104.3 Spontaneous symmetry breaking . . . 2061
104.3.1 The superconducting analogy . . . 2061
104.3.2 Goldstone's theorem . . . 2062
104.3.3 The Anderson–Higgs mechanism . . . 2064
104.3.4 The 1964 papers . . . 2065
104.4 The Glashow–Weinberg–Salam model . . . 2066
104.4.1 The electroweak Lagrangian . . . 2066
104.4.2 Mixing and the weak mixing angle . . . 2070
104.4.3 Fermion masses and the Yukawa couplings . . . 2072
104.4.4 Custodial symmetry and the ρ parameter . . . 2074
104.5 Renormalizability . . . 2077
104.5.1 't Hooft's proofs . . . 2077
104.5.2 Dimensional regularization and gauge cancellations . . . 2080
104.5.3 Anomaly cancellation . . . 2081
104.6 Experimental confirmation . . . 2083
104.6.1 Weak neutral currents . . . 2083
104.6.2 Discovery of the W and Z bosons . . . 2084
104.6.3 LEP, SLD and the Z resonance . . . 2085
104.6.4 Precision fits and the W mass . . . 2087
104.7 The Higgs boson . . . 2087
104.7.1 Search and discovery . . . 2087
104.7.2 Quantum numbers and couplings . . . 2089
104.7.3 The potential and the self-coupling . . . 2091
104.8 What the model does not explain . . . 2092

104.8.1 Vacuum stability . . . 2092
104.8.2 Open questions, stated honestly . . . 2093

105 Discrete Symmetries and CPT 2095
105.1 The three discrete operations . . . 2096
105.1.1 Parity . . . 2096
105.1.2 Charge conjugation . . . 2100
105.1.3 Time reversal . . . 2102
105.2 Parity violation . . . 2106
105.2.1 The tau–theta puzzle and the Lee–Yang question . . . 2106
105.2.2 The experimental collapse of 1957 . . . 2107
105.2.3 Parity violation as a precision tool . . . 2110
105.3 CP violation . . . 2111
105.3.1 The neutral kaon system . . . 2111
105.3.2 The 1964 discovery . . . 2116
105.3.3 The CKM phase . . . 2118
105.3.4 CP violation beyond the kaon . . . 2120
105.4 Direct tests of time reversal . . . 2121
105.4.1 The CPLEAR asymmetry . . . 2121
105.4.2 Time reversal in the B system . . . 2122
105.4.3 Electric dipole moments as T tests . . . 2123
105.5 The CPT theorem . . . 2125
105.5.1 Statement and hypotheses . . . 2125
105.5.2 Consequences and loopholes . . . 2129
105.5.3 Experimental tests . . . 2131
105.6 The baryon asymmetry . . . 2132
105.6.1 Sakharov's conditions . . . 2132
105.6.2 Why the Standard Model fails . . . 2134
105.7 The strong CP problem . . . 2135
105.7.1 The theta term . . . 2135
105.7.2 The experimental bound and its status . . . 2137

106 Path-Integral Quantization 2139
106.1 The path integral in quantum mechanics . . . 2140
106.1.1 Dirac's Lagrangian formulation . . . 2140
106.1.2 Feynman's sum over histories . . . 2141
106.1.3 Time slicing, the measure and the classical limit . . . 2145
106.2 Euclidean formulation . . . 2148
106.2.1 Wick rotation . . . 2148
106.2.2 The Feynman–Kac formula . . . 2149
106.2.3 Reconstruction of the real-time theory . . . 2152
106.3 Functional quantization of fields . . . 2153
106.3.1 Generating functionals . . . 2153
106.3.2 Free fields and the perturbative expansion . . . 2155
106.3.3 Fermions and Grassmann integration . . . 2159
106.3.4 The effective action . . . 2162
106.3.5 The LSZ reduction formula . . . 2165
106.4 Gauge fields . . . 2166
106.4.1 Faddeev–Popov ghosts . . . 2166
106.4.2 BRST symmetry . . . 2169
106.4.3 Slavnov–Taylor identities . . . 2172
106.4.4 The Gribov ambiguity . . . 2173

106.5 The lattice . . . 2174
106.5.1 Wilson's lattice gauge theory . . . 2174
106.5.2 Monte Carlo evidence . . . 2178
106.6 Topology of the gauge vacuum . . . 2180
106.6.1 Instantons . . . 2180
106.6.2 Theta vacua . . . 2182
106.7 Anomalies . . . 2184
106.7.1 The Adler–Bell–Jackiw anomaly . . . 2184
106.7.2 Neutral pion decay as the measurement . . . 2186
106.7.3 Fujikawa's derivation from the measure . . . 2188
106.7.4 Anomaly cancellation . . . 2190

107 Nuclear Forces and Nuclear Structure 2193
107.1 Discovery of the nucleus . . . 2194
107.1.1 Radioactivity . . . 2194
107.1.2 Rutherford scattering . . . 2195
107.1.3 The neutron and the constitution of nuclei . . . 2197
107.2 The nucleon–nucleon interaction . . . 2199
107.2.1 Yukawa's exchange mechanism . . . 2199
107.2.2 The pion . . . 2201
107.2.3 The deuteron . . . 2203
107.2.4 Phenomenological and effective-field-theory potentials . . . 2206
107.3 Nuclear masses and binding . . . 2208
107.3.1 The binding-energy curve . . . 2208
107.3.2 The semi-empirical mass formula . . . 2209
107.3.3 Radii, form factors and the charge distribution . . . 2213
107.4 Nuclear models . . . 2215
107.4.1 The liquid-drop model and the compound nucleus . . . 2216
107.4.2 Magic numbers and the shell model . . . 2217
107.4.3 The collective model . . . 2221
107.4.4 Where the models fail . . . 2222
107.5 Radioactive decay . . . 2223
107.5.1 Alpha decay . . . 2223
107.5.2 Beta decay . . . 2225
107.5.3 Gamma decay and the Mössbauer effect . . . 2228
107.6 Fission and fusion . . . 2231
107.6.1 Fission . . . 2231
107.6.2 Fusion . . . 2234
107.6.3 The heaviest nuclei . . . 2237

108 The Renormalization Group 2239
108.1 Conventions carried into this chapter . . . 2239
108.2 Origins in field theory . . . 2241
108.2.1 The arbitrariness of the subtraction point . . . 2241
108.2.2 The Callan–Symanzik equation . . . 2243
108.2.3 Renormalization schemes and their arbitrariness . . . 2245
108.3 Regularization . . . 2247
108.3.1 Dimensional regularization . . . 2247
108.3.2 Other regulators and the counterterm expansion . . . 2249
108.4 The Wilsonian picture . . . 2251
108.4.1 Block spins and Kadanoff scaling . . . 2251
108.4.2 Integrating out momentum shells . . . 2253

108.4.3 Fixed points, relevant and irrelevant operators . . . 2256
108.4.4 Universality . . . 2257
108.5 Running couplings in the Standard Model . . . 2259
108.5.1 Asymptotic freedom . . . 2260
108.5.2 The measured running . . . 2261
108.5.3 Landau poles and triviality . . . 2263
108.6 Effective field theory . . . 2265
108.6.1 Decoupling . . . 2265
108.6.2 Phenomenological Lagrangians and power counting . . . 2267
108.6.3 The Standard Model as an effective theory . . . 2269
108.7 The renormalization group beyond perturbation theory . . . 2273
108.7.1 Scale invariance and its breaking . . . 2273
108.7.2 Monotonicity of the flow . . . 2275

109 Axiomatic Quantum Field Theory 2277
109.1 Why axioms . . . 2277
109.1.1 Fields as operator-valued distributions . . . 2277
109.1.2 Haag's theorem . . . 2279
109.1.3 What axiomatization is for . . . 2280
109.2 The Wightman axioms . . . 2281
109.2.1 Statement of the axioms . . . 2281
109.2.2 Wightman functions and reconstruction . . . 2283
109.2.3 Analyticity and the Wightman–Hall domain . . . 2286
109.2.4 The Reeh–Schlieder theorem . . . 2288
109.2.5 Borchers classes . . . 2290
109.3 Theorems from the axioms . . . 2290
109.3.1 The PCT theorem . . . 2290
109.3.2 Spin and statistics . . . 2293
109.3.3 The Källén–Lehmann representation . . . 2296
109.3.4 Asymptotic states and LSZ . . . 2298
109.4 Algebraic quantum field theory . . . 2300
109.4.1 Haag–Kastler nets . . . 2300
109.4.2 States, GNS and superselection . . . 2301
109.4.3 Modular theory . . . 2302
109.5 The Euclidean route . . . 2304
109.5.1 Osterwalder–Schrader axioms . . . 2304
109.5.2 Reflection positivity and the lattice . . . 2306
109.6 The operator product expansion . . . 2307
109.7 Constructive results and what is missing . . . 2309
109.7.1 Models below four dimensions . . . 2309
109.7.2 Triviality of the four-dimensional scalar . . . 2309
109.7.3 The Yang–Mills mass gap . . . 2311
109.7.4 What axiomatics does and does not secure . . . 2311

110 Experiment: Parity Violation 2313
110.1 Historical context and the prediction under test . . . 2313
110.1.1 Parity as a conserved quantum number . . . 2313
110.1.2 The tau–theta puzzle . . . 2314
110.1.3 Lee and Yang: parity untested in the weak interaction . . . 2315
110.1.4 The observable and what a measurement must deliver . . . 2315
110.2 Apparatus . . . 2317
110.2.1 The polarized cobalt-60 source . . . 2317

110.2.2 Adiabatic demagnetization and the cryostat . . . 2318
110.2.3 Beta and gamma detection . . . 2320
110.3 Procedure . . . 2321
110.3.1 The run cycle . . . 2321
110.3.2 Interleaving, and why it is not optional . . . 2322
110.3.3 The controls . . . 2322
110.4 Observations and data . . . 2323
110.4.1 Gamma anisotropy as the polarization thermometer . . . 2323
110.4.2 The beta asymmetry and its warm-up decay . . . 2323
110.4.3 Numerical results . . . 2324
110.4.4 Systematic checks . . . 2326
110.5 Interpretation . . . 2326
110.5.1 Maximal violation and the V–A structure . . . 2326
110.5.2 Charge conjugation, CP and CPT . . . 2327
110.5.3 Neutrino helicity . . . 2327
110.6 Immediate confirmation: the pion–muon–electron chain . . . 2329
110.6.1 Garwin, Lederman and Weinrich . . . 2329
110.6.2 Friedman and Telegdi . . . 2331
110.7 Modern repetitions and precision . . . 2332
110.7.1 Neutral currents and the weak mixing angle . . . 2332
110.7.2 Atomic parity violation . . . 2332
110.7.3 Polarized electron scattering . . . 2334
110.7.4 The weak charge of the proton . . . 2336
110.7.5 Consistency and what remains open . . . 2338
110.8 Primary references . . . 2339

111 Experiment: CP Violation 2341
111.1 Historical context and the prediction under test . . . 2342
111.1.1 The neutral kaon system . . . 2342
111.1.2 Regeneration . . . 2343
111.1.3 CP as the symmetry that was supposed to survive . . . 2344
111.1.4 The observable and what a measurement must deliver . . . 2345
111.2 Apparatus . . . 2345
111.2.1 The Brookhaven beam and the decay volume . . . 2345
111.2.2 The two-arm spectrometer . . . 2346
111.3 Procedure . . . 2349
111.3.1 Trigger and event recording . . . 2349
111.3.2 Reconstruction in the mass-angle plane . . . 2349
111.3.3 Backgrounds and the control samples . . . 2350
111.4 Observations and data . . . 2350
111.4.1 The forward peak at the kaon mass . . . 2350
111.4.2 The branching ratio and the parameter epsilon . . . 2351
111.4.3 Charge asymmetry in semileptonic decay . . . 2353
111.4.4 The measured CP-violating observables . . . 2353
111.5 Interpretation . . . 2353
111.5.1 Indirect versus direct violation . . . 2353
111.5.2 The CKM matrix and the Jarlskog invariant . . . 2355
111.6 Direct CP violation in the kaon system . . . 2356
111.6.1 NA31 and the first evidence . . . 2356
111.6.2 NA48 and KTeV . . . 2356
111.6.3 The Standard Model prediction and what it is worth . . . 2358
111.7 CP violation beyond the kaons . . . 2359

111.7.1 The B factories . . . 2359
111.7.2 Neutral B_s mesons at the LHC . . . 2361
111.7.3 Charm . . . 2362
111.7.4 Direct T violation . . . 2363
111.7.5 The unitarity triangle . . . 2364
111.8 Cosmological relevance and open questions . . . 2365
111.8.1 The Sakharov conditions . . . 2365
111.8.2 Insufficiency of Standard Model CP violation . . . 2366
111.8.3 Electric dipole moments and the strong CP problem . . . 2367
111.9 Primary references . . . 2369

112 Experiment: The Electron Anomalous Magnetic Moment 2371
112.1 Historical context and the prediction under test . . . 2372
112.1.1 Dirac's $g = 2$ . . . 2372

124.6 Fluctuation theorems . . . 2640
124.6.1 The steady-state fluctuation theorem . . . 2640
124.6.2 Work relations far from equilibrium . . . 2641
124.6.3 Experimental verification . . . 2641
124.6.4 Stochastic thermodynamics and information . . . 2641

125 Phonons and Lattice Dynamics 2643
125.1 The crystal lattice . . . 2643
125.1.1 Bravais lattices and the crystallographic restriction . . . 2643
125.1.2 Point groups, space groups and the basis . . . 2643
125.1.3 The reciprocal lattice and Brillouin zones . . . 2644
125.1.4 Quasicrystals: the exception that fixed the rule . . . 2644
125.2 Experiment: the lattice made visible . . . 2644
125.2.1 Laue diffraction of X-rays . . . 2644
125.2.2 Bragg's law and structure determination . . . 2644
125.2.3 Structure factor and systematic absences . . . 2645
125.3 Heat capacity of solids . . . 2645
125.3.1 The Dulong–Petit law and its failure . . . 2645
125.3.2 The Einstein model . . . 2646
125.3.3 The Debye model and the cubic law . . . 2646
125.3.4 Calorimetric tests at low temperature . . . 2646
125.4 Lattice dynamics . . . 2647
125.4.1 The Born–von Kármán theory . . . 2647
125.4.2 Acoustic and optical branches . . . 2647
125.4.3 Quantization: the phonon . . . 2647
125.4.4 Polar crystals and the Lyddane–Sachs–Teller relation . . . 2648

125.5 Measured dispersion relations . . . 2648
125.5.1 Inelastic neutron scattering . . . 2648
125.5.2 Inelastic X-ray and light scattering . . . 2649
125.5.3 The Debye–Waller factor . . . 2649
125.6 Anharmonicity . . . 2649
125.6.1 Thermal expansion and the Grüneisen parameter . . . 2649
125.6.2 Phonon–phonon scattering and umklapp . . . 2650
125.6.3 Thermal conductivity of insulators . . . 2650

126 Electrons in Solids: Band Theory 2651
126.1 The free-electron metal . . . 2651
126.1.1 Drude's kinetic model . . . 2651
126.1.2 The Wiedemann–Franz law . . . 2652
126.1.3 What the classical electron gas cannot do . . . 2653
126.1.4 The Sommerfeld model . . . 2654
126.2 Electrons in a periodic potential . . . 2654
126.2.1 Bloch's theorem . . . 2654
126.2.2 Reciprocal lattice and Brillouin zones . . . 2654
126.2.3 Nearly free electrons . . . 2654
126.2.4 Tight binding and Wannier functions . . . 2654
126.2.5 The Kronig–Penney model . . . 2655
126.3 Band structure and the classification of solids . . . 2655
126.3.1 Filling and Wilson's criterion . . . 2655
126.3.2 Semimetals, semiconductors and the gap scale . . . 2655
126.3.3 Computing band structures . . . 2656
126.3.4 Density functional theory . . . 2656
126.4 Semiclassical dynamics of Bloch electrons . . . 2656
126.4.1 Group velocity and effective mass . . . 2656
126.4.2 Holes . . . 2656
126.4.3 Bloch oscillations and Zener breakdown . . . 2656
126.4.4 Magnetotransport and the Hall coefficient . . . 2656
126.5 The Fermi surface and how it is measured . . . 2657
126.5.1 Landau levels and quantum oscillations . . . 2657
126.5.2 The de Haas–van Alphen effect . . . 2657
126.5.3 Shubnikov–de Haas and cyclotron resonance . . . 2657
126.5.4 Photoemission . . . 2658
126.6 Transport and scattering . . . 2658
126.6.1 Residual resistivity and Matthiessen's rule . . . 2658
126.6.2 Phonon scattering and the Bloch–Grüneisen law . . . 2658
126.7 Where the one-electron picture fails . . . 2659
126.7.1 Fermi-liquid theory . . . 2659
126.7.2 Mott insulators and the Hubbard model . . . 2659
126.7.3 Disorder and localization . . . 2659

127 Semiconductors 2661
127.1 What a semiconductor is . . . 2661
127.1.1 Wilson's band picture . . . 2661
127.1.2 The band structures of silicon, germanium and gallium arsenide . . . 2662
127.1.3 Measuring the gap optically . . . 2662
127.2 Carriers and their statistics . . . 2663
127.2.1 Intrinsic conduction . . . 2663
127.2.2 Doping and extrinsic conduction . . . 2663

127.2.3 The Hall effect as a carrier measurement . . . 2664
127.2.4 Drift, diffusion and mobility . . . 2664
127.2.5 Recombination and carrier lifetime . . . 2664
127.3 Junctions and rectification . . . 2664
127.3.1 Metal–semiconductor contacts . . . 2664
127.3.2 The p–n junction . . . 2665
127.3.3 The Haynes–Shockley experiment . . . 2665
127.3.4 Tunnelling and the Esaki diode . . . 2666
127.4 Devices . . . 2666
127.4.1 The transistor . . . 2666
127.4.2 The MOSFET and the inversion layer . . . 2667
127.4.3 The integrated circuit . . . 2667
127.5 Light and semiconductors . . . 2667
127.5.1 Photoconductivity and the solar cell . . . 2667
127.5.2 Light-emitting diodes . . . 2667
127.5.3 The semiconductor laser and heterostructures . . . 2668
127.5.4 Excitons . . . 2668
127.6 Low-dimensional semiconductors . . . 2668
127.6.1 Quantum wells and superlattices . . . 2668
127.6.2 The two-dimensional electron gas . . . 2668

128 Experiment: The Quantum Hall Effect 2669
128.1 Historical context and the prediction under test . . . 2669
128.1.1 The classical Hall effect . . . 2669
128.1.2 Two-dimensional electron gases . . . 2670
128.1.3 Landau quantization and what was expected . . . 2670
128.2 Apparatus . . . 2670
128.2.1 The silicon MOSFET Hall bar . . . 2670
128.2.2 Heterostructure samples . . . 2670
128.2.3 Cryogenics, magnets and electrical metrology . . . 2670
128.3 Procedure . . . 2670
128.4 Observations . . . 2671
128.4.1 The integer plateaux . . . 2671
128.4.2 Exactness and universality . . . 2672
128.4.3 The fractional plateaux . . . 2672
128.5 Interpretation . . . 2673
128.5.1 Laughlin's gauge argument . . . 2673
128.5.2 Disorder, localization and plateau width . . . 2673
128.5.3 Edge states . . . 2673
128.5.4 Topology: TKNN and the Chern number . . . 2673
128.5.5 The Laughlin state and fractional charge . . . 2673
128.6 Later measurements and precision . . . 2674
128.6.1 Fractional charge and anyon statistics measured . . . 2674
128.6.2 Composite fermions . . . 2674
128.6.3 Graphene and the relativistic quantum Hall effect . . . 2674
128.6.4 Quantum spin Hall and topological insulators . . . 2675
128.6.5 The quantum anomalous Hall effect . . . 2675
128.7 Metrology: the ohm and the SI . . . 2676

129 Magnetism in Matter **2677**
129.1 The magnetic response of matter . . . 2677
129.1.1 Diamagnetism . . . 2677
129.1.2 Paramagnetism and the Curie law . . . 2678
129.1.3 The Bohr–van Leeuwen theorem . . . 2679
129.1.4 Magnetism of the conduction electrons . . . 2679
129.2 Where the moments come from . . . 2680
129.2.1 Local moments and the effective moment . . . 2680
129.2.2 The gyromagnetic ratio measured . . . 2680
129.3 Ferromagnetism . . . 2681
129.3.1 Weiss's molecular field . . . 2681
129.3.2 Exchange . . . 2682
129.3.3 The Heisenberg model . . . 2682
129.3.4 Itinerant ferromagnetism . . . 2682
129.4 Antiferromagnetism and ferrimagnetism . . . 2682
129.4.1 Néel's theory . . . 2682
129.4.2 Neutron diffraction as the decisive evidence . . . 2682
129.4.3 Superexchange and RKKY coupling . . . 2683
129.5 Domains and hysteresis . . . 2683
129.5.1 Domain structure and the Barkhausen effect . . . 2683
129.5.2 Imaging domains . . . 2683
129.5.3 Domain walls and anisotropy . . . 2684
129.6 Spin waves . . . 2684
129.6.1 Magnons and the three-halves law . . . 2684
129.6.2 Magnons measured by neutron scattering . . . 2685
129.7 Magnetic phase transitions . . . 2685
129.8 Magnetic resonance . . . 2685
129.8.1 Electron spin resonance . . . 2685
129.8.2 Nuclear magnetic resonance . . . 2685
129.9 Magnetotransport and spintronics . . . 2685
129.9.1 Giant magnetoresistance . . . 2685
129.9.2 Tunnelling magnetoresistance and spin transport . . . 2686

130 Superconductivity and Superfluidity **2687**
130.1 Discovery and phenomenology . . . 2687
130.1.1 Vanishing resistance . . . 2687
130.1.2 The Meissner–Ochsenfeld effect . . . 2688
130.1.3 Critical temperature, field and current . . . 2689
130.1.4 The two-fluid picture . . . 2689
130.2 Phenomenological electrodynamics . . . 2689
130.2.1 The London equations . . . 2689
130.2.2 Non-local response and the coherence length . . . 2689
130.2.3 Ginzburg–Landau theory . . . 2689
130.2.4 Type II superconductors and the Abrikosov lattice . . . 2690
130.3 Microscopic theory . . . 2690
130.3.1 The isotope effect . . . 2690
130.3.2 The energy gap . . . 2690
130.3.3 Cooper pairing . . . 2691
130.3.4 The BCS ground state . . . 2691
130.3.5 Broken gauge symmetry . . . 2691
130.4 Macroscopic quantum coherence . . . 2691
130.4.1 Off-diagonal long-range order . . . 2691

130.4.2 Flux quantization . . . 2692
130.4.3 The Josephson effects . . . 2692
130.4.4 SQUIDs and quantum metrology . . . 2693
130.5 Superconductors beyond the BCS regime . . . 2693
130.5.1 The cuprates . . . 2693
130.5.2 Pairing symmetry in the cuprates . . . 2693
130.5.3 Other families . . . 2693
130.5.4 What remains unexplained . . . 2694
130.6 Superfluid helium-4 . . . 2694
130.6.1 The lambda transition and the discovery of superflow . . . 2694
130.6.2 Bose–Einstein condensation as the mechanism . . . 2694
130.6.3 The two-fluid model . . . 2695
130.6.4 The excitation spectrum and rotons . . . 2695
130.6.5 Quantized circulation and vortices . . . 2695
130.7 Superfluid helium-3 . . . 2696
130.7.1 Discovery of the superfluid phases . . . 2696
130.7.2 The order parameter and its consequences . . . 2696
130.8 Where the phenomena reappear . . . 2696

131 Experiment: Superconductivity 2697
131.1 Historical context and the claim under test . . . 2697
131.1.1 The race to liquefy the permanent gases . . . 2697
131.1.2 Three rival predictions for the low-temperature resistance . . . 2697
131.1.3 Mercury as the test material . . . 2698
131.2 Apparatus . . . 2698
131.2.1 The Leiden cryostat and the helium cycle . . . 2698
131.2.2 Resistance measurement . . . 2698
131.2.3 Magnetometry for flux expulsion . . . 2698
131.2.4 Tunnel junctions . . . 2698
131.3 Procedure . . . 2698
131.3.1 The 1911 mercury run . . . 2698
131.3.2 Field-cooled and zero-field-cooled protocols . . . 2699
131.3.3 Isotope separation and the mercury series . . . 2699
131.4 Observations . . . 2699
131.4.1 The mercury transition . . . 2699
131.4.2 Bounds on the residual resistivity . . . 2700
131.4.3 Critical temperatures and critical fields . . . 2701
131.4.4 The isotope exponent . . . 2701
131.4.5 The gap . . . 2701
131.4.6 The flux quantum . . . 2702
131.4.7 Josephson currents and Shapiro steps . . . 2702
131.5 Interpretation . . . 2703
131.5.1 What each measurement establishes . . . 2703
131.5.2 What the 1986 discovery did not settle . . . 2703
131.6 Modern repetitions and precision . . . 2704
131.6.1 Metrology: the Josephson volt . . . 2704
131.6.2 SQUID magnetometry and the London moment . . . 2704
131.6.3 High-pressure hydrides and the standard of proof . . . 2704
131.6.4 Datasets . . . 2704

132 Experiment: Neutron Scattering and the Structure of Solids **2705**
132.1 Why the neutron, and not the X-ray . . . 2705
132.2 Shull and Smart: antiferromagnetic order in MnO (1949) . . . 2706
132.2.1 Apparatus . . . 2707
132.2.2 Procedure . . . 2707
132.2.3 Observations and data . . . 2707
132.2.4 Interpretation . . . 2708
132.2.5 Primary references . . . 2708
132.3 Brockhouse and Stewart: phonons in aluminium (1955) . . . 2708
132.3.1 Apparatus . . . 2708
132.3.2 Procedure . . . 2709
132.3.3 Observations and data . . . 2709
132.3.4 Interpretation . . . 2710
132.3.5 Primary references . . . 2710
132.4 Brockhouse: spin waves in magnetite (1957) . . . 2710
132.4.1 Apparatus . . . 2710
132.4.2 Procedure . . . 2710
132.4.3 Observations and data . . . 2710
132.4.4 Interpretation . . . 2712
132.4.5 Primary references . . . 2712
132.5 Brockhouse and Iyengar: the normal modes of germanium (1958) . . . 2712
132.5.1 Apparatus . . . 2712
132.5.2 Procedure . . . 2712
132.5.3 Observations and data . . . 2712
132.5.4 Interpretation . . . 2713
132.5.5 Primary references . . . 2713
132.6 The Debye–Waller factor, measured on the same patterns . . . 2713
132.7 What the neutron settled . . . 2715
132.8 Hodgkin, Hauptman and Karle, and Klug: the phase problem (1934–1969) . . . 2716
132.8.1 Apparatus . . . 2716
132.8.2 Procedure . . . 2717
132.8.3 Observations and data . . . 2717
132.8.4 Interpretation . . . 2721
132.8.5 Primary references . . . 2722

XIII Frontiers and Open Problems **2723**

133 What We Observe but Do Not Understand **2725**
133.1 The mass and mixing puzzles . . . 2725
133.2 The hierarchy problem . . . 2725
133.3 Dark matter . . . 2726
133.4 Dark energy and the Hubble tension . . . 2726
133.5 The baryon asymmetry . . . 2726
133.6 Confinement and the Yang–Mills mass gap . . . 2726
133.7 What lies outside this treatise . . . 2727

134 The Dark Sector: Evidence Without Explanation **2729**
134.1 The dynamical evidence . . . 2729
134.1.1 Cluster velocity dispersions . . . 2729
134.1.2 Galaxy rotation curves . . . 2729
134.1.3 Neutral-hydrogen curves beyond the optical disc . . . 2730

134.1.4 Galaxy stability and halo masses . . . 2730
134.1.5 X-ray hydrostatic cluster masses . . . 2730
134.2 Gravitational lensing . . . 2730
134.2.1 Strong lensing . . . 2730
134.2.2 Weak lensing and shear surveys . . . 2730
134.2.3 The Bullet Cluster . . . 2730
134.2.4 Microlensing and the compact-object bound . . . 2731
134.3 Cosmological evidence . . . 2731
134.3.1 The microwave-background budget . . . 2731
134.3.2 Nucleosynthesis and the baryon count . . . 2731
134.3.3 Baryon acoustic oscillations . . . 2731
134.3.4 Structure formation . . . 2731
134.4 Candidates and the searches that found nothing . . . 2731
134.4.1 What a candidate must satisfy . . . 2731
134.4.2 Direct detection: null results . . . 2732
134.4.3 The DAMA claim and its non-confirmation . . . 2732
134.4.4 Axions . . . 2732
134.4.5 Collider and indirect searches . . . 2732
134.4.6 Primordial black holes . . . 2732
134.5 Modified dynamics as the rival hypothesis . . . 2732
134.5.1 MOND and the radial-acceleration relation . . . 2732
134.5.2 Where modified dynamics fails . . . 2733
134.6 Dark energy . . . 2733
134.6.1 The supernova evidence for acceleration . . . 2733
134.6.2 The cosmological constant and its problem . . . 2733
134.6.3 The equation of state . . . 2733
134.7 Tensions and the honest status . . . 2733
134.7.1 The Hubble tension . . . 2733
134.7.2 The S_8 tension . . . 2734
134.7.3 What is and is not known . . . 2734

135 Quantum Gravity: The Honest Status 2735
135.1 Why the question arises . . . 2735
135.1.1 Two frameworks with incompatible foundations . . . 2735
135.1.2 The Planck scale . . . 2736
135.1.3 Must gravity be quantized at all? . . . 2736
135.2 What is established . . . 2736
135.2.1 Gravity as an effective field theory . . . 2736
135.2.2 Perturbative non-renormalizability . . . 2736
135.2.3 Quantum field theory in curved spacetime . . . 2736
135.2.4 Black-hole thermodynamics as theory . . . 2736
135.2.5 The information problem . . . 2737
135.3 What has actually been measured . . . 2737
135.3.1 Quantum matter in a classical gravitational field . . . 2737
135.3.2 Newton's law at short range . . . 2737
135.3.3 Graviton and photon propagation speed . . . 2737
135.3.4 Lorentz invariance at the highest energies . . . 2737
135.3.5 Classical black-hole predictions confirmed . . . 2738
135.4 What has not been measured . . . 2738
135.4.1 Hawking radiation . . . 2738
135.4.2 Analogue systems are analogues . . . 2738
135.4.3 Gravitational decoherence and collapse models . . . 2738

135.4.4 Planck-scale interferometry . . . 2738
135.5 Proposed experiments . . . 2738
135.5.1 Tabletop gravitational entanglement . . . 2738
135.5.2 Other proposals . . . 2739
135.6 Programmes without evidence . . . 2739
135.6.1 The editorial position . . . 2739
135.6.2 String theory . . . 2739
135.6.3 Supersymmetry and the collider nulls . . . 2739
135.6.4 Loop quantum gravity . . . 2739
135.6.5 Asymptotic safety . . . 2739
135.7 Status . . . 2740

136 Experiment: Dark-Matter Searches and Their Null Results 2741
136.1 What is being searched for, and what a null result bounds . . . 2742
136.1.1 The halo the searches assume . . . 2742
136.1.2 Elastic recoil kinematics . . . 2742
136.1.3 How to read an exclusion curve . . . 2742
136.2 LUX-ZEPLIN: the largest xenon target (2023) . . . 2743
136.2.1 Apparatus . . . 2743
136.2.2 Procedure . . . 2743
136.2.3 Observations and data . . . 2743
136.2.4 Interpretation . . . 2744
136.2.5 Primary references . . . 2745
136.3 XENONnT: the same signature in an independent detector (2023) . . . 2745
136.3.1 Apparatus . . . 2745
136.3.2 Procedure . . . 2745
136.3.3 Observations and data . . . 2745
136.3.4 Interpretation . . . 2746
136.3.5 Primary references . . . 2746
136.4 Cryogenic bolometers: the low-mass frontier . . . 2746
136.5 DAMA/LIBRA and the annual-modulation claim (2008–2018) . . . 2747
136.5.1 Apparatus . . . 2747
136.5.2 Procedure . . . 2747
136.5.3 Observations and data . . . 2748
136.5.4 Interpretation . . . 2749
136.5.5 Primary references . . . 2749
136.6 ADMX: the axion haloscope (2018–2020) . . . 2749
136.6.1 Apparatus . . . 2749
136.6.2 Procedure . . . 2749
136.6.3 Observations and data . . . 2749
136.6.4 Interpretation . . . 2750
136.6.5 Primary references . . . 2750
136.7 ATLAS: missing transverse momentum at the Large Hadron Collider (2021) 2750
136.7.1 Apparatus . . . 2750
136.7.2 Procedure . . . 2751
136.7.3 Observations and data . . . 2751
136.7.4 Interpretation . . . 2752

Appendices **2755**

A Long Proofs **2759**
A.1 The Quadrupole Formula for Gravitational Radiation . . . 2759
A.1.1 Setup: linearized geometry . . . 2760
A.1.2 Gauge freedom and the Lorenz gauge . . . 2761
A.1.3 Vacuum solutions: plane waves and the transverse–traceless gauge . . . 2762
A.1.4 Physical effect: geodesic deviation and the strain . . . 2763
A.1.5 Energy carried by the wave: the Isaacson tensor . . . 2764
A.1.6 Generation: the quadrupole formula . . . 2765
A.1.7 Application: the circular compact binary . . . 2767
A.2 Oppenheimer–Snyder Collapse: the Interior Matching . . . 2771
A.2.1 The interior: a contracting closed dust universe . . . 2771
A.2.2 The boundary, and the matching conditions . . . 2772
A.2.3 The global picture . . . 2773
A.3 The Cantor–Schröder–Bernstein Theorem . . . 2773
A.4 The Completeness Theorem . . . 2775
A.4.1 Soundness . . . 2775
A.4.2 Maximal consistent sets . . . 2776
A.4.3 Henkin witnesses . . . 2777
A.4.4 The term model . . . 2778
A.4.5 The truth lemma . . . 2778
A.4.6 Completeness, and compactness . . . 2779
A.5 Arithmetization and the Incompleteness Theorems . . . 2780
A.5.1 Gödel numbering . . . 2780
A.5.2 Representability . . . 2781
A.5.3 The diagonal lemma . . . 2785
A.5.4 Rosser's form of the first theorem . . . 2786
A.5.5 The derivability conditions and the second theorem . . . 2786
A.5.6 Church's theorem . . . 2787
A.6 The Universal Turing Machine . . . 2788
A.6.1 Coding a machine as a string . . . 2788
A.6.2 Extra tapes buy no extra power . . . 2789
A.6.3 Construction of U . . . 2789
A.7 Completeness of the Real Numbers . . . 2791
A.7.1 Statement . . . 2791
A.7.2 The construction: Dedekind cuts . . . 2791
A.7.3 Order and the least-upper-bound property . . . 2792
A.7.4 The field operations . . . 2792
A.7.5 Consequences . . . 2793
A.8 Equivalence of the Einstein–Hilbert Action in Metric and Vielbein Variables 2794
A.8.1 Statement . . . 2794
A.8.2 A contraction lemma for the Levi-Civita symbol . . . 2794
A.8.3 Proof of the theorem . . . 2795
A.9 Wigner's Theorem on Quantum Symmetries . . . 2797
A.9.1 Orthonormal bases map to orthonormal bases . . . 2797
A.9.2 Phase alignment along a basis . . . 2797

A.9.3 The induced scalar map . . . 2798
A.9.4 Proof of the theorem . . . 2798
A.10 The Classification of Kinematical Algebras . . . 2799
A.10.1 The generators and the hypotheses . . . 2800
A.10.2 Step one: the hypotheses reduce the algebra to five constants . . . 2800
A.10.3 Step two: the Jacobi identity eliminates two of the five . . . 2801
A.10.4 Step three: rescaling reduces the constants to their signs . . . 2802
A.10.5 Step four: the enumeration . . . 2802
A.10.6 Two corollaries the enumeration makes visible . . . 2803
A.11 Invariant Bilinear Forms on an Expanded Algebra . . . 2804
A.12 Darboux's Theorem: Local Canonical Coordinates . . . 2807
A.12.1 Statement . . . 2808
A.12.2 The pullback of a k-form . . . 2808
A.12.3 Flows of time-dependent vector fields . . . 2810
A.12.4 The local converse of the Poincaré lemma . . . 2813
A.12.5 Moser's homotopy argument . . . 2814
A.12.6 Reading the result . . . 2816
A.13 The Korn–Lichtenstein Theorem and the Elliptic Canonical Form . . . 2817
A.13.1 Statement . . . 2817
A.13.2 From the canonical form to a Beltrami equation . . . 2818
A.13.3 Normalizing the Beltrami coefficient . . . 2820
A.13.4 The Cauchy and Beurling transforms . . . 2821
A.13.5 The construction and the Jacobian . . . 2823
A.14 The Cauchy–Kovalevskaya Theorem . . . 2825
A.14.1 Formal series, the recursion, and the reduction . . . 2825
A.14.2 Majorants . . . 2827
A.14.3 The majorant problem has a closed-form solution . . . 2828
A.14.4 Proof of the theorem . . . 2829
A.15 The Stäckel Conditions and the Eleven Separable Systems . . . 2831
A.15.1 Orthogonal coordinates and the Laplacian . . . 2832
A.15.2 What separation means, and what it forces . . . 2833
A.15.3 The three systems the treatise uses . . . 2835
A.15.4 The generic system: confocal quadrics . . . 2836
A.15.5 The enumeration . . . 2839
A.16 The Mean-Value Property Characterizes Harmonic Functions . . . 2841
A.16.1 Statement . . . 2842
A.16.2 Differentiation under the integral sign . . . 2842
A.16.3 A radial mollifier . . . 2843
A.16.4 The mollification reproduces the function . . . 2845
A.16.5 Proof of the theorem . . . 2846
A.17 Kruzhkov's Doubling of Variables and the Entropy Solution . . . 2847
A.17.1 Statement . . . 2848
A.17.2 The inputs this treatise does not build . . . 2848
A.17.3 From the admissible entropies to Kruzhkov's family . . . 2849
A.17.4 Doubling the variables . . . 2851
A.17.5 The limit and the cone estimate . . . 2852
A.17.6 Existence by vanishing viscosity . . . 2853
A.18 Lévy's Continuity Theorem . . . 2856
A.18.1 Statement . . . 2856
A.18.2 The two facts imported from Lebesgue theory . . . 2856
A.18.3 The Dirichlet integral . . . 2857

A.18.4 Helly's selection theorem . . . 2858
A.18.5 The inversion formula . . . 2859
A.18.6 Tightness from continuity at the origin . . . 2860
A.18.7 Proof of the theorem . . . 2861
A.19 The Lindeberg–Feller Central Limit Theorem . . . 2862
A.19.1 Statement and notation . . . 2863
A.19.2 Lindeberg's condition implies uniform asymptotic negligibility . . . 2863
A.19.3 The uniform second-order expansion . . . 2864
A.19.4 Two product estimates . . . 2864
A.19.5 Proof of the theorem . . . 2865
A.20 The Berry–Esseen Inequality . . . 2867
A.20.1 Statement . . . 2867
A.20.2 The Fejér kernel . . . 2867
A.20.3 Esseen's smoothing inequality . . . 2868
A.20.4 The characteristic function of the standardised sum . . . 2870
A.20.5 Integration, and the constant . . . 2872
A.21 Wilks' Theorem in the Multi-Parameter Case . . . 2873
A.21.1 Setting and notation . . . 2873
A.21.2 What is quoted . . . 2874
A.21.3 The uniform quadratic expansion . . . 2875
A.21.4 Localisation of both estimators . . . 2876
A.21.5 Replacing the surface by its tangent space . . . 2877
A.21.6 The chi-squared limit . . . 2878
A.22 Rice's Formula for the Expected Number of Upcrossings . . . 2879
A.22.1 Hypotheses and statement . . . 2880
A.22.2 The joint law of the field and its derivative . . . 2881
A.22.3 Kac's counting integral . . . 2881
A.22.4 Taking the expectation . . . 2882
A.22.5 Evaluation . . . 2883
A.23 The Hilbert–Schmidt Theorem for Compact Self-Adjoint Operators . . . 2885
A.23.1 Statement . . . 2885
A.23.2 Compactness in sequential form . . . 2886
A.23.3 The supremum is attained: the first eigenvector . . . 2886
A.23.4 The recursion . . . 2887
A.23.5 Passage to the limit . . . 2888
A.24 The Spectral Theorem for a Bounded Self-Adjoint Operator . . . 2889
A.24.1 Statement . . . 2890
A.24.2 The polynomial calculus . . . 2890
A.24.3 The continuous calculus . . . 2891
A.24.4 The spectral measures . . . 2892
A.24.5 The Borel calculus . . . 2892
A.24.6 The projection-valued measure . . . 2893
A.24.7 The multiplication form . . . 2895
A.25 Stone's Theorem on One-Parameter Unitary Groups . . . 2897
A.25.1 Statement . . . 2897
A.25.2 Vector-valued integrals . . . 2897
A.25.3 The domain is dense . . . 2898
A.25.4 The generator is closed and self-adjoint . . . 2899
A.25.5 The converse: exponentiating a self-adjoint operator . . . 2900
A.26 Von Neumann's Criterion for Self-Adjoint Extensions . . . 2904
A.26.1 Statement . . . 2904

A.26.2 The basic identity . . . 2904
A.26.3 The Cayley transform . . . 2905
A.26.4 From an isometry back to an operator . . . 2906
A.26.5 Proof of the criterion . . . 2907
A.26.6 The two worked cases . . . 2908
A.27 The Nuclear Spectral Theorem of Gelfand and Maurin . . . 2910
A.27.1 Hypotheses and statement . . . 2910
A.27.2 The direct integral . . . 2911
A.27.3 What nuclearity buys . . . 2911
A.27.4 Generalized eigenvectors, and completeness . . . 2913
A.28 The Implicit Function Theorem . . . 2914
A.28.1 Statement . . . 2915
A.28.2 The contraction . . . 2915
A.28.3 Existence and uniqueness of the implicit map . . . 2916
A.28.4 Continuity, differentiability and the derivative formula . . . 2917
A.28.5 The two consequences the treatise uses . . . 2918
A.28.6 Reading the result . . . 2920
A.29 The General Stokes Theorem for Differential Forms . . . 2920
A.29.1 Manifolds with boundary . . . 2921
A.29.2 Orientation and the integral of an n-form . . . 2921
A.29.3 Bump functions and partitions of unity . . . 2923
A.29.4 Statement and the half-space computation . . . 2924
A.29.5 Proof of the theorem . . . 2926
A.29.6 The instance stated in the chapter . . . 2926
A.29.7 What is quoted, and what is not . . . 2928
A.30 The Poincaré–Birkhoff–Witt Theorem . . . 2928
A.30.1 Statement . . . 2929
A.30.2 The filtration, and spanning . . . 2929
A.30.3 The action on the polynomial algebra . . . 2930
A.30.4 Independence, and proof of the theorem . . . 2932
A.30.5 Consequences: the symbol and the symmetrization map . . . 2932
A.31 Cartan's Criterion for Semisimplicity . . . 2934
A.31.1 Statement . . . 2934
A.31.2 Solvability, and the language of the proof . . . 2934
A.31.3 The easy half: an abelian ideal lies in the radical of the Killing form . . . 2935
A.31.4 The Jordan decomposition . . . 2936
A.31.5 Engel's theorem . . . 2936
A.31.6 The trace lemma . . . 2937
A.31.7 Proof of the criterion . . . 2939
A.31.8 Consequences, and the case of $\mathfrak{so}(p,q)$ . . . 2939
A.32 Racah's Theorem on the Number of Casimir Operators . . . 2941
A.32.1 Statement . . . 2941
A.32.2 The centre of the enveloping algebra and the invariant polynomials . . . 2942
A.32.3 The two quoted theorems . . . 2943
A.32.4 The count . . . 2944
A.32.5 The count checked against the chapter's algebras . . . 2945
A.33 Covering Spaces and the Fundamental Group of the Rotation Group . . . 2946
A.33.1 Statement . . . 2946
A.33.2 Two lifting lemmas . . . 2947
A.33.3 The monodromy theorem . . . 2949
A.33.4 Covering homomorphisms and deck transformations . . . 2950

A.33.5 The rotation group . . . 2950
A.34 The Structure Constants of $\mathfrak{su}(3)$ . . . 2951
A.34.1 One trace for both arrays . . . 2952
A.34.2 Which triples can be nonzero at all . . . 2952
A.34.3 Family (1): three diagonal indices . . . 2954
A.34.4 Family (2): one diagonal index and one off-diagonal pair . . . 2954
A.34.5 Family (3): one index from each pair . . . 2955
A.34.6 The tables . . . 2955
A.34.7 A Jacobi check . . . 2956
A.35 Simplicity of $\mathfrak{su}(3)$ . . . 2957
A.35.1 Statement . . . 2957
A.35.2 Complexification . . . 2957
A.35.3 The root decomposition . . . 2958
A.35.4 Walking round the hexagon . . . 2959
A.35.5 Proof of the theorem . . . 2959
A.36 From the Little Algebra to the Labels of a Massive Representation . . . 2960
A.36.1 Conventions, and what is assumed . . . 2961
A.36.2 Statement . . . 2961
A.36.3 The geometry of the mass shell . . . 2962
A.36.4 The induced representation . . . 2963
A.36.5 The classification, and the count . . . 2965
A.36.6 The observed case . . . 2966
A.37 Whitehead's Lemmas and the Rigidity of Semisimple Algebras . . . 2967
A.37.1 The Chevalley–Eilenberg complex . . . 2967
A.37.2 The Casimir operator of a representation . . . 2969
A.37.3 Averaging a cocycle against the Casimir . . . 2970
A.37.4 Complete reducibility . . . 2971
A.37.5 Trivial coefficients . . . 2972
A.37.6 The Whitehead lemmas . . . 2973
A.38 The Second Cohomology of the Galilei Algebra . . . 2975
A.38.1 The algebra, and the two spaces . . . 2975
A.38.2 Three tensor lemmas . . . 2976
A.38.3 Solving the cocycle condition . . . 2977
A.38.4 The coboundaries, and the quotient . . . 2978
A.39 Central Extensions of Three Infinite-Dimensional Algebras . . . 2979
A.39.1 The Virasoro cocycle . . . 2980
A.39.2 The Kac–Moody cocycle . . . 2982
A.39.3 The Schwinger term . . . 2985
A.40 The Strengthened Jacobi Condition and Conjugate Points . . . 2988
A.40.1 Statement . . . 2988
A.40.2 The accessory equation as a first-order system . . . 2989
A.40.3 Continuous dependence on the initial point . . . 2989
A.40.4 The Sturm separation theorem . . . 2991
A.40.5 Proof of the equivalence . . . 2992
A.40.6 The displaced initial point . . . 2993
A.41 Tonelli's Existence Theorem for an Integrand Depending on the Function . . . 2994
A.41.1 Statement . . . 2995
A.41.2 The Sobolev space in one dimension . . . 2995
A.41.3 The Arzelà–Ascoli theorem and the compact embedding . . . 2997
A.41.4 Weak lower semicontinuity with y present . . . 2998
A.41.5 Proof of the theorem . . . 3000

A.42 Completeness of the Sturm–Liouville Eigenfunctions in the Energy Norm . 3001
A.42.1 Statement . . . 3002
A.42.2 The energy space . . . 3002
A.42.3 The Green function and the inverse operator . . . 3003
A.42.4 Compactness and the spectral decomposition . . . 3006
A.42.5 From the weighted norm to the energy norm . . . 3007
A.43 The Plateau Problem: the Architecture of Douglas' Proof . . . 3009
A.43.1 Setting and statement . . . 3009
A.43.2 The Dirichlet integral dominates the area . . . 3010
A.43.3 The Douglas functional . . . 3011
A.43.4 The conformal group and the three-point normalisation . . . 3012
A.43.5 Compactness: the Courant–Lebesgue estimate . . . 3014
A.43.6 The two quoted inputs, and the conclusion . . . 3015
A.44 Change of Variables in a Multiple Integral . . . 3018
A.44.1 What the derivation uses . . . 3018
A.44.2 Sets of zero content . . . 3019
A.44.3 Iterated integration in $\mathbb{R}^N$ . . . 3020
A.44.4 Two reductions . . . 3021
A.44.5 Permutations and primitive maps . . . 3022
A.44.6 The local factorisation . . . 3023
A.44.7 From compact support to the theorem . . . 3024
A.44.8 Reading the result . . . 3026
A.45 The Helmholtz Decomposition . . . 3026
A.45.1 What the derivation uses . . . 3027
A.45.2 The kernel is integrable, and uniformly so . . . 3027
A.45.3 Differentiating under the integral sign . . . 3028
A.45.4 Poisson's equation . . . 3029
A.45.5 Existence of the decomposition . . . 3030
A.45.6 Decay at infinity . . . 3030
A.45.7 Uniqueness . . . 3031
A.45.8 Reading the result . . . 3031
A.46 The Quotient Manifold Theorem . . . 3032
A.46.1 What the derivation uses, and what it must state itself . . . 3033
A.46.2 The orbit space is Hausdorff and second countable . . . 3034
A.46.3 Orbits are embedded submanifolds . . . 3034
A.46.4 The slice . . . 3035
A.46.5 The charts and the smooth structure . . . 3036
A.46.6 The universal property and uniqueness . . . 3037
A.46.7 Reading the result . . . 3038
A.47 The Liouville–Arnold Theorem . . . 3039
A.47.1 Setting and statement . . . 3039
A.47.2 The commuting fields and the level set . . . 3040
A.47.3 The translation action and the torus . . . 3040
A.47.4 The action variables . . . 3042
A.47.5 The angles, and the proof of the theorem . . . 3043
A.48 Marsden–Weinstein Reduction . . . 3044
A.48.1 Setting and statement . . . 3045
A.48.2 Two facts of symplectic linear algebra . . . 3046
A.48.3 The level set is a manifold . . . 3046
A.48.4 The degenerate directions of the restricted form . . . 3047
A.48.5 Descent of the form . . . 3048

A.48.6 Descent of the dynamics . . . 3049
A.48.7 The example the chapter names . . . 3049
A.48.8 What is quoted here . . . 3050
A.49 The Stone–von Neumann Theorem . . . 3051
A.49.1 Statement, conventions and units . . . 3051
A.49.2 The Weyl operators and their composition law . . . 3052
A.49.3 Two analytic tools . . . 3053
A.49.4 The Gaussian average . . . 3054
A.49.5 The vacuum vector . . . 3056
A.49.6 The intertwining unitary . . . 3057
A.49.7 The Schrödinger system . . . 3058
A.49.8 What is quoted here . . . 3059
A.50 Hudson's Theorem: the Pure States of Non-Negative Wigner Function . . . 3060
A.50.1 Statement and conventions . . . 3060
A.50.2 Gaussian integrals . . . 3061
A.50.3 The easy direction . . . 3062
A.50.4 Coherent states, and where the Wigner function cannot vanish . . . 3063
A.50.5 An entire function without zeros . . . 3064
A.50.6 What normalisability forces . . . 3066
A.50.7 Recovering the wavefunction . . . 3067
A.50.8 Scope, and what is quoted . . . 3068
A.51 The Jacobi Identity for the Dirac Bracket . . . 3069
A.51.1 Notation, and the four identities consumed . . . 3069
A.51.2 Route A: the direct expansion . . . 3070
A.51.3 Route B: the bracket of the induced symplectic form . . . 3072
A.52 The Gauss–Codazzi Form of the Einstein–Hilbert Lagrangian . . . 3073
A.52.1 The kit: normal, inverse metric, projector, determinant . . . 3074
A.52.2 The extrinsic curvature, and the dictionary . . . 3075
A.52.3 The Gauss equation . . . 3077
A.52.4 The Codazzi equation . . . 3078
A.52.5 The twice-normal contraction . . . 3078
A.52.6 Assembling the Lagrangian . . . 3079
A.52.7 The boundary term . . . 3081
A.53 The Hypersurface-Deformation Algebra . . . 3082
A.53.1 Conventions: weights, smearing functions, and the bracket . . . 3082
A.53.2 The momentum constraint generates the spatial drag . . . 3083
A.53.3 The first two brackets . . . 3084
A.53.4 The variation of the intrinsic curvature . . . 3085
A.53.5 The third bracket . . . 3085
A.53.6 The geometric reading . . . 3087
A.54 Existence and Uniqueness of a Nilpotent BRST Charge . . . 3088
A.54.1 The extended phase space and its two gradings . . . 3088
A.54.2 The Koszul–Tate differential . . . 3089
A.54.3 The recursion . . . 3091
A.54.4 Existence . . . 3092
A.54.5 Termination at the displayed terms . . . 3093
A.54.6 Uniqueness . . . 3093
A.55 Bertrand's Theorem . . . 3094
A.55.1 The orbit equation and its circular solutions . . . 3095
A.55.2 First stage: closure near a circle forces a power law . . . 3096
A.55.3 Second stage: the third-order solvability condition . . . 3097

A.55.4 The two laws, and that they really do close . . . 3099
A.56 Isotropic and Cubic Elastic Tensors . . . 3100
A.56.1 What is proved here, and what is proved elsewhere . . . 3101
A.56.2 The rotation group of the cube leaves four constants . . . 3101
A.56.3 From twenty-one constants to three, and then to two . . . 3103
A.57 Reduction of Three-Dimensional Elasticity to the Kirchhoff Plate Equation 3105
A.57.1 Kinematics: the Kirchhoff hypothesis . . . 3105
A.57.2 Plane stress, not plane strain . . . 3106
A.57.3 Integrating the energy across the thickness . . . 3107
A.57.4 The field equation . . . 3109
A.57.5 The free edge: three conditions are one too many . . . 3110
A.58 Hertz's Solution for the Elastic Half-Space Under an Axisymmetric Pressure 3112
A.58.1 What is quoted here . . . 3112
A.58.2 Superposition and the contact conditions . . . 3113
A.58.3 The elliptic pressure and its displacement . . . 3114
A.58.4 Matching, and the coefficient $\frac{4}{3}$ . . . 3115
A.58.5 Checks and consequences . . . 3117
A.59 D'Alembert's Paradox for a Body of Arbitrary Shape . . . 3118
A.59.1 Statement and hypotheses . . . 3118
A.59.2 The far field carries no source . . . 3118

List of Experiments

20.3 Galileo's Inclined Planes (1604–1638) . . . 750
20.4 Absolute Ballistic Gravimetry (1995–present) . . . 751

33 The Cavendish Torsion Balance (1798) 1103
34.1 Galileo and Huygens: isochronism (1602–1673) . . . 1121
34.2 Coulomb: the torsion pendulum (1784) . . . 1125
34.3 Kater: the reversible pendulum (1818) . . . 1130
34.5 Foucault: the pendulum at the Panthéon (1851) . . . 1135
35.1 Mersenne: the laws of the vibrating string (1636) . . . 1143
35.2 Melde: standing waves on a driven string (1860) . . . 1145
35.3 Chladni: the nodal figures of a vibrating plate (1787) . . . 1148
35.4 Newton, Laplace and the speed of sound (1687–1822) . . . 1151
35.5 Kundt's tube: sound speeds from dust figures (1866) . . . 1154
35.6 Buys Ballot: the Doppler effect on a moving train (1845) . . . 1156
36.1 Efflux from a vessel: Torricelli's law (1738) . . . 1159
36.2 Poiseuille: flow in fine capillaries (1840) . . . 1163
36.3 Reynolds: the dye filament and the critical number (1883) . . . 1165
36.4 Bénard: cellular convection (1900) . . . 1170
36.5 Prandtl: the boundary layer made visible (1904) . . . 1174
37.3 Michelson and Morley: the search for the aether wind (1887) . . . 1184
37.4 Fizeau: light dragged by moving water (1851) . . . 1185
37.5 Cavity resonators: the modern Michelson–Morley (1979–2015) . . . 1186
41.1 Ives and Stilwell: the moving atomic clock (1938) . . . 1219
41.2 Rossi and Hall: muon survival with altitude (1941) . . . 1220
41.3 Frisch and Smith: Mount Washington to sea level (1963) . . . 1221
41.4 The CERN muon storage ring (1977) . . . 1222
41.5 Hafele and Keating: caesium clocks flown around the world (1972) . . . 1223
41.6 Bertozzi: the speed limit (1964) . . . 1224
47.1 The Hulse–Taylor Binary Pulsar (PSR B1913+16) (1974–2016) . . . 1297
47.3 GW150914 (2015) . . . 1299

50 Black-Hole Observations (1972–2022) 1343

51 The Cosmic Microwave Background 1357
53.1 Le Verrier and the perihelion of Mercury (1859) . . . 1395
53.2 Dyson, Eddington and Davidson: the eclipse of 1919 (1919) . . . 1398
53.3 Pound, Rebka and Snider: redshift in a tower (1960–1965) . . . 1400
53.4 Shapiro: the radar time delay (1964–2003) . . . 1402
53.5 The Eötvös lineage and MICROSCOPE (1922–2022) . . . 1405
53.6 Lunar laser ranging and Gravity Probe B (1969–2011) . . . 1408

56 The Mechanical Equivalent of Heat **1431**
57.1 Stern: the direct measurement of molecular speeds (1920) . . . 1437
57.2 Miller and Kusch: the shape of the speed distribution (1955) . . . 1439
57.3 Maxwell: the viscosity of air is independent of its density (1866) . . . 1441
57.4 Graham: the diffusion and transpiration of gases (1833–1846) . . . 1443
57.5 Loschmidt: the size of an air molecule (1865) . . . 1445
57.6 Joule and Thomson: the porous plug (1852) . . . 1446
57.8 Giauque and MacDougall: cooling below one kelvin by adiabatic demagnetization (1933) . . . 1448

63 Electromagnetism **1495**

67 Wave Optics **1531**
67.8 Gabor: holography and the recording of phase (1948, 1962) . . . 1538

72 Franck–Hertz **1585**
73.1 Stefan: the fourth power from Tyndall's data (1879) . . . 1591
73.2 Lummer and Kurlbaum: a realizable black body (1898) . . . 1593
73.3 Lummer and Pringsheim: the failure of Wien's law (1899) . . . 1595
73.4 Rubens and Kurlbaum: the far-infrared radiance (1900) . . . 1597
73.5 Radiometric realization of the kelvin (2019) . . . 1599
74.1 Hertz and Hallwachs: ultraviolet light discharges a metal (1887–1888) . . . 1603
74.2 Lenard: the electron energy is independent of the intensity (1902) . . . 1605
74.3 Millikan: a direct photoelectric determination of Planck's constant (1916) . . . 1607
74.4 Compton: the wavelength shift of scattered X-rays (1923) . . . 1610
74.5 Bothe and Geiger: coincidence of scattered quantum and recoil electron (1925) 1612
74.6 Grangier, Roger and Aspect: single-photon anticorrelation at a beamsplitter (1986) . . . 1615
75.1 Davisson and Germer: electron diffraction by a nickel crystal (1927) . . . 1620
75.2 Thomson and Reid: electron transmission rings (1927) . . . 1622
75.3 Estermann and Stern: diffraction of neutral molecular beams (1930) . . . 1623
75.4 The electron double slit and its single-electron build-up (1961–1989) . . . 1625
75.5 Colella, Overhauser and Werner: gravitationally induced quantum interference (1975) . . . 1627
75.6 Molecule interferometry, from fullerenes to macromolecules (1999–2019) . . . 1629
76.1 Röntgen: a new kind of rays (1895) . . . 1635
76.2 Barkla: characteristic radiation and the transversality of X-rays (1905–1911) 1638
76.3 Friedrich, Knipping and von Laue: diffraction by a crystal (1912) . . . 1640
76.4 The Braggs: the reflection law and the X-ray spectrometer (1913) . . . 1641
76.5 Moseley: the high-frequency spectra of the elements (1913–1914) . . . 1643
76.6 Siegbahn: precision X-ray spectroscopy (1916–1925) . . . 1645
80.2 Stern–Gerlach (1921–1922) . . . 1672

89 Bell Tests **1745**

90 Precision Spectroscopy and Atomic Clocks **1753**
91.2 Alpha decay and the Geiger–Nuttall relation (1911, 1928) . . . 1764
91.3 Fowler and Nordheim: cold field emission from metals (1928) . . . 1767
91.4 Esaki: the tunnel diode and negative differential resistance (1958) . . . 1769
91.5 Giaever: tunnelling spectroscopy of the superconducting gap (1960) . . . 1771
91.6 Binnig and Rohrer: the scanning tunnelling microscope (1982) . . . 1773

95 The Positron **1807**

98 Neutrino Helicity **1831**

110 Parity Violation **2313**

111 CP Violation **2341**

112 The Electron Anomalous Magnetic Moment (2023) **2371**

113 The Higgs Boson Discovery (2012) **2401**

114 Neutrino Oscillations **2437**

116 Deep Inelastic Scattering **2519**
117.2 Rutherford: the first artificial transmutation (1919) . . . 2554
117.3 Cockcroft and Walton: lithium split by accelerated protons (1932) . . . 2559
117.4 Lawrence and Livingston: the cyclotron (1932) . . . 2566
117.5 Wilson: the expansion cloud chamber (1912) . . . 2570
117.6 Glaser: the bubble chamber (1952) . . . 2576
117.7 Charpak: the multiwire proportional chamber (1968) . . . 2580

119 Brownian Motion and Avogadro's Number **2595**

121 Bose–Einstein Condensation **2611**
122.8 Zewail: femtosecond probing of the transition state (1987) . . . 2623

128 The Quantum Hall Effect **2669**

131 Superconductivity **2697**
132.2 Shull and Smart: antiferromagnetic order in MnO (1949) . . . 2706
132.3 Brockhouse and Stewart: phonons in aluminium (1955) . . . 2708
132.4 Brockhouse: spin waves in magnetite (1957) . . . 2710
132.5 Brockhouse and Iyengar: normal modes of germanium (1958) . . . 2712
132.8 Hodgkin, Hauptman and Karle, and Klug: the phase problem (1934–1969) . . . 2716
136.2 LUX-ZEPLIN: dark-matter search in seven tonnes of liquid xenon (2023) . . . 2743
136.3 XENONnT: nuclear-recoil dark-matter search at the Gran Sasso laboratory (2023) . . . 2745
136.5 DAMA/LIBRA: annual modulation in sodium iodide, and the same-target replications (2008–2018) . . . 2747
136.6 ADMX: microwave-cavity search for halo axions (2018–2020) . . . 2749
136.7 ATLAS: jet plus missing transverse momentum search in proton–proton collisions (2021) . . . 2750
136.8 Fermi Large Area Telescope: search for annihilation gamma rays from dwarf spheroidal galaxies (2009–) . . . 2752

List of Pending Derivations

1 Classical Thermodynamics: all derivations of this chapter are pending. . . . 1415

2 Kinetic Theory of Gases: all derivations of this chapter are pending. 1423

3 The H-theorem: that the binary-collision integral of the Boltzmann transport equation makes the functional $H = \int f \ln f \, \mathrm{d}^3 v$ non-increasing in time, with stationarity exactly on the Maxwell distribution; together with an explicit statement of the molecular-chaos assumption on which the monotonicity rests, and of what the reversibility and recurrence objections do and do not refute. 1426

4 Experiment: The Mechanical Equivalent of Heat: all derivations of this chapter are pending. 1431

5 The Chapman–Enskog transport coefficients: that the first-order solution of the Boltzmann transport equation about local equilibrium fixes the numerical coefficients left undetermined by the mean-free-path argument, and in particular gives the ratio of thermal conductivity to viscosity times specific heat as $5/2$ for a monatomic gas, against the value 1 of the elementary estimate. . . 1445

6 The residual internal field of a paramagnetic salt: that the dipolar sum over the lattice of magnetic ions, together with the crystal-field splitting of the ground multiplet, fixes the ordering temperature and hence the floor under a single demagnetization stage, so that the cooling ratio is a computable property of the salt rather than a fitted parameter. 1454

7 The spectroscopic entropy of a gas: that the translational, rotational, vibrational and electronic partition functions, evaluated from band-spectrum constants and molecular masses, give the absolute molar entropy against which the calorimetric integration is compared, together with the symmetry number and the nuclear-spin terms that cancel between the two routes. . . 1454

8 Gradient identity Equation (58.12): direct differentiation of $|\boldsymbol{x} - \boldsymbol{x}'|^{-1}$ (asserted without proof in the source). 1459

9 Distributional Laplacian of $|\boldsymbol{x} - \boldsymbol{x}'|^{-1}$, Equation (58.17) (asserted without proof in the source). 1459

10 Continuity and interface conditions of the electrostatic field and the ideal-conductor boundary conditions, including Equation (58.25): the source reserves these headings without content, while its worked problems use the results. 1462

11 Ideal-dipole potential Equation (58.30), field Equation (58.31) and force Equation (58.32): to be derived from the multipole expansion of Section 58.2.5 and from the energy of a distribution in an external field, both of which the source reserves without content. 1465

12 Magnetostatics: all derivations of this chapter are pending. 1467

13 Inseparability of magnetic poles: derive, from the Amperian representation of a magnetized body by bound currents, that every subdivision of such a body again carries a complete circulating current and is therefore again a dipole, and connect the statement to the vanishing divergence of the magnetic field. 1468

14 Monopole searches: derive the flux quantum that an induction detector would register for the passage of one Dirac charge through a superconducting loop, and the conversion of a null exposure into a flux limit per unit area, time and solid angle. The Dirac quantization argument itself requires the quantum mechanics of Part IX and is stated, not derived, here. 1472

15 The Maxwell Equations: all derivations of this chapter are pending. 1473

16 The flux rule: derive it from the Maxwell–Faraday equation together with the Lorentz force acting on the charge carriers of a moving circuit, using the transport theorem for a surface whose boundary moves with the circuit, and show that the two physically distinct mechanisms — an induced electric field in the transformer case, a magnetic force on carried charge in the motional case — combine into the single total rate of change of the flux. 1473

17 Angular momentum of the electromagnetic field: derive the angular momentum density from the field momentum density, and show that for a circularly polarized beam of angular frequency ω the ratio of angular momentum to energy is $1/\omega$, so that reversing the handedness transfers twice that amount per unit energy. 1477

18 Electromagnetic Waves and Optics: all derivations of this chapter are pending. 1479

19 Brewster's angle: derive the Fresnel amplitude coefficients for the two polarizations from the interface conditions on the tangential fields, and show that the coefficient for light polarized in the plane of incidence has a simple zero exactly where the reflected and refracted directions are perpendicular, which by the sine law is at the angle whose tangent is the refractive index. 1482

20 The axial bright point: derive it from the Huygens–Fresnel superposition of secondary wavelets over the plane of the obstacle, showing that every point of the disc's rim is equidistant from the axial field point, so that the wavelets from the rim arrive exactly in phase whatever the radius of the disc, and evaluate the resulting on-axis amplitude for an ideal circular obstacle. . . . 1484

21 Dispersion: derive the frequency dependence of the refractive index from the response of bound charges to the field of the wave, obtaining normal dispersion away from resonance and anomalous dispersion with absorption near it, and recover the empirical Sellmeier form as its low-loss limit. The model belongs to the treatment of electrodynamics in matter, and the discreteness of the solar lines themselves is not classical at all and awaits the atomic chapters. 1485

22 Electrodynamics in Matter: all derivations of this chapter are pending. . . . 1487

23 The magnetic response of matter: derive the Bohr–van Leeuwen theorem, that a classical system of charges in thermal equilibrium has identically zero magnetization because the magnetic field enters the classical Hamiltonian only through a shift of the canonical momenta, which is absorbed by a translation of the integration variables in the partition function. The theorem states that the phenomenon above has no classical explanation at all, so every classical model in this section is a parametrization and not a derivation, and the real account is the quantum one of the magnetism chapter. 1490

24 Ferromagnetic hysteresis: derive the energy dissipated per unit volume per cycle as the area enclosed by the loop traced in the plane of applied field against magnetization, and identify precisely which hypothesis behind a linear constitutive relation the loop violates. The microscopic origin — domains, exchange coupling and magnetocrystalline anisotropy — is quantum and belongs to the magnetism chapter. 1490

25 Absorption and dispersion: derive the Kramers–Kronig relations, in which the real and imaginary parts of the permittivity are each the Hilbert transform of the other. The only physical input is causality — no response before the stimulus — which makes the response function analytic in the upper half of the complex frequency plane, whence a contour integral gives the pair of dispersion relations and the sum rules that follow from the high-frequency limit. The argument needs the complex analysis of the corresponding methods chapter, and it is worth noting that it uses no model of the medium at all. . 1492

26 The Faraday effect: derive the difference between the refractive indices of the two circular polarizations for a medium of bound charges in a magnetic field along the ray, by solving the driven oscillator equation with the magnetic force included; then show that a linear polarization, resolved into two circular components of equal amplitude, emerges rotated by half the accumulated phase difference, which gives the Verdet constant. The non-reciprocity should be derived too, and it follows from the field being an axial vector that does not reverse when the propagation direction does. 1493

27 Experiments: Electromagnetism: all derivations of this chapter are pending. 1495

28 The Coulomb exponent: derive the interior field of a uniformly charged spherical shell for a force law with exponent $2 + \delta$, show that it vanishes identically only when δ is zero, and give the conversion of a measured null voltage between concentric conductors into a bound on δ. Then relate δ to a photon rest mass through the Yukawa form that a massive vector field gives in place of the Coulomb potential. 1496

29 The ratio of the units: show that the electrostatic and electromagnetic definitions of the unit of charge differ by a factor with the dimensions of a speed, equal in SI terms to the reciprocal square root of the product of the electric and magnetic constants, and hence that this measurement determines exactly the combination that reappears as the propagation speed in the vacuum wave equation. The error budget of the original determination, and its agreement with the contemporary optical values, are to be reconstructed here. 1498

30 Generalized Classical Field Theory: all derivations of this chapter are pending. 1503

31 Radiation and Scattering of Electromagnetic Waves: all derivations of this chapter are pending. 1509

32 The Larmor formula: derive the fields of a point charge in arbitrary motion from the retarded potentials, separate the velocity field, which falls as the inverse square of the distance and carries no energy to infinity, from the acceleration field, which falls as the inverse first power and is proportional to the acceleration, and integrate the Poynting flux of the acceleration field over a sphere of large radius. 1510

33 Synchrotron radiation: derive the emission of a charge on a circular orbit at arbitrary speed from the acceleration field and the relativistic generalization of the Larmor formula, obtaining the forward collimation into a cone whose half-angle is the reciprocal of the Lorentz factor, the critical frequency proportional to the cube of that factor divided by the orbit radius, the power-law spectrum below it, the energy radiated per turn, and the degree and sense of the polarization. 1516

34 Plasmas and Magnetohydrodynamics: all derivations of this chapter are pending. 1519

35 Landau damping: solve the linearized Vlasov–Poisson initial-value problem by Laplace transform, analytically continue the dielectric function below the real axis to obtain the correct prescription for the singularity at the phase velocity, and derive the damping rate proportional to the slope of the distribution function there. Then give the resonant-particle reading — particles slightly slower than the wave gain energy and slightly faster ones lose it, and a Maxwellian has more of the former — and explain why the process is not thermodynamically irreversible, the information being carried into fine structure in velocity space and recoverable as a plasma-wave echo. 1523

36 Alfvén waves: linearize the ideal magnetohydrodynamic equations about a uniform field and a uniform density, retaining the tension part of the Lorentz force, and obtain the transverse mode propagating along the field at the speed above, together with the fast and slow magnetosonic modes and their anisotropic phase speeds. The tension reading should be derived as well — the magnetic force decomposed into a pressure and a tension along the field lines, whence the wave speed is the tension divided by the mass per unit length in exactly the form of a wave on a string. 1526

37 Magnetic reconnection: derive the Sweet–Parker current sheet from mass and flux conservation across a resistive layer, obtaining a reconnection rate scaling as the inverse square root of the magnetic Reynolds number, and show by substituting coronal values that this rate is orders of magnitude too slow for a flare. Then derive Petschek's slow-shock geometry with its much weaker logarithmic dependence, and state honestly which of the modern resolutions — plasmoid instability of thin sheets, or the collisionless Hall and pressure-tensor terms in Ohm's law — the measurements support. 1527

38 The solar wind: derive Parker's transonic solution. Integrate the steady, spherically symmetric momentum equation for an isothermal corona in the Sun's gravitational field, exhibit the critical point at which the flow speed equals the sound speed, show that of the family of solutions only the transonic branch matches both a subsonic base and a vanishing pressure at large distance, and obtain the asymptotic speed. The contrasting hydrostatic solution must be shown to leave a finite pressure at infinity, which is the argument that rules it out. 1528

39 Experiment: Wave Optics: all derivations of this chapter are pending. . . . 1531

40 The diffraction limit: derive the chromatic resolving power of a grating from the angular width of an order — the wavelength divided by the order times the number of rulings — using the N-aperture sum and the convention that two lines are resolved when the maximum of one falls on the first zero of the other. Then derive the imaging bound from the requirement that at least two diffracted orders from a periodic object be collected by the objective, which gives the smallest resolvable period as the wavelength divided by twice the numerical aperture, and state the hypotheses — linearity in the illumination, far-field collection — on which the bound depends. 1536

41 Diffraction efficiency of a hologram: what fraction of the reconstructing beam is delivered into the reconstruction, derived for a thin absorption record and a thin phase record by expanding the transmittance of a sinusoidal grating, and for a thick phase record by the coupled-wave treatment in which two waves exchange energy under the Bragg condition. What has to be established is that only a volume record can send almost all of the incident light into a single order — which is what makes a white-light reflection hologram bright enough to look at — while the thin records are bounded well below that. . 1543

42 Single-quantum interference: the derivation is quantum and belongs to the later parts. What must be shown here is negative and can be made precise — that no classical field theory reproduces the combination of a single localized detection with a fringe pattern of full visibility, since the second-order correlation at zero delay is bounded below by unity for any classical field, while the measured value for a heralded single photon falls well below it. The wave account of this chapter must therefore be read as the high-occupancy limit of something else. 1545

43 Black-Body Radiation and Planck's Hypothesis: all derivations of this chapter are pending. 1549

44 Wien's adiabatic argument: a slow compression of a perfectly reflecting cavity leaves the entropy unchanged while shifting every mode frequency, which forces the universal function of Kirchhoff's theorem into the scaling form given by ν cubed times a function of ν/T alone; and the maximisation of the corresponding wavelength density, which turns that scaling form into a fixed product of peak wavelength and temperature. 1552

45 The low-frequency limit of the cavity spectral density: that each mode carries the equipartition energy given by Boltzmann's constant times the temperature, so that the spectral density becomes proportional to the square of the frequency times the temperature, and the radiance at fixed long wavelength is therefore linear in T. 1553

46 The quantum theory of lattice heat capacities: the mean energy of a quantised oscillator applied to the vibrational degrees of freedom of a crystal, which gives the exponential freeze-out of a single Einstein frequency; and the replacement of that single frequency by the elastic-continuum mode spectrum with a cut-off preserving the total mode count, which produces the observed cubic low-temperature law. 1556

47 Why the expanding universe leaves a Planck spectrum Planckian: thermal equilibrium of matter and radiation before recombination fixes the form, and the redshift of every mode by a common factor rescales the spectral density into another Planck spectrum with the temperature inversely proportional to the scale factor, so that no spectral distortion is generated by the expansion itself. The limits on distortions then become limits on energy release after equilibrium was lost. 1557

48 The Photon: Photoelectric and Compton Effects: all derivations of this chapter are pending. 1559

49 The classical accumulation time: the energy an electromagnetic wave of a stated irradiance delivers per second to a target of atomic cross-section, compared with the work function of the metal, giving the delay a wave theory requires before the first electron can be emitted; and the demonstration that no redistribution of energy within the classical field shortens it, which is what makes item 4 above a contradiction rather than an estimate. 1560

50 The angular momentum of a circularly polarized wave: the flux of angular momentum computed from the Maxwell stress tensor for a beam of finite transverse extent, its ratio to the energy flux, and the torque this predicts on a half-wave plate that reverses the handedness; and the identification of that ratio with one unit of the reduced Planck constant per quantum, which is what makes the result a statement about the spin of the photon rather than about the field alone. 1563

51 The angular correlation implied by the collision kinematics: the recoil-electron direction as a function of the scattering angle of the quantum, obtained from the same conservation laws that give the wavelength shift; the rate of accidental coincidences to be subtracted from the observed rate, given the counting rates and the resolving time; and the contrasting prediction of statistical-only conservation, under which the two directions are independent and the coincidence rate is the accidental rate alone. 1565

52 The two bounds that make the measurement decisive: the classical inequality on the normalised joint detection rate, from the Cauchy–Schwarz inequality applied to the intensity correlations of any positive classical intensity distribution; and the quantum prediction that a one-quantum state incident on a beam splitter gives a vanishing joint rate, together with the correction for the imperfect heralding and the accidental coincidences of a real source. . . 1566

53 Atomic Models and Spectra: all derivations of this chapter are pending. . . 1567

54 Two things must be derived and only the second is classical. That a bound system radiates at a discrete set of frequencies at all follows only from the quantisation of its internal energies, and is taken up in the quantum-mechanics part; that emission and absorption occur at the same wavelengths is the detailed-balance content of Kirchhoff's radiation theorem, and follows from the equilibrium argument of the black-body chapter applied frequency by frequency. 1568

55 The term structure: that there exists a set of stationary energies of the atom whose differences, divided by Planck's constant, are exactly the observed frequencies. The stationary-state postulate assumed in the Bohr section below turns the combination principle into a law rather than deriving it; the derivation proper is the eigenvalue problem for the atomic Hamiltonian, solved for hydrogen in the quantum-mechanics part. 1569

56 The Rutherford cross-section: the relation between impact parameter and scattering angle for a repulsive inverse-square force, read off the Kepler hyperbola of the classical two-body problem, and the Jacobian that converts it into a differential cross-section; the summation over foil thickness that gives the counting rate actually measured; and the remark, which must be made honestly, that the same expression is also the exact Born approximation for a Coulomb potential, so that a mechanics now known to be wrong gave the right answer here for a reason no one could have known in 1911. 1570

57 Stability of the atomic ground state: the existence of a lowest energy level, which no classical bound system in an inverse-square potential possesses, and the bound relating the localisation of the electron to its kinetic energy which fixes the size and energy of that level. The derivation belongs to the quantum-mechanics part, where the hydrogen atom is solved; what can be established here is only the negative statement of the remark below. 1571

58 Two derivations of different standing. The normal triplet follows classically, from the Larmor precession that a magnetic field imposes on a bound charge: the three normal modes of an isotropic oscillator in a field, their frequencies, and the circular and linear polarizations of the light each of them emits. The anomalous patterns do not follow at all without the electron spin and the coupling of spin to orbital angular momentum, and their treatment belongs to the angular-momentum chapter of the quantum-mechanics part; what must be recorded here is that the empirical splitting factor was fitted, not derived. 1575

59 Matter Waves: all derivations of this chapter are pending. 1577

60 Diffraction of a thermal beam: the grating condition for a two-dimensional surface lattice, and the shape of the observed maxima when the incident beam is not monochromatic but carries the Maxwellian velocity distribution of the oven, each velocity class contributing its own de Broglie wavelength. What must be shown is that the position of each maximum tracks the most probable momentum in the predicted way as the source temperature is varied, which is the quantitative content of the experiment. 1579

61 The accumulation statistics: that the arrival positions are independent samples drawn from the squared modulus of the single-particle amplitude, so that the histogram of many arrivals converges on the intensity pattern of the wave while no individual arrival carries any fringe at all. What must be derived is the convergence itself and its rate, and what must be stated is that the probabilistic reading of the amplitude is an additional postulate and not a consequence of the de Broglie relation. 1580

62 The gravitationally induced phase: the local wavenumber of a neutron in a linear potential, obtained from the free-particle dispersion relation with the gravitational potential energy subtracted from the total energy; the phase accumulated along each arm as the line integral of that wavenumber; and the reduction of the difference to the stated product of the squared mass, the acceleration of free fall, the enclosed area and the wavelength. The systematic corrections that must accompany it — bending of the crystal under its own weight as the device is rotated, and the Sagnac phase from the Earth's rotation — belong with it. 1581

63 The rotation operator for a spin-half state: that the generator of rotations has half-integer eigenvalues, so that a rotation by a full turn acts as minus the identity rather than the identity, and that a spin-half state therefore carries a representation of the covering group and not of the rotation group. The interferometric argument that turns this global sign into a measurable relative phase must accompany it, together with the relation between the applied magnetic field, the transit time and the precession angle. 1582

64 The eigenvalue problem for a particle in a linear potential above a hard wall: the equation reduces to Airy's equation, the admissible solutions are the decaying Airy function shifted so as to vanish at the mirror, and the eigenvalues are therefore fixed by its zeros. The classical turning-point heights follow from the eigenvalues, and it is those heights that the absorber measures; the step positions predicted this way are to be compared with the observed ones. 1582

65 Two things, of which only the first is optics. The near-field Talbot–Lau fringe condition and its scaling with mass and wavelength, which is what fixes the grating periods and the source coherence a given molecular mass demands. And the decoherence criterion: how much which-path information the emission or scattering of a single photon of given wavelength carries, and hence the residual gas pressure and internal temperature at which the fringes must disappear — the quantitative statement of what these experiments do and do not bound. 1583

66 Experiment: Franck–Hertz: all derivations and data analysis of this chapter are pending. 1585

67 Why the glow layers sit where they do: an electron starting from rest at the cathode reaches the excitation energy after falling through a fixed potential difference, so the luminous shells mark equal potential intervals, and their migration towards the cathode as the voltage is raised follows from the field distribution in the tube. The dependence of the effective spacing on current and geometry requires in addition the branching among the accessible neon levels and the collision cross-section of each. 1589

68 The effective spacing: the excitation cross-sections of the competing mercury levels as functions of electron energy, and the weighted mean interval they produce in a tube of given vapour density and geometry; and the mechanism of the drift with maximum number, in which electrons surviving several accelerating stages sample a different mixture of levels from those excited near the first drop. 1590

69 Experiment: The Blackbody Spectrum Measured: what is pending is the tabulation of the measured radiance against wavelength and temperature for each experiment, in SI with its uncertainty budget, together with the residuals against the Wien and the Planck distributions. The phenomena stated below each carry their derivation inline. 1591

70 Experiment: The Photoelectric Effect and Compton Scattering: what is pending is the tabulation of the measured numbers for each experiment, in SI with its uncertainty budget — stopping potential against frequency for each emitting metal, scattered wavelength against scattering angle, coincidence and singles counts against resolving time, and the gated detection probabilities of the beamsplitter experiment. The phenomena stated below carry their derivations inline except where a pending derivation is marked against them individually. 1603

71 The operational definition of the stopping potential. The measured current does not fall to zero at a sharp potential but approaches it along a tail, because the emitted electrons have a distribution of energies rather than a single maximum, because electrons originate at a range of depths below the surface, and because the collector is not equipotential. What is pending is the derivation of the shape of that current–voltage curve near its foot from the energy distribution of the photoelectrons, and the demonstration that the extrapolation Millikan used recovers the true intercept without bias — the point being that the linearity of the plotted line is a statement about a quantity defined by an extrapolation, and that extrapolation must be shown not to have manufactured it. 1609

72 The angular correlation measured by the cloud-chamber experiment. What is pending is the direction of the recoil electron as a function of the scattering angle of the quantum, obtained from the same conservation laws that give the wavelength shift, together with the angular spread introduced by the initial motion of the struck electron and by multiple scattering of the recoil track in the chamber gas — the latter being what sets the accuracy with which the predicted correlation can be confirmed, and hence what the measurement is really comparing. 1614

73 Experiment: Matter Waves Observed: what is pending is the apparatus and procedure of each measurement and the tabulation of its data — scattered intensity against angle and accelerating voltage, ring radii against voltage, diffraction angle against source temperature, fringe visibility against count, neutron intensity against tilt angle, and molecular fringe contrast against internal temperature and residual gas — each in SI with its uncertainty budget. The phenomena stated below each carry their derivation inline. . . 1619

74 The quantitative decoherence rates: the thermal photon emission spectrum of a hot molecule and the resulting product of which-path factors as a function of internal temperature, giving the predicted visibility curve; and the collisional case, in which the localization length follows from the momentum transfer distribution of the residual gas at a given pressure and temperature, giving the predicted decay of visibility with pressure. Both are stated qualitatively in the derivation above from the single-photon overlap; what must be supplied is the master equation whose decoherence rate they are, together with the statement of which of its assumptions the data actually test. 1631

75 X-ray spectra and the charge of the nucleus: the classical account of the emission itself, namely the bremsstrahlung continuum radiated by cathode-ray electrons decelerated in the anticathode, and its short-wavelength cut-off. . 1637

76 Characteristic X-radiation: the quantum account, in which the primary beam ejects an electron from an inner shell and the radiation is emitted when an outer electron fills the vacancy, so that the excitation threshold is the binding energy of the shell and the monotone hardening along the table is the growth of that binding energy with nuclear charge. 1639

77 The X-ray term system: the derivation of the K, L and M level multiplicities from the quantum numbers of the many-electron atom, with the L and M splittings as the combined effect of screening and of spin-orbit coupling, and the identification of an absorption edge with a one-electron binding energy. 1646

78 From Poisson brackets to commutators: statement of the canonical quantization rule and derivation of the canonical commutation relations between conjugate coordinates, which are used throughout the following chapters. . 1653

79 Justification of the coordinate-representation rule $p_i = -\mathrm{i}\hbar\,\partial_i$ from the canonical commutation relations; the source asserts the rule without derivation. . 1653

80 Statement and derivation of the generalized uncertainty relation bounding the product of the uncertainties of two non-commuting observables by the mean value of their commutator. 1654

81 Elementary Quantum Systems: all derivations of this chapter are pending. . 1655

82 Resonant transmission by an attractive well: the condition under which the amplitudes reflected from its two edges cancel, making it perfectly transparent, and the three-dimensional form of the same statement as an s-wave phase shift passing through a half turn at the Ramsauer minimum 1658

83 The Gamow factor: semiclassical penetration of the Coulomb barrier by a particle whose energy lies below its top, the exponential of the integrated imaginary momentum across the forbidden region, and the linear dependence of the logarithm of the decay constant on the inverse square root of the alpha energy that follows from it 1658

84 Angular Momentum and Spin: all derivations of this chapter are pending. . 1661

85 Landé's g factor from the projection theorem: that the matrix elements of any vector operator inside one multiplet are proportional to those of the total angular momentum, so that the observed splitting unit becomes a closed formula in the three quantum numbers of the level, and that fitting it to the data requires the electron's own gyromagnetic factor to be twice the orbital one 1665
86 Force on a magnetic dipole in an inhomogeneous field 1673
87 Quantum derivation of the two-valued splitting from spin-1/2 (to Chapter 79) 1674
88 Sequential SG probabilities from the measurement postulates 1675
89 The Hydrogen Atom: all derivations of this chapter are pending. 1677
90 The bound-state eigenvalues of the Coulomb problem: the radial equation for the potential that falls as the inverse first power of the distance, the termination of its series solution which quantizes the energy as minus a constant over the square of an integer, and the identification of that constant with a combination of the electron mass, the elementary charge and Planck's constant 1678
91 The ℓ-independence of the Coulomb spectrum: the conserved Runge–Lenz vector peculiar to the inverse-square-law force, the closure of its commutators with the angular momentum on the algebra of SO(4) for bound states, and the identification of the levels with irreducible representations of that group whose dimension is the square of the principal quantum number 1680
92 The radiative level shift: the interaction of the bound electron with the fluctuating quantized electromagnetic field, the difference between the bound and free self-energies which is what remains finite after regularization, and the vacuum-polarization contribution of opposite sign that accompanies it . 1681
93 The ground-state hyperfine splitting of hydrogen: the Fermi contact interaction between the electron and nuclear magnetic moments, its expectation value in the ground state, which is proportional to the probability density of the electron at the origin, and the resulting separation of the singlet from the triplet 1682
94 Approximation Methods: all derivations of this chapter are pending. 1685
95 Identical Particles: all derivations of this chapter are pending. 1691
96 The Ramberg–Snow bound: the energy displacement of the anomalous X-ray line produced by the extra screening of a doubly occupied inner shell, the number of fresh electrons that a given charge delivers into the target lattice, and the conversion of a null count and its background into an upper limit on the violation probability 1696
97 The two-particle correlation of a chaotic source: the sum over the two indistinguishable histories by which one particle from each of two source points reaches the two detectors, the factor of two it produces in the zero-delay coincidence rate for symmetric states, and its replacement by zero for antisymmetric ones, together with the loss of the effect once the path difference exceeds the coherence length 1697
98 The degenerate electron gas: its zero-temperature pressure obtained from the exclusion principle and the filling of momentum space up to the Fermi momentum, the change of the exponent relating pressure to density once that momentum exceeds the electron mass times the speed of light, and the resulting limiting mass, which is of the order of the cube of the Planck mass divided by the square of the nucleon mass 1698
99 Entanglement and Bell Tests: all derivations of this chapter are pending. . . 1699
100 Interpretations (Evidence-Anchored): all derivations of this chapter are pending. 1707
101 Scattering Theory: all derivations of this chapter are pending. 1713

102 Open Quantum Systems and Decoherence: all derivations of this chapter are pending. . . . 1723
103 Eigenstate thermalization: that the expectation of a local observable in an individual many-body energy eigenstate is a smooth function of the energy density alone, so that any superposition confined to a narrow energy window relaxes to the microcanonical value of every local observable; and that the entanglement entropy of a small subregion then grows to the thermodynamic entropy that subregion would carry at the corresponding temperature . . . 1727
104 Atoms and Molecules: all derivations of this chapter are pending. . . . 1733
105 The Heitler–London calculation: that the symmetrized and the antisymmetrized products of two hydrogenic ground-state orbitals have expectation energies differing by twice an exchange integral; that this integral has the sign, over the relevant range of internuclear distance, which puts the singlet below the separated atoms and the triplet above them; and the size of the discrepancy that remains between so simple a variational estimate and the measured dissociation energy . . . 1739
106 Experiment: Bell Tests: all derivations of this chapter are pending. . . . 1745
107 The detection-efficiency threshold: the least heralding efficiency at which the observed coincidence and singles rates cannot be reproduced by any local model free to decide which pairs go undetected, worked out both for the CHSH inequality with a maximally entangled state and for the Eberhard inequality with a partially entangled one, the latter threshold being the lower and being the reason the photonic experiments deliberately used a non-maximally entangled state . . . 1751
108 Experiment: Precision Spectroscopy and Atomic Clocks: all derivations of this chapter are pending. . . . 1753
109 Magnitude of the interband tunnel current: the transmission of a carrier across the forbidden gap of a uniformly biased semiconductor, the imaginary wavevector inside the gap obtained by continuing the two-band dispersion relation, and the resulting exponential dependence of the peak current on the gap, the effective mass and the junction field . . . 1770
110 The tunnel current between a normal metal and a superconductor: the elastic-tunnelling current as the convolution of the two densities of states with the difference of the two Fermi functions [1198], the BCS quasiparticle density of states with its square-root edge at the gap, and the consequence that the differential conductance at low temperature is proportional to that density of states evaluated at the bias energy . . . 1772
111 The tunnel current as a probe of the local density of states: the transfer-Hamiltonian expression for the current between two weakly coupled electrodes in terms of the overlap of their surface wavefunctions [1198], and its reduction, for a tip modelled by a single spherically symmetric orbital, to the local density of states of the sample at the position of the tip and at the bias energy [1765] . . . 1774
112 The Klein–Gordon Equation: all derivations of this chapter are pending. . . . 1779
113 Determination of the spin and parity of the boson near 125 GeV from the angular distributions of its four-lepton and diphoton decays, and the electroweak argument that requires an elementary scalar field in the first place. The experiment is the Higgs discovery chapter of Part XII and the mechanism is the electroweak chapter of the same part. . . . 1786
114 The Dirac Equation: all derivations of this chapter are pending. . . . 1787

115 Separation of the Dirac equation in a Coulomb potential and solution of the resulting radial system in closed form, together with its expansion in powers of the nuclear charge times the fine-structure constant, which must reproduce the Bohr levels at leading order and the fine-structure intervals at the next. 1791

116 The radiative level shift between the two lowest hydrogen states of equal total angular momentum. Deriving it requires the quantized electromagnetic field, the electron self-energy and the vacuum polarization, and a renormalization prescription, so it lies outside relativistic quantum mechanics altogether and belongs to the quantum-electrodynamics chapter of Part XII. 1792

117 Bargmann's theorem for the Poincaré group: the proof computes the second cohomology of the Lie algebra $\mathfrak{iso}(3,1)$ and shows every local phase cocycle is a coboundary, then lifts to the simply connected cover; see [1029]. The cohomological machinery is not yet developed in this treatise. 1796

118 Completeness of the classification: that the representation defined by Equations (94.21) and (94.22) is irreducible precisely when D is, and that *every* irreducible unitary representation of the cover with $\hat{P}$-spectrum on the given orbit is equivalent to an induced one, is Mackey's imprimitivity theorem, specialized by Wigner to this group [849]. The systematic imprimitivity machinery is not yet developed in this treatise. 1803

119 Experiment: The Positron: all derivations of this chapter are pending. . . . 1807

120 The identification of the penetrating cosmic-ray component as a heavy lepton rather than as the quantum of the nuclear force: its anomalously weak absorption in nuclei against the strong coupling a nuclear-force carrier must have, and the three-body shape of its decay electron spectrum. The muon's own phenomenology is taken up in the cosmic-ray chapter of Part XII. . . . 1812

121 The CPT theorem — that any local, Lorentz-invariant quantum field theory with a Hermitian Hamiltonian and the normal spin–statistics connection is invariant under the combined operation of charge conjugation, parity and time reversal — together with the equalities of mass, lifetime and magnetic moment that follow from it, and the reasons a null result here bounds rather than confirms. 1812

122 The Weyl Equation and Neutrinos: all derivations of this chapter are pending. 1815

123 Extraction of the invisible width of the Z from the measured total and visible widths at the resonance peak, and the Standard Model expression for the partial width into one neutrino species, whose ratio is the species count. The measurement requires the electroweak theory of Part XII to convert a width into a number. 1818

124 The shape of the beta spectrum near its endpoint as a function of the neutrino mass, and the reason the observable is the incoherent sum of squared mixing amplitudes times squared masses rather than any single mass; and, separately, the free-streaming suppression of the matter power spectrum by massive neutrinos, whose derivation belongs to the cosmology part and whose model dependence must be stated with the bound. 1821

125 The two-neutrino and neutrinoless double beta decay rates: the phase-space and nuclear-matrix-element factorization, the effective Majorana mass that the neutrinoless rate measures, and the argument that observing the decay implies a Majorana mass term whatever mechanism drives it. The nuclear matrix elements are the dominant systematic and must be presented as such. 1822

126 Higher-Spin Wave Equations: all derivations of this chapter are pending. . . 1825

127 Experiment: Neutrino Helicity: all derivations of this chapter are pending. . 1831

128 The Michel spectrum: the most general Lorentz-invariant four-fermion matrix element for muon decay, its reduction to four measurable parameters in the decay distribution, and the values those parameters take when the current is the purely left-handed one. Deriving it also shows which combinations of couplings the experiment cannot separate, which is what makes the bounds on right-handed admixtures the shape they are. 1835

129 The parity-violating asymmetry in the scattering of longitudinally polarized electrons, as the interference between the photon-exchange and neutral-current amplitudes, and its expression in terms of the weak mixing angle; together with the analogous expression for the parity-non-conserving amplitude in a heavy atom, where the nuclear weak charge and the atomic structure factorize. Both belong to the electroweak chapter of Part XII. 1836

130 The general left–right parametrization of the charged current, the observables in beta and muon decay that are first order in the right-handed admixture as against those that are second order, and the translation of a null asymmetry into a bound on the mixing angle and on the mass of an additional charged vector boson. The distinction between the two orders is what determines how the sensitivity scales, and it must be stated with the bounds. 1836

131 The indefinite-metric mode algebra of covariant quantization, displayed just above: that the gauge-fixing term makes all four components of the potential dynamical, that the covariant equal-time bracket $[A_\mu, \pi^\nu]$ then delivers $-\eta_{\lambda\lambda'}$ where the Coulomb-gauge algebra has $\delta_{\lambda\lambda'}$, and hence that the timelike mode has negative norm. It needs a basis of four polarization vectors orthonormal in the Minkowski metric, which this chapter does not set up, so it belongs in the long-proof appendix. 1863

132 Consistency of the Gupta–Bleuler subsidiary condition displayed just above: that the subspace it selects carries a non-negative norm, that timelike and longitudinal quanta occur in it only in zero-norm combinations, and that those combinations contribute nothing to any observable, so that the counting reduces to the two transverse polarizations. It runs through the mode decomposition of the gauge-fixed field and belongs in the long-proof appendix, next to the indefinite-metric algebra above. 1864

133 The spin–statistics theorem for arbitrary spin, by analytic continuation of the Wightman functions to the Jost points: this is a long argument and belongs in the long-proof appendix. The two cases relevant to the Standard Model — spin 0 and spin 1/2 — are proved in full in the text below. 1873

134 Haag's theorem: the proof runs through the equality of all equal-time vacuum expectation values under the unitary, the reconstruction of the theory from them, and the identification of the mass from the two-point function. It is a page or two of distribution-theoretic argument and belongs in the long-proof appendix; the statement and its consequences are used here, and the axiomatic setting in which the hypotheses are stated is the axiomatic quantum field theory chapter. 1879

135 Klein–Nishina cross-section: the spin-summed trace computation of the two-diagram Compton amplitude leading to the squared matrix element and, after the rest-frame kinematics, to the angular distribution; the same computation gives the total cross section as a function of the ratio of photon energy to electron rest energy. It is a page of Dirac-algebra manipulation of the kind carried out in full for the vertex correction below, and belongs in Appendix A. 1894

136 Tree-level cross-sections: the spin-summed trace computations for Møller, Bhabha, muon-pair and two-photon annihilation, and the Born-approximation Bethe–Heitler bremsstrahlung cross-section together with the definition of the radiation length that follows from it. Each is an application of the trace technology established in the next subsection and belongs in Appendix A. . 1895

137 The field-strength renormalization as a residue, and its bound: the Källén–Lehmann spectral representation of the exact fermion two-point function, obtained by inserting a complete set of eigenstates of the four-momentum and using the spectrum condition; the positivity of the spectral density, which follows because each weight is a squared modulus of a vacuum-to-state matrix element; the isolated one-particle delta whose weight is the field-strength constant, identifying it with the residue of the exact propagator at its pole; and the sum rule from the canonical equal-time anticommutator, which normalizes the total spectral weight to one and hence bounds the constant between zero and one, the deficit being the weight carried by the multiparticle continuum. The subsection of the axiomatic chapter named for this representation is at present a reserved heading, so the derivation is owed there or in Appendix A. 1904

138 The Bogoliubov–Parasiuk–Hepp–Zimmermann theorem: the recursive subtraction, the combinatorial proof that the forest formula solves the recursion, and Hepp's sector decomposition establishing absolute convergence of the subtracted integrand, together with the demonstration that overlapping divergences require no counterterm beyond those of the local Lagrangian. This is a long combinatorial argument and belongs in Appendix A; the statement is used here only to license the claim that the four constants suffice at every order. 1911

139 Bloch–Nordsieck cancellation: the explicit infrared part of the one-loop form factor with a photon mass regulator, the integral of the eikonal emission rate up to the detector resolution, the demonstration that the coefficient functions of the two logarithms are equal and opposite, and the exponentiation of the soft series into the Sudakov form factor. The structure and its physical reading are established above; what is owed is the coefficient function, and it belongs in Appendix A. 1913

140 Kinoshita–Lee–Nauenberg theorem: the classification of the singular regions of a Feynman integral in the massless limit — soft and collinear — and the proof that the sum over the degenerate subspace of initial and final states is free of them, together with the counting that shows why an average over degenerate initial states is needed and not only a sum over final ones. It belongs in Appendix A. 1914

141 Hadronic vacuum polarization from data: the once-subtracted dispersion relation for the renormalized polarization function in the cut plane, with the subtraction fixed by the renormalization condition at zero momentum transfer and the convergence of the integral argued from the behaviour of the function at infinity; the optical theorem identifying the discontinuity across the timelike cut with the measured ratio of the annihilation cross section into hadrons to that into muon pairs; and the resulting integral over that measured ratio, which is the number quoted above as the hadronic half of the shift in the coupling at the mass of the Z boson. Only the analyticity input is proved in the treatise, in the Fourier and integral-transforms chapter; the dispersion integral itself is owed, and belongs in Appendix A. 1916

142 Lamb shift, covariant completion: the relativistic one-loop self-energy of a bound electron, which supplies the constant accompanying Bethe's logarithm and fixes the cutoff-independence of the result; the binding corrections organized as an expansion in $Z\alpha$; and the finite-nuclear-size term through which the proton charge radius enters the comparison. The non-relativistic leading term and the vacuum-polarization term are derived in full above; this box covers the remainder, and it belongs in Appendix A. 1919

143 Light-by-light scattering: the explicit four-photon amplitude from a closed charged-fermion loop, the demonstration by gauge invariance that the six box diagrams combine into a finite answer despite a superficial degree of divergence of zero, the expansion of the one-loop effective action of a constant field yielding the coefficients in the Euler–Heisenberg Lagrangian, and the phase-space integration giving the low-energy cross-section. It belongs in Appendix A. 1921

144 Bound-state QED: the annihilation rates of para- and ortho-positronium quoted above, the ground-state hyperfine splitting of positronium and of muonium, and the systematic expansion of a two-body bound-state energy in powers of α and $\ln \alpha$ that organizes them. The selection rule forbidding a two-photon decay of a $J = 1$ state is cited rather than derived here and is proved in the discrete-symmetry chapter. This box belongs in Appendix A. 1923

145 Muon decay, the parts not derived here: the phase-space function $f(z)$ of the electron-mass correction, obtained by repeating the phase-space integral of this section with $p_e^2 = m_e^2 c^2$ retained; the one-loop electromagnetic correction $[25/4 - \pi^2]$, which is a QED calculation of the kind carried out in the QED chapter but applied to a contact operator; and the spin-dependent decay distribution $x^2[(3 - 2x) + P_\mu \cos\theta\,(2x - 1)]$ obtained by keeping the muon spin projector in place of the average taken in the trace lemma. All three are Appendix A material and all three are quoted with their numerical values in the derivation above. 1954

146 The $[\Delta I = 1/2]$ enhancement in nonleptonic strange decays: why the isospin-one-half amplitude dominates the isospin-three-halves one by a factor near twenty, when the current–current operator produces both with comparable coefficients. The explanation combines short-distance operator mixing under the renormalization group with long-distance hadronic matrix elements, so the derivation belongs with the strong-interaction and renormalization-group material rather than here; the measured ratio is quoted with its source above. 1957

147 The hadronic neutral-current ratio: the prediction for the ratio of neutral-current to charged-current rates on an isoscalar nuclear target, which is what the Gargamelle hadronic sample actually measured. It requires the quark-parton content of the nucleon and the quark neutral-current couplings derived in this section, and therefore belongs with the deep-inelastic material rather than here; the leptonic ratio, which needs nothing beyond this chapter, is derived above. 1964

148 Renormalizability of Yang–Mills theory. The proof combines the power-counting theorem, which for a gauge theory in four dimensions gives superficial degree of divergence four minus the number of external lines weighted by their dimension exactly as in the abelian case, with the Slavnov–Taylor identities, which show that the divergent structures allowed by power counting are constrained to be gauge invariant and therefore already present in the Lagrangian. The regularization must respect the gauge symmetry, and dimensional regularization does. This is a long argument of the same shape as the BPHZ theorem of the electromagnetic chapter and belongs beside it in Appendix A. 1984

149 Collinear factorization to all orders. What is available inline is the leading-order statement, which is the impulse approximation together with the observation that the collinear logarithms are universal because they come from the region where the emitted parton is nearly on shell and therefore long-lived compared with the hard collision. The all-orders proof requires showing that the leading regions of the loop momenta are exhausted by hard, collinear and soft subgraphs, that the soft gluons cancel or are absorbed into eikonal lines, and that what remains is the same operator matrix element in every process. That analysis, and the counterexamples at subleading power, belong in Appendix A. 1998

150 The exact order-α_s three-jet distribution. What is derived inline is the soft and collinear structure, which is where the rate is concentrated and which already excludes a scalar gluon. The full matrix element requires the spin-summed trace over the two interfering diagrams in which the gluon is emitted from the quark and from the antiquark, together with the three-body phase space in the Dalitz variables; and the corresponding statement for a scalar emitter, needed to make the exclusion quantitative rather than qualitative. Both are trace computations of the kind carried out for the electromagnetic processes and belong beside them in Appendix A. 2001

151 Confinement: no analytic derivation from the continuum Lagrangian exists, and none should be implied. What is available is Wilson's area law for the loop expectation value, exact in the strong-coupling lattice expansion, together with the numerical demonstration that the lattice theory joins continuously onto the asymptotically free continuum. Closing the gap between those two statements is an open problem, not an exercise. 2005

152 The short-distance two-W box amplitude for the kaon mass difference. What is carried out inline is the GIM structure of the internal sum, the dimensional check of every factor, and the numerical evaluation; the loop integral itself — the box function in its limit of internal mass small against the W mass, together with the reduction of the four-quark operator to the decay constant and the bag parameter — is not derived here and belongs in Appendix A. . 2019

153 The phase-space function $f(x) = 1 - 8x + 8x^3 - x^4 - 12x^2 \ln x$ for a purely leptonic charged-current decay with a *massive* daughter lepton. The muon-decay rate inherited from the weak-interactions chapter is derived there only for a massless daughter, where $f(0) = 1$; the massive case is the one used above, and the three-body phase-space integral that produces it belongs in Appendix A. 2022

154 The tree-level partial width of the Z into a fermion pair. The formula is stated above with its dimensional check and then used to count the neutrino species; its derivation from the neutral-current Lagrangian — the squared matrix element summed over final and averaged over initial polarizations, times the two-body phase space — is not carried out here and belongs in Appendix A. 2025

155 The loop function $S_0(x)$ and the B-meson box amplitude for the mass difference. Both are stated above and then used twice to weigh the top quark, so the derivation is load-bearing: the box integral for an internal mass comparable with the W mass, whose value is S_0, is not carried out here and belongs in Appendix A. 2034

156 The wave-packet coherence length for neutrino oscillation, including its factor $4\sqrt{2}$. What is given inline is the group-velocity separation, which fixes the scaling with the packet width, the energy and the squared-mass splitting; the Gaussian overlap integral that fixes the numerical coefficient, and with it the precise meaning of the packet width, is not carried out here and belongs in Appendix A. 2040

157 The one-loop coefficient in the top contribution to the rho parameter: the W and Z vacuum-polarization integrals with a t–b doublet in the loop, regulated dimensionally, whose difference at zero momentum transfer gives the factor $3/8\sqrt{2}\pi^2$ quoted from Veltman's paper above; and the accompanying logarithmic dependence on the scalar mass, which is what the screening theorem asserts. Belongs in Appendix A. 2077

158 The loop-induced scalar vertices: the amplitudes for $h \to \gamma\gamma$ and $h \to gg$, from the W and top triangles, which have no tree-level counterpart and which supply the discovery channel and the dominant production mechanism (gluon fusion) respectively; together with the resulting production cross-sections at the LHC. These require the full one-loop tensor reduction and belong in Appendix A. Also owed are the three-body off-shell rates $h \to WW^*$ and $h \to ZZ^*$, whose branching fractions the table quotes without derivation. What is derived above is the two-body tree-level fermionic width formula and the tau and muon entries computed from it; every other entry of the branching table quotes the standard values. 2089

159 Vacuum stability: the coupled integration of the one-loop renormalization-group equations for the quartic coupling, the top Yukawa and the three gauge couplings from the electroweak scale upward, which is what locates the zero of the quartic near 1×10^{10} GeV; and the bounce action governing the tunnelling rate out of the electroweak minimum. The beta function and its sign are derived in the text above; the integration and the bounce belong in Appendix A. 2093

160 The axiomatic CPT theorem: Jost's proof requires the Wightman axioms, the analyticity of the Wightman functions in the forward tube, the extended tube and the edge-of-the-wedge theorem. None of that machinery is developed here; the axiomatic-QFT chapter reserves it, and the proof belongs in Appendix A alongside it. What is proved in this chapter is the Lagrangian-level theorem, which is weaker in that it assumes a Lagrangian, a field content and a perturbative expansion. 2127

161 The spin–statistics theorem for arbitrary spin: the free-field computation sketched here settles spin 0 and spin 1/2, but the general statement requires the analyticity of the two-point Wightman function and the same extended-tube machinery as the axiomatic CPT proof. It belongs in Appendix A next to it, and the identical-particle chapter of Part IX states the result it needs. 2130

162 The triangle anomaly and the Chern–Simons current: the derivation that the baryon current's divergence is proportional to the topological density, whether by the triangle diagram or by the non-invariance of the path-integral measure, is not carried out in this chapter. It belongs to the path-integral chapter of this part, which reserves the anomaly, and to Appendix A. What is used here is only the integrated statement, that a change of Chern-Simons number by one unit changes baryon number by the number of generations. 2134

163 Osterwalder–Schrader reconstruction: the derivation above establishes the easy half in quantum mechanics — that reflection positivity is the positivity of the reconstructed inner product — and states the field-theoretic theorem. The construction of the Wightman functions from the Schwinger functions by analytic continuation in the time arguments, and the verification of the spectrum condition and locality, are not carried out here; they belong in Appendix A, alongside the axiomatic material of the axiomatic quantum field theory chapter of this part. 2153

164 The Gribov horizon and Singer's obstruction: the derivation above establishes the criterion — a copy exists exactly when the Faddeev–Popov operator acquires a normalizable zero mode — and states that configurations reaching it exist. Gribov's explicit spherically symmetric family, the proof that the Gribov region is convex and bounded, and Singer's theorem that the bundle of gauge fields over the orbit space admits no continuous global section are stated here and not proved; all three belong in Appendix A. 2174

165 The Nielsen–Ninomiya theorem: the fermion doubling of the naive operator is derived above, but the no-go theorem itself — that no local, chirally symmetric, doubler-free operator exists, proved by counting the zeros of the energy–momentum relation as a topological invariant of the Brillouin torus — is stated and not proved here. It belongs in Appendix A. 2178

166 The instanton fluctuation determinant: the Bogomolny bound, the integrality of the winding number and the exponential weight are derived above, but the explicit self-dual solution of Belavin, Polyakov, Schwartz and Tyupkin and the one-loop determinant about it, which supply the measure over collective coordinates quoted in the dilute-gas remark, are not computed here. They belong in Appendix A. 2182

167 The chiral matching for the pion two-photon coupling: the phase space, the polarization sum and the colour counting of the neutral-pion width are derived above, but the step from the anomalous divergence of the axial isospin current to the effective coupling $g_{\pi\gamma\gamma}$ — the partial conservation of the axial current, the pion pole dominance and the normalization by the decay constant — is quoted rather than derived. It belongs in Appendix A, alongside the chiral material of the QCD chapter of this part. 2188

168 The effective-range expansion itself: the proof that $k \cot \delta_0$ is an even analytic function of the wave number at low energy, with the scattering length and the effective range as its first two coefficients. It is the premise of the proposition above; its derivation belongs to the low-energy section of the scattering-theory chapter, where it is not yet written. 2204

169 Chiral power counting: the derivation of the counting formula for the exponent, by assembling the powers of Q from each propagator, each loop integration and each vertex of the effective Lagrangian, and the demonstration that every bracket in the sum is non-negative for a Lagrangian consistent with chiral symmetry. It belongs in Appendix A, since it needs the full vertex enumeration and runs to several pages; the statement and its consequences are used above without it. 2208

170 The Breit–Wigner formula: the derivation of the single-level resonance cross-section used above, with its partial widths and the statistical spin factor g, from the pole structure of the S matrix. It is taken here as a premise; its derivation belongs to the resonance section of the scattering-theory chapter, where it is not yet written. 2217

171 The Rayleigh plane-wave expansion: the expansion of a plane wave in Legendre polynomials and spherical Bessel functions, with the small-argument behaviour $j_L(x) \sim x^L/(2L+1)!!$ used above. Both are premises of the forbiddenness ladder; the expansion belongs to the chapter on Fourier and integral transforms, where it is not yet derived. 2227

172 The multipole normalization: the coefficient $8\pi(L+1)/L[(2L+1)!!]^2$ of the electric multipole rate is quoted, not derived. Its derivation — the multipole expansion of the quantized radiation field, the normalization of the vector spherical harmonics and Fermi's golden rule — belongs in Appendix A; the power counting in kR and the dimensional structure are derived in the text. 2229

173 The Debye–Waller factor: the derivation of the zero-phonon probability $f = \exp(-k^2 \langle x^2 \rangle)$ for a harmonic lattice, and of the Debye-model zero-temperature mean square displacement $\langle x^2 \rangle = 3\hbar^2/(4Mk_B\Theta_D)$. Both are premises of the proposition above; they belong to the chapter on phonons and lattices, where they are not yet derived. 2231

174 The fission barrier: the deformation energy surface of the charged liquid drop beyond second order, through the saddle point to the scission configuration, giving the barrier height as a function of the fissility x and its collapse to zero as x approaches one. It belongs in Appendix A, since it requires the multipole expansion of the electrostatic energy of an arbitrary axially symmetric shape. The second-order result and the critical fissility are derived in the text. . . . 2233

175 The shell correction: the derivation that a low single-particle level density near a closed shell adds several MeV of binding relative to the smooth liquid-drop average and so restores a fission barrier — the Strutinsky shell-correction method. It belongs in Appendix A; the phenomenon above uses the statement without it. 2237

176 The $O(N)$ combinatorial factors of the one-loop shell integration: the explicit index contractions of $(\phi \cdot \phi)^2$ that produce $(N+2)/6$ in the mass renormalization and $(N+8)/6$ in the vertex renormalization, for general N. The $N = 1$ case is counted in the derivation above and both general factors reduce to it; the general count belongs in Appendix A. 2255

177 The two-loop coefficient $b_1 = 102 - \frac{38}{3} n_f$ of the SU(3) beta function: the two-loop vacuum-polarization, vertex and self-energy graphs, their renormalization, and the cancellation that leaves a scheme-independent result. It is quoted from the Particle Data Group here and it fixes the whole two-loop column of the table above, so it is a number the book uses and does not yet derive; the derivation belongs in Appendix A. 2262

178 Appelquist–Carazzone to all orders: the proof that in a mass-dependent scheme the effects of a heavy field on light-field observables are exhausted, at every order in the loop expansion and for a heavy field of any spin whose mass is an independent parameter, by a finite renormalization of the light theory's parameters plus corrections of positive power in the ratio of the probe energy to the heavy mass. What is derived in the text is the one-loop case for a heavy Dirac fermion in quantum electrodynamics, including the quadratic suppression rate; the general theorem belongs in Appendix A. . . 2266

179 Weinberg's generality claim: the demonstration that a Lagrangian containing every term allowed by the assumed symmetries and built from the light fields generates the most general S-matrix consistent with analyticity, perturbative unitarity and cluster decomposition, that is, that no further S-matrix satisfying those constraints exists which the construction fails to reach. The predictivity half of the theorem is derived in the text above; the generality half belongs in Appendix A. 2268

180 The trace anomaly, complete: the operator equation for the trace of the improved energy–momentum tensor in a non-abelian gauge theory, with the numerical coefficient of the beta-function term obtained by explicit regularization rather than by the scaling argument given in the text, together with the demonstration that the result is independent of the regulator used and that the improvement terms do not contribute. The structure — proportionality to the beta function times the operator conjugate to the coupling, and vanishing of the trace exactly at a zero of the beta function — is derived above; the coefficient is not, and the full operator derivation belongs in Appendix A. . 2274

181 The four-dimensional a-theorem: the construction of the dilaton effective action for a spontaneously broken conformal symmetry, the identification of the difference of the anomaly coefficients with the coefficient of the four-derivative dilaton self-interaction, and the positivity of that coefficient from the analyticity and unitarity of forward dilaton scattering, by an argument of the same shape as an unsubtracted dispersion relation. The statement is used here only qualitatively, to say that the flow has a direction; the proof is several pages and belongs in Appendix A. 2275

182 The Bargmann–Hall–Wightman extension theorem: that the holomorphic Wightman function on the forward tube extends single-valuedly to the extended tube and is covariant under the complex Lorentz group; together with Jost's characterization of the real points of that extended tube as the totally spacelike configurations, stated below. These are the substantial analytic imports of the chapter and belong in Appendix A, together with the Paley–Wiener–Schwartz theorem and the edge-of-the-wedge theorem they use. Everything the chapter derives from them is derived explicitly in the text, and the non-emptiness of the set of real points is derived below. 2287

183 Borchers' theorem: that two relatively local Wightman fields generate the same asymptotic states and hence the same S matrix. The argument runs through the Haag–Ruelle construction and belongs in Appendix A next to it. The consequence used in this book, that a field redefinition leaves scattering amplitudes unchanged, is stated with its mechanism in the text. 2290

184 The analytic continuation of the finite-dimensional representation matrix $S([\Lambda])$ along the path joining the identity to the total inversion in the complex Lorentz group, which is what supplies the factor $(-1)^{2s}$ used in the half-integer case. The path itself and the scalar case are derived in full in the text; the index bookkeeping for arbitrary spin follows Burgoyne and belongs in Appendix A with the Bargmann–Hall–Wightman theorem it rests on. . . . 2295

185 The Jost–Schroer theorem: a Wightman field whose two-point function is that of a free field of mass m is a free field. The argument runs through the analyticity of the truncated Wightman functions in the extended tube and the vanishing of the truncated two-point function's support off the mass shell; it belongs in Appendix A beside the other analyticity results of this chapter. 2298

186 The Haag–Ruelle convergence estimate: that the vectors of the displayed limit form a Cauchy family, with the rate supplied by cluster decomposition together with the stationary-phase decay of a wave packet built on an isolated mass shell. The construction and its mechanism are given in the text; the estimate is a page of analysis and belongs in Appendix A. 2299

187 The Doplicher–Haag–Roberts reconstruction: that localizable superselection sectors of a local net form the representation category of a compact group, with Bose or Fermi statistics forced in $[3+1]$ dimensions, and that a field algebra carrying that group exists. The statement, its inputs and its two limitations are given in the text; the proof is long and belongs in Appendix A. 2302

188 Modular theory: the Tomita–Takesaki theorem, that the polar decomposition of the Tomita operator yields a modular automorphism group preserving the algebra and a conjugation exchanging it with its commutant; and the Bisognano–Wichmann identification of that group, for a wedge in a Wightman theory, with the boosts preserving the wedge. Both are stated with their hypotheses and used only through the KMS property, from which the acceleration temperature is derived in full in the text. The two proofs are long and belong in Appendix A. 2304

189 Triviality of the four-dimensional scalar: the correlation-inequality argument bounding the connected four-point function of the lattice model above dimension four, and the tree-diagram bound that settles the marginal four-dimensional case. Both are results in classical probability rather than in field theory and are quoted here with their citations; they belong in Appendix A. What is derived in the text is the consequence, the scale at which the isolated scalar coupling diverges. 2309

190 Doubly differential muon-decay rate from the $V-A$ four-fermion matrix element, i.e. the angular factor $[(3-2x)+P_{\mu}(2x-1)\cos\theta]$ that is quoted rather than computed here; the energy spectrum alone is parametrized in the weak-interactions chapter, and the integration of the angular factor is carried out in this chapter. Belongs in the long-proofs appendix 2331

191 Atomic many-body calculation converting the measured caesium amplitude into a nuclear weak charge: the relativistic coupled-cluster evaluation of the valence electron density at the nucleus and its error budget. Belongs in the long-proofs appendix; the mixing of opposite-parity states and the Z-cubed scaling are derived in this chapter 2334

192 Coefficients of the deep-inelastic parity-violating asymmetry on an isoscalar target: the combinations $1 - \frac{20}{9}\sin^2\theta_W$ and $1 - 4\sin^2\theta_W$ follow from the electron and quark neutral-current couplings C_{1q}, C_{2q} contracted with the quark-parton structure functions of a deuteron, and are quoted rather than derived here. Belongs in the long-proofs appendix; the couplings themselves are written down in this chapter for the proton case, and the deep-inelastic kinematics live in the deep-inelastic chapter 2336

193 One-loop electroweak corrections to the weak charge of the proton: the ρ factor, the charge-radius term, and the WW, ZZ and γZ box graphs that together shift the tree value $1 - 4\sin^2\theta_W = 0.047$ to the Standard Model prediction near 0.071. They are a third of the predicted value, so the comparison with experiment does not exist without them. Belongs in the long-proofs appendix 2337

194 The short-distance box-diagram computation of the $[\Delta S = 2]$ mixing amplitude, giving the mass difference and epsilon in terms of the CKM elements and the quark masses — the step that converts the measured epsilon into a constraint on the unitarity triangle. It is an appendix-scale calculation requiring the loop functions of the box with internal charm and top, and it belongs in Appendix A rather than in an experiment chapter. 2359

195 The U-spin relation between the direct CP asymmetries of $[B^0 \to K^+\pi^-]$ and $[B_s^0 \to K^-\pi^+]$ is stated here in outline only. Owed: the explicit tree-plus-penguin decomposition, the action of the $d \leftrightarrow s$ interchange on each amplitude, and the width weighting that turns the amplitude statement into the ratio -1, together with the size of the U-spin-breaking corrections. This belongs in Appendix A. No key in the bibliography covers the U-spin literature, so the claim carries no citation. 2362

196 The three-loop, chirally suppressed Cabibbo–Kobayashi–Maskawa contribution to the neutron electric dipole moment is quoted here as an order of magnitude and is not derived. Owed: the argument that the one- and two-loop quark diagrams cancel by the Glashow–Iliopoulos–Maiani mechanism because the rephasing invariant needs all six quark masses, and the resulting estimate of order $3 \times 10^{-53}\,\mathrm{C\,m}$. This belongs in Appendix A. The bibliography carries no key for the electric-dipole calculation, so the estimate is uncited. 2368

197 The invariance theorem for a tilted and elliptical Penning trap: the general Brown–Gabrielse result, that the sum of squares of the three measured mode frequencies equals the squared free-space cyclotron frequency independently of the tilt angle and the ellipticity parameter. Belongs in Appendix A beside the ideal-trap identity proved in this chapter. 2383

198 The dispersive representation of the hadronic vacuum-polarization contribution to a lepton anomaly: analyticity of the photon self-energy, the optical theorem relating its discontinuity to the total hadronic cross section, and the derivation of the kernel $[K(s)]$ from the one-loop vertex with a dressed photon propagator. Belongs in Appendix A. 2395

199 The coefficient of the scalar-mass logarithm in the radiative correction Δr, written parametrically in this subsection, together with the constant term that accompanies it — which is not a refinement at the measured mass but comparable to the logarithm itself. Obtaining both requires the one-loop W and Z self-energies with the scalar circulating, renormalized on shell. The electroweak chapter already records the same logarithm as owed, in the paragraph following its screening-theorem discussion; the two belong together in Appendix A. Nothing in this chapter is evaluated numerically from the coefficient. 2404

200 The Standard Model production cross sections quoted in this section. Obtaining them requires the partonic amplitudes — above all the top-quark triangle that drives gluon fusion, which has no tree-level counterpart — convolved with the measured parton distributions and corrected to next-to-next-to-leading order in the strong coupling, where the corrections are large (a K factor near two for gluon fusion). The loop amplitude and the resulting cross sections are already recorded as owed in the electroweak chapter's pending derivation of the loop-induced scalar vertices; the convolution and the perturbative corrections belong with them in Appendix A. What is derived in this chapter from those inputs is everything downstream of them: the produced event counts, the channel comparison, the mass resolution and the significance. . 2413

201 The azimuthal distributions that separate 0^+ from 0^- and from the spin-2 hypotheses in $H \to ZZ^* \to 4\ell$. What is owed is the decay amplitude for each hypothesis — the scalar contraction of the two boson polarizations, the Levi-Civita contraction that a pseudoscalar is restricted to, and the tensor couplings — projected onto the two lepton pairs and integrated to give the distribution in the angle between their decay planes, exhibiting the $\cos\Phi$ term the scalar produces, its absence for the pseudoscalar, and the $\cos 2\Phi$ term of opposite sign that the pseudoscalar carries. It belongs in Appendix A beside the vector-boson vertices of the electroweak chapter, whose loop-induced counterparts are already recorded as owed there. 2427

202 The double-production cross section $\sigma(gg \to HH)$ as a function of κ_λ: the interference of the top-loop triangle carrying the trilinear vertex with the top-loop box that does not, giving the quadratic whose minimum locates the least sensitive value of κ_λ, and the normalization that puts the rate three orders of magnitude below single production. The location of the minimum and the absolute rate are stated in this subsection on the authority of the experimental compilations and are not derived here; the two loop amplitudes belong in Appendix A with the single-production ones already recorded as owed. The published constraint on κ_λ quoted below is a measurement and needs no derivation. 2432

203 The Störmer theory itself: the first integral of the motion of a charge in a magnetic dipole field, the partition of directions at each point into an allowed and a forbidden cone that follows from it, and the integration supplying the coefficient one quarter in the vertical cutoff together with the full azimuthal form used in the east–west subsection below. Belongs in Appendix A; both formulae are quoted here from the source cited beside them, and only their consequences are derived 2477

204 The Bethe–Heitler bremsstrahlung cross section, the resulting exponential energy-loss law, and the radiation length of air and of lead used throughout this chapter. Belongs in Appendix A or in the bremsstrahlung section of the radiation and scattering chapter, which currently reserves the heading . . . 2482

205 The Frank–Tamm intensity formula in SI, obtained from the retarded fields of a uniformly moving charge in a dispersive medium by Fourier transform in space and time. Belongs in Appendix A; this chapter quotes the result and uses only its numerical consequences 2494

206 The non-resonant streaming instability by which the accelerated particles amplify the magnetic field at the shock, and the saturation level that fixes $[B]$ in the maximum-energy estimate. Belongs in Appendix A; the estimate in this chapter takes the amplified field from the X-ray filament observations instead of deriving it 2503

207 The photopion energy-loss length as a proper integral of the measured $p\gamma$ cross section over the Planck spectrum and over collision angle, replacing the order-of-magnitude estimate given here. Belongs in Appendix A 2507

208 The perturbative correction to the Gross–Llewellyn Smith sum rule. The parton-model value of 3 is derived in the text above; what is still owed is the calculation of the coefficient function that multiplies it by $1 - \alpha_s/\pi - \ldots$, order by order, and the demonstration that the same coefficient function is the one appearing in the Bjorken sum rule for polarized scattering. That is what makes a measurement of this integral a competitive determination of the strong coupling, and it belongs in Appendix A alongside the other sum rules. 2542

209 The nuclear modification of parton distributions, stated as the open problem it is: no derivation from quantum chromodynamics currently reproduces the observed dependence on the momentum fraction. The candidate mechanisms — nucleon swelling, pion-cloud enhancement, multi-quark clusters, and a dependence on the local nuclear density rather than on the mass number — each account for part of the shape and none for all of it, and they are not mutually exclusive. What is owed in Appendix A is a statement of what each predicts and of which measurements discriminate among them. 2547

210 The Ellis–Jaffe sum rule, the theoretical number the EMC measurement contradicts. What is owed is the derivation of the expectation for the first moment of the polarized proton structure function from the octet axial charges: the isovector combination fixed by the neutron beta-decay ratio, the octet combination fixed by the hyperon semileptonic decays under the flavour symmetry of the baryon octet, and the assumption of an unpolarized strange sea that sets the singlet piece equal to the octet one — together with the leading perturbative correction, which lowers the parton-model value. Only that chain shows why the expected number is near 0.19 and which of its assumptions the measurement actually falsifies. It belongs in Appendix A beside the other sum rules; this book's bibliography carries no entry for the original Ellis–Jaffe paper. 2548

211 The decomposition of the proton spin into quark spin, gluon spin and orbital contributions, and the reason the split is ambiguous. What is owed is the demonstration that the gauge-invariant decomposition of the angular momentum of a gauge theory into a "spin" and an "orbital" part is not unique — different decompositions differ by terms that vanish for a free field and do not vanish here — so that a measured ΔG has meaning only relative to a stated convention and factorization scheme. It belongs in Appendix A with the operator definitions written out. 2548

212 The thermal-spike calculation of bubble nucleation: the temperature field around an ionising track from the heat equation with a line source, the fraction of the deposited energy thermalised within the critical radius before the bubble can grow, and the resulting threshold in $[\mathrm{d}E/\mathrm{d}x]$ as a function of the superheat. It belongs in Appendix A; the derivation above establishes the barrier and the mechanism but treats the energy delivery as instantaneous and perfectly local. 2579

213 Statistical Mechanics: all derivations of this chapter are pending. 2589

214 Experiment: Brownian Motion and Avogadro's Number: all derivations of this chapter are pending. 2595

215 Molecular origin of the agitation: the unbalanced momentum delivered by molecular impacts on a grain of radius a, and the reason the relative size of the resulting fluctuation grows as the grain shrinks 2596

216 The rotational displacement law for a sphere, in which the mean square angular displacement grows linearly in time with a coefficient carrying the inverse cube of the grain radius rather than its first power — the different power being what makes agreement between the two routes an independent check and not a repetition 2599

217 The velocity autocorrelation of the Ornstein–Uhlenbeck process obtained from the Langevin equation, its short-time ballistic limit, and the crossover to the diffusive law at the momentum relaxation time; and separately the hydrodynamic-memory kernel that replaces it for a sphere in a dense fluid . 2601

218 Quantum Statistics: all derivations of this chapter are pending. 2603

219 Exclusion derived rather than postulated: the symmetrisation of the state of identical particles, the vanishing of a totally antisymmetric state with two coincident single-particle labels, and the spin–statistics theorem that assigns antisymmetry to half-integer spin 2604

220 Saturation of the excited-state population of the ideal Bose gas: that the sum over excited modes of the Bose occupation is bounded above at fixed temperature and volume when the chemical potential reaches the ground-state energy, so that any further particles must enter the ground state; the resulting critical temperature, condensate fraction and heat-capacity cusp in three dimensions 2606

221 The ground-state pressure of the ideal Fermi gas, its persistence at zero temperature, the softening of the equation of state when the Fermi momentum becomes relativistic, and the resulting limiting mass for a self-gravitating degenerate sphere 2608

222 The two-particle detection amplitude for identical particles from a chaotic source, the interference of the direct and exchanged terms, and the resulting second-order correlation of two at zero separation for bosons against zero for fermions, with the source coherence length as the correlation scale 2609

223 Experiment: Bose–Einstein Condensation: all derivations of this chapter are pending. 2611

224 The polarization-gradient (Sisyphus) mechanism: the spatially modulated light shifts of the ground-state sublattice in a standing wave of varying polarization, the optical pumping that preferentially transfers an atom from a hill to the bottom of the next well, the resulting friction coefficient, and the recoil energy as the residual floor 2612

225 Interference of two overlapping expanding condensates: the fringe spacing set by the relative momentum of the two sources, and the emergence of a definite relative phase from repeated measurement on a state of fixed total atom number, in which no relative phase exists before the first detection . . 2615
226 The Bose–Hubbard description of atoms in a deep optical lattice, the tunnelling and on-site interaction parameters expressed through the lattice depth and the scattering length, and the mean-field estimate of the ratio at which the compressible superfluid gives way to the gapped, integer-filled insulator 2617
227 Quantum Optics and the Photon: all derivations of this chapter are pending. 2619
228 The shape of the pump–probe signal for two fragments separating on a repulsive potential energy surface: the classical clocking relation that maps probe detuning onto internuclear separation, the wave-packet computation of the fluorescence yield as a function of delay, and the extraction of the free-fragment appearance time from the saturating on-resonance curve . . . 2625
229 The two-state model of alkali-halide dissociation: the diabatic covalent and ionic curves and the adiabatic well their crossing produces, the Landau–Zener probability of remaining on the adiabatic branch at each pass, and the resulting periodic recurrences with a geometrically decaying envelope and a step-wise product signal 2625
230 Phase Transitions and Critical Phenomena: all derivations of this chapter are pending. 2627
231 The scattered intensity as the Fourier transform of the density–density correlation function; the Ornstein–Zernike form with its Lorentzian structure factor and correlation length; and the fluctuation–response identity that ties the forward scattering to the isothermal compressibility, so that a diverging compressibility and a diverging correlation length are one statement 2630
232 Universality as the basin of attraction of a fixed point of the coarse-graining flow: that the couplings distinguishing one microscopic system from another are irrelevant in the technical sense, so that the singular behaviour is governed by the fixed point alone; and the accompanying calculation of the exponents, developed in the renormalization-group chapter 2633
233 The superfluid transition as the three-dimensional XY universality class, and the calculation of its specific-heat exponent to a precision comparable with the measurement, by renormalization-group and high-order perturbative methods; together with the hyperscaling relation that ties the negative sign of the exponent to the correlation-length exponent in three dimensions . . . 2633
234 The orientational order parameter as a traceless symmetric second-rank tensor, forced by the equivalence of the director and its negative; the cubic invariant that this symmetry permits and that therefore makes the isotropic–nematic transition weakly first order, with a small latent heat and a jump in the order parameter; and the purely entropic hard-rod mechanism that produces the same transition with no attraction at all 2634
235 Nonequilibrium Thermodynamics and Transport: all derivations of this chapter are pending. 2637
236 Phonons and Lattice Dynamics: all derivations of this chapter are pending. 2643
237 The crystallographic restriction, proved from the integrality of the matrix of a lattice rotation in the lattice basis and hence of its trace, which admits only two-, three-, four- and six-fold axes; and the demonstration that a non-periodic but long-range-ordered point set can nevertheless have a Fourier transform consisting of sharp discrete peaks, so that sharp diffraction does not entail a periodic lattice 2644

238 The Grüneisen relation: that a phonon frequency depends on volume, quantified by the logarithmic derivative of frequency with respect to volume; the resulting thermal pressure of the phonon gas; and the equality of that pressure gradient with the elastic restoring stress, which yields the expansion coefficient as the product of the compressibility, the heat capacity and the mean logarithmic derivative, together with the sign reversal produced by transverse modes that stiffen under expansion 2649

239 Why a harmonic crystal has infinite thermal conductivity, and why anharmonicity alone is not enough: that three-phonon processes conserving the total crystal momentum cannot degrade a heat current, so that a finite thermal resistance requires umklapp processes in which the summed wavevector leaves the Brillouin zone and is returned by a reciprocal-lattice vector; the exponential freezing-out of those processes at low temperature; and the kinetic-theory expression for the conductivity in terms of heat capacity, group velocity and mean free path, whose crossover to boundary-limited and isotope-limited scattering produces the observed maximum 2650

240 Electrons in Solids: Band Theory: all derivations of this chapter are pending. 2651

241 The dynamics of a nearly filled band described through its vacancies: that the total current of a filled band vanishes, so that the current of an almost-filled band equals minus the current of the missing states; that a wave packet near a band maximum has negative band curvature and therefore responds as a particle of positive charge and positive mass; and the resulting positive Hall coefficient, with the multi-band and open-orbit corrections that govern its magnitude 2653

242 Bloch's theorem for a periodic potential and the counting that follows from it: that the allowed wavevectors in one Brillouin zone number the primitive cells of the crystal, so that each band holds exactly two electrons per cell; that a crystal whose bands are either completely full or completely empty has no states available at infinitesimal excitation energy and therefore carries no current at zero temperature; and the consequent identification of a semiconductor as an insulator whose gap is comparable with the thermal energy 2655

243 Semiclassical quantization of a closed cyclotron orbit, giving orbits of quantized area in reciprocal space evenly spaced in the magnetic field; the resulting oscillation of the free energy as successive quantized tubes cross the Fermi surface, periodic in the inverse field with a frequency proportional to the extremal cross-sectional area; and the Lifshitz–Kosevich amplitude with its temperature and scattering damping factors 2657

244 That a Bloch state is a stationary state of the perfect periodic potential and therefore propagates without attenuation, so that resistance requires a departure from periodicity; the Boltzmann equation in the relaxation-time approximation and the additivity of scattering rates from independent channels that yields Matthiessen's rule, together with the conditions under which the additivity fails; and the electron–phonon calculation giving the linear high-temperature and the steep low-temperature resistivity 2658

245 The Hubbard Hamiltonian, in which a hopping amplitude competes with an on-site repulsion, and the localization of one electron per site when the repulsion exceeds the bandwidth — a transition to an insulating state that occurs at fixed, partial band filling and therefore has no description in band theory at all; noting that no controlled solution of this model in three dimensions exists, so the derivation available is a limiting-case argument and not a theory 2659

246 Semiconductors: all derivations of this chapter are pending. 2661

247 The hydrogenic impurity level: a donor treated as a charge screened by the dielectric constant of the host and binding an electron of the band effective mass, giving a binding energy reduced from the hydrogenic value by the effective-mass ratio and by the square of the relative permittivity, hence tens of meV; and the charge-neutrality condition combined with the law of mass action, which yields the freeze-out, saturation and intrinsic regimes as limits of one expression 2664

248 The p–n junction in equilibrium: the diffusion of carriers across the metallurgical boundary, the depletion region and built-in potential that arrest it, and the equality of drift and diffusion currents that fixes that potential through the law of mass action; then, under bias, the Boltzmann factor by which the barrier lowering multiplies the minority-carrier density at the depletion edge, the diffusion of those excess carriers into the neutral regions, and the resulting saturation current — together with the recombination, high-injection and series-resistance terms by which real diodes depart from the ideal law . . . 2665

249 Transistor action from the junction physics already in hand: injection of minority carriers across a forward-biased emitter junction, their diffusion across a base thin compared with the diffusion length so that few recombine, and their collection by the reverse-biased collector junction; the resulting current gain as the fraction surviving the base, and the power gain as the product of that fraction with the ratio of the collector to the emitter impedance — the transfer of current from a low-resistance to a high-resistance circuit that gives the device its name 2666

250 Radiative recombination of injected minority carriers across a direct gap: the emission spectrum as the joint density of states weighted by the carrier occupations, giving a peak just above the gap with a width of order the thermal energy; the selection rule that suppresses the process in an indirect-gap material, where a phonon must participate, and the competing non-radiative Auger and trap-assisted channels that fix the internal quantum efficiency 2668

251 Experiment: The Quantum Hall Effect: all derivations of this chapter are pending. 2669

252 Laughlin's gauge argument: that adiabatically threading one flux quantum through a Hall cylinder is a gauge transformation and must map the spectrum to itself, so that its only effect is to transfer an integer number of electrons from one edge to the other; the resulting Hall conductance as that integer times the square of the elementary charge over Planck's constant, with no reference to the Hamiltonian; and the requirement of a mobility gap at the Fermi level that makes the process adiabatic — together with the topological restatement in which the integer is the Chern number of the occupied states, which cannot change under any smooth deformation of the sample 2672

253 Laughlin's correlated wavefunction for filling one over an odd integer, an incompressible liquid rather than a filled single-particle band; the plasma analogy that fixes its density and its excitation gap; the antisymmetry requirement that forces the exponent to be odd; and the hierarchy or composite-fermion construction that accounts for the remaining observed fractions 2673

254 The quasihole of the correlated ground state and the determination of its charge from the deficit of density produced by adiabatically threading one flux quantum, together with the plasma analogy that makes the deficit exact; and the Schottky formula for the noise of a Poisson stream of independent carriers, whose proportionality to charge times current is what converts a noise measurement into a charge measurement 2674

255 Landau quantization of a linear rather than quadratic dispersion, which gives level energies proportional to the square root of the product of level index and field and places one level exactly at zero energy; the shared occupation of that zero level by electrons and holes, which shifts the filling sequence by one half; the fourfold spin and valley degeneracy of the observed steps; and the Berry phase of the cyclotron orbit that appears as the offset in the Shubnikov–de Haas phase 2675

256 That a quantized Hall conductance requires only a gapped band structure with broken time-reversal symmetry and a non-zero topological invariant of the occupied bands, not a uniform magnetic field; the lattice model exhibiting this with zero net flux through the unit cell; and the mechanism by which magnetic dopants in a strong-spin–orbit thin film open the required gap in the surface states 2675

257 Magnetism in Matter: all derivations of this chapter are pending. 2677

258 Diamagnetism as the induced response of the bound electrons: the Larmor precession an applied field imposes on an atomic charge distribution, the induced moment opposing the field by Lenz's rule, and the resulting susceptibility proportional to the mean square radius of the electronic charge distribution and to the number of electrons per unit volume, with no temperature dependence because no level populations change 2678

259 The two-sublattice molecular-field theory, giving the Néel temperature, the susceptibility maximum at it and the negative Curie–Weiss intercept above it; and the magnetic neutron cross section, in which the neutron's own moment couples to the ordered electronic moments so that the scattering amplitude alternates between sublattices, producing reflections at the reciprocal-lattice vectors of the doubled magnetic cell that are absent from the nuclear pattern 2683

260 Superconductivity and Superfluidity: all derivations of this chapter are pending. 2687

261 Why the normal state cannot produce this: the temperature-independent residual resistivity that impurity scattering guarantees in any metal, so that a discontinuous drop to zero requires a new state rather than a limit of the old one; and the conversion of the persistent-current decay bound into a resistivity bound through the inductance of the loop 2688

262 Why an electron–phonon-mediated pairing energy carries the phonon frequency as its prefactor, so that the transition temperature inherits the ionic mass dependence; and the corrections — from the screened Coulomb repulsion between the electrons, and from strong coupling — that reduce the exponent below one half without removing the effect 2690

263 The gap as the energy to break one pair, obtained from the self-consistent gap equation of the pairing theory; the quasiparticle dispersion, whose minimum is the gap and whose density of states diverges at the gap edge, giving the observed tunnelling threshold and infrared edge; and the exponential activation of the heat capacity, together with the derivation of the measured ratio of twice the gap to the transition temperature as a parameter-free consequence of weak coupling 2691

264 Two weakly coupled condensates described by their amplitudes and phases: the coupled equations of motion for the pair, in which the current across the barrier is proportional to the sine of the phase difference and the phase difference evolves at a rate proportional to the electrochemical potential difference; the resulting zero-voltage supercurrent and the alternating current at the Josephson frequency; and the spatial variation of the phase difference across a junction in a field, whose integral gives the diffraction-like dependence of the critical current on the enclosed flux 2693

265 The two-fluid description in which the liquid behaves as an interpenetrating mixture of a normal component carrying all the entropy and all the viscosity and a superfluid component carrying neither, and the reconciliation of the capillary and rotating-body measurements that it provides; the thermomechanical effect as the statement that a temperature difference and a pressure difference are equivalent driving forces for the superfluid component; and Landau's criterion, in which an excitation spectrum with no low-lying free-particle branch forbids dissipation below a critical velocity — which is why an ideal Bose gas would condense without being a superfluid 2694

266 Experiment: Superconductivity: all derivations and data tables of this chapter are pending. 2697

267 The inference chain from the raw run: how a four-terminal measurement removes lead and contact resistance so that the reading belongs to the specimen; how the galvanometer sensitivity and the measuring current together convert into the quoted upper limit on the resistance; and the control observations that exclude the obvious alternative, a short circuit developing on cooling, by their dependence on measuring current and on applied magnetic field 2700

268 The inference from the measured isotope exponent: that a lattice frequency scales as the inverse square root of the ionic mass with the force constants, which are electronic, held fixed, so that an exponent of one half identifies the phonon energy as the prefactor of the pairing scale; and the corrections from the screened Coulomb repulsion, which enter the exponent and depress it below one half without altering the identification 2701

269 The coherence factors: that the matrix element for a process between quasiparticle states is a sum of two amplitudes whose relative sign depends on the behaviour of the perturbation under time reversal, so that the two combinations cancel and reinforce respectively; and the resulting opposite temperature dependences of ultrasonic attenuation and nuclear spin relaxation just below the transition, against the divergent density of states at the gap edge that both share 2702

270 What can and cannot be derived here: the demonstration that flux expulsion on field cooling requires a bulk, thermodynamic superconducting phase and excludes a percolating filamentary path; and the reading of the half-integer flux quantum trapped at a tricrystal ring as a sign change of the order parameter between directions. The mechanism itself is not derived anywhere in this treatise and is recorded as an open problem 2704

271 The one-phonon scattering cross section itself: the factor that weights each peak by the square of the projection of the polarization vector on the momentum transfer, by the Bose population of the mode, and by the Debye–Waller factor, so that the measured intensities constrain the eigenvectors of the dynamical matrix and not only its eigenvalues 2709

272 The mode sum for the mean square displacement, giving $2W$ in terms of the measured dispersion relation, its evaluation in the Debye model with the zero-point term separated from the thermal one, and the resulting temperature dependence of the attenuation at fixed momentum transfer 2714

273 The probability distribution of the triplet phase sum: the random-atom model in which the atomic positions are independent and uniform over the cell, the central-limit argument that makes the joint distribution of three normalized structure factors Gaussian, and the conditional distribution of the phase sum that follows from it, giving the hyperbolic tangent in the centrosymmetric case and the von Mises form in general 2720

274 The contrast transfer function of a defocused electron microscope: the weak-phase-object approximation, the phase shift introduced by defocus and by spherical aberration, and the resulting oscillating transfer function whose zeros must be filled in by combining images taken at different defocus . . . 2722

275 The Dark Sector: all derivations of this chapter are pending. 2729

276 Quantum Gravity: The Honest Status: all derivations of this chapter are pending. 2735

277 Experiment: Dark-Matter Searches: the standard halo model and the nuclear form factor that together convert a measured recoil spectrum into a bound on a cross-section, and the statistical construction of a 90 per cent confidence exclusion contour in the presence of an estimated background, are pending. The kinematic and rate arguments of this chapter are derived inline. 2741

278 The form factor and the recoil spectrum: derivation of the Helm form factor as the Fourier transform of a uniform nuclear density convolved with a surface term, its first zero in relation to the recoil energies of interest for xenon, and the resulting distortion of the differential rate away from the pure exponential that the maximum-recoil relation alone would give; together with the detector response function that converts a recoil energy into an expected number of scintillation photons and ionization electrons, which is what actually sets the threshold 2744

279 The quantitative incompatibility: the calculation that converts a modulation amplitude measured in sodium iodide into an allowed region in the mass–cross-section plane, including the quenching factors for sodium and for iodine recoils, which are measured quantities with their own uncertainties and which set the recoil-energy scale of the claimed region; and the comparison of that region against the exclusion curves of the xenon experiments, together with an enumeration of the non-standard halo and interaction assumptions — streams, inelastic scattering, isospin-violating couplings — that have been proposed to reconcile them and the reasons each is now disfavoured 2748

280 The thermal relic cross-section: solution of the Boltzmann equation for a species annihilating in an expanding universe, freeze-out when the annihilation rate falls below the expansion rate, and the resulting inverse proportionality of the relic abundance to the annihilation cross-section, which is what fixes the benchmark value quoted above from the abundance measured in the dark sector chapter; and the reason the required value falls near a weak-scale cross-section, which is the coincidence that motivated a generation of searches 2753

281 Digits and irrationality of π: an explicit error bound pinning $\pi = 3.141592653\ldots$, and Niven's proof that π is irrational. The latter needs $\sin\pi = 0$ and $\cos\pi = -1$, hence the addition formulas, which the real-analysis chapter does not yet establish — it defines π as twice the first positive zero of the cosine series and proves it is the circle constant, but computes no decimal of it. 3175

Part I

Foundations

Chapter 1

Epistemology and the Scientific Method

1.1 What physics is

Physics is the attempt to describe, with the least possible number of independent assumptions, everything that can be observed in Nature, and to predict what will be observed next. Three commitments separate it from every neighbouring discipline. First, its statements are *quantitative*: they concern numbers obtained by measurement, and are meaningless without a statement of how those numbers were obtained and how much they may be trusted (Chapter 2). Second, its statements are *testable*: a proposition belongs to physics only if some conceivable observation could refute it [1173]. Third, its statements are *connected*: isolated regularities are catalogued, but the goal is always the smallest set of principles from which the catalogue follows deductively.

This treatise takes the second commitment as a hard rule of scope. Theories of great mathematical beauty whose predictions have not been observed — string theory, supersymmetry, supergravity, grand unification — are not treated here, however influential they may be as research programs; they are named only once, in Chapter 133, precisely in order to say honestly that the evidence for them is currently absent. What *is* treated is everything for which Nature has already voted: from the parabola of a thrown stone (Chapter 20) to the strain of 10^{-21} that two colliding black holes imprinted on an interferometer (Chapter 47).

1.2 Physics, mathematics, and philosophy

Mathematics supplies the language in which physical principles are stated and their consequences extracted. The relationship is asymmetric: mathematics owes physics nothing, while physics without mathematics cannot even formulate a prediction. Why abstract structures invented for their own sake — complex numbers, Riemannian geometry, group representations — repeatedly turn out to be exactly what Nature uses is a genuine puzzle, famously called the *unreasonable effectiveness of mathematics* [1195]. This treatise responds to that effectiveness practically: Part II develops the mathematics in the generality it deserves — often in arbitrary dimension $D = p + q$ and signature (p, q) — while the physical parts instantiate it in the observed $3 + 1$ dimensions.

Philosophy, by contrast, supplies the questions physics cannot answer from within: what counts as an explanation, whether unobservable entities exist, how theory choice works when data underdetermine it [1233]. We borrow from it sparingly and explicitly — and from one tradition in particular, for reasons set out in Section 1.3. Where an interpretive question has no observable consequence — as with the interpretations of quantum mechanics — this

treatise states the competing readings and the experiments that bound them (Chapter 85), and goes no further.

1.3 Why this treatise follows analytic philosophy

The preceding section borrowed from philosophy; this one says from which philosophy, and why. The borrowing is not incidental. The rule that governs what may appear in this book — only physics for which Nature has already voted — is not itself a result of physics, since no experiment establishes it. It is a philosophical position, and a treatise that acts on one owes its reader the argument rather than the posture.

1.3.1 The choice cannot be avoided

Three questions must be settled before the first equation is written. What counts as evidence? What counts as having explained something? Which apparently physical questions are questions at all? Physics does not answer them from within: an experiment can decide between two theories, but no experiment can decide whether a proposition is the kind of thing an experiment could decide.

Every treatise answers all three regardless — in its selection of material, in what it is willing to call a derivation, and in the questions it declines to discuss. The only real choice is whether the answers are stated or merely enacted. Enacted, they are usually inconsistent: the same textbook will define temperature by the procedure that measures it on one page and speak of the wavefunction as a thing on the next, without noticing that the two paragraphs answer to incompatible theories of meaning. This treatise states its answers instead, and takes them from the analytic tradition — the line running from Frege's logic [207] through the Vienna Circle [624] to the modern philosophy of science.

1.3.2 What the commitment amounts to

"Analytic" here names a method, not a creed, and the method reduces to five working rules.

1. **Logical form, not grammatical form.** A well-formed sentence need not pose a well-formed question. "What is the temperature of this single molecule?" is impeccable English and has no answer, because temperature is a property of an ensemble in equilibrium and of nothing else (Chapter 55). Before a question is answered it is worth asking what would count as an answer.

2. **To explain is to derive.** A phenomenon is explained when it is exhibited as a consequence of premises that are stated in full [915]. That is editorial rule 2 of this treatise in one sentence, and it is why an unproved claim here is marked as pending rather than covered by a plausible-sounding paragraph: the premise list is either complete or it is visibly not.

3. **Content through procedure.** A quantity that no procedure could measure carries no empirical content [565]. Hence the fixed structure of every experiment box — apparatus, procedure, data with uncertainties — and hence the axiomatic status of the SI (Chapter 2). The strong form of this rule, which *identifies* a quantity with one procedure, is too strong and was abandoned: thermodynamic temperature is fixed by the agreement of gas thermometry, radiation pyrometry and Johnson-noise thermometry, not by any one of them (Chapter 54). What survives is the demand that at least one procedure exist and that all of them agree.

4. **Convention separated from content.** Parts of any theory are decisions rather than discoveries [309], and the stipulations that tie a formalism to measurements — Reichenbach's coordinative definitions [619] — must be declared as such. Which coordinates, which gauge, which metric signature, which unit system: none of these is measured. The empirical content is what stays invariant when they are varied. This is why the SI is imposed by axiom and labelled a convention, and why Part II is written for signature (p, q) instead of quietly building $3 + 1$ into the mathematics.

5. **Triage before answer.** Every question is first sorted: empirical, to be settled by measurement; conventional, to be settled by stipulation and then recorded; or defective, to be repaired or dropped. Delivering that verdict is a result, not an evasion — "the aether's rest frame" was disposed of in the third category (Chapter 37).

1.3.3 Why this tradition and not another

Three reasons of principle, and a fourth of practice.

It was built out of this material. Analytic philosophy is the only school formed in direct response to the crises of physics and mathematics between 1880 and 1930. Mach's critique of absolute space [225] is part of the prehistory of general relativity; Einstein's operational dissection of simultaneity is conceptual analysis performed by a physicist (Chapter 38), and he stated the methodology explicitly [473]: "insofar as the propositions of mathematics refer to reality, they are not certain; and insofar as they are certain, they do not refer to reality." Frege's new logic, and the paradox that struck it, opened the foundational crisis (Section 3.6); the Vienna Circle assembled around relativity and the new quantum theory [624]; Reichenbach's philosophy of space and time [619] is also a technical treatment of the conventionality of simultaneity. The working vocabulary of a careful physicist — operational definition, auxiliary hypothesis, underdetermination, model error as distinct from statistical error — is that tradition's vocabulary. Adopting it costs no translation.

Its results occasionally become physics. The traffic runs both ways, and this is the strongest single argument for the choice. Einstein, Podolsky and Rosen raised a philosophical objection to the completeness of quantum mechanics [753]; Bell converted the objection into an inequality between measurable correlations [1271] (Chapter 84); experiment then decided it, against local hidden variables (Chapter 89). A tradition that can promote a metaphysical dispute into a laboratory result has demonstrated the only credential this treatise recognizes.

It audits itself to destruction. Its central doctrine was proposed, refuted and abandoned in public. The verification principle fails its own test; Duhem showed that no hypothesis meets experience alone [325] and Quine generalized the holism until the analytic–synthetic distinction went with it [987]; Popper replaced verifiability by falsifiability [1173]; Kuhn supplied the historical objection [1233]; Lakatos replaced the single falsifiable theory by the progressive or degenerating research programme [1428]; and from inside mathematics Gödel ended the dream of complete formalization [681]. The full sequence is set out in Section 3.7, with what remains of it in Section 3.7.3. What matters here is the pattern: a book whose own rule is that no assertion stands without its derivation cannot consistently adopt a philosophy that exempts itself from that treatment.

It yields the decisions this book must make. Beyond provenance and self-audit, the tradition supplies standards for choices that recur on every page: whether a subject is admissible (testability); whether an explanation is finished (derivation from stated premises);

how a superseded theory relates to its successor — as a limit case with a stated domain of validity rather than as an error, so that Newtonian mechanics survives inside relativity and quantum mechanics [1214] (Chapters 40 and 77); and how a theory relates to its mathematics, namely as a class of mathematical models together with a rule mapping some of their features onto measurements [1193]. That last one is literally the architecture of this book: Part II builds the structures, and the physical parts supply the interpretation and the measured numbers.

1.3.4 What the alternatives would cost

Four alternatives deserve naming. None is dismissed as foolish; each is declined for a stated reason.

1. **A priori metaphysics** — determining the structure of Nature by reason in advance of measurement. Its track record in physics is the argument against it: Aristotle's natural places, Descartes' vortices, Kant's Euclidean space and absolute simultaneity as preconditions of any possible experience, all refuted by measurement (Part IV). Where a priori reasoning has succeeded in physics it did so as symmetry argument (Chapter 21) — and symmetry claims are empirical, as parity discovered when an experiment found it violated (Chapter 110). Accepting this alternative would license precisely what editorial rule 1 excludes.

2. **Phenomenological and hermeneutic traditions.** Their questions are real ones: how a scientific object is constituted in experience, how a practice is situated in its history. But they yield no procedure for deciding whether a given claim belongs in a physics book, and no account of when a derivation is complete. They are not false; they are the wrong instrument for this particular job.

3. **History- and sociology-first accounts** [1233, 1544]. As description these are substantially right, and the five-station cycle of Section 1.4 is an idealization that says so. Feyerabend's demonstration that no proposed rule of method has gone unviolated in some successful episode is accepted here without reserve. The reply is that this treatise legislates presentation, not discovery: how a result was found may be as anarchic as the record shows, but what is asserted in a book still has to come with its evidence, its premises and an admission of what remains unproven.

4. **Instrumentalism and constructive empiricism** [1652]. This is not a rival method but an answer, within the same tradition, to a question the treatise deliberately leaves open: whether the unobservable structures of a successful theory are real or are devices for organizing observations. Where that dispute acquires observable consequences it is treated as experimental (Chapter 89); where it does not, the competing readings are reported and the matter is left there (Chapter 85).

1.3.5 The price of the choice

The tradition's failures are part of the reason to trust it, and they are inherited along with the method.

1. **No sharp line of demarcation.** Holism guarantees that any prediction can be rescued by adjusting an auxiliary hypothesis, so testability is a policy applied case by case with the reasons given, not a decision procedure. The dark sector is treated as physics because it has independent quantitative signatures in several channels (Chapter 134); programmes with no such signature are named once, to record that absence honestly (Chapters 133 and 135).

2. **No theory-free observation.** Every number in this book was produced by an apparatus modelled with theory, so the observational base is not neutral ground (Chapter 2). The response is disclosure — apparatus, procedure, calibration and uncertainty budget in every experiment box — not the pretence of raw data.

3. **No complete formalization.** Axiomatization is a tool with a proven ceiling [681]. It is used where it earns its keep (Chapters 77 and 109) and not imposed elsewhere for appearances.

4. **No theory of discovery.** Logical reconstruction is not history: derivations here are ordered for validity, not chronology, and Planck's radiation law was a successful fit years before anyone could say why it worked (Chapter 68). Where the order of discovery carries the lesson, it is recorded in the experiment chapters rather than smuggled into the proofs.

1.3.6 How the choice shows on the page

The commitment is not decorative; it is the reason this book has the shape it has. The numbers below are those of the five rules in Section 1.3.2.

- *Phenomenon* boxes state what was observed, with its uncertainty — rule 3.
- *Experiment* boxes carry a fixed field structure, so that the procedure giving each term its content is on the page and not in the reader's imagination — rule 3, made procedural.
- Definitions and axioms are declared before use, and conventions are labelled conventions rather than presented as findings — rule 4.
- Every phenomenon carries its derivation, or a visible *pending derivation* marker collected in a front-matter list — rule 2, and the bookkeeping that holism demands.
- Sources are cited so that a reader can retrieve them and check the claim independently; where a source cannot be retrieved, that fact is recorded rather than hidden — rule 2 applied to the evidence base.
- Where no observation discriminates between competing readings, the treatise stops (Chapter 85) — rule 5.

Remark 1.1. The commitment is methodological, not partisan. No physical result in this book depends on it: the Lorentz transformations, the mass of the Higgs boson and the CMB power spectrum are what they are under any philosophy. What depends on it is everything editorial — what was included, what was allowed to count as a derivation, what was left out and for which reason — and that is exactly the part a reader cannot check against Nature, and must therefore be told.

1.4 The scientific method as used in this treatise

The working cycle of physics, as this treatise practices it, has five stations.

1. **Phenomenon.** Something is observed, reproducibly, with stated apparatus and stated uncertainty. In the text, such facts are boxed in the *Phenomenon* environment.

2. **Model.** A mathematical structure is proposed whose solutions mimic the phenomenon. Its assumptions are listed explicitly.

3. **Derivation.** The phenomenon is *proven* to follow from the model. This treatise's first editorial rule is that this step is never skipped: every Phenomenon carries its derivation inline, in Appendix A, or — when not yet written — as a visibly marked pending derivation.

4. **Prediction.** The model is pushed beyond the data that motivated it, into statements that could fail.

5. **Experiment.** The prediction is confronted with Nature, in an experiment reported with apparatus, procedure, data, and uncertainty — the fixed structure of every *Experiment* box in this book. A failed confrontation sends the cycle back to station 2 with the failure as new input.

Galileo's inclined planes [4] already exhibit the full cycle, and Newton's *Principia* [14] is its first complete monument: observed regularities (Kepler's laws), a model (three laws of motion and universal gravitation), derivations, and predictions reaching to the tides. The cycle has not changed since; only the precision has, from Galileo's pulse beats to the 10^{-18} m displacement sensitivity of a gravitational-wave interferometer.

Remark 1.2. The method never certifies a theory as true; it certifies survival under attempted refutation [1173]. Newtonian gravity survived for two centuries before the perihelion of Mercury and the bending of starlight retired it to the status of a limit case (Chapter 42). Every theory in this treatise, including the best-tested ones, is to be read with that clause attached.

1.5 Primitive notions

Every deductive structure must start from undefined terms. Physics is no exception; the following notions are taken as primitives, sharpened but never fully defined by the theories built on them.

Definition 1.3 (System)**.** A *system* is the part of Nature under study, conceptually separated from the rest (its *environment*) by a stated boundary. The separation is a choice of the physicist, and a fallible one: much of thermodynamics and of quantum measurement theory is the study of what that boundary costs.

Definition 1.4 (State)**.** The *state* of a system is the minimal set of data that, together with the dynamical laws, determines the outcome statistics of every measurement that can be performed on it. What data suffice is itself a physical discovery: a point in phase space classically (Chapter 22), a ray in Hilbert space quantum mechanically (Chapter 77).

Definition 1.5 (Space and time)**.** *Space* is the catalogue of possible coincidences of systems; *time* the ordering of events along a system's history. Both enter pre-relativistic physics as an absolute stage (Chapter 18) and are demoted to dynamical, observer-dependent structure by relativity (Parts IV and V).

Definition 1.6 (Particle and field)**.** A *particle* is a system idealized as carrying its full state at a single spatial point; a *field* is a system whose state assigns data to every point of space. The deepest lesson of twentieth-century physics is that the second notion is the fundamental one, the first emerging as its quantized excitations (Part XI).

Definition 1.7 (Law and theory)**.** A *law* is a compact statement of an observed regularity, valid in a stated domain. A *theory* is a deductive structure from which many laws follow, together with the specification of its own domain of validity. Neither term implies certainty; both are graded by the evidence recorded in their experiment boxes.

1.6 How this treatise is organized

Three threads are interwoven throughout. *Mathematical physics* (Part II) develops the language once, in general dimension, so that no later part need pause for it. *Theoretical physics* (Parts III to XIII) builds the models and carries out the derivations. *Experimental physics* lives inside the theory parts as dedicated experiment chapters placed immediately after the theory each experiment tests, and is indexed globally by the List of Experiments in the front matter. Two conventions bind all three threads: SI units are used axiomatically everywhere (Chapter 2), and no observed phenomenon is left without its derivation or an explicit admission that the derivation is pending.

Remark 1.8 (The logical structure is itself a checked object). The chains this organization promises — axiom or postulate to definition, theorem and equation, to observed phenomenon, to the experiment that tests it, to the source that reports it — are not left to the prose. They are maintained alongside the text as a knowledge base in two presentations at once: a relational one (entity tables of the objects just named, with primary and foreign keys, plus junction tables for the many-to-many relations) and a property multigraph (every object a node; every non-empty foreign-key cell and every junction row an edge of a declared type). The two are one dataset presented twice: objects and nodes are in bijection, so are relationship instances and edges, either presentation rebuilds the other, and every consistency rule is computed in both languages — as relational algebra and as graph traversal — with the verdicts required to agree. That correspondence is developed in a manuscript in preparation [2433], an unpublished self-citation the reader cannot yet retrieve; nothing here depends on it, because the equivalence just stated is verified mechanically over this book's own data on every build, and the verification is published with the book's validation report.

Chapter 2

Measurement, SI Units, and the Theory of Errors

2.1 Measurement

A *measurement* is a physical interaction between a system and an apparatus whose outcome is a number (or a set of numbers) together with a unit and a statement of uncertainty. All three components are mandatory: a number without a unit does not identify a quantity, and a number without an uncertainty does not identify how strongly it constrains a theory [1945, 2129]. The quantity a measurement intends to determine is called the *measurand*.

Definition 2.1 (Physical quantity)**.** A *physical quantity* is a property of a system that can be compared quantitatively with a reference property of the same kind, the *unit*. The result of the comparison is the *numerical value*, so that every quantity Q decomposes as $Q = \{Q\}\,[Q]$ with $\{Q\}$ a real number and $[Q]$ the unit.

2.2 The International System of Units

Axiom 2.2 (SI)**.** All physical quantities in this treatise are expressed in the International System of Units (SI), in every branch of physics.

Since the 2019 revision, the SI is defined not by artefacts but by fixing the exact numerical values of seven defining constants — the caesium hyperfine frequency $\Delta\nu_{\mathrm{Cs}}$, the speed of light c, the Planck constant h, the elementary charge e, the Boltzmann constant k, the Avogadro constant N_A, and the luminous efficacy K_{cd} — from which the seven base units (second, metre, kilogram, ampere, kelvin, mole, candela) are derived [2333]. The complete tables, with the CODATA 2018 values of the remaining measured constants, are collected in Appendix B [2392].

Two practical consequences of Axiom 2.2 run through the whole treatise. First, equations keep their constants: c, G, $\hbar$ and k are never set to one, so every formula can be evaluated against an experiment without unit bookkeeping. Where a natural-unit shortcut is genuinely illuminating it appears inside a flagged remark with the conversion stated. Second, every reported number carries its unit through the typography itself, e.g. $g_0 = 9.806\,65\,\mathrm{m/s^2}$ (exact, by convention [2333]).

2.2.1 Dimensional analysis

Every physical quantity has a *dimension*, a formal product of powers of the base dimensions $\mathsf{T}, \mathsf{L}, \mathsf{M}, \mathsf{I}, \Theta, \mathsf{N}, \mathsf{J}$. An equation between quantities is admissible only if both sides carry the

same dimension; this trivial requirement is unreasonably powerful, because it constrains the possible form of an answer before any dynamics is solved.

Theorem 2.3 (Buckingham π theorem)**.** *Let a physical relation connect n quantities $q_1, \dots, q_n$ whose dimensions involve r independent base dimensions. Then the relation can be rewritten as a relation among $n - r$ independent dimensionless combinations $\pi_1, \dots, \pi_{n-r}$ of the q_i.*

Rests on Axiom 2.2.

Derivation. *Derives Theorem 2.3.*

Write the dimension of each q_i as an integer (or rational) exponent vector in the r-dimensional space of base dimensions. The map sending a monomial $q_1^{a_1} \cdots q_n^{a_n}$ to its dimension is linear in the exponents a_i, with matrix M of shape $r \times n$ and rank $r' \le r$. Dimensionless monomials are precisely the kernel of M, which by the rank–nullity theorem (Chapter 5) has dimension $n - r'$. Choosing a basis $\pi_1, \dots, \pi_{n-r'}$ of the kernel, any dimensionally consistent relation among the q_i, being invariant under independent rescalings of the base units, can depend on the q_i only through kernel monomials, hence is a relation among the π_j. With the customary assumption that the r base dimensions actually occur independently, $r' = r$. □

Example 2.4. For a pendulum of length ℓ, mass m, in gravity g, with period T: the four quantities involve $\mathsf{T}, \mathsf{L}, \mathsf{M}$, so there is $4 - 3 = 1$ dimensionless group, $\pi = T\sqrt{g/\ell}$. Dimensional analysis alone forces $T = C\sqrt{\ell/g}$ with C a pure number — mass cannot appear. Dynamics is needed only for $C = 2\pi$ (Chapter 28).

2.3 The theory of errors

No measurement returns the measurand exactly. The deviations are of two kinds, treated by two different disciplines.

Definition 2.5 (Random and systematic errors)**.** A *random error* varies unpredictably between repetitions of the measurement under nominally identical conditions; it is treated statistically, and shrinks under repetition. A *systematic error* biases every repetition the same way (a miscalibrated scale, a clock that runs slow); it is immune to repetition and must be hunted by varying the apparatus and the method. The corresponding quantitative statements are called *type A* and *type B* uncertainty evaluations [2129].

2.3.1 Repeated measurements

Let $x_1, \dots, x_N$ be independent repetitions of a measurement of a quantity whose true value is μ, each modelled as a random variable with mean μ and variance σ^2 (the probabilistic machinery is developed in Chapter 11).

Definition 2.6 (Sample mean and variance)**.**

$$\bar{x} = \frac{1}{N}\sum_{i=1}^{N} x_i\,, \qquad s^2 = \frac{1}{N-1}\sum_{i=1}^{N} (x_i - \bar{x})^2\,. \tag{2.1}$$

Theorem 2.7 (The mean improves as $1/\sqrt{N}$)**.** *$\bar{x}$ is an unbiased estimator of μ, and its standard deviation is $\sigma/\sqrt{N}$.*

Rests on Definition 2.6.

Derivation. *Derives Theorem 2.7.*

Linearity of the expectation gives $\langle \bar{x} \rangle = \frac{1}{N} \sum_i \langle x_i \rangle = \mu$. For the variance, since the x_i are independent, variances add:

$$\operatorname{var} \bar{x} = \frac{1}{N^2} \sum_{i=1}^{N} \operatorname{var} x_i = \frac{\sigma^2}{N} , \tag{2.2}$$

whence the standard deviation of the mean is $\sigma/\sqrt{N}$. An analogous computation shows $\langle s^2 \rangle = \sigma^2$, which is the reason for the $N - 1$ (Bessel) denominator. □

The standard uncertainty quoted for a type-A evaluation is therefore $u = s/\sqrt{N}$. The ubiquity of the Gaussian distribution for random errors is explained by the central limit theorem, proved as Theorem 11.46: a sum of many small independent disturbances tends to a Gaussian whatever the individual disturbances look like. The form that applies here is the Lindeberg–Feller one (Theorem 11.48), since the disturbances acting on a measurement — a thermal drift, a vibration, a quantisation step, a reading error — are independent but certainly not identically distributed.

Two hypotheses of that theorem are worth keeping in view, because a measurement can violate either. The contributions must have finite variance: a heavy-tailed error source need not average down at all (Remark 11.47). And none may dominate — Theorem 11.48 implies that every individual source contributes a vanishing fraction of the total variance, so a single dominant source defeats its hypothesis. The converse does not hold, and the theorem is not a licence to argue backwards: failing the condition does not by itself make the total non-Gaussian, and satisfying every variance share is not enough on its own.

The rate of approach is $O(M^{-1/2})$ in the number M of contributing sources, by the Berry–Esseen bound Equation (11.40) — which additionally assumes a finite third absolute moment. That bound is uniform in the deviation, so it constrains the *absolute* error of the Gaussian approximation equally everywhere; in the tails, where the probability being approximated is itself tiny, the *relative* error is correspondingly larger. Since a coverage factor $k = 3$ is a claim about a tail probability, it deserves more caution than the same approximation applied near the centre.

2.3.2 Propagation of uncertainty

Derived quantities inherit uncertainty from their inputs.

Theorem 2.8 (First-order propagation)**.** *Let $f(x_1, \dots, x_n)$ be differentiable, and let the x_i be independent measurements with standard uncertainties u_i small enough that f is approximately linear over their spread. Then the standard uncertainty of $y = f(x_1, \dots, x_n)$ is*

$$u_y^2 = \sum_{i=1}^{n} \left(\frac{\partial f}{\partial x_i} \right)^2 u_i^2 . \tag{2.3}$$

Derivation. *Derives Theorem 2.8.*

Expand f to first order about the means, $y - \langle y \rangle \approx \sum_i \frac{\partial f}{\partial x_i}(x_i - \langle x_i \rangle)$. Squaring and taking expectations, the cross terms $\langle (x_i - \langle x_i \rangle)(x_j - \langle x_j \rangle) \rangle$ vanish for $i \neq j$ by independence, leaving exactly Equation (2.3). For correlated inputs the covariances reappear as $2 \sum_{i<j} \frac{\partial f}{\partial x_i} \frac{\partial f}{\partial x_j} \operatorname{cov}(x_i, x_j)$ [2129]. □

Corollary 2.9 (Quotients and powers)**.** *For $y = x_1^{a_1} \cdots x_n^{a_n}$, relative uncertainties combine as $(u_y/y)^2 = \sum_i a_i^2 \, (u_i/x_i)^2$.*
Rests on Theorem 2.8.

Derivation. *Derives Corollary 2.9.*

Apply Theorem 2.8 to $\ln y = \sum_i a_i \ln x_i$, for which $\partial \ln y / \partial \ln x_i = a_i$. □

2.3.3 Combining and fitting data

Theorem 2.10 (Weighted mean)**.** *Given independent measurements x_i of the same quantity with uncertainties u_i, the linear combination of minimal variance is*

$$\hat{x} = \frac{\sum_i x_i/u_i^2}{\sum_i 1/u_i^2}\,, \qquad u_{\hat{x}}^2 = \left(\sum_i \frac{1}{u_i^2}\right)^{-1}. \tag{2.4}$$

Rests on Theorem 2.7.

Derivation. *Derives Theorem 2.10.*

Seek $\hat{x} = \sum_i w_i x_i$ with $\sum_i w_i = 1$ (unbiasedness) and $\operatorname{var}\hat{x} = \sum_i w_i^2 u_i^2$ minimal. With a Lagrange multiplier λ (Chapter 21 uses the same device for constraints), $\partial_{w_i}\left[\sum_j w_j^2 u_j^2 - \lambda\left(\sum_j w_j - 1\right)\right] = 0$ gives $w_i = \lambda/(2u_i^2)$; the constraint fixes λ, yielding Equation (2.4), and substitution gives the stated variance. □

Theorem 2.11 (Least-squares line)**.** *Given points (x_i, y_i), $i = 1, \dots, N$, with equal uncertainties on the y_i and negligible uncertainty on the x_i, the line $y = a + bx$ minimizing $\chi^2 = \sum_i (y_i - a - bx_i)^2$ has*

$$b = \frac{\overline{xy} - \bar{x}\,\bar{y}}{\overline{x^2} - \bar{x}^2}\,, \qquad a = \bar{y} - b\,\bar{x}\,, \tag{2.5}$$

where overbars denote sample means.

Rests on Definition 2.6.

Derivation. *Derives Theorem 2.11.*

$\partial_a \chi^2 = -2\sum_i (y_i - a - bx_i) = 0$ gives $\bar{y} = a + b\bar{x}$; $\partial_b \chi^2 = -2\sum_i x_i(y_i - a - bx_i) = 0$ gives $\overline{xy} = a\bar{x} + b\overline{x^2}$. Solving the two linear equations yields Equation (2.5). The second-derivative matrix is positive definite (its determinant is proportional to the variance of the x_i), so the extremum is the minimum. □

2.3.4 Reporting

A result is reported as $y = (\hat{y} \pm u)\,[\,\text{unit}\,]$, the uncertainty with at most two significant figures and the value rounded to match. Where higher confidence is wanted, an expanded uncertainty $U = k\,u$ is quoted with the *coverage factor* k stated ($k = 2$ covers about 95 % for a Gaussian) [2129]. When an experiment box in this treatise quotes asymmetric bounds (as the gravitational-wave observations of Chapter 47 do), they are the bounds of the quoted posterior interval of the discovery analysis.

2.4 A worked example: timing a pendulum

Suppose a pendulum of length $\ell = (0.9500 \pm 0.0005)\,\text{m}$ swings with small amplitude, and 50 periods are timed five times with a stopwatch reading to 0.01 s: $T_{50} = 97.81\,\text{s}$, $97.95\,\text{s}$, $97.73\,\text{s}$, $98.02\,\text{s}$, $97.89\,\text{s}$. The sample mean is $\bar{T}_{50} = 97.88\,\text{s}$ with $s = 0.11\,\text{s}$, so $u_{\bar{T}_{50}} = s/\sqrt{5} = 0.05\,\text{s}$, and the period is $T = (1.9576 \pm 0.0010)\,\text{s}$. With $T = 2\pi\sqrt{\ell/g}$ (derived in Chapter 28), $g = 4\pi^2\ell/T^2$; Corollary 2.9 gives

$$\frac{u_g}{g} = \sqrt{\left(\frac{u_\ell}{\ell}\right)^2 + \left(2\,\frac{u_T}{T}\right)^2} \approx 1.2 \times 10^{-3}\,, \tag{2.6}$$

so $g = (9.79 \pm 0.01)\,\text{m/s}^2$ — consistent with the local value and eight orders of magnitude less precise than the ballistic gravimetry of Section 20.4, which is the same physics with the error budget engineered down [1906, 1945].

Part II

Mathematical Methods

Chapter 3

Logic, Sets, and Maps

Propositional logic, sets, maps, and equivalence classes form the raw language in which the rest of this treatise is written. This chapter fixes that language: what we mean by a definition, an axiom, and a theorem; how propositions combine under logical operators; what sets, numbers, and maps are; and how an equivalence relation partitions a set into classes.

The chapter then turns the language on itself. Comparing infinite sets uncovers a strict hierarchy of infinities (Section 3.5); unrestricted set-building collapses in Russell's paradox, and the Zermelo–Fraenkel axioms repair it (Section 3.6); Hilbert's demand that mathematics certify its own consistency, completeness, and decidability is answered — negatively — by Gödel's incompleteness theorems (Section 3.8) and by Turing's analysis of computation (Section 3.9). We close by asking, with the full twentieth-century record on the table, whether mathematics can be built free of contradiction, and what the honest answer means for a book that intends to derive physics from evidence and proof (Section 3.10). A physics treatise owes its readers this chapter: every derivation in the book is a formal proof in the sense made precise here, and the limits of that method are part of its description.

3.1 Logic

3.1.1 Propositions

Definitions

The definition of the word *definition* is redundant in an obvious sense. We could say instead: the accepted meaning of *definition* is... — but then, what is the definition of *accepted meaning*? Better still: what is *something*? And beyond that: why does something exist? Whenever we try to reach a primordial question we run into problems, circular loops, and paradoxes. To avoid entering into philosophical discussion (though such discussion is never wasted), we simply adopt the dictionary meaning [2236]: a *definition* is a declarative sentence that states with clarity and exactness the generic and specific characteristics of something, concrete or abstract.

In mathematical notation, when we wish to record a definition — that is, when an equality holds not as the result of other equalities but by fiat — we use the symbol :=. For example, let $\Diamond$ be an object. We define $\blacklozenge$ by $\blacklozenge := \Diamond^{-1}$, and we define $\Diamond\Diamond^{-1}$ by $\Diamond\Diamond^{-1} := \circlearrowleft$. Every time the object $\blacklozenge$ appears we may replace it by $\Diamond^{-1}$, since by definition they are exactly the same thing, and likewise we may replace $\Diamond\Diamond^{-1}$ by $\circlearrowleft$. For instance,

$$\Diamond\blacklozenge = \Diamond\Diamond^{-1} = \circlearrowleft \ .$$

A definition need not be a fundamental truth. However, for an idea built from definitions — together with the observations made upon them — to be consistent, a definition must be

irrevocable within its context (at least, this book demands it). We cannot build an idea on definitions that we later change, much less on new definitions that contradict the earlier ones. In what follows, the definitions we give will not be dictionary entries but will be tailored to the studies we undertake.

Generalization and specification of a definition

It is often necessary to extend a definition so that it covers more concepts; when this happens one usually renames the definition to fit the new context. As a toy example, define first a *hydroliving* object as an object that lives on Earth and contains at least ten hydrogen atoms. We ourselves are then hydroliving objects. Now extend the definition to an object living anywhere in the Milky Way that contains at least ten hydrogen atoms, which we call *locally hydroliving*: we have generalized the definition, and we are locally hydroliving. We may also *sharpen* the parameters of a definition, cutting down the candidates that satisfy it: call *submarine hydroliving* a hydroliving object that is born, lives, and reproduces in the sea.

We call *generalization* and *specification* of a definition, respectively, the definitions obtained by enlarging or reducing the set of candidates satisfying the original one. Both notions are relative to the aspect of the definition being modified; for example, one may generalize and specify simultaneously by defining a *locally hydrolivoid* object as one living in the Milky Way but containing at least 1 000 000 hydrogen atoms.

Definition 3.1 (Logical proposition)**.** A *logical proposition* p (or simply a proposition) is a declarative sentence that can be only one of two ways: true or false. The quality of a proposition of being true or false is its *truth value*, which we denote by T if true and F if false.

For example, let $p =$ "Albert Einstein was born in 1879". The truth value of p is T, since that is indeed what happened. Let $q =$ "Paul Adrien Maurice Dirac was born in 1790". The truth value of q is F, because Dirac was born in 1902.

Definition 3.2 (Axiom)**.** An *axiom* is a proposition assumed irrevocably true.

An axiom, accompanied by the pertinent definitions, allows one to build a self-consistent idea (not necessarily consistent with other ideas). The word *axiom* is used in mathematics; in physics one uses, depending on the importance of the proposition in its context, the words *law*, *principle*, or *postulate*. As an example, let $\ltimes$ be given and define $\rtimes := -\ltimes$. Separately, enunciate the axiom $-(-\ltimes) = \ltimes$. We conclude a new, consistent statement: $-\rtimes = \ltimes$.

Definition 3.3 (Theorem)**.** Within a context of axioms and definitions, a *theorem* is a proposition whose truth value has been demonstrated.

In the preceding example it is a theorem that $-\rtimes = \ltimes$. In the literature it is not customary to call every demonstrated result a theorem: depending on the relevance of the result one speaks of a *theorem*, a *lemma*, a *corollary*, or even a *proposition* — the last not to be confused with a logical proposition.

Definition 3.4 (Theory)**.** A *theory* is an agglomeration of axioms, definitions, theorems, and interpretations of results that model the behaviour of a concrete or abstract entity, and whose good correspondence between model and results is vouched for by us as human beings, through our senses and available technology.

3.1.2 Logical operators

Given a proposition, we can form new propositions from it. For example, let $p =$ "It is raining outside". The truth value of p is not settled — until we look outside we

do not know whether it is raining — but from p we may consider the proposition q = "It is not raining outside". Moreover, given the proposition r = "I put on a coat", from p and r we can form s = "If it is raining outside, then I put on a coat".

Definition 3.5 (Logical operator)**.** A *logical operator* is an entity that takes one or more propositions and generates a new proposition.

Definition 3.6 (Truth table)**.** The truth value of a proposition generated by a logical operator is a function of the truth values of the propositions that generate it. The table of all possible truth values of the generated proposition is its *truth table*.

In the trivial case, the truth table of a single proposition p is

p
T
F

(3.1)

Definition 3.7 (Negation)**.** Let p be a proposition. The *negation* operator $\neg$ takes p into the proposition

$$\neg p = \text{"It is not true that } p\text{"}\,, \tag{3.2}$$

whose truth table is

p	$\neg p$
T	F
F	T

(3.3)

For example, let p = "Today is Monday". Its negation is

$$\neg p = \text{"It is not true that today is Monday"}\,,$$

which we read more naturally as "Today is not Monday". According to the table, if it is true that today is Monday, then it is false that today is not Monday; conversely, if it is false that today is Monday, it is true that today is not Monday.

Definition 3.8 (Conjunction)**.** Let p and q be propositions. The *conjunction* operator $\wedge$ takes p and q into the proposition

$$p \wedge q = p \text{ and } q\,, \tag{3.4}$$

whose truth table is

p	q	$p \wedge q$
T	T	T
T	F	F
F	T	F
F	F	F

(3.5)

For example, let p = "I am in Asia" and q = "I am in Africa". Then $p \wedge q$ = "I am in Asia and I am in Africa". Common sense tells us it is impossible to be in two places at once, i.e. $p \wedge q$ is false. According to the table this may be because it is false that I am in Asia, false that I am in Africa, or false that I am in either place.

Definition 3.9 (Disjunction)**.** Let p and q be propositions. The *disjunction* operator $\vee$ takes p and q into the proposition

$$p \vee q = p \text{ or } q\,, \tag{3.6}$$

whose truth table is

p	q	$p \vee q$
T	T	T
T	F	T
F	T	T
F	F	F

(3.7)

For example, let $p =$ "I will arrive at 8:00" and $q =$ "I will arrive at 8:05". Then $p \vee q =$ "I will arrive at 8:00 or at 8:05".

Definition 3.10 (Exclusive disjunction)**.** The *exclusive disjunction* operator $\veebar$ generates the proposition $p \veebar q$ with truth table

p	q	$p \veebar q$
T	T	F
T	F	T
F	T	T
F	F	F

(3.8)

Definition 3.11 (Conditional)**.** Let p and q be propositions. The *conditional* operator $\rightarrow$ takes p and q into the proposition

$$p \rightarrow q = \text{"If } p\text{, then } q\text{"}\,, \tag{3.9}$$

whose truth table is

p	q	$p \rightarrow q$
T	T	T
T	F	F
F	T	T
F	F	T

(3.10)

For example, let $p =$ "Today is Sunday" and $q =$ "Today I will rest". Then $p \rightarrow q =$ "If today is Sunday, then I will rest". From the table: if today really is Sunday but it is false that I will rest, then it is indeed false that "if today is Sunday, then I will rest". On the other hand, if today is not Sunday but I do rest anyway, the conditional stands. Even if today is neither Sunday nor a day I rest, the proposition is true, because my not resting on a non-Sunday takes nothing away from my resting when Sunday does come.

Definition 3.12 (Biconditional)**.** Let p and q be propositions. The *biconditional* operator $\leftrightarrow$ takes p and q into the proposition

$$p \leftrightarrow q = p \text{ if and only if } q\,, \tag{3.11}$$

whose truth table is

p	q	$p \leftrightarrow q$
T	T	T
T	F	F
F	T	F
F	F	T

(3.12)

For example, let $p =$ "Wake me up" and $q =$ "It is 10:00". Then $p \leftrightarrow q =$ "Wake me up if and only if it is 10:00".

Definition 3.13 (Logical expression)**.** A *logical expression* is a proposition composed of propositions and logical operators.

For example, given propositions p and q, a logical expression is

$$s = \neg p \wedge (p \to q)\,. \tag{3.13}$$

The expression s can take various truth values depending on the truth values of p and q. Let us build its truth table. First, from Equation (3.3),

p	$\neg p$
T	F
T	F
F	T
F	T

From Equation (3.10),

p	q	$p \to q$
T	T	T
T	F	F
F	T	T
F	F	T

Then, from Equation (3.5),

$\neg p$	$p \to q$	$\neg p \wedge (p \to q)$
F	T	F
F	F	F
T	T	T
T	T	T

3.1.3 Implications and logical equivalences

Definition 3.14 (Tautology)**.** A logical expression is a *tautology* if all of its possible truth values are T.

Definition 3.15 (Contradiction)**.** A logical expression is a *contradiction* if all of its possible truth values are F.

Definition 3.16 (Contingency)**.** A logical expression is a *contingency* if among its possible truth values we find both truths and falsehoods.

All the logical operators above generate propositions that are contingencies, as their truth tables show. Indeed, any single proposition is a contingency, since it can be true or false. A more elaborate example is the expression defined in Equation (3.13).

Definition 3.17 (Logical equivalence)**.** Two logical expressions s and t built from the same propositions are *logically equivalent*, written $s \equiv t$, if and only if the expression $s \leftrightarrow t$ is a tautology — equivalently, if and only if s and t have identical truth tables.

Rests on Definitions 3.12 and 3.14.

Remark 3.18 (Object language and metalanguage). The distinction between $\leftrightarrow$ and $\equiv$ is not pedantry, and it will matter a great deal in Section 3.8. The connective $\leftrightarrow$ belongs to the language we are studying: it builds one proposition out of two. The symbol $\equiv$ belongs to the language in which we *talk about* that language, and asserts a fact about truth tables. The first is called the *object language*, the second the *metalanguage*. The same split separates $\to$ from $\Longrightarrow$ and, later, provability from truth. Confusing the two levels is the single most common way to misread Gödel's theorems.

Proposition 3.19 (Conditional as disjunction)**.** *For any propositions p and q,*

$$(p \to q) \equiv (\neg p \vee q)\,. \tag{3.14}$$

Rests on Definitions 3.7, 3.9, 3.11 and 3.17.

Proof. *Derives Proposition 3.19.*

Both expressions are built from the same two propositions, so both truth tables have the same four rows. Reading $\neg p$ from Equation (3.3), $p \to q$ from Equation (3.10) and $\neg p \vee q$ from the disjunction table,

p	q	$\neg p$	$p \to q$	$\neg p \vee q$
T	T	F	T	T
T	F	F	F	F
F	T	T	T	T
F	F	T	T	T

The fourth and fifth columns agree row by row, so $(p \to q) \leftrightarrow (\neg p \vee q)$ takes the value T in every row and is a tautology. □

Proposition 3.20 (De Morgan's laws)**.** *For any propositions p and q,*

$$\neg(p \wedge q) \equiv \neg p \vee \neg q\,, \tag{3.15}$$

$$\neg(p \vee q) \equiv \neg p \wedge \neg q\,. \tag{3.16}$$

Rests on Definitions 3.7 to 3.9 and 3.17.

Proof. *Derives Proposition 3.20.*

Tabulate all four rows at once:

p	q	$\neg(p \wedge q)$	$\neg p \vee \neg q$	$\neg(p \vee q)$	$\neg p \wedge \neg q$
T	T	F	F	F	F
T	F	T	T	F	F
F	T	T	T	F	F
F	F	T	T	T	T

Columns three and four agree, and so do columns five and six. □

Proposition 3.21 (Contraposition)**.** *For any propositions p and q,*

$$(p \to q) \equiv (\neg q \to \neg p)\,. \tag{3.17}$$

Rests on Proposition 3.19 and Equation (3.3).

Proof. *Derives Proposition 3.21.*

By Proposition 3.19 applied to the right-hand side, $\neg q \to \neg p$ is equivalent to $\neg(\neg q) \vee \neg p$. Double negation gives $\neg(\neg q) \equiv q$ — immediate from Equation (3.3), read twice — so the right-hand side is equivalent to $q \vee \neg p$. Disjunction is symmetric in its two arguments, as its truth table shows, hence $q \vee \neg p \equiv \neg p \vee q$, which by Proposition 3.19 again is $p \to q$. □

The contrapositive $\neg q \to \neg p$ must not be confused with the *converse* $q \to p$, which is *not* equivalent to $p \to q$: rows two and three of Equation (3.10) differ under the exchange of p and q. Asserting the converse from the conditional is the fallacy of *affirming the consequent*, and it is a standing hazard in experimental physics: a theory p predicting an observation q is not confirmed as true by observing q, since some rival theory may predict the same q. What the observation of $\neg q$ does establish — by Equation (3.17) — is $\neg p$. This asymmetry between confirmation and refutation is the logical skeleton of falsificationism [1173] and of Remark 1.2.

Proposition 3.22 (Algebra of propositions)**.** *For any propositions p, q, r the following equivalences hold:*

$$\neg(\neg p) \equiv p\,, \tag{3.18}$$

$$p \wedge q \equiv q \wedge p\,, \qquad p \vee q \equiv q \vee p\,, \tag{3.19}$$

$$(p \wedge q) \wedge r \equiv p \wedge (q \wedge r)\,, \qquad (p \vee q) \vee r \equiv p \vee (q \vee r)\,, \tag{3.20}$$

$$p \wedge (q \vee r) \equiv (p \wedge q) \vee (p \wedge r)\,, \tag{3.21}$$

$$p \vee (q \wedge r) \equiv (p \vee q) \wedge (p \vee r)\,, \tag{3.22}$$

$$p \wedge p \equiv p\,, \qquad p \vee p \equiv p\,, \tag{3.23}$$

$$p \wedge (p \vee q) \equiv p\,, \qquad p \vee (p \wedge q) \equiv p\,, \tag{3.24}$$

$$p \vee \neg p \equiv T\,, \tag{3.25}$$

$$p \wedge \neg p \equiv F\,, \tag{3.26}$$

$$(p \leftrightarrow q) \equiv (p \to q) \wedge (q \to p)\,. \tag{3.27}$$

Rests on Definitions 3.6 and 3.17.

Proof. *Derives Proposition 3.22.*

Each is a finite truth-table check: the expressions involve at most three propositions, hence at most $2^3 = 8$ rows, and the two sides are compared row by row exactly as in Proposition 3.20. We display only the least mechanical one, the first distributive law Equation (3.21):

p	q	r	$q \vee r$	$p \wedge (q \vee r)$	$(p \wedge q) \vee (p \wedge r)$
T	T	T	T	T	T
T	T	F	T	T	T
T	F	T	T	T	T
T	F	F	F	F	F
F	T	T	T	F	F
F	T	F	T	F	F
F	F	T	T	F	F
F	F	F	F	F	F

The last two columns coincide. □

Equation (3.25) is the *law of the excluded middle*: a proposition is true or its negation is, with no third option. It is a theorem of the two-valued truth tables of Definition 3.1 precisely because we built those tables with two values. Whether it should be assumed when reasoning about infinite collections — where no finite inspection can decide which disjunct holds — is the point at which intuitionism parts company with classical mathematics (Section 3.6.4). This treatise reasons classically, and says so.

3.1.4 Predicates and quantifiers

Propositional logic is too coarse for mathematics or physics. The sentence "x is greater than 3" has no truth value until x is supplied; only then does it become a proposition. Such an incomplete sentence is a predicate, and completing it is what quantifiers do.

Definition 3.23 (Predicate)**.** A *predicate* P on a set X is a rule assigning to each $x \in X$ a proposition $P(x)$. The set of elements for which the proposition is true,

$$\{x \in X \mid P(x)\}\,, \tag{3.28}$$

is the *truth set* of P. Predicates of several variables, $P(x, y)$, $P(x, y, z), \ldots$, are defined in the same way on products of sets (Definition 3.38).

Rests on Definitions 3.1 and 3.38.

Definition 3.24 (Quantifiers)**.** Let P be a predicate on a set X. The *universal quantifier* $\forall$ and the *existential quantifier* $\exists$ build the propositions

$$\forall x \in X,\ P(x) = \text{“}P(x) \text{ is true for every } x \text{ in } X\text{”}, \tag{3.29}$$

$$\exists x \in X \mid P(x) = \text{“}P(x) \text{ is true for at least one } x \text{ in } X\text{”}. \tag{3.30}$$

We write $\exists!\, x \in X \mid P(x)$ — “there exists a unique x” — for the conjunction of $\exists x \in X \mid P(x)$ with the uniqueness clause $\forall x, x' \in X,\ (P(x) \wedge P(x')) \to x = x'$.

Rests on Definition 3.23.

Over a finite set $X = \{x_1, \dots, x_n\}$ the quantifiers are abbreviations for finite connectives,

$$\forall x \in X,\ P(x) \ \equiv\ P(x_1) \wedge \cdots \wedge P(x_n), \qquad \exists x \in X \mid P(x) \ \equiv\ P(x_1) \vee \cdots \vee P(x_n), \tag{3.31}$$

and this is the way to remember their negations: De Morgan's laws (Proposition 3.20) pass to the limit of infinite X, where the finite reading is no longer available but the rule survives,

$$\neg\,(\forall x \in X,\ P(x)) \equiv \exists x \in X \mid \neg P(x), \tag{3.32}$$

$$\neg\,(\exists x \in X \mid P(x)) \equiv \forall x \in X,\ \neg P(x). \tag{3.33}$$

To refute a universal claim one exhibits a single counterexample; to refute an existential claim one must argue about every element. This is why “no experiment has ever violated the second law” is a far weaker statement than “the second law holds”, and why the search for a violating experiment is nonetheless the right way to test it.

Remark 3.25 (The order of quantifiers is not free)*.* Quantifiers of the same kind commute; quantifiers of different kinds do not. The proposition

$$\forall \varepsilon > 0,\ \exists \delta > 0 \mid \cdots$$

allows δ to depend on ε, while

$$\exists \delta > 0 \mid \forall \varepsilon > 0,\ \cdots$$

demands one δ serving all ε at once, and is strictly stronger. The whole difference between continuity and uniform continuity, or between pointwise and uniform convergence, lives in that exchange (Chapter 7); so does the difference between a bound that holds for each energy and a bound that holds uniformly in energy.

3.1.5 Methods of proof

Every result asserted in this treatise carries a derivation, by editorial rule. The derivations use a small and closed repertoire of argument forms, each of which is a tautology of Proposition 3.22 put to work.

1. **Direct proof.** To establish $p \to q$, assume p and derive q by a chain of previously established implications. The underlying tautology is transitivity of the conditional, $((p \to r) \wedge (r \to q)) \to (p \to q)$, together with *modus ponens*, $(p \wedge (p \to q)) \to q$.

2. **Contraposition.** To establish $p \to q$, assume $\neg q$ and derive $\neg p$. Legitimate by Proposition 3.21. The proof of injectivity in Definition 3.45 uses exactly this move.

3. **Contradiction** (*reductio ad absurdum*). To establish p, assume $\neg p$ and derive a contradiction $q \wedge \neg q$, which is false by Equation (3.26); since a false conclusion cannot follow from a true assumption, $\neg p$ is false and, by Equation (3.18), p holds.

4. **Cases.** If $p_1 \vee \cdots \vee p_n$ is a tautology and each $p_i \to q$ has been proved, then q holds. The two-case version rests on Equation (3.25).

5. **Induction.** To establish $\forall n \in \mathbb{N},\ P(n)$, prove $P(1)$ and prove $\forall n \in \mathbb{N},\ P(n) \to P(n+1)$. This is not a tautology of propositional logic but an axiom about $\mathbb{N}$ — Axiom 3.34 below — and it is the one place where the structure of the natural numbers enters a proof.

6. **Counterexample.** To refute $\forall x \in X,\ P(x)$, exhibit one x with $\neg P(x)$, by Equation (3.32). One suffices; no number of confirming instances does the opposite job.

Example 3.26 (Irrationality of the square root of two)**.** Proof by contradiction, in its classical instance. Suppose $\sqrt{2} \in \mathbb{Q}$. Then there are $n, m \in \mathbb{Z}$ with $m \neq 0$ such that $\sqrt{2} = n/m$, and we may take the fraction in lowest terms, i.e. with n and m not both even. Squaring and clearing the denominator,

$$n^2 = 2m^2\,, \tag{3.34}$$

so n^2 is even. An odd $n = 2k+1$ has $n^2 = 2(2k^2+2k)+1$ odd, so by contraposition n is even: $n = 2j$ for some $j \in \mathbb{Z}$. Substituting into Equation (3.34) gives $4j^2 = 2m^2$, that is $m^2 = 2j^2$, and the same argument makes m even. Then n and m are both even, contradicting the choice of lowest terms. Hence $\sqrt{2} \notin \mathbb{Q}$, and the irrational numbers of Section 3.2.2 are not an optional embellishment of $\mathbb{Q}$ but a necessity forced by the diagonal of a unit square.

3.2 Sets

Set theory descends through Cantor, Frege, Russell, and Zermelo–Fraenkel. In what follows we shall not include all the formalism that the full theory demands; we give only the definitions, axioms, and theorems that allow us to understand the many aspects of mathematical physics whose properties we can link with nature.

3.2.1 Sets

Definition 3.27 (Element)**.** We consider an *element* x to be an object that satisfies some collection of logical propositions.

Definition 3.28 (Set)**.** A *set* is an abstract grouping of elements that satisfy the same logical propositions.

For example, the vowels form the set X given by

$$\begin{aligned} X &= \{x \mid x \text{ is a vowel}\} \\ &= \{a, e, i, o, u\}\ . \end{aligned}$$

Notation 3.29 (Membership). That x is an element of the set X is written $x \in X$; that it is not, $x \notin X$. Membership is the sole primitive relation of set theory: every other notion in this section is defined from it, from $\in$ and from the logical apparatus of Section 3.1. The two displays above illustrate the two ways of presenting a set — by *extension*, listing its elements, and by *comprehension*, giving a predicate (Definition 3.23) whose truth set it is.

Definition 3.30 (Subset)**.** Let X and Y be sets. We say X is a *subset* of Y, written $X \subset Y$, if and only if every element of X is an element of Y:

$$X \subset Y \iff \forall x \in X,\ x \in Y\,. \tag{3.35}$$

In particular, every set is a subset of itself. If $X \subset Y$ and $X \neq Y$ we call X a *proper* subset of Y.

Two sets are equal when they have the same elements, and nothing else about them counts: a set is determined by its extension alone. This is the *principle of extensionality*, and in the axiomatic treatment of Section 3.6.2 it is promoted to an axiom. It is what licenses the double-inclusion argument Equation (3.47) used throughout this book, and it is the reason $\{a, e, i, o, u\}$ and $\{e, a, u, i, o, a\}$ are the same set: order and repetition are features of the notation, not of the object.

Definition 3.31 (Empty set)**.** The *empty set* is the set with no elements, denoted $\varnothing$.

Every set has the empty set as a subset: the condition Equation (3.35) quantifies over the elements of $\varnothing$, of which there are none, so it holds vacuously — an instance of rows three and four of Equation (3.10). Extensionality makes the empty set unique, since any two sets with no elements have the same elements. That so much can be built from nothing at all is the first sign that the naive notion of set carries more weight than it looks able to bear; Section 3.6 shows where it breaks and how the Zermelo–Fraenkel axioms repair it.

Definition 3.32 (Trivial subsets)**.** Given a set X, it always has as subsets itself and the empty set. When it matters to refer to this fact, we call these the *trivial* subsets of X.

3.2.2 Numbers

Number theory is an essential branch of mathematics that studies the properties of numbers. We shall not define *number*; instead we explain a way of understanding the familiar number sets.

Natural numbers $\mathbb{N}$

The set known as the *natural numbers* is a set of numbers with which we can identify, for example, a quantity of whole objects. Concretely: take the proposition "a farmer owns cows", assumed true. We can then assert that the farmer has one, two, three, or more cows. The farmer cannot have infinitely many cows, for they would not fit in the world, and cannot have none, for that would be a contradiction. We write

$$\mathbb{N} = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, \ldots\} \,. \tag{3.36}$$

That description says what $\mathbb{N}$ is *for*, not what it *is*. The axiomatic characterization is Peano's [245], and it needs one undefined operation: the successor, "the next one after".

Axiom 3.33 (Peano axioms)**.** The natural numbers form a set $\mathbb{N}$ carrying a distinguished element $1 \in \mathbb{N}$ and a map $S : \mathbb{N} \longrightarrow \mathbb{N}$, called the *successor*, such that

1. 1 is not a successor: $\forall n \in \mathbb{N},\ S(n) \neq 1$;
2. distinct numbers have distinct successors, i.e. S is injective (Definition 3.45):

$$S(n) = S(m) \implies n = m \,.$$

The two clauses forbid the successor chain from closing back on itself, but by themselves they do not forbid stray elements sitting outside the chain $1, S(1), S(S(1)), \ldots$ altogether. Excluding those is the work of the fifth and deepest of Peano's axioms, which is also the licence for the induction proofs of Section 3.1.5.

Axiom 3.34 (Principle of induction)**.** Let P be a predicate on $\mathbb{N}$. If $P(1)$ holds and $\forall n \in \mathbb{N},\ P(n) \to P(S(n))$ holds, then $\forall n \in \mathbb{N},\ P(n)$. Equivalently, in the language of Definition 3.30: the only subset of $\mathbb{N}$ containing 1 and closed under S is $\mathbb{N}$ itself.

Addition and multiplication are then *defined* by recursion on the successor — $n+1 := S(n)$, $n+S(m) := S(n+m)$, $n \cdot 1 := n$, $n \cdot S(m) := n \cdot m + n$ — and every familiar arithmetic law is a theorem proved by induction. This matters beyond arithmetic: the axioms above, written in first-order logic with induction restricted to predicates expressible in that language, constitute *Peano arithmetic* (Definition 3.83), the theory whose incompleteness Gödel proved.

Integers $\mathbb{Z}$

The set known as the *integers* consists of the natural numbers together with a new element, the *number zero*, denoted 0, which quantifies the existence of nothing: given the proposition "a farmer owns no sheep", we say the farmer has zero sheep.

The set also contains, for each natural number, a dual element manifesting its opposite. Consider a sport played by two teams, where a team gains a point by stealing a banner from the other and loses a point when a banner is stolen from it. If a team has two banners stolen at the start, what is its score? Clearly it has gained nothing, but we intuit it holds something dual to the number 2 — something like "minus 2". Writing these dual numbers with the minus sign $-$ on the left, the set of integers is

$$\mathbb{Z} = \{\ldots, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, \ldots\} \ . \tag{3.37}$$

Several subsets of $\mathbb{Z}$ are heavily used in mathematics and physics. Among them:

1. *Even numbers*: the set

$$\{2n \mid n \in \mathbb{Z}\} = \{\ldots, -4, -2, 0, 2, 4, \ldots\} \ , \tag{3.38}$$

   that is, the set of all multiples of 2 (positive and negative), clearly a subset of $\mathbb{Z}$.

2. *Odd numbers*: the set

$$\{2n+1 \mid n \in \mathbb{Z}\} = \{\ldots, -5, -3, -1, 1, 3, 5, \ldots\} \ , \tag{3.39}$$

   that is, the set of all multiples of 2, plus or minus 1.

3. *Prime numbers*: the natural numbers that are multiples only of 1 and of themselves. For example, 4 is a multiple of 1, 2, and 4, so it is not prime; 5 is a multiple only of 1 and 5, so it is prime. By convention 1 is not considered prime, since the primes satisfy many properties in number theory that 1 does not. The set of primes is denoted $\mathbb{P}$; its first ten elements are

$$\mathbb{P} = \{2, 3, 5, 7, 11, 13, 17, 19, 23, 29, \ldots\} \ . \tag{3.40}$$

   Note that the only even prime is 2.

Rational numbers $\mathbb{Q}$

The set known as the *rational numbers* is a set of numbers with which we can identify portions. If we have a watermelon and eat half of it, we say we have eaten the fraction "one half" of the watermelon, written $\frac{1}{2}$. We could likewise have eaten $\frac{1}{3}$ of it, or even $\frac{2}{2}$, which corresponds to eating the whole watermelon. In a fraction, the upper number is the *numerator* and the lower one the *denominator*. These new numbers, together with the integers, form the set of rational numbers

$$\mathbb{Q} = \left\{ \frac{n}{m} \mid n, m \in \mathbb{Z},\ m \neq 0 \right\} \ , \tag{3.41}$$

where zero is excluded as a denominator because it leads to complications: there is no practical or canonical way to define how many times zero fits into an arbitrary number.

Irrational numbers $\mathbb{R} \setminus \mathbb{Q}$

Geometry produces new numbers whose infinite decimal expansions follow no known general formula. A classic example is the number π, the ratio of the perimeter of a circle to its diameter,

$$\pi = \frac{P_{\bigcirc}}{D_{\bigcirc}} = 3.141\,592\,653\,589\,793\,238\,46\ldots\,. \tag{3.42}$$

Another example is the length of the diagonal of a unit square, the Pythagorean number $\sqrt{2}$. These new numbers are called the *irrational numbers*. That they exist at all — that the rationals do not already exhaust the number line — is not an observation but a theorem, proved for $\sqrt{2}$ in Example 3.26. That they are in fact the overwhelming majority of the real numbers is a much later and much stranger result, Theorem 3.69.

Real numbers $\mathbb{R}$

The rationals together with the irrationals form the *real numbers* $\mathbb{R}$. We have no general symbolic rule for them, but graphically we can represent them by a straight line built out of them, as in Figure 3.1: each $x \in \mathbb{R}$ is a point of the line.

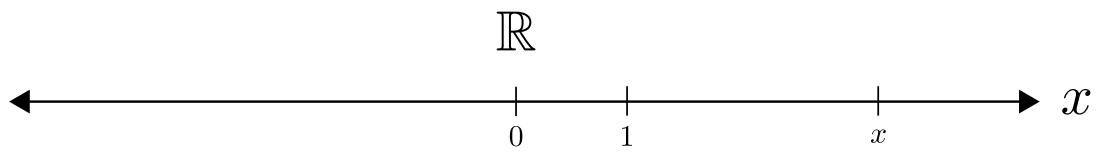

Figure 3.1: The real line: a graphical representation of the set $\mathbb{R}$.

The number sets assemble into the hierarchy

$$\mathbb{C} \supset \begin{cases} \mathbb{R} \supset \begin{cases} \mathbb{Q} \supset \mathbb{Z} \supset \mathbb{N} \\ \mathbb{R} \setminus \mathbb{Q} \end{cases} \\ \mathbb{I} \end{cases} \tag{3.43}$$

where $\mathbb{I}$ denotes the imaginary numbers and $\mathbb{C}$ the complex numbers, both studied in detail in Chapter 8.

3.2.3 Operations with sets

The logical operators of Section 3.1.2 induce operations on sets, because a set is the truth set of a predicate and the operators combine predicates. Each definition below pairs one connective with one symbol, and this pairing is the whole content of the subject.

Definition 3.35 (Union, intersection, difference)**.** Let X and Y be sets. We define

$$X \cup Y := \{x \mid x \in X \ \vee \ x \in Y\}\,, \tag{3.44}$$
$$X \cap Y := \{x \mid x \in X \ \wedge \ x \in Y\}\,, \tag{3.45}$$
$$X \setminus Y := \{x \mid x \in X \ \wedge \ x \notin Y\}\,, \tag{3.46}$$

called respectively the *union*, the *intersection* and the *difference* of X and Y. When all sets under discussion are subsets of one ambient set U, the *complement* of X in U is $X^{\mathrm{c}} := U \setminus X$.

Rests on Definitions 3.7 to 3.9.

The complement is defined relative to a stated ambient set and never absolutely. There is no set of all things to take complements in: assuming one is exactly the mistake that produces Russell's paradox (Theorem 3.75).

Definition 3.36 (Disjoint sets)**.** Two sets X and Y are *disjoint* if and only if $X \cap Y = \varnothing$.

Two properties will be used repeatedly in this book. First, mutual inclusion implies equality — this is extensionality in working form:

$$(X \subset Y) \ \wedge \ (Y \subset X) \implies X = Y \,. \tag{3.47}$$

Second, intersecting with the empty set yields the empty set:

$$X \cap \varnothing = \varnothing \,. \tag{3.48}$$

Proposition 3.37 (De Morgan's laws for sets)**.** *Let X, Y be subsets of an ambient set U. Then*

$$(X \cup Y)^{\mathrm{c}} = X^{\mathrm{c}} \cap Y^{\mathrm{c}} \,, \tag{3.49}$$

$$(X \cap Y)^{\mathrm{c}} = X^{\mathrm{c}} \cup Y^{\mathrm{c}} \,. \tag{3.50}$$

Rests on Definition 3.35 and Equations (3.15), (3.16) and (3.47).

Proof. *Derives Proposition 3.37.*

Let $u \in U$. By Definition 3.35, $u \in (X \cup Y)^{\mathrm{c}}$ means $\neg(u \in X \vee u \in Y)$, which by Equation (3.16) is equivalent to $(u \notin X) \wedge (u \notin Y)$, i.e. to $u \in X^{\mathrm{c}} \cap Y^{\mathrm{c}}$. Every step is an equivalence, so each set is contained in the other and Equation (3.47) gives equality. The second law follows the same way from Equation (3.15). □

That proof is the template for the whole algebra of sets: commutativity, associativity, distributivity and absorption of $\cup$ and $\cap$ are the set-theoretic shadows of Equations (3.19) to (3.22) and (3.24), obtained by the same translation and proved by the same two lines. We shall use them without further comment.

For families of more than two sets, indexed by an arbitrary set I — finite, countable, or neither — we write

$$\bigcup_{i \in I} X_i := \{x \mid \exists\, i \in I \mid x \in X_i\} \,, \qquad \bigcap_{i \in I} X_i := \{x \mid \forall\, i \in I, \ x \in X_i\} \,. \tag{3.51}$$

The pairing of $\cup$ with $\exists$ and of $\cap$ with $\forall$ is the same one as before, now in its quantified form; the negation rules Equations (3.32) and (3.33) turn into De Morgan's laws for arbitrary families.

Definition 3.38 (Ordered pair and Cartesian product)**.** The *ordered pair* (x, y) is an object satisfying

$$(x, y) = (x', y') \iff (x = x') \wedge (y = y') \,. \tag{3.52}$$

The *Cartesian product* of the sets X and Y is the set of ordered pairs

$$X \times Y := \{(x, y) \mid x \in X, \ y \in Y\} \,, \tag{3.53}$$

and analogously for finitely many factors; we write X^n for the product of n copies of X.

Remark 3.39 (Pairs are sets too). Equation (3.52) states the property an ordered pair must have, not what it is. If ordered pairs are to be sets like everything else, the standard implementation is Kuratowski's [477],

$$(x, y) := \{\{x\}, \{x, y\}\} \,, \tag{3.54}$$

from which Equation (3.52) is a short exercise in extensionality. The implementation is a convenience, not a discovery: nothing in mathematics or physics depends on *which* coding is chosen, only on the fact that *some* coding satisfies Equation (3.52). The same remark will apply, with far greater force, to Gödel's coding of formulas as numbers (Section 3.8.3).

Cartesian products are the reason this section belongs in a physics book. Configuration space is a product of position ranges, phase space a product of configuration and momentum spaces (Chapter 22), spacetime a product of a time axis with a spatial manifold in every chart, and a relation — including every equivalence relation of Section 3.4 and every map of Section 3.3 — is formally a subset of a product.

3.2.4 Cardinality

Definition 3.40 (Cardinal)**.** The *cardinal* of a set X, written $|X|$, is the number of elements it contains. A set is *finite* if and only if its cardinal is 0 or lies in $\mathbb{N}$; otherwise it is *infinite*.

For example, the cardinal of the set of vowels is $|\{a, e, i, o, u\}| = 5$, and $|\varnothing| = 0$. The cardinal of the set of naturals greater than or equal to 6 and less than 15 is $|\{6, 7, 8, 9, 10, 11, 12, 13, 14\}| = 9$. Other sets are infinite: $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, and even the set of reals between 0 and 1.

Writing $|\mathbb{R}| = \infty$, as is often done informally, throws away the most interesting fact in this chapter. Both $\mathbb{N}$ and $\mathbb{R}$ are infinite, yet we intuit that $\mathbb{R}$ is somehow "more" infinite — and that intuition is correct, provable, and the beginning of a whole hierarchy (Section 3.5). Until the tools for comparing infinite sets are in place we confine the arithmetic of cardinals to finite sets.

Definition 3.41 (Power set)**.** Let X be a set. The *power set* of X is the set of all possible subsets of X, denoted $\mathcal{P}(X)$.

Rests on Definition 3.30.

For example, if $X = \{a, b, c\}$, then

$$\mathcal{P}(X) = \{\varnothing, \{a\}, \{b\}, \{c\}, \{a, b\}, \{a, c\}, \{b, c\}, X\} .$$

Proposition 3.42 (Cardinal of the power set)**.** *For every finite set X,*

$$|\mathcal{P}(X)| = 2^{|X|} . \tag{3.55}$$

Rests on Definitions 3.40 and 3.41, Axiom 3.34, and Equations (3.25) and (3.26).

Proof. *Derives Proposition 3.42.*

By induction (Axiom 3.34) on $n = |X|$, the statement $P(n)$ being "every set of cardinal n has exactly 2^n subsets".

Base. If $n = 0$ then $X = \varnothing$, whose only subset is $\varnothing$ itself, so $\mathcal{P}(\varnothing) = \{\varnothing\}$ and $|\mathcal{P}(X)| = 1 = 2^0$.

Step. Assume $P(n)$ and let $|X| = n + 1$. Since $n + 1 \geq 1$ the set is non-empty; pick $a \in X$ and put $Y := X \setminus \{a\}$, so $|Y| = n$. Split the subsets of X according to whether they contain a:

$$\mathcal{A} := \{A \in \mathcal{P}(X) \mid a \notin A\} , \qquad \mathcal{B} := \{A \in \mathcal{P}(X) \mid a \in A\} .$$

These are disjoint by Equation (3.26) and exhaust $\mathcal{P}(X)$ by Equation (3.25). Now $\mathcal{A}$ is exactly $\mathcal{P}(Y)$, since a subset of X omitting a is a subset of Y and conversely; hence $|\mathcal{A}| = 2^n$ by the induction hypothesis. And the map $B \longmapsto B \setminus \{a\}$ sends $\mathcal{B}$ into $\mathcal{P}(Y)$ with inverse $A \longmapsto A \cup \{a\}$, so it is a bijection (Definition 3.47) and $|\mathcal{B}| = 2^n$ as well. Adding the two disjoint families,

$$|\mathcal{P}(X)| = 2^n + 2^n = 2^{n+1} ,$$

which is $P(n + 1)$. By induction $P(n)$ holds for every n. □

The exponential notation is not a coincidence of counting. Sending a subset $A \subset X$ to its indicator function — the map taking the value 1 on A and 0 elsewhere — is a bijection between $\mathcal{P}(X)$ and the set $\mathcal{F}(X, \{0, 1\})$ of Definition 3.52, for finite and infinite X alike. This is why the power set is also written 2^X, and why Theorem 3.71 below can be read as the statement that there are always more functions on a set than points in it.

3.3 Maps

3.3.1 Maps

Consider two non-empty sets X and Y. In the everyday sense we can always relate some element of X with some element of Y by means of an arbitrary rule: some elements of X may be related to several elements of Y, others to none. The relations that turn out to be most useful are the more disciplined ones, in which *each* element of X is related to *one and only one* element of Y: we demand both the existence of a related element in Y and its uniqueness.

Definition 3.43 (Map)**.** A *map* (also *function* or *application*) f from X to Y is an assignment rule relating the elements of X with elements of Y that satisfies the axiom of existence and uniqueness:

$$\forall\, x \in X,\ \exists!\ f(x) \in Y \mid \text{to } x \text{ we assign } f(x)\,, \tag{3.56}$$

written in notation $x \longmapsto f(x)$. To make the related sets explicit we write $f : X \longrightarrow Y$, and we call X the *domain* of f and Y the *codomain* of f.

Rests on Definitions 3.24 and 3.28.

We may picture a map as a "machine" to which we feed an element of the domain, and which transforms it into an element of the codomain. For example, the map f assigning to each natural number its square root is

$$\begin{array}{rccc} f: & \mathbb{N} & \longrightarrow & \mathbb{R} \\ & n & \longmapsto & \sqrt{n}\,. \end{array}$$

Definition 3.44 (Image)**.** Let $f : X \longrightarrow Y$ be a map. The *image* of f is

$$f(X) = \{y \in Y \mid y = f(x),\ x \in X\} \subset Y\,. \tag{3.57}$$

Not every element of the codomain need be the result of mapping some element of the domain. Note that the image of a map is defined canonically: a map brings its image with it, uniquely determined, which is not the case for the codomain. One must not confuse this with two distinct maps sharing the same assignment formula: the image of

$$\begin{array}{rccc} f: & \mathbb{N} & \longrightarrow & \mathbb{R} \\ & n & \longmapsto & \sqrt{n} \end{array}$$

is different from the image of

$$\begin{array}{rccc} g: & \mathbb{R} & \longrightarrow & \mathbb{R} \\ & x & \longmapsto & \sqrt{x}\,. \end{array}$$

Definition 3.45 (Injective map)**.** A map $f : X \longrightarrow Y$ is *injective* if and only if

$$x \neq x' \implies f(x) \neq f(x')\,. \tag{3.58}$$

Injectivity means that two distinct elements of the domain are mapped to distinct elements of the codomain. The definition is equivalent to: $f : X \longrightarrow Y$ is injective if and only if

$$f(x) = f(x') \implies x = x'\,, \tag{3.59}$$

since the two implications are contrapositives of one another.

Definition 3.46 (Surjective map)**.** A map $f : X \longrightarrow Y$ is *surjective* if and only if

$$f(X) = Y\,, \tag{3.60}$$

which is equivalent to saying that

$$\forall\, y \in Y,\ \exists\, x \in X \mid y = f(x)\,. \tag{3.61}$$

Definition 3.47 (Bijective map)**.** A map $f : X \longrightarrow Y$ is *bijective*, or a *bijection*, if and only if

$$\forall\, y \in Y,\ \exists!\, x \in X \mid y = f(x)\,. \tag{3.62}$$

Bijectivity sharpens surjectivity by demanding uniqueness in the existence. A more practical characterization is the following.

Proposition 3.48 (Characterization of bijectivity)**.** *A map $f : X \longrightarrow Y$ is bijective if and only if it is injective and surjective.*

Rests on Definitions 3.45 to 3.47.

Proof. *Derives Proposition 3.48.*

Both directions unpack Definition 3.47, whose content is that each $y \in Y$ has an antecedent and has only one.

($\Longrightarrow$) Let f be bijective. The existential half of $\exists!\, x \in X \mid y = f(x)$ says that every $y \in Y$ is attained, i.e. $f(X) = Y$, which is surjectivity. For injectivity, suppose $f(x) = f(x')$ and call this common value y. Then x and x' are both antecedents of y, and the uniqueness half forces $x = x'$.

($\Longleftarrow$) Let f be injective and surjective, and let $y \in Y$. Surjectivity supplies at least one $x \in X$ with $f(x) = y$. If $x' \in X$ also satisfies $f(x') = y$, then $f(x) = f(x')$ and injectivity gives $x = x'$. So the antecedent exists and is unique, which is $\exists!\, x \in X \mid y = f(x)$. □

Definition 3.49 (Composition map)**.** Let $f : X \longrightarrow Y$ and $g : Y \longrightarrow Z$ be maps. The *composition of g with f* is the map

$$\begin{aligned} g \circ f : X &\longrightarrow Z \\ x &\longmapsto g(f(x))\,. \end{aligned}$$

Definition 3.50 (Identity map)**.** The *identity map* on X is

$$\begin{aligned} \mathrm{id}_X : X &\longrightarrow X \\ x &\longmapsto x\,. \end{aligned}$$

Definition 3.51 (Inverse map)**.** Let $f : X \longrightarrow Y$ be a bijection. The *inverse map* $f^{-1} : Y \longrightarrow X$ is the map assigning to each $y \in Y$ the unique $x \in X$ with $f(x) = y$; it satisfies $f^{-1} \circ f = \mathrm{id}_X$ and $f \circ f^{-1} = \mathrm{id}_Y$.

Rests on Definitions 3.47, 3.49 and 3.50.

Definition 3.52 (Set of maps)**.** We define $\mathcal{F}(X, Y)$ as the set of all maps of the form $f : X \longrightarrow Y$.

Definition 3.53 (Preimage)**.** Let $f : X \longrightarrow Y$ be a map and $B \subset Y$. The *preimage* of B under f is

$$f^{-1}(B) := \{x \in X \mid f(x) \in B\} \subset X\,. \tag{3.63}$$

The notation is a deliberate abuse: $f^{-1}(B)$ is defined for every map, bijective or not, and is a set, whereas the inverse map of Definition 3.51 exists only for bijections and returns an element. The two agree, up to the identification of a point with the singleton containing it, exactly when f is a bijection.

Proposition 3.54 (Preimages respect the set operations)**.** *Let $f : X \longrightarrow Y$ and let $B, C \subset Y$. Then*

$$f^{-1}(B \cup C) = f^{-1}(B) \cup f^{-1}(C)\,, \tag{3.64}$$

$$f^{-1}(B \cap C) = f^{-1}(B) \cap f^{-1}(C)\,, \tag{3.65}$$

$$f^{-1}(B^{\mathrm{c}}) = f^{-1}(B)^{\mathrm{c}}\,. \tag{3.66}$$

Images respect unions, $f(A \cup A') = f(A) \cup f(A')$, but in general only $f(A \cap A') \subset f(A) \cap f(A')$.

Rests on Definitions 3.35 and 3.53 and Equation (3.47).

Proof. *Derives Proposition 3.54.*

For the first identity, $x \in f^{-1}(B \cup C)$ says $f(x) \in B \vee f(x) \in C$, which is $x \in f^{-1}(B) \vee x \in f^{-1}(C)$; the second and third replace $\vee$ by $\wedge$ and by $\neg$ in the same way. Each step is an equivalence of propositions, so Equation (3.47) applies. For images the corresponding step is not an equivalence: $y \in f(A \cap A')$ requires *one* x lying in both A and A', whereas $y \in f(A) \cap f(A')$ allows two different antecedents, one in each. A non-injective map exhibits the gap — take $f(x) = x^2$ on $\mathbb{R}$ with $A = \{1\}$ and $A' = \{-1\}$, for which $f(A \cap A') = \varnothing$ while $f(A) \cap f(A') = \{1\}$. □

This asymmetry is why preimages, not images, are the right notion in topology (continuity is "preimages of open sets are open", Chapter 6) and in measure theory (a random variable is measurable when preimages of intervals are measurable, Chapter 11).

Definition 3.55 (Restriction)**.** Let $f : X \longrightarrow Y$ and $A \subset X$. The *restriction* of f to A is the map $f|_A : A \longrightarrow Y$ with $f|_A(a) = f(a)$ for every $a \in A$.

Proposition 3.56 (Composition is associative)**.** *Let $f : X \longrightarrow Y$, $g : Y \longrightarrow Z$ and $h : Z \longrightarrow W$. Then*

$$h \circ (g \circ f) = (h \circ g) \circ f \,, \tag{3.67}$$

and $f \circ \mathrm{id}_X = f = \mathrm{id}_Y \circ f$.

Rests on Definitions 3.49 and 3.50.

Proof. *Derives Proposition 3.56.*

Two maps with the same domain and codomain are equal when they agree at every point. For $x \in X$, both sides of Equation (3.67) unfold to $h(g(f(x)))$ by Definition 3.49 applied twice; the bracketing only records the order in which the unfolding was performed, and the result does not depend on it. The identity laws are immediate from Definition 3.50. □

Associativity with a two-sided identity is precisely the axiom system of a monoid, and the bijections of a set onto itself — which by Proposition 3.57 are closed under composition and by Definition 3.51 under inversion — form a group, the symmetric group of the set. That is the bridge from this chapter to Chapter 4, and through it to every symmetry argument in the physical parts of this treatise.

Proposition 3.57 (Composition of bijective maps)**.** *Let $f : X \longrightarrow Y$ and $g : Y \longrightarrow Z$ be bijections. Then $g \circ f : X \longrightarrow Z$ is a bijection, and*

$$(g \circ f)^{-1} = f^{-1} \circ g^{-1} \,. \tag{3.68}$$

Rests on Propositions 3.48 and 3.56 and Definition 3.51.

Proof. *Derives Proposition 3.57.*

By Proposition 3.48 it suffices to prove that $g \circ f$ is injective and surjective.

Injective. Suppose $(g \circ f)(x) = (g \circ f)(x')$, that is $g(f(x)) = g(f(x'))$. Since g is injective, $f(x) = f(x')$; since f is injective, $x = x'$.

Surjective. Let $z \in Z$. Since g is surjective there is $y \in Y$ with $g(y) = z$, and since f is surjective there is $x \in X$ with $f(x) = y$. Then $(g \circ f)(x) = g(f(x)) = g(y) = z$.

For Equation (3.68), compose and use associativity (Proposition 3.56):

$$(f^{-1} \circ g^{-1}) \circ (g \circ f) = f^{-1} \circ (g^{-1} \circ g) \circ f = f^{-1} \circ \mathrm{id}_Y \circ f = f^{-1} \circ f = \mathrm{id}_X \,,$$

and symmetrically $(g \circ f) \circ (f^{-1} \circ g^{-1}) = \mathrm{id}_Z$. A two-sided inverse of a bijection is unique — if u and v both invert w then $u = u \circ \mathrm{id} = u \circ (w \circ v) = (u \circ w) \circ v = \mathrm{id} \circ v = v$ — so $f^{-1} \circ g^{-1}$ is *the* inverse of $g \circ f$. □

3.4 Equivalence classes

3.4.1 Equivalence relations

Definition 3.58 (Equivalence relation)**.** Consider a set $X = \{x, y, z, \ldots\}$. A relation $\sim$ on X is an *equivalence relation* if and only if it satisfies

1. Reflexivity:
$$\forall x \in X,\ x \sim x\,. \tag{3.69}$$
2. Symmetry:
$$\forall x, y \in X,\ x \sim y \implies y \sim x\,. \tag{3.70}$$
3. Transitivity:
$$\forall x, y, z \in X,\ x \sim y \ \wedge\ y \sim z \implies x \sim z\,. \tag{3.71}$$

Two elements $x, y \in X$ with $x \sim y$ are said to be *equivalent*.

Definition 3.59 (Equivalence class)**.** Consider a set X with an equivalence relation $\sim$, and let $a \in X$. The set of all elements of X equivalent to a,
$$[a] = \{x \in X \mid x \sim a\}\,, \tag{3.72}$$
is the *equivalence class*[1] of a, and a is called the *representative* of the class $[a]$.
Rests on Definition 3.58.

By reflexivity, $a \in [a]$. Moreover, let $b \in [a]$; then $b \sim a$ and, by symmetry, $a \sim b$. Now let $x \in [a]$; then $x \sim a$ and, by transitivity, $x \sim b$. Since x is arbitrary in $[a]$, every element of $[a]$ is equivalent to b, and we conclude that any element of $[a]$ may serve as its representative.

Two examples:

- On the set $\mathbb{R}$, define the relation
$$x \sim y \iff \exists\, n \in \mathbb{Z} \mid y = x + 2\pi n, \qquad x, y \in \mathbb{R}\,,$$
which is indeed an equivalence relation:
  1. $x \sim x$, since there exists $0 \in \mathbb{Z}$ such that
  $$x = x + 2\pi \cdot 0\,.$$
  2. Suppose $x \sim y$. Then there exists $n \in \mathbb{Z}$ such that
  $$\begin{aligned} & y = x + 2\pi n \\ \implies\ & x = y - 2\pi n \\ \implies\ & x = y + 2\pi m, \quad m \in \mathbb{Z}\,, \end{aligned}$$
  hence $y \sim x$ and symmetry holds.
  3. Suppose $x \sim y$ and $y \sim z$. Then there exist $n, m \in \mathbb{Z}$ such that
  $$y = x + 2\pi n, \quad z = y + 2\pi m\,.$$
  Adding the equations gives
  $$z = x + 2\pi(n + m), \quad n + m \in \mathbb{Z}\,,$$
  hence $x \sim z$ and transitivity holds.

[1] Equivalence classes are colloquially called simply *classes*.

One says that x and y are *congruent modulo* 2π; in particular 0 and 2π are congruent, i.e. they belong to the same equivalence class. If you know the trigonometric functions, this is surely something you had always intuited.

- In a non-leap year of the Gregorian calendar, define the relation

$$x \sim y \iff x \text{ has their birthday on the same day as } y\,,$$

which is an equivalence relation, very direct to verify. There are clearly 365 equivalence classes.

3.4.2 Quotient space

Theorem 3.60 (Equivalence classes partition the set)**.** *Let $\sim$ be an equivalence relation on a set X. Two equivalence classes are either disjoint or identical: for any classes $[a]$ and $[b]$,*

$$[a] \cap [b] \neq \varnothing \implies [a] = [b]\,, \tag{3.73}$$

or, equivalently, in view of the logical property Equation (3.14),

$$[a] \cap [b] = \varnothing \quad \vee \quad [a] = [b]\,. \tag{3.74}$$

The relation $\sim$ therefore divides X into disjoint classes: it partitions *the set.*
Rests on Definitions 3.36, 3.58 and 3.59 and Equation (3.47).

Proof. *Derives Theorem 3.60.*
Suppose the classes $[a]$ and $[b]$ are not disjoint,

$$[a] \cap [b] \neq \varnothing\,.$$

We must prove $[a] = [b]$: if they share at least one element, they are the same class. Recall that by definition

$$[a] = \{x \in X \mid x \sim a\}\,, \quad [b] = \{x \in X \mid x \sim b\}\ .$$

By reflexivity $[a] \neq \varnothing$, since $a \sim a$, and analogously $[b] \neq \varnothing$; there is thus no obstruction to considering $[a] \cap [b] \neq \varnothing$ (we make this remark because of property Equation (3.48) of set theory).

Since $[a] \cap [b] \neq \varnothing$, there exists $c \in [a] \cap [b]$ satisfying $c \sim a$ and $c \sim b$. By symmetry $a \sim c$, and finally by transitivity $a \sim b$.

Let $x \in [a]$; then $x \sim a$. Since also $a \sim b$, transitivity gives $x \sim b$, which means $x \in [b]$ for all $x \in [a]$, i.e. $[a] \subset [b]$. Analogously, starting from $y \in [b]$ we conclude $[b] \subset [a]$. By double inclusion, Equation (3.47), we conclude $[a] = [b]$. □

Definition 3.61 (Quotient space)**.** Consider a set X and an equivalence relation $\sim$ among its elements. The *quotient space* is

$$\frac{X}{\sim} = \{[y] \mid y \in X\}\ , \tag{3.75}$$

that is, the quotient space is the set of all equivalence classes given by $\sim$.
Rests on Definition 3.59.

Quotienting is how physics disposes of descriptive surplus. Angles are real numbers modulo 2π, the example above. States in quantum mechanics are vectors of a Hilbert space modulo nonzero complex scaling, which is why the state space is the projective space $\mathcal{P}(\mathcal{H})$ and why the global phase of a wavefunction is unobservable (Chapter 77). Gauge fields related by a gauge transformation are the same physical configuration, and the physical configuration space is the quotient by the gauge group (Chapter 64). In each case the equivalence relation encodes exactly what no measurement can distinguish, and Theorem 3.60 guarantees that this notion of "same physical situation" is consistent: the classes never partly overlap.

3.5 The infinite

Cardinality was defined in Section 3.2.4 by counting, which works only for finite sets. Cantor's insight was that comparison does not require counting: two shepherds can agree that they have equally many sheep by pairing the animals off, without either of them knowing how to count. The pairing is a bijection, and it makes sense whether the flocks are finite or not [188].

3.5.1 Equipotence and countability

Definition 3.62 (Equipotence)**.** Two sets X and Y are *equipotent*, written $X \approx Y$, if and only if there exists a bijection $f : X \longrightarrow Y$. We then say they have the same *cardinal*, $|X| = |Y|$.
Rests on Definitions 3.40 and 3.47.

Proposition 3.63. *Equipotence is reflexive, symmetric and transitive.*
Rests on Definitions 3.50, 3.51 and 3.62 and Proposition 3.57.

Proof. *Derives Proposition 3.63.*
Reflexivity: id_X is a bijection of X onto itself. Symmetry: if $f : X \longrightarrow Y$ is a bijection then so is $f^{-1} : Y \longrightarrow X$, by Definition 3.51. Transitivity: if $f : X \longrightarrow Y$ and $g : Y \longrightarrow Z$ are bijections then so is $g \circ f$, by Proposition 3.57. □

Remark 3.64. Proposition 3.63 lists the three clauses of Definition 3.58, but it stops short of calling $\approx$ an equivalence relation, and the omission is deliberate. An equivalence relation lives on a *set*, and there is no set of all sets to put this one on (Section 3.6). The classes of $\approx$ are therefore proper classes, not elements of a quotient set. Cardinals are recovered inside ZFC by choosing a canonical representative of each class rather than by forming the quotient.

Definition 3.65 (Countable set)**.** A set is *countably infinite* if and only if it is equipotent to $\mathbb{N}$, and *at most countable* (or simply *countable*) if it is finite or countably infinite. A set that is neither is *uncountable*. The cardinal of $\mathbb{N}$ is denoted $\aleph_0$.
Rests on Definition 3.62 and Axiom 3.33.

Being countably infinite means precisely that the elements can be arranged in an infinite list $x_1, x_2, x_3, \ldots$ in which every element appears exactly once: the list *is* the bijection. The natural numbers are trivially countable, via $n \longmapsto n$. Three less obvious examples follow, and each is a warning that infinite sets do not behave like finite ones.

Example 3.66 (The integers are countable)**.** Although $\mathbb{N} \subset \mathbb{Z}$ properly — $\mathbb{Z}$ contains 0 and all the negatives besides — the two sets are equipotent. Interleave the signs:

$$f : \mathbb{N} \longrightarrow \mathbb{Z}\,, \qquad f(1) = 0\,, \qquad f(2k) = k\,, \qquad f(2k+1) = -k \quad (k \in \mathbb{N})\,, \tag{3.76}$$

which lists $\mathbb{Z}$ as $0, 1, -1, 2, -2, 3, -3, \ldots$. Every integer occurs, and occurs once, so f is a bijection and $|\mathbb{Z}| = \aleph_0$.

That a proper subset can be equipotent to the whole is impossible for finite sets and characteristic of infinite ones — indeed Dedekind took it as the *definition* of infinite [237]. It is the content of the parable of Hilbert's hotel: a hotel with rooms $1, 2, 3, \ldots$, all occupied, still accommodates a new guest by moving the occupant of room n to room $n + 1$.

Proposition 3.67 (Countability of the plane of naturals)**.** $\mathbb{N} \times \mathbb{N}$ *is countably infinite.*
Rests on Definitions 3.38, 3.47 and 3.65.

Proof. *Derives Proposition 3.67.*

Enumerate the pairs along the finite antidiagonals $m+n=2,3,4,\ldots$, each of which contains finitely many pairs, taking them in order of increasing m. Explicitly, the Cantor pairing map

$$\pi : \mathbb{N}\times\mathbb{N} \longrightarrow \mathbb{N}\,, \qquad \pi(m,n) = \frac{(m+n-2)(m+n-1)}{2} + m \tag{3.77}$$

sends the antidiagonal $m+n=d$ onto the block of integers $\{T_{d-2}+1,\ldots,T_{d-2}+(d-1)\}$, where $T_k = k(k+1)/2$ is the k-th triangular number and $d-1$ is the number of pairs on that antidiagonal. Consecutive blocks abut without gap or overlap, since $T_{d-2}+(d-1)=T_{d-1}$, and within a block m runs over $1,\ldots,d-1$ injectively. Hence π is a bijection. □

Corollary 3.68 (The rationals are countable)**.** $|\mathbb{Q}| = \aleph_0$.
Rests on Proposition 3.67, Definition 3.65, and Equation (3.76).

Proof. *Derives Corollary 3.68.*

Each positive rational is n/m with $n,m\in\mathbb{N}$, so $(n,m)\longmapsto n/m$ maps $\mathbb{N}\times\mathbb{N}$ onto the positive rationals. A surjection from a countable set makes the target at most countable: list the source by Proposition 3.67 and strike out every term whose value has already appeared, leaving a list of the positive rationals without repetition. That list is infinite because $\mathbb{N}$ embeds in it, so the positive rationals are countably infinite. Interleaving with the negatives and 0 as in Equation (3.76) gives $|\mathbb{Q}| = \aleph_0$. □

So the rationals, dense though they are — between any two of them lies another — are no more numerous than the integers. At this point one might guess that all infinite sets are equipotent, and that "infinite" admits no useful gradation. Cantor showed otherwise.

3.5.2 The diagonal argument

Theorem 3.69 (Uncountability of the continuum)**.** *The set $\mathbb{R}$ is uncountable. More precisely, no map $f:\mathbb{N}\longrightarrow[0,1)$ is surjective [249].*
Rests on Definitions 3.46 and 3.65.

Proof. *Derives Theorem 3.69.*

Let $f:\mathbb{N}\longrightarrow[0,1)$ be any map. Each value has a decimal expansion

$$f(n) = 0.a_{n1}a_{n2}a_{n3}\ldots\,, \qquad a_{nk}\in\{0,1,\ldots,9\}\,,$$

and where a number admits two expansions — one ending in all 0s, one in all 9s — we fix the first, so that the digits a_{nk} are well defined functions of n and k.

Now build a number that differs from every listed one, using the diagonal digits a_{nn}. Define

$$b_n := \begin{cases} 5 & \text{if } a_{nn}\neq 5\,,\\ 4 & \text{if } a_{nn}=5\,, \end{cases} \tag{3.78}$$

and set $b := 0.b_1b_2b_3\ldots$. Since every digit of b is 4 or 5, we have $b\in[0,1)$; moreover b's expansion neither terminates in all 0s nor in all 9s, so it is the *only* expansion of b and the digits of b are exactly the b_n.

Suppose $b=f(n)$ for some $n\in\mathbb{N}$. Comparing the n-th digits of the two (unique, on our convention) expansions gives $b_n = a_{nn}$, contradicting Equation (3.78), which was rigged so that $b_n\neq a_{nn}$. Hence $b\neq f(n)$ for every n, and f is not surjective.

Since no map $\mathbb{N}\longrightarrow[0,1)$ is surjective, none is bijective, so $[0,1)$ is uncountable; and $[0,1)\subset\mathbb{R}$, so $\mathbb{R}$ is uncountable too — an at most countable set has no uncountable subset. □

Corollary 3.70. *The irrational numbers are uncountable, and in this precise sense almost every real number is irrational.*
Rests on Theorem 3.69 and Corollary 3.68.

Proof. *Derives Corollary 3.70.*
If $\mathbb{R} \setminus \mathbb{Q}$ were at most countable then $\mathbb{R} = \mathbb{Q} \cup (\mathbb{R} \setminus \mathbb{Q})$ would be the union of two at most countable sets, hence at most countable — interleave the two lists — contradicting Theorem 3.69. □

The pattern of the proof, not its arithmetic, is what matters. A list is given; a new object is built by disagreeing with the n-th listed object in its n-th feature; the new object cannot be on the list. This *diagonal argument* reappears at every turn in the rest of the chapter: in Cantor's theorem immediately below, in Russell's paradox (Theorem 3.75), in Gödel's undecidable sentence (Theorem 3.87), and in Turing's halting problem (Theorem 3.96). They are four faces of one idea.

Theorem 3.71 (Cantor)**.** *For every set X there is no surjection $f : X \longrightarrow \mathcal{P}(X)$. Consequently $|X| < |\mathcal{P}(X)|$, and there is no largest cardinal.*
Rests on Definitions 3.41 and 3.46, Axiom 3.76, and Equation (3.26).

Proof. *Derives Theorem 3.71.*
Let $f : X \longrightarrow \mathcal{P}(X)$ be any map. Each $x \in X$ is thereby assigned a subset $f(x) \subset X$, and it makes sense to ask whether x belongs to the subset assigned to it. Collect the elements for which the answer is no:

$$D := \{x \in X \mid x \notin f(x)\} \ . \tag{3.79}$$

This is a legitimate subset of X — it is carved out of the existing set X by a predicate, as the axiom of separation requires (Axiom 3.76) — so $D \in \mathcal{P}(X)$.

Suppose $D = f(d)$ for some $d \in X$. Ask whether $d \in D$. By the definition Equation (3.79), $d \in D$ holds if and only if $d \notin f(d)$; but $f(d) = D$, so $d \in D$ holds if and only if $d \notin D$. That is $p \leftrightarrow \neg p$, a contradiction by Equation (3.26). Hence D is in the image of no element and f is not surjective.

Since $x \longmapsto \{x\}$ is an injection $X \longrightarrow \mathcal{P}(X)$ while no surjection exists, the inequality is strict. Applying the theorem to $\mathcal{P}(X)$, then to $\mathcal{P}(\mathcal{P}(X))$, and so on produces an unending strictly increasing chain of cardinals. □

Theorem 3.71 generalizes Proposition 3.42 from finite sets to all sets, and it strengthens Theorem 3.69: taking $X = \mathbb{N}$ gives an uncountable set directly, and one can show $|\mathcal{P}(\mathbb{N})| = |\mathbb{R}|$, the cardinal of the continuum, written $\mathfrak{c} = 2^{\aleph_0}$. Comparison of cardinals is made rigorous by the following theorem, whose proof is long enough to belong in the appendix.

Theorem 3.72 (Cantor–Schröder–Bernstein)**.** *If there exist injections $f : X \longrightarrow Y$ and $g : Y \longrightarrow X$, then there exists a bijection between X and Y. Hence $|X| \leq |Y|$ and $|Y| \leq |X|$ imply $|X| = |Y|$.*
Rests on Definitions 3.45, 3.47 and 3.62.

Full derivation: Appendix A.3 (p. 2773).
Derives Theorem 3.72.

3.5.3 The continuum hypothesis

Cantor found $\aleph_0 = |\mathbb{N}|$ and $\mathfrak{c} = |\mathbb{R}|$ with $\aleph_0 < \mathfrak{c}$, and could not settle the obvious next question: is there anything strictly in between?

Axiom 3.73 (Continuum hypothesis)**.** There is no set X with $\aleph_0 < |X| < \mathfrak{c}$; equivalently, every uncountable subset of $\mathbb{R}$ is equipotent to $\mathbb{R}$, i.e. $\mathfrak{c} = \aleph_1$, the least uncountable cardinal.

Hilbert placed the question first on his list of twenty-three problems for the new century [291], and its resolution took two thirds of that century and came in two halves, neither of them an answer in the sense Hilbert expected.

1. Gödel showed in 1938 that if ZF is consistent, then so is ZFC together with the continuum hypothesis [815]. He did it by constructing the universe L of *constructible sets*, an inner model of ZF in which both the axiom of choice and Axiom 3.73 come out true. So Axiom 3.73 cannot be refuted from the axioms.

2. Cohen showed in 1963 that if ZF is consistent, then so is ZFC together with the *negation* of the continuum hypothesis [1249]. His method, *forcing*, adjoins to a model new sets constructed by finite approximations, in such a way that the cardinal $\mathfrak{c}$ can be pushed above $\aleph_1$ while every axiom of ZFC survives. So Axiom 3.73 cannot be proved from the axioms either.

Together: the continuum hypothesis is *independent* of ZFC. It is not that we do not yet know whether it is true; it is that the axioms we use for mathematics do not decide it, as the parallel postulate is not decided by the other axioms of geometry. One may adjoin it or its negation and get consistent mathematics either way.

Remark 3.74 (Does the physicist care?). Directly, no — and it is worth being clear why not. Physical predictions are statements about measured quantities with finite precision, and the mathematics that generates them lives, almost without exception, in separable spaces: the Hilbert spaces of quantum mechanics have countable orthonormal bases (Chapter 12), fields are described by functions determined by their values on a countable dense set, and every experimental record is a finite list of rationals with uncertainties. No measurement can distinguish a world in which Axiom 3.73 holds from one in which it fails, because nothing observable depends on the cardinal arithmetic strictly between $\aleph_0$ and $\mathfrak{c}$.

Indirectly, it matters a great deal, and this is the reason the section is here. The continuum hypothesis is the first proof that a perfectly meaningful mathematical question can be immune to the axioms used to pose it. Physics inherits mathematics wholesale; it is entitled to know that its inherited language has questions it cannot answer, and where the boundary runs. The rest of this chapter maps that boundary.

3.6 The crisis of foundations

Definition 3.28 says a set is a grouping of elements satisfying the same logical propositions. Taken at face value this is the principle of *unrestricted comprehension*: every predicate P determines a set $\{x \mid P(x)\}$. It is the natural reading; it is, in the guise of Basic Law V on value-ranges, what Frege built his reduction of arithmetic to logic upon [257]; and it is false.

3.6.1 Russell's paradox

Theorem 3.75 (Russell, 1901)**.** *Unrestricted comprehension is inconsistent.*
Rests on Definitions 3.7, 3.12 and 3.28.

Proof. *Derives Theorem 3.75.*

Sets can be elements of sets, so for any set x the sentence $x \in x$ is a well formed proposition and $x \notin x$ is its negation. Apply unrestricted comprehension to the predicate $P(x) =$ "$x \notin x$" and let

$$R := \{x \mid x \notin x\} \,. \tag{3.80}$$

Ask whether $R \in R$. By Equation (3.80), an object belongs to R if and only if it does not belong to itself; applied to R itself this reads

$$R \in R \iff R \notin R \,, \tag{3.81}$$

which is $p \leftrightarrow \neg p$. Both truth values of p make Equation (3.81) false, while comprehension asserts it. The principle therefore yields a contradiction. □

Russell communicated the argument to Frege in June 1902, while the second volume of Frege's *Grundgesetze* was at the printer; Frege appended a note beginning "Hardly anything more unwelcome can befall a scientific writer than that one of the foundations of his edifice be shaken after the work is finished". The exchange is reprinted in [1349].

Compare Equation (3.80) with the set D of Theorem 3.71. They are the same construction: Russell's paradox is Cantor's diagonal argument applied to the map that sends each set to itself. Cantor's theorem is a theorem because D is carved out of an existing set X; Russell's is a paradox because R is carved out of nothing at all. That distinction is the entire repair.

3.6.2 The Zermelo–Fraenkel axioms

Zermelo's response [350], completed by Fraenkel and Skolem [488], was to abandon comprehension as a general principle and to legislate instead exactly which set formations are permitted. Sets are then not *defined* at all: like "point" in geometry or "event" in relativity, "set" and "$\in$" are primitive notions (Section 1.5), constrained only by axioms.

Axiom 3.76 (Zermelo–Fraenkel with choice)**.** The theory ZFC is written in first-order logic with the single non-logical symbol $\in$, and consists of:

1. **Extensionality.** Sets with the same elements are equal.
2. **Pairing.** For all a, b there is a set $\{a, b\}$.
3. **Union.** For every set A there is a set $\bigcup A$ whose elements are the elements of the elements of A.
4. **Power set.** For every set A there is a set $\mathcal{P}(A)$ whose elements are the subsets of A.
5. **Infinity.** There is a set containing $\varnothing$ and closed under $x \longmapsto x \cup \{x\}$ — an infinite set exists, and this is where $\mathbb{N}$ comes from.
6. **Separation** (an axiom for each predicate P). For every set A, the collection $\{x \in A \mid P(x)\}$ is a set.
7. **Replacement** (an axiom for each definable function F). The image $\{F(x) \mid x \in A\}$ of a set is a set.
8. **Foundation.** Every non-empty set has an element disjoint from it; equivalently, there is no infinite descending chain $\cdots \in x_2 \in x_1 \in x_0$.
9. **Choice.** For every set of non-empty sets there is a function selecting one element from each.

Axioms 1–8 constitute ZF; adjoining 9 gives ZFC. Items 6 and 7 are *schemata*: infinitely many axioms, one per predicate, since first-order logic cannot quantify over predicates.

Separation is the repair. It permits $\{x \in A \mid P(x)\}$ but never $\{x \mid P(x)\}$: a set may only be sieved out of a set already known to exist. Russell's R is unobtainable, since no prior set is available to sieve. What survives of his argument is a theorem.

Corollary 3.77 (There is no set of all sets)**.** *For every set A there is a set that is not an element of A.*

Rests on Axiom 3.76.

Proof. *Derives Corollary 3.77.*

Let A be a set. By separation, $B := \{x \in A \mid x \notin x\}$ is a set. Suppose $B \in A$. Then $B \in B$ holds if and only if $B \in A$ and $B \notin B$, and since $B \in A$ was assumed, this reduces to $B \in B \iff B \notin B$, a contradiction. Hence $B \notin A$, so A fails to contain the set B. $\square$

The universe of sets is thus not itself a set — it is a *proper class*, and Remark 3.64 was an instance of the same fact. Foundation goes further and rules out $x \in x$ outright, so that the sets form a cumulative hierarchy built up from $\varnothing$ by iterated power sets. Nothing in physics ever reaches beyond the first few dozen levels of that hierarchy.

3.6.3 The axiom of choice

The ninth axiom is different in kind from the other eight. Each of those gives an explicit recipe for the set it asserts; choice asserts that a selection exists without providing any rule for making it. For finitely many non-empty sets the selection can be made one at a time and choice is a theorem; for infinitely many it is a genuine assumption.

Axiom 3.78 (Choice)**.** Let $\{X_i\}_{i \in I}$ be a family of non-empty sets indexed by any set I. Then there exists a map

$$c : I \longrightarrow \bigcup_{i \in I} X_i \quad \text{with} \quad c(i) \in X_i \ \text{ for every } i \in I\,. \tag{3.82}$$

Choice is equivalent, over ZF, to a list of statements that look nothing like it and are used constantly: Zermelo's well-ordering theorem (every set admits a well ordering), Zorn's lemma (a partially ordered set in which every chain has an upper bound has a maximal element), the statement that every vector space has a basis (Chapter 5), Tychonoff's theorem on products of compact spaces (Chapter 6), and the claim that every surjection has a right inverse.

Its cost is that it produces objects no construction could reach. Vitali's non-measurable subset of $\mathbb{R}$ and the Banach–Tarski decomposition — a solid ball cut into five pieces and reassembled, by rigid motions alone, into two balls of the original size — both follow from choice, and both are immune to physical interpretation precisely because the pieces have no volume. The lesson for physics is not that choice is false but that measure-theoretic hygiene is mandatory: probability is defined on a σ-algebra of measurable sets, and the pathological sets are simply not in it (Chapter 11).

Remark 3.79 (How much choice does physics use?)*.* Far less than the full axiom. The Hilbert spaces of quantum mechanics are separable, and constructing a countable orthonormal basis from a countable dense set by Gram–Schmidt needs only *dependent choice*, a weak fragment consistent with ZF plus "every set of reals is measurable". Where full choice does enter — the Hahn–Banach theorem, the existence of a basis for a non-separable space, the spectral theorem in its most general form (Chapter 12) — the applications physics makes of the result can invariably be recovered constructively in the separable case. No experimental prediction has ever depended on the axiom of choice.

3.6.4 Three answers to the crisis

The paradoxes forced a question that mathematics had never needed to ask: what are its statements *about*, and what makes a proof valid? Three programmes answered differently, and their disagreement is the direct ancestor of the results in the remainder of this chapter.

1. **Logicism** (Frege, Russell, Whitehead). Mathematics is a branch of logic: numbers are definable in purely logical terms and arithmetic truths are logical truths. *Principia Mathematica* [365] carried the reduction out in three volumes: the cardinal groundwork

for $1 + 1 = 2$ is proposition *54.43, midway through the first volume, and the arithmetical proposition itself is *110.643, on page 86 of the second. The paradoxes were blocked with a ramified theory of types forbidding a collection to contain itself. The programme foundered on its own repairs: the axioms of infinity and of reducibility, needed to make the development work, are not plausibly *logical* truths, so the reduction relocated the problem rather than dissolving it.

2. **Formalism** (Hilbert). Mathematics is the manipulation of finite strings of symbols according to stated rules; questions of what the symbols denote are set aside. Infinite objects are "ideal elements", admissible so long as reasoning with them never yields a false statement about finite ones [546]. Hilbert's programme is the demand that this be *proved*, by finitary means, once and for all. It is the subject of Sections 3.8 and 3.10.

3. **Intuitionism** (Brouwer). Mathematics is a mental construction, and a mathematical object exists only when it has been constructed [401]. On this view $\forall x\, P(x)$ asserts a method producing a proof of $P(x)$ for each x, and $\exists x\, P(x)$ asserts a construction exhibiting a witness. The law of the excluded middle Equation (3.25) then fails for infinite domains: to assert $p \vee \neg p$ over $\mathbb{N}$ is to claim a decision procedure one may not possess. Proof by contradiction survives for refutations but not for existence claims — an intuitionist rejects a proof that some x exists which merely shows that the non-existence of x is absurd.

This treatise reasons classically, uses ZFC without apology, and states the fact rather than assuming it. But the intuitionist objection has an afterlife the physicist should recognize: a constructive existence proof yields an algorithm, and a classical one need not. When a physical theory guarantees that a solution, a ground state, or an equilibrium *exists*, only the constructive version tells anyone how to compute it — and Section 3.9 shows that the gap between the two is not always bridgeable, even in principle. Bishop's constructive redevelopment of analysis [1341] shows how much of the working mathematics of physics can be had on those terms, which is more than the classical mathematician expects and less than the physicist would like.

3.7 The analytical perspective

The same decades that produced the paradoxes produced a movement in philosophy that took the new logic as its instrument: analytical philosophy. Its founding conviction was that philosophical problems are to be attacked by analysing the logical structure of the language in which they are posed — and its central case study was physics. This treatise's first editorial rule, that only physics with observational evidence is in scope, is a philosophical commitment, not a mathematical one. It deserves an argument rather than an assertion, and the argument was worked out here.

3.7.1 The linguistic turn

Frege's *Begriffsschrift* [207] introduced quantifiers, variables and a rigorous notion of proof, replacing two millennia of syllogistic; Section 3.1.4 is his legacy. His *Grundlagen* [228] then asked what a number *is*, and answered by analysing the sentences numbers occur in rather than by introspecting about quantity. That reversal — study the statement, not the thing — is the linguistic turn.

Frege's distinction between the *sense* of an expression and its *reference* is the part a physicist uses daily. "The morning star" and "the evening star" refer to the same object,

Venus, but differ in sense, which is why their identity was a discovery and not a triviality. The pattern recurs throughout this book. Inertial mass and gravitational mass have entirely different senses — one is the resistance to acceleration in Chapter 19, the other the coupling to a gravitational field — and their identity is an empirical finding, tested to parts in 10^{15} and elevated to the equivalence principle (Chapter 42). Energy and mass, inertia and curvature, temperature and mean kinetic energy: each is an identity of reference across a difference of sense, each was an experimental result, and none is a definition.

Russell's theory of descriptions supplied the second tool. The sentence "the present King of France is bald" is not about a bald man; analysed, it asserts that exactly one thing kings France and that it is bald — a perfectly meaningful claim, and false, with no ghostly monarch required. The grammatical form of a sentence can thus misrepresent its logical form. This is precisely what happened to the aether: "the frame in which the aether is at rest" is a definite description whose presupposition fails, and special relativity did not find that frame moving oddly, it denied that the description picks anything out (Chapter 37). A physicist who keeps the distinction in view is protected against a whole family of pseudo-questions — "what is the wavefunction really made of", "where was the particle before measurement" — which may or may not have answers, but which certainly do not have them merely because the grammar of the question is well formed.

3.7.2 Logical positivism and its collapse

Wittgenstein's *Tractatus* [496] pushed the programme to its limit: propositions picture facts, the sense of a proposition is the state of affairs it depicts, and what cannot be depicted cannot be said. Its closing proposition — whereof one cannot speak, thereof one must be silent — was read by the Vienna Circle as a mandate. Their manifesto [624] proposed the *verification principle*: the meaning of a statement is the method of its verification, and a statement admitting no verification is not false but meaningless. Metaphysics was to be eliminated, not refuted.

For a while physics appeared to vindicate them, because physics had just done it. Einstein's 1905 analysis of simultaneity is the operationalist move in its purest form: instead of asking what simultaneity *is*, he asked what procedure establishes it, found that the procedure is frame-dependent, and derived the Lorentz transformations from that (Chapter 38). Heisenberg's 1925 matrix mechanics was motivated by the resolve to build a theory from observable transition frequencies and intensities alone, discarding unobservable electron orbits (Chapter 70). Two revolutions in twenty years, both achieved by discarding a quantity no experiment could reach.

The principle nonetheless failed, in three distinct ways, and the failures are as instructive as the successes.

1. **Self-refutation.** The verification principle is not itself verifiable by any observation, so by its own criterion it is meaningless. No repair commanded agreement.

2. **Holism.** Quine argued that no individual statement can be confronted with experience on its own [987]: a prediction follows only from a theory together with auxiliary hypotheses about apparatus, background and approximation, so a failed prediction refutes the conjunction and never says which conjunct to abandon. The analytic–synthetic distinction on which the positivists relied — truths of meaning versus truths of fact — does not survive the analysis either. Every anomalous result in this book illustrates the point: the anomalous perihelion of Mercury could in principle have been an unseen planet, and deciding otherwise took decades and independent evidence.

3. **Verification is the wrong relation.** A universal law has infinitely many instances and can never be verified by finitely many observations, but a single counterinstance

refutes it. Popper therefore replaced verifiability by *falsifiability* as the criterion of scientific status [1173]. This is nothing but Equation (3.17) taken seriously, as Section 3.1.3 already noted.

Kuhn added the historical objection [1233]: observations are theory-laden, the auxiliary hypotheses are supplied by the reigning framework, and scientists abandon a framework not when a refutation arrives but when a better framework does.

3.7.3 The position this treatise takes

The programme did not survive, but its residue is the working philosophy of modern physics, and it is worth stating explicitly what this book has adopted from the wreckage.

1. **Demarcation by testability, not by verifiability.** Editorial rule 1 admits a subject when observation could in principle decide against it. That is why the Standard Model is in and string theory, supersymmetry and speculative quantum gravity are named only in Chapter 135 and only to record that the evidence is absent.

2. **Operational meaning of quantities.** A physical quantity is individuated by the procedure that measures it and the unit that reports it, which is why the SI is treated as axiomatic here (Chapter 2) and why every experiment in this book carries apparatus, procedure and uncertainty.

3. **Holism, taken as a bookkeeping obligation.** Since no prediction confronts data alone, the auxiliary assumptions must be visible. That is the real function of editorial rule 2: a derivation is the complete list of what a prediction depends on, and a *pending derivation* is an admission that the list is not yet complete.

4. **No final truth.** Survival under attempted refutation is what the method certifies, never truth (Remark 1.2).

What this treatise does *not* do is settle the question the positivists thought they had dissolved: whether the unobservable structures of a successful theory — quantum states, gauge fields, spacetime curvature — are real, or are instruments for organizing observations. Where an interpretive dispute has observable consequences, it is an experimental question and is treated as one (Chapter 89); where it has none, this book reports the competing readings and stops (Chapter 85). That restraint is itself the analytical inheritance: not every well formed question has an answer, and one of the uses of logic is to tell which.

There is a last, sharper lesson, and the following sections prove it rather than argue it. The Vienna Circle's ambition was a language for science in which every meaningful question could be settled by inspection of the world plus computation. Within four years of the manifesto, Gödel had shown that no such language exists even for arithmetic.

3.8 Formal systems and incompleteness

Hilbert's answer to the paradoxes (Section 3.6.4) was to make mathematical reasoning itself a mathematical object. Strip the meaning from a proof and what remains is a finite sequence of finite strings, each obtained from earlier ones by stated rules. Such an object can be studied with the same rigour as a triangle, and the study of it is *metamathematics*.

3.8.1 Formal systems

Definition 3.80 (Formal system)**.** A *formal system* T consists of

1. a finite or countable *alphabet* of symbols;
2. a set of *formulas*: those finite strings over the alphabet that a purely syntactic rule declares well formed;
3. a set of *axioms*, distinguished formulas;
4. a finite set of *rules of inference*, each taking finitely many formulas to a formula.

A *derivation* of φ in T is a finite sequence of formulas ending in φ, each member of which is an axiom or follows from earlier members by a rule. We write $T \vdash \varphi$ — "T proves φ" — when a derivation exists, and $T \nvdash \varphi$ when none does.

Everything in Definition 3.80 is finite and mechanical. Whether a given string is a formula, whether a given formula is an axiom, whether a given sequence is a derivation: each is settled by inspection, without understanding what the symbols mean. This is the whole point. A formal system is a game with tokens, and its trustworthiness rests on the fact that a clerk who understands nothing can check a proof.

Definition 3.81 (Effective axiomatization)**.** A formal system is *effectively axiomatized* if there is a mechanical procedure that, given a formula, decides whether it is an axiom.
Rests on Definition 3.80.

"Mechanical procedure" is made precise in Section 3.9; until then the intuitive reading suffices. The condition excludes a cheap evasion of the theorems below — taking as axioms *all* true statements of arithmetic gives a complete theory, but no clerk could ever recognize its axioms, and it is therefore no use to anyone.

Definition 3.82 (Consistency, completeness, soundness)**.** Let T be a formal system in a language with negation.

1. T is *consistent* if there is no formula φ with both $T \vdash \varphi$ and $T \vdash \neg\varphi$.
2. T is *negation-complete* if for every sentence φ of its language, $T \vdash \varphi$ or $T \vdash \neg\varphi$: the system decides every question expressible in it.
3. T is *sound* with respect to an interpretation if every provable sentence is true under that interpretation.
4. T is *decidable* if there is a mechanical procedure that, given a sentence, determines whether $T \vdash \varphi$.

Rests on Definitions 3.7 and 3.80.

Consistency is indispensable, because an inconsistent system proves everything: from φ and $\neg\varphi$ the tautology $(\varphi \wedge \neg\varphi) \to \psi$ — vacuously true since its antecedent is false by Equation (3.26) — yields any ψ whatever by modus ponens. A theory that proves everything distinguishes nothing and says nothing.

Definition 3.83 (Peano arithmetic)**.** *Peano arithmetic*, denoted PA, is the first-order theory in the language $\{0, S, +, \cdot\}$ whose axioms are: S is injective and takes the value 0 nowhere; the recursion equations

$$n + 0 = n\,, \quad n + S(m) = S(n + m)\,, \qquad n \cdot 0 = 0\,, \quad n \cdot S(m) = n \cdot m + n\,, \tag{3.83}$$

which are those of Section 3.2.2 rebased at 0, as first-order arithmetic conventionally is; and the induction schema: for each formula φ of the language, the axiom

$$(\varphi(0) \wedge \forall n\,(\varphi(n) \to \varphi(Sn))) \to \forall n\,\varphi(n)\,. \tag{3.84}$$

Rests on Definition 3.80 and Axioms 3.33 and 3.34.

Equation (3.84) is weaker than Axiom 3.34. The axiom of Section 3.2.2 quantifies over *all* predicates on $\mathbb{N}$, of which there are uncountably many by Theorem 3.71; Equation (3.84) provides one axiom for each of the countably many formulas of a first-order language. That gap between second-order and first-order induction is exactly where incompleteness will enter.

3.8.2 Completeness — what logic does deliver

Before the negative results, the positive one, and it is easy to confuse them because both are called "completeness".

Theorem 3.84 (Gödel's completeness theorem, 1930)**.** *A sentence of first-order logic is derivable from a set of premises if and only if it is true in every structure satisfying those premises:*

$$T \vDash \varphi \iff T \vdash \varphi\,. \tag{3.85}$$

Equivalently, a consistent first-order theory has a model [654].

Rests on Definitions 3.80 and 3.82.

Full derivation: Appendix A.4 (p. 2775).

Derives Theorem 3.84.

This says that the proof calculus of first-order logic misses nothing: semantic consequence and syntactic derivability coincide. Note carefully what it is *about* — the logic, not any particular theory. It says that whatever follows from the axioms of a theory can be proved from them. It does not say the axioms settle every question, and the theorem of the next subsection says they do not.

Remark 3.85 (Two senses of "complete"). Theorem 3.84 concerns *semantic* completeness of a logic: everything true in all models is provable. Definition 3.82 defines *negation* completeness of a theory: every sentence or its negation is provable. Gödel proved the first in 1930 and refuted the second, for arithmetic, in 1931. Both results are his, they point in opposite directions, and mixing them up is the commonest error made about this subject.

3.8.3 Arithmetization

Gödel's decisive move was to make arithmetic talk about itself. Assign to every symbol a number, to every finite string of symbols the number coding its sequence of symbols, and to every finite sequence of strings — that is, every derivation — a number coding it. Any injective coding with mechanically computable encoding and decoding will do; the choice matters as little as the choice of Kuratowski pairs in Remark 3.39. Write $\ulcorner\varphi\urcorner$ for the numeral denoting the code of the formula φ: its *Gödel number*.

Syntactic properties become arithmetical properties under this coding. "n codes a well formed formula", "m codes a derivation of the formula coded by n" — these are conditions on numbers, decidable by finite computation, and for an effectively axiomatized theory they can be expressed by formulas of the language of arithmetic and proved of the right numbers inside PA. In particular there is a formula $\mathrm{Prov}_T(x)$ of one free variable, the *provability predicate*, such that

$$\mathrm{Prov}_T(x) \text{ expresses "}\exists m \text{ such that } m \text{ codes a } T\text{-derivation of the formula coded by } x\text{"}\,. \tag{3.86}$$

The construction is elementary but long; it is carried out in Appendix A.5.

Lemma 3.86 (Diagonal lemma)**.** *Let T be a theory in which the elementary syntactic functions are representable, and let $\psi(x)$ be any formula with one free variable. Then there is a sentence σ with*

$$T \vdash \ \sigma \leftrightarrow \psi(\ulcorner \sigma \urcorner)\,. \tag{3.87}$$

Rests on Definitions 3.80 and 3.83.

Full derivation: Appendix A.5 (p. 2780).

Derives Lemma 3.86.

The sentence σ asserts of its own Gödel number that it has the property ψ; informally, σ says "I am ψ". This is the diagonal argument of Section 3.5.2 once more, now applied to formulas indexed by their own codes, and it is the only sleight of hand in the entire subject. Nothing self-referential is smuggled in: σ is an ordinary arithmetical sentence about numbers, which happens to be true exactly when a certain number — its own code — has a certain computable property.

3.8.4 The first incompleteness theorem

Theorem 3.87 (Gödel, 1931)**.** *Let T be an effectively axiomatized, consistent theory that proves a modest amount of arithmetic — enough to represent the computable functions, which PA and ZFC amply do. Then there is a sentence G_T of the language of T such that*

$$T \nvdash G_T \qquad \text{and} \qquad T \nvdash \neg G_T\,. \tag{3.88}$$

T is therefore not negation-complete. Moreover G_T is true of the natural numbers [681, 786].

Rests on Lemma 3.86, Equation (3.86), and Definitions 3.81 and 3.82.

Proof. *Derives Theorem 3.87.*

Apply Lemma 3.86 to the formula $\psi(x) = \neg\mathrm{Prov}_T(x)$. This yields a sentence G_T with

$$T \vdash \ G_T \leftrightarrow \neg\mathrm{Prov}_T(\ulcorner G_T \urcorner)\,, \tag{3.89}$$

a sentence that, read through the coding, says "I am not provable in T".

T does not prove G_T. Suppose $T \vdash G_T$. Then some finite derivation of G_T exists; let m be its code. The statement "m codes a derivation of G_T" is a true statement about particular numbers, verified by a finite computation, and a theory representing the computable functions proves every such true statement. Hence $T \vdash \mathrm{Prov}_T(\ulcorner G_T \urcorner)$, and by Equation (3.89), $T \vdash \neg G_T$. So T proves both G_T and $\neg G_T$, contradicting consistency. Therefore $T \nvdash G_T$.

G_T is true. What the previous paragraph established is that no derivation of G_T exists. That is precisely what G_T asserts, so G_T is a true sentence about the natural numbers.

T does not prove $\neg G_T$. If T is sound — if it proves only truths — this is immediate: $\neg G_T$ is false, so T cannot prove it. Soundness is a stronger hypothesis than consistency, and Gödel replaced it by the syntactic condition of ω-consistency; Rosser later removed even that, at the cost of a subtler sentence, so that bare consistency suffices [786]. Both refinements are carried out in Appendix A.5. □

Note what the theorem does not permit: patching. Adjoin G_T to T as a new axiom and the resulting theory $T' = T + G_T$ is still effectively axiomatized, still consistent, still arithmetically adequate — so the theorem applies again and produces $G_{T'}$, undecided by T'. The gap cannot be closed by adding axioms, one at a time or infinitely many, so long as a clerk can recognize the axioms.

3.8.5 The second incompleteness theorem

Consistency is itself an arithmetical statement: T is consistent exactly when some particular sentence has no derivation, say

$$\mathrm{Con}_T := \neg \mathrm{Prov}_T(\ulcorner 0 = 1 \urcorner)\,. \tag{3.90}$$

Theorem 3.88 (Gödel's second incompleteness theorem)**.** *Let T be effectively axiomatized and contain, or interpret, PA. This is more than Theorem 3.87 demands — representing the computable functions does not by itself make the derivability conditions below available — and PA and ZFC both qualify. If T is consistent, then*

$$T \nvdash \mathrm{Con}_T\,. \tag{3.91}$$

No such theory can prove its own consistency [681].
Rests on Theorem 3.87, Equation (3.90), and Definition 3.83.

Derivation. *Derives Theorem 3.88.*

The first half of the proof of Theorem 3.87 is an argument, from the consistency of T, to the unprovability of G_T — that is, an argument for $\mathrm{Con}_T \to G_T$. The content of the second theorem is that this argument can itself be formalized inside T, giving

$$T \vdash\ \mathrm{Con}_T \to G_T\,. \tag{3.92}$$

Granting Equation (3.92), suppose $T \vdash \mathrm{Con}_T$. Modus ponens would give $T \vdash G_T$, which Theorem 3.87 forbids for consistent T. Hence $T \nvdash \mathrm{Con}_T$.

Establishing Equation (3.92) requires that Prov_T behave inside T the way provability behaves outside it. The sufficient conditions, isolated by Hilbert and Bernays [839] and streamlined by Löb [1074], are the three *derivability conditions*:

$$T \vdash \varphi \implies T \vdash \mathrm{Prov}_T(\ulcorner \varphi \urcorner)\,, \tag{3.93}$$

$$T \vdash \mathrm{Prov}_T(\ulcorner \varphi \to \chi \urcorner) \to (\mathrm{Prov}_T(\ulcorner \varphi \urcorner) \to \mathrm{Prov}_T(\ulcorner \chi \urcorner))\,, \tag{3.94}$$

$$T \vdash \mathrm{Prov}_T(\ulcorner \varphi \urcorner) \to \mathrm{Prov}_T(\ulcorner \mathrm{Prov}_T(\ulcorner \varphi \urcorner) \urcorner)\,. \tag{3.95}$$

Verifying them for a specific coding is laborious rather than deep. The verification and the derivation of Equation (3.92) from them are given in Appendix A.5. □

Remark 3.89 (Löb's theorem). The derivability conditions have a striking consequence: if $T \vdash \mathrm{Prov}_T(\ulcorner \varphi \urcorner) \to \varphi$, then $T \vdash \varphi$ [1074]. A theory can affirm "if this is provable then it is true" only of things it already proves. Taking φ to be $0 = 1$ recovers Theorem 3.88. Whatever confidence we have that provable arithmetic statements are true, arithmetic cannot supply it from within.

3.8.6 What the theorems do not say

Few results have been abused more, so the boundaries deserve stating as plainly as the theorems.

1. **They do not exhibit an unknowable truth.** We know G_T is true — Theorem 3.87 proves it, in a metatheory. The sentence is unprovable *in* T, and provable in any reasonable stronger system; PA's Gödel sentence is a theorem of ZFC. Incompleteness is always relative to a fixed system.

2. **They do not apply to every formal system.** A theory must be effectively axiomatized, consistent, and strong enough to represent computation. Drop the last and complete decidable theories abound: the theory of dense linear orders, Presburger arithmetic — the naturals with addition but not multiplication [666] — and, most strikingly, Tarski's result that the first-order theory of the real closed fields, and with it all of elementary algebra and Euclidean geometry, is complete and decidable [992]. Multiplication together with addition on the integers is what tips a theory over the edge.

3. **They do not show mathematics is inconsistent, or unreliable.** They show a specific ambition — self-certification — is unattainable. See Section 3.10.

4. **They do not settle whether minds exceed machines.** Arguments that a human "sees" the truth of G_T while a machine cannot assume that the human's own reasoning is a consistent formal system and that we know which one; neither premise is available. The question is open and these theorems do not close it.

5. **They do not by themselves make physics incomplete.** A physical theory is not a formal system in the required sense, and its content is fixed by measurement rather than derivation. Genuine undecidability results in physics exist, and they come from computability (Section 3.9), not from Gödel numbering.

Remark 3.90 (Independent statements that are not contrived)*.* The sentence G_T is built for the purpose and of no independent interest, which for forty years left the impression that incompleteness was a curiosity confined to self-reference. Paris and Harrington closed that escape [1608]: a natural finitary strengthening of Ramsey's combinatorial theorem, whose statement mentions nothing about provability, is true and unprovable in PA. Goodstein's theorem [874], about certain rapidly growing integer sequences that nevertheless terminate, is another: Kirby and Paris showed it too escapes PA [1690]. Ordinary mathematics does reach past the boundary.

Theorem 3.91 (Tarski's undefinability of truth)**.** *Let T be a consistent theory as above. There is no formula* $\mathrm{True}(x)$ *of the language of arithmetic such that $\varphi \leftrightarrow \mathrm{True}(\ulcorner\varphi\urcorner)$ holds for every sentence φ [761].*

Rests on Lemma 3.86 and Definition 3.82.

Proof. *Derives Theorem 3.91.*

Suppose such a formula existed. Apply Lemma 3.86 to $\neg\mathrm{True}(x)$ to obtain a sentence λ with $\lambda \leftrightarrow \neg\mathrm{True}(\ulcorner\lambda\urcorner)$. Combining with the assumed property of True at $\varphi = \lambda$ gives $\lambda \leftrightarrow \neg\lambda$, a contradiction. □

The sentence λ says "I am false": it is the liar paradox, made into a theorem instead of a contradiction by locating the fault correctly. Truth for a language is definable, but only in a richer metalanguage — exactly the stratification anticipated in Remark 3.18. Provability, by contrast, *is* expressible in the object language, which is why Equation (3.86) exists. That asymmetry between truth and provability is the substance of incompleteness.

3.9 Computability and decidability

Two of Hilbert's demands survived Theorem 3.87: even if a theory cannot prove every truth, one might still hope for a mechanical procedure that decides, of any given sentence, whether it is provable. Hilbert and Ackermann posed this as *das Entscheidungsproblem* — the decision problem — and called it the principal problem of mathematical logic [606]. Answering it required saying what a mechanical procedure *is*, a question nobody had needed

to make precise. Three answers arrived within a year of one another, and they turned out to define the same class.

3.9.1 Turing machines

Turing's analysis began not with mathematics but with a description of a human computer at work: a person with a pencil, an unlimited supply of ruled paper, a finite number of states of mind, and a finite book of rules, attending to one square at a time [803]. Idealizing this gives the following.

Definition 3.92 (Turing machine)**.** A *Turing machine* is a tuple $M = (Q, \Gamma, \sqcup, \Sigma, \delta, q_0)$ where

1. Q is a finite set of *states*;
2. Γ is a finite *tape alphabet* containing a distinguished *blank* symbol $\sqcup$;
3. $\Sigma \subset \Gamma \setminus \{\sqcup\}$ is the *input alphabet*;
4. $q_0 \in Q$ is the *initial state*;
5. the *transition function* δ is a partial map

$$\delta : Q \times \Gamma \longrightarrow Q \times \Gamma \times \{L, R\} \ . \tag{3.96}$$

The machine acts on a tape of cells unbounded in both directions, each holding one symbol of Γ, all but finitely many blank, with a head positioned over one cell. A *configuration* is the triple consisting of the tape contents, the head position and the current state. One *step* reads the scanned symbol a in state q, and if $\delta(q, a) = (q', a', D)$ is defined, writes a' in place of a, moves the head one cell in the direction D and enters state q'. If $\delta(q, a)$ is undefined the machine *halts*. The machine *computes* the partial function sending an input string, written on an otherwise blank tape with the head at its first symbol, to the tape contents at halting; where it never halts, the function is undefined.

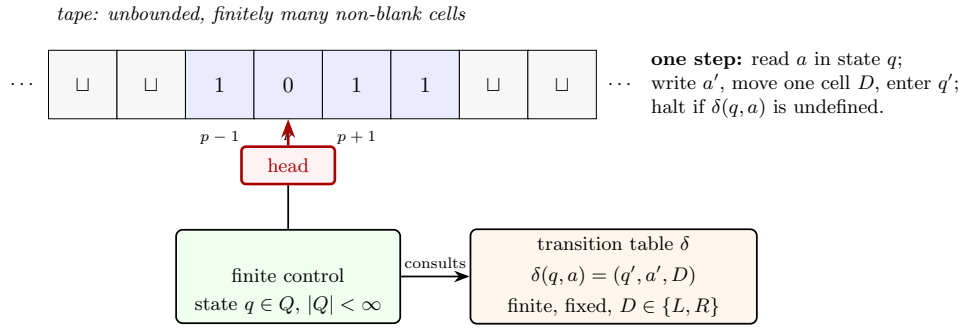

Figure 3.2: A Turing machine (Definition 3.92). The tape is unbounded and holds finitely many non-blank symbols; the head reads and writes one cell at a time; the finite control is in one of finitely many states and consults a fixed finite table δ. Everything unbounded is on the tape, and everything the machine *is* — the state set and the table — is finite. That separation is what makes the machine codeable as a number and hence a possible input to another machine.

Nothing about this device is electronic, and nothing about it is fast. Its significance is that it is manifestly mechanical and just as manifestly unrestricted in the memory it may use — and that the machine itself, being finite, can be written down as a finite string and so coded by a number $\ulcorner M \urcorner$, exactly as formulas were coded in Section 3.8.3.

Definition 3.93 (Computable function, decidable set)**.** A partial function on strings is *computable* if some Turing machine computes it. A set is *decidable* if its indicator function is computable — some machine halts on every input and reports correctly whether the input belongs to the set. A set is *semi-decidable* if some machine halts exactly on its members.
Rests on Definition 3.92.

Definition 3.81 can now be read literally: a theory is effectively axiomatized when its set of axioms is decidable. And a theory that is effectively axiomatized has a semi-decidable set of theorems — enumerate all finite derivations in order and watch for one ending in the target sentence — which is why Prov_T of Equation (3.86) exists.

Axiom 3.94 (Church–Turing thesis)**.** Every function computable by any mechanical procedure whatsoever is computable by a Turing machine.

This is not a theorem and cannot be one, since "mechanical procedure" on the left is informal. It is an empirical and conceptual claim, and its support is the convergence of independent attempts: Church's λ-definable functions [773], Kleene's general recursive functions [778], Post's combinatory processes [784] and Turing's machines all define the same class, and every model of computation proposed since — register machines, cellular automata, the physical computers on our desks, quantum computers — has been proved no more powerful in what it can compute at all, whatever the differences in efficiency.

Theorem 3.95 (Universal machine)**.** *There exists a Turing machine U which, on input the pair $(\ulcorner M \urcorner, w)$, simulates M on w: it halts precisely when M halts on w, with the same output.*
Rests on Definitions 3.92 and 3.93.

Full derivation: Appendix A.6 (p. 2788).
Derives Theorem 3.95.

The universal machine is why a computer is a general-purpose device rather than a special-purpose one, and it is the technological content of [803]. For the present chapter its importance is that programs are data: a machine can be fed to a machine, including to itself.

3.9.2 The halting problem

Theorem 3.96 (Turing)**.** *There is no Turing machine which, given $(\ulcorner M \urcorner, w)$, always halts and correctly reports whether M halts on input w. The halting problem is undecidable [803].*
Rests on Definitions 3.92 and 3.93.

Proof. *Derives Theorem 3.96.*

Suppose such a machine H existed, halting on every input and returning *yes* when M halts on w and *no* otherwise.

Construct from it a machine D which, on input a single machine code $\ulcorner M \urcorner$, runs H on the pair $(\ulcorner M \urcorner, \ulcorner M \urcorner)$ — asking whether M halts when fed its own code — and then does the opposite of the answer:

$$D(\ulcorner M \urcorner) = \begin{cases} \text{loop forever} & \text{if } H \text{ answers yes}, \\ \text{halt} & \text{if } H \text{ answers no}. \end{cases} \tag{3.97}$$

D is an ordinary machine, built from H by adding a copying step and a deliberate infinite loop, so it has a code $\ulcorner D \urcorner$.

Run D on $\ulcorner D \urcorner$. If D halts on $\ulcorner D \urcorner$, then H answered *yes*, and Equation (3.97) made D loop forever — so it does not halt. If D does not halt on $\ulcorner D \urcorner$, then H answered *no*, and Equation (3.97) made D halt. Either branch contradicts itself: D halts on its own code if and only if it does not. Since D was built from H by unimpeachable steps, the fault lies with the assumption that H exists. □

That is the diagonal argument for the fourth time, and the family resemblance is now unmistakable: replace "does not contain itself" by "does not halt on its own code" and Russell becomes Turing; replace it by "is not provable" and Russell becomes Gödel.

Theorem 3.97 (Rice)**.** *Let $\mathcal{P}$ be any set of partial computable functions that is neither empty nor all of them. Then the set of machine codes $\{\ulcorner M \urcorner \mid M \text{ computes a function in } \mathcal{P}\}$ is undecidable.*

Rests on Theorems 3.95 and 3.96 and Definition 3.93.

Proof. *Derives Theorem 3.97.*

Write $\varnothing$ for the nowhere-defined function, computed by a machine that immediately loops. Replacing $\mathcal{P}$ by its complement if necessary — which changes decidability not at all — assume $\varnothing \notin \mathcal{P}$, and pick $g \in \mathcal{P}$, computed by some machine G.

Given an arbitrary pair $(\ulcorner M \urcorner, w)$, build the machine N which, on any input x, first simulates M on w using Theorem 3.95, and only if that simulation halts goes on to simulate G on x and return its output. If M halts on w, then N computes $g \in \mathcal{P}$; if M does not halt on w, then N halts on no input and computes $\varnothing \notin \mathcal{P}$. The code $\ulcorner N \urcorner$ is obtained from $(\ulcorner M \urcorner, w)$ by a computable transformation.

A decision procedure for $\mathcal{P}$ would therefore decide, of any $(\ulcorner M \urcorner, w)$, whether M halts on w, contradicting Theorem 3.96. □

Rice's theorem is the sweeping form of the bad news: *no* non-trivial question about what a program computes — as opposed to how it is written — is answerable by a general algorithm. Not "does it ever output zero", not "does it compute the same function as this other program", not "does it terminate on all inputs".

3.9.3 The Entscheidungsproblem answered

Theorem 3.98 (Church–Turing)**.** *The set of valid sentences of first-order logic is undecidable: no mechanical procedure determines, of an arbitrary first-order sentence, whether it is provable [772, 803].*

Rests on Theorem 3.96 and Definitions 3.80 and 3.93.

Full derivation: Appendix A.5 (p. 2780).

Derives Theorem 3.98.

The proof encodes the behaviour of a Turing machine into a first-order sentence which is valid if and only if the machine halts, reducing Theorem 3.96 to the decision problem. Hilbert's principal problem of mathematical logic thus has a negative answer, and the two negative answers fit together: by Theorem 3.84 the valid sentences are exactly the provable ones, so they are semi-decidable — search all derivations — but by Theorem 3.98 not decidable. A search that will succeed if there is anything to find, but that gives no sign of when to stop, is the best any general procedure can do.

The corresponding statement for arithmetic is sharper still: the set of true sentences of arithmetic is not even semi-decidable, which is Theorem 3.91 in computational dress.

3.9.4 Where decision procedures do exist

The negative results are about *general* procedures over *all* sentences of a sufficiently rich language. Restrict the language and algorithms reappear, sometimes spectacularly.

1. **Propositional logic** is decidable: build the truth table, as in Proposition 3.22. The cost is 2^n rows for n propositions, and whether an essentially faster method exists is the P versus NP problem, still open.

2. **Presburger arithmetic** — the naturals with addition and order but *without* multiplication — is consistent, complete and decidable [666]. Multiplication is what makes arithmetic able to encode syntax, and hence what makes it incomplete.

3. **Real closed fields.** Tarski proved that the first-order theory of $(\mathbb{R}, +, \cdot, <)$ admits elimination of quantifiers and is therefore complete and decidable [992]. Every statement of elementary algebra and of Euclidean and analytic geometry expressible with real variables, polynomials, equalities, inequalities and quantifiers can be settled by algorithm. This is the technical foundation of computer algebra and of automated geometry; it also means that the real-number algebra a physicist actually manipulates sits on the decidable side of the line. The decision procedure is doubly exponential and rarely practical, but it exists.

The boundary between these islands and the undecidable ocean is sharp and somewhat surprising: the reals with addition and multiplication are decidable, the integers with addition are decidable, but the integers with addition *and* multiplication are not.

3.9.5 Undecidability inside physics

Physical questions can be phrased so as to encode computations, and when they are, they inherit undecidability. Three results, in increasing order of physical relevance.

1. **Hilbert's tenth problem.** There is no algorithm deciding whether an arbitrary polynomial equation in several variables with integer coefficients has an integer solution. Davis, Putnam and Robinson reduced the question to the arithmetic definability of exponential growth, and Matiyasevich completed the proof in 1970 by showing the Fibonacci sequence is Diophantine [1429, 1496]. Diophantine constraints are not exotic in physics — they govern commensurability of orbital periods, lattice matching conditions and anomaly-cancellation conditions on integer charges.

2. **Tilings and ground states.** Whether a finite set of tile shapes tiles the plane is undecidable [1326], and a tiling problem can be rewritten as the problem of finding the ground-state configuration of a classical lattice model with finite-range interactions. The ground-state energy density of a general such model is therefore not computable by any algorithm uniform in the model.

3. **The spectral gap.** Cubitt, Pérez-García and Wolf constructed a family of translationally invariant, nearest-neighbour Hamiltonians on a two-dimensional lattice of spins, depending on a parameter, such that determining whether the model is gapped or gapless in the thermodynamic limit is undecidable [2251]. The construction embeds a universal Turing machine in the low-energy physics: the model is gapped exactly when the encoded machine fails to halt.

Remark 3.99 (How to read these results honestly). They do not say that Nature computes something uncomputable, and they do not say any particular laboratory question is unanswerable. Every one of them concerns an *infinite family* of idealized models and asks for a single algorithm covering the whole family. A specific finite system has a finite-dimensional Hamiltonian whose gap is computable to any desired accuracy by diagonalization; what fails is the existence of a general criterion — a finite set of rules, a closed-form classification — valid for all models at once. The thermodynamic limit, not quantum mechanics, is where the undecidability enters, since it is the limit that supplies the unbounded tape.

The practical content is a warning about ambitions rather than about measurements. Programmes seeking a complete classification of quantum phases, or a general algorithm to determine whether a lattice model is gapped — the Yang–Mills mass gap being the

celebrated instance (Chapter 133) — are seeking something that provably does not exist in full generality. Progress must come by restricting the class of models, exactly as Section 3.9.4 restricts the language. That is a genuine, and genuinely useful, piece of physical knowledge.

3.10 Can mathematics be built without contradictions?

The question that opened the crisis can now be asked precisely, and answered precisely — though not in the form anyone wanted.

3.10.1 What Hilbert asked for

Hilbert's programme had a definite shape [546]. Mathematics was to be split into a *finitary* part, concerning concrete finite configurations of symbols, whose meaning and reliability nobody doubts, and an *ideal* part — infinite sets, arbitrary real numbers, the whole Cantorian apparatus — introduced because it makes the theory smooth, in the way that points at infinity make projective geometry smooth. The programme demanded a proof, *carried out by finitary means alone*, that the ideal part never yields a false finitary statement. Consistency was the crux: an inconsistent system proves everything, so a consistency proof would license the entire ideal apparatus at one stroke, and the mathematician could then use infinite sets with a clear conscience while regarding them as convenient fictions.

Hilbert put the case in an address broadcast from Königsberg on 8 September 1930, ending with the words carved on his gravestone: we must know, we shall know [658]. The previous day, at a conference in the same city, Gödel had mentioned to a roundtable that he could construct true but unprovable arithmetical statements. Almost nobody present grasped what they had heard.

1. Theorem 3.87 killed the hope that a single effectively axiomatized system could settle every arithmetical question.

2. Theorem 3.88 killed the programme proper: since finitary reasoning is certainly formalizable within PA, and PA cannot prove its own consistency, no finitary proof of the consistency of PA — let alone of analysis or set theory — can exist.

3. Theorem 3.98 killed the remaining hope of a mechanical decision procedure.

3.10.2 What survived: relative consistency

What did *not* die is the mathematical study of consistency, which became one of the most productive branches of logic. The trick is to stop demanding absolute certification and to measure systems against each other instead.

Gentzen proved in 1936 that Peano arithmetic is consistent [776]. There is no contradiction with Theorem 3.88, because his proof is not carried out inside PA: it uses finitary reasoning *plus* one transfinite ingredient, induction along the ordinal

$$\varepsilon_0 = \sup\left\{\omega,\ \omega^{\omega},\ \omega^{\omega^{\omega}},\ \dots\right\}, \tag{3.98}$$

the first ordinal not reachable from ω by finitely many exponentiations. Every proper initial segment of ε_0 admits an induction principle provable in PA; ε_0 itself does not, and that single step beyond is exactly what a consistency proof costs. The number ε_0 is thereby a measurement of the strength of PA, and assigning such *proof-theoretic ordinals* to theories is now a discipline in its own right.

The same relativization organizes set theory. None of the following results asserts consistency outright; each transfers it:

$$\mathrm{Con}(\mathrm{ZF}) \implies \mathrm{Con}(\mathrm{ZFC})\,, \tag{3.99}$$

$$\mathrm{Con}(\mathrm{ZF}) \implies \mathrm{Con}(\mathrm{ZFC} + \mathrm{CH})\,, \tag{3.100}$$

$$\mathrm{Con}(\mathrm{ZF}) \implies \mathrm{Con}(\mathrm{ZFC} + \neg\mathrm{CH})\,, \tag{3.101}$$

$$\mathrm{Con}(\mathrm{ZFC}) \implies \mathrm{Con}(\mathrm{PA})\,. \tag{3.102}$$

The first two are Gödel's, by the constructible universe [815]; the third is Cohen's, by forcing [1249]. Equation (3.102) runs one way only: ZFC proves the consistency of PA — it constructs a model, namely $\mathbb{N}$ — and by Theorem 3.88 PA cannot return the favour, nor can ZFC certify itself. Stronger axioms of infinity extend the ladder upward indefinitely, each rung provably consistent relative to the ones above and never to itself.

3.10.3 The honest answer

Can mathematics be constructed without contradictions? The precise answers are these.

1. **Almost certainly yes** — but this cannot be proved from within, and never will be. Any proof of the consistency of a system strong enough for ordinary mathematics must use assumptions strictly stronger than the system it certifies, whose own consistency is then open. The regress does not terminate. Absolute self-certification is not merely undone; it is impossible.

2. **Consistency is not an unknowable, though.** It is a mathematical statement with a definite truth value, provable in stronger systems, refutable in principle by a single explicit derivation of $0 = 1$, and studied quantitatively by ordinal analysis. What is unavailable is a proof using nothing but means we are already certain of.

Remark 3.100 (Consistency has the epistemic status of a physical law). The parallel is exact, and it is the reason this section belongs in a physics treatise. The statement "ZFC is consistent" is *falsifiable*: a derivation of a contradiction would refute it decisively, and could be checked by any competent clerk. It is *unverifiable*: no finite body of successful practice establishes it, just as no finite run of confirming experiments establishes a universal law (Section 3.7.2). And it is *well corroborated*: a century of intensive, adversarial use by thousands of mathematicians, an enormous body of consequences, and a family of natural inner models have all failed to produce a contradiction, exactly as two centuries of mechanics failed to refute Newton.

We are therefore in the same position with respect to the foundations of mathematics as with respect to the foundations of physics: holding a well-tested conjecture, aware that it is a conjecture, and getting on with the work (Remark 1.2). That is not a comfortable position, but it is an honest one, and it is the only one available.

3.10.4 How much of this reaches physics

Very little, and the reason is worth stating precisely rather than comfortingly.

The heavy axioms of ZFC — power set applied without limit, replacement, full choice — are what generate the exotic cardinals and the independence phenomena. Physics uses almost none of that. The programme of *reverse mathematics* determines, for each classical theorem, exactly which axioms are needed to prove it [2149], and the answer for the mathematics of physics is consistently: far less than ZFC. The convergence of sequences, the intermediate value theorem, the existence and uniqueness of solutions to ordinary differential equations (Chapter 9), the Riemann and Lebesgue integrals, the spectral theorem for separable Hilbert

spaces (Chapter 12) — these live in weak subsystems of second-order arithmetic whose consistency strength is at or below that of PA itself. Physics never leaves the lower reaches of the hierarchy, and its mathematics is certified by Gentzen's theorem, not left waiting on the consistency of ZFC.

Suppose, nonetheless, that a contradiction in ZFC were found tomorrow. What would happen to physics? Essentially nothing. Every measured value in this book would still be what the apparatus reported, since a measurement is a physical event and not a theorem. The derivations would be re-examined and, in overwhelming likelihood, re-derived in a repaired system, because they never used the offending strength in the first place — exactly as the discovery that unrestricted comprehension is inconsistent (Theorem 3.75) invalidated not one line of Newtonian mechanics or one entry in a laboratory notebook. Foundations are the plumbing of mathematics; when plumbing fails it is replaced, and the building stands.

Remark 3.101 (The position of this treatise)*.* This book reasons classically, works in ZFC, assumes its consistency, and now has said so explicitly rather than silently. Every derivation it contains is a proof in the sense of Definition 3.80 — informal in presentation, formalizable in principle — and the editorial rule that no phenomenon may be stated without its derivation is therefore a commitment whose meaning and whose limits are both fixed by this chapter. The limits are real: there are arithmetical truths no derivation in a fixed system will reach (Theorem 3.87), questions no algorithm will settle (Theorem 3.96), and physical model classes whose gross qualitative behaviour admits no general criterion (Remark 3.99).

None of that licenses vagueness, and it is worth being clear why. What the theorems remove is the dream of a complete, self-certifying, mechanically decidable body of knowledge. What they leave entirely intact is the obligation to prove what one asserts, to state what one assumes, and to report what one measured. The rest of this treatise does exactly that.

Chapter 4

Algebraic Structures

Algebra begins when a bare set is equipped with a rule for combining its elements. This chapter builds that idea up axiom by axiom: binary operations and closure first, then associativity, neutral and inverse elements, until the simple structures (semigroups, monoids, groups) and the composite ones (rings, fields, modules, vector spaces, algebras) emerge as successive strengthenings of the same scheme. The second half of the chapter studies groups in detail — the structure that physics uses to express symmetry — including their basic examples, the maps that preserve them, the symmetric group, the decompositions of a group into conjugacy classes and cosets, the quotient group, and the direct product.

4.1 Binary operations and algebraic structures

4.1.1 Binary operations

Consider two sets A and B. We may ask whether, starting from A and B, it is possible to define a set containing all the possible combinations of two elements of A and of B respectively. For example, let $A = \{a, b\}$ and $B = \{\alpha, \beta\}$. Is the collection of the pairings (a, α), (a, β), (b, α) and (b, β) then a set? The answer is yes, owing to the arbitrariness in the definition of a set (Definition 3.28). According to the historical account, René Descartes was the first to think of ordering pairs of numbers in this way.

Definition 4.1 (Cartesian product)**.** The *Cartesian product* of two sets A and B, denoted $A \times B$, is the set containing as elements all the possible pairs of combinations of elements of A and B. The elements of $A \times B$ are called 2-*tuples*. The generalization is immediate: the elements of the Cartesian product $A_1 \times \ldots \times A_n$ are called n-*tuples*.

Rests on Definition 3.28.

As an example, note that it is also possible to construct the Cartesian product of a set with itself,

$$\{a, b\} \times \{a, b\} = \{(a, a), (a, b), (b, a), (b, b)\} ,$$

where it must be noted that $(a, b) \neq (b, a)$, since they are distinct combinations.

Definition 4.2 (Binary operation)**.** Consider the sets A and X. A *binary operation* $*$ is a map of the form

$$\begin{array}{rccc} * : & A \times A & \longrightarrow & X \\ & (a, b) & \longmapsto & a * b \, . \end{array}$$

Rests on Definitions 3.43 and 4.1.

Definition 4.3 (Algebraic structure)**.** Consider a set A and an arbitrary set X, together with a binary operation $* : A \times A \longrightarrow X$. The set A together with the operation $*$ is called an *algebraic structure*, and is denoted $(A, *)$.

Rests on Definition 4.2.

For example, the set $\{0,1\} \subset \mathbb{Z}$ together with ordinary addition,

$$\begin{array}{rccc} + : & \{0,1\} \times \{0,1\} & \longrightarrow & \{0,1,2\} \\ & (a,b) & \longmapsto & a+b\,, \end{array}$$

forms an algebraic structure whose binary operation is made explicit by the table

$+$	0	1
0	0	1
1	1	2

The closure axiom

Consider an algebraic structure $(A, *)$. If the binary operation has not previously been fixed explicitly, in general $a * b$ need not be an element of A. The current theories of physics, however, rest on a mathematical formalism in which sets lacking such an internal mechanism are not of interest, and we therefore present the formalism only for algebraic structures that possess one.

Definition 4.4 (Internal binary operation; magma)**.** A binary operation $* : A \times A \longrightarrow X$ is an *internal binary operation* (IBO) if and only if $X = A$. An algebraic structure $(A, *)$ whose operation $*$ is an IBO is said to be *closed*, to be a *magma*, or to have *closure* with respect to $*$. Closure is expressed formally by the axiom

$$\forall\ a, b \in A,\ \ a * b \in A\,. \tag{4.1}$$

Rests on Definitions 4.2 and 4.3.

Remark 4.5. When no ambiguity is possible or relevant, we shall refer to a closed algebraic structure simply as an algebraic structure, and we shall denote an algebraic structure $(A, *)$ simply by A, the name of its underlying set.

The associativity axiom

Just as happens with the real numbers, we can formalize the fact that the product of one number with the product of two others equals the product of the first two with the last.

Definition 4.6 (Associativity)**.** An algebraic structure $(A, *)$ satisfies the property of *associativity* if and only if

$$\forall\ a, b, c \in A,\ \ a * (b * c) = (a * b) * c\,. \tag{4.2}$$

Rests on Definition 4.3.

Remark 4.7. The associativity axiom is genuinely important because of the following property. Consider the equation $a = b * c$. With associativity available we may operate on the whole equation with a further quantity d; that is, $a * d = (b * c) * d$, or equivalently $a * d = b * (c * d)$. If we did not have that property we would be left with something like $a * d = b * c * d$, an expression devoid of meaning, since we have not defined $*$ as a "ternary operation".

The commutativity axiom

For the real numbers, the order of the factors does not alter the product. We can formalize this for algebraic structures through the following axiom.

Definition 4.8 (Commutativity; abelian structure)**.** An IBO $*$ is *commutative* — equivalently, an algebraic structure $(A, *)$ is *abelian* with respect to $*$ — if and only if the following axiom holds:

$$\forall\ a, b \in A,\ \ a * b = b * a\,. \tag{4.3}$$

Rests on Definition 4.4.

The neutral-element axiom and uniqueness

In order to construct more sophisticated structures, we may demand the existence of an element e_A whose operation with any element is irrelevant.

Definition 4.9 (Neutral element)**.** An element e_A of an algebraic structure $(A, *)$ is a *neutral element* if and only if it satisfies the axiom

$$\forall\, a \in A,\ \exists\, e_A \in A \mid a * e_A = a \ \wedge\ e_A * a = a\,. \tag{4.4}$$

Rests on Definition 4.3.

We must observe that the axiom does not assert commutativity among all the elements of the set: commutation is demanded only for the neutral element. Many of the structures we shall define make use of this axiom, which will let us uncover properties usable throughout mathematical physics. On occasion, when we wish to specify the symbol employed for the neutral element, we shall denote the algebraic structure by $(A, *, e_A)$.

Proposition 4.10 (Uniqueness of the neutral element)**.** *The neutral element of an algebraic structure is unique.*

Rests on Definition 4.9.

Proof. *Derives Proposition 4.10.*

Consider two neutral elements e_A and f_A. By the axiom we have $e_A = e_A * f_A$, and furthermore

$$\begin{aligned} f_A &= f_A * e_A \\ &= e_A * f_A \qquad\qquad \text{by Equation (4.4)}\,, \end{aligned}$$

hence $e_A = f_A$. □

The inverse-element axiom

Let $(A, *, e_A)$ be an algebraic structure equipped with the neutral-element axiom. A further axiom we may impose is that to each element a there be assigned a dual element a^{-1} such that, when the two are operated, the neutral element results.

Definition 4.11 (Inverse element)**.** An algebraic structure $(A, *, e_A)$ satisfies the *inverse-element axiom* if and only if

$$\forall\, a \in A,\ \exists\, a^{-1} \in A \mid a * a^{-1} = e_A \ \wedge\ a^{-1} * a = e_A\,, \tag{4.5}$$

and we call a^{-1} an *inverse element* of a.

Rests on Definition 4.9.

Substructures

Consider a closed algebraic structure $(A, *)$, and let $S \subseteq A$ be a non-empty subset. The IBO $*$ induces a new binary operation $*_S : S \times S \longrightarrow A$. Then $(S, *_S)$ is an algebraic structure, but not necessarily a closed one. If, however, we restrict the codomain, the operation $*'_S : S \times S \longrightarrow S$ is by definition an IBO, and $(S, *'_S)$ is a closed algebraic structure. When no ambiguity is possible we shall simply write $*'_S = *$.

Definition 4.12 (Substructure)**.** $(S, *)$ is a *substructure* of $(A, *)$ if and only if

1. $S \neq \varnothing$;
2. $\forall\, a, b \in S,\ a * b \in S$.

We further introduce the notation

$$(S, *) \text{ substructure of } (A, *) \quad \overset{\text{not.}}{\Longleftrightarrow} \quad S \leq A\,.$$

Rests on Definition 4.4.

4.1.2 Maps between algebraic structures

Product of maps

Consider the algebraic structures $(A, *_A)$ and $(B, *_B)$. As we know (Definition 3.52), $\mathcal{F}(A, B)$ is the set of all maps from A to B. Let us define the IBO

$$\begin{array}{rccccccc} *: & \mathcal{F}(A,B)\times\mathcal{F}(A,B) & \longrightarrow & \mathcal{F}(A,B) & & & & \\ & (f,g) & \longmapsto & f*g: & A & \longrightarrow & B \\ & & & & a & \longmapsto & (f*g)(a) = f(a) *_B g(a)\,. \end{array}$$

Given the maps f and g, we have thereby defined a new map $f * g \in \mathcal{F}(A, B)$, which we shall call the *product of maps*.

Neutral map

Let $(A, *_A)$ be an algebraic structure and $(B, *_B, e_B)$ an algebraic structure satisfying the neutral-element axiom. Consider a map of the form

$$\begin{array}{rccc} \Theta: & A & \longrightarrow & B \\ & a & \longmapsto & e_B\,, \end{array}$$

that is, a map assigning to every element of A the neutral element of B. We shall call this map the *neutral map*, *neutral function*, or *neutral operator*. Now consider a map $f : A \longrightarrow B$. We see that

$$\begin{aligned} (f * \Theta)(a) &= f(a) *_B \Theta(a) \\ &= f(a) *_B e_B \\ &= f(a)\,, \end{aligned}$$

so, since a is arbitrary, we simply have $f * \Theta = f$, and analogously $\Theta * f = f$.

Opposite map

The previous two headings supplied $\mathcal{F}(A, B)$ with an operation and with a neutral element for it. One ingredient is missing before the set of maps is a group in its own right, and it is the pointwise inverse.

Let $(A, *_A)$ be an algebraic structure and let $(B, *_B, e_B)$ satisfy both the neutral-element axiom and the inverse-element axiom Equation (4.5). Given $f : A \longrightarrow B$, define

$$\begin{array}{rccc} f^{\mathrm{op}}: & A & \longrightarrow & B \\ & a & \longmapsto & (f(a))^{-1}\,, \end{array} \tag{4.6}$$

which we call the *opposite map* of f: it inverts the value of f at each point separately, and does nothing else.

Notation 4.13 (The opposite map is not the inverse map). The superscript is op, and not -1, on purpose. The symbol f^{-1} is already spoken for twice over in Chapter 3: it is the inverse map of a bijection (Definition 3.51), which exists only when f is bijective and satisfies $f^{-1} \circ f = \mathrm{id}_A$; and it is the preimage (Definition 3.53), which returns a subset. The opposite map Equation (4.6) is neither. It is defined for *every* f, bijective or not, it involves no composition, and the inversion happens in the codomain B rather than between A and B. The three notions coincide in no interesting case, and conflating them is the commonest slip in this part of the subject.

Rests on Equation (4.6) and Definitions 3.51 and 3.53.

For f^{op} to be a map at all, the value $(f(a))^{-1}$ must be determined by $f(a)$ — the existence and uniqueness demanded by Definition 3.43. Existence is the inverse-element axiom. Uniqueness is *not* automatic: Equation (4.5) asserts that an inverse exists, not that it is unique, and the proof of uniqueness (Proposition 4.21) needs associativity. We therefore assume throughout this heading that $(B, *_B)$ is associative — in practice that B is a group, Definition 4.20 — and note that without it Equation (4.6) selects one inverse among possibly several and is a definition only after such a selection has been made.

Granting that, the opposite map does for $\mathcal{F}(A, B)$ exactly what a^{-1} does for B:

$$\begin{aligned}(f * f^{\mathrm{op}})(a) &= f(a) *_B f^{\mathrm{op}}(a) \\ &= f(a) *_B (f(a))^{-1} \\ &= e_B \\ &= \Theta(a)\,,\end{aligned}$$

and since $a \in A$ was arbitrary, $f * f^{\mathrm{op}} = \Theta$. The same computation with the factors exchanged gives $f^{\mathrm{op}} * f = \Theta$.

Proposition 4.14 (Maps into a group form a group)**.** *Let A be a non-empty set and $(B, *_B, e_B)$ a group. Then $(\mathcal{F}(A, B), *)$ is a group, with neutral element the neutral map Θ and with the inverse of f given by f^{op}. If B is abelian, so is $\mathcal{F}(A, B)$.*

Rests on Definition 4.20, Equation (4.6), and Proposition 4.21.

Proof. *Derives Proposition 4.14.*

Each group axiom is checked pointwise, which is available because two maps are equal exactly when they agree at every point.

Closure. $f * g$ was defined as a map $A \longrightarrow B$, so it lies in $\mathcal{F}(A, B)$.

Associativity. For every $a \in A$,

$$((f * g) * h)(a) = (f(a) *_B g(a)) *_B h(a) = f(a) *_B (g(a) *_B h(a)) = (f * (g * h))(a)\,,$$

the middle step being associativity in B.

Neutral element. $f * \Theta = \Theta * f = f$ was shown under the previous heading.

Inverses. $f * f^{\mathrm{op}} = f^{\mathrm{op}} * f = \Theta$ was shown above, and f^{op} is well defined because inverses in a group are unique by Proposition 4.21.

Commutativity. If B is abelian then $(f * g)(a) = f(a) *_B g(a) = g(a) *_B f(a) = (g * f)(a)$ for every a, so $f * g = g * f$. □

This small proposition is used more often in physics than its size suggests. It is the reason that the B-valued functions on any set inherit B's algebraic structure without further argument: real-valued functions on a region form an abelian group under pointwise addition, and with the scalar multiplication of Chapter 5 a vector space — which is what makes function spaces the natural home of fields (Chapter 12). When B is a Lie group rather than $\mathbb{R}$, the same pointwise construction produces the group of gauge transformations, the maps from spacetime into the gauge group, whose structure is the subject of Chapter 14 and whose physical content occupies Chapter 64. Nothing in the construction requires A to carry any structure at all; only the codomain does the work.

4.1.3 Kernel and image

Definition 4.15 (Kernel)**.** Let $(A, *_A)$ be an algebraic structure and $(B, *_B, e_B)$ an algebraic structure satisfying the neutral-element axiom, and consider a map $f : A \longrightarrow B$. The *kernel* of f is the set

$$\ker f = \{a \in A \mid f(a) = e_B\}\,. \tag{4.7}$$

Rests on Definition 4.9.

Definition 4.16 (Image)**.** Let $(A, *_A)$ and $(B, *_B)$ be algebraic structures and $f : A \longrightarrow B$ a map. The *image* of f is the set

$$\operatorname{im} f = \{b \in B \mid b = f(a),\ a \in A\}\ . \tag{4.8}$$

As a set this is Definition 3.44, the image of a map; it is restated here only to fix the notation $\operatorname{im} f$ used throughout this chapter. Nothing about the structures enters the definition, and nothing is claimed by it — that the image of a homomorphism is itself a structure of the same kind is a separate statement and needs its own proof.

Rests on Definitions 3.43 and 3.44.

Proposition 4.17 (Trivial kernel of a homomorphism)**.** *Consider two algebraic structures satisfying the neutral-element axiom, $(A, *_A, e_A)$ and $(B, *_B, e_B)$, and let $f : A \longrightarrow B$ be a homomorphism. Then*

$$\ker f = \{e_A\} \iff f \text{ is injective}\,. \tag{4.9}$$

Rests on Definitions 4.11, 4.15 and 4.39.

Proof. *Derives Proposition 4.17.*

($\Rightarrow$) We must prove that if $\ker f = \{e_A\}$ then f is injective. Indeed, since $e_A \in \ker f$,

$$f(e_A) = e_B\,. \tag{4.10}$$

On the other hand, let $a_1, a_2 \in A$ and suppose that $f(a_1) = f(a_2)$. Operating on both sides with $*_B\, f(a_2^{-1})$,

$$\begin{aligned} f(a_1) *_B f(a_2^{-1}) &= f(a_2) *_B f(a_2^{-1}) \\ f(a_1 *_A a_2^{-1}) &= f(a_2 *_A a_2^{-1}) \\ &= f(e_A) \\ &= e_B\,, \end{aligned}$$

so $a_1 *_A a_2^{-1} \in \ker f$; hence $a_1 *_A a_2^{-1} = e_A$, and therefore $a_1 = a_2$. This proves injectivity.

($\Leftarrow$) Conversely, suppose f is injective. Because f is a homomorphism and $e_A = e_A *_A e_A$,

$$f(e_A) = f(e_A *_A e_A) = f(e_A) *_B f(e_A)\,,$$

and operating on the right with $*_B\ (f(e_A))^{-1}$ leaves $e_B = f(e_A)$ — the computation stated on its own account in Proposition 4.42. Hence $e_A \in \ker f$, that is, $\{e_A\} \subseteq \ker f$. Conversely, let $a \in \ker f$. Then $f(a) = e_B = f(e_A)$, and injectivity gives $a = e_A$; thus $\ker f \subseteq \{e_A\}$. The two inclusions together give $\ker f = \{e_A\}$. □

4.2 Simple algebraic structures

The conditions defining an algebraic structure form a purely abstract set of axioms. The axioms we now impose are chosen because the resulting structures are relevant to physics: they possess properties that we can link with nature.

4.2.1 Semigroups, monoids, and groups

Definition 4.18 (Semigroup)**.** An algebraic structure $(A, *)$ is a *semigroup* if and only if

1. $\forall\ a, b \in A, \quad a * b \in A$;
2. $\forall\ a, b, c \in A, \quad a * (b * c) = (a * b) * c$;

that is, $(A, *)$ is a magma whose elements moreover satisfy associativity under $*$.
Rests on Definitions 4.4 and 4.6.

For example, the set of natural numbers together with addition as internal binary operation forms a semigroup with infinitely many elements, the closure and associativity properties being clearly satisfied; this semigroup is moreover abelian. Another example is the abelian semigroup formed by the set $\{0, 1\} \subset \mathbb{Z}$ together with the usual multiplication, whose internal operation is summarized in the table

$\cdot$	0	1
0	0	0
1	0	1

(4.11)

Here closure is clear, and associativity follows[1] from the associativity of $\mathbb{Z}$.

Definition 4.19 (Monoid)**.** An algebraic structure $(A, *)$ is a *monoid* if and only if

1. $\forall\ a, b \in A, \quad a * b \in A$;
2. $\forall\ a, b, c \in A, \quad a * (b * c) = (a * b) * c$;
3. $\forall\ a \in A,\ \exists\ e_A \in A \mid a * e_A = a \quad \wedge \quad e_A * a = a$;

that is, $(A, *)$ is a semigroup possessing in addition a neutral element (which, as we have seen, is unique).
Rests on Definitions 4.9 and 4.18.

Returning to the earlier example, $(\mathbb{N}, +)$ is not a monoid, since that set contains no element serving as a neutral element for addition. However, if we adjoin the number zero to the naturals, that very element fulfils the property with respect to addition, so $(\mathbb{N} \cup \{0\}, +, 0)$ is a monoid. Another example, easy to check, is the monoid $(\mathbb{N}, \cdot, 1)$. Finally, the example of Equation (4.11) is furthermore an abelian monoid.

Definition 4.20 (Group)**.** An algebraic structure $(A, *)$ is a *group* if and only if

1. $\forall\ a, b \in A, \quad a * b \in A$;
2. $\forall\ a, b, c \in A, \quad a * (b * c) = (a * b) * c$;
3. $\forall\ a \in A,\ \exists\ e_A \in A \mid a * e_A = a \quad \wedge \quad e_A * a = a$;
4. $\forall\ a \in A,\ \exists\ a^{-1} \in A \mid a * a^{-1} = e_A \quad \wedge \quad a^{-1} * a = e_A$;

that is, $(A, *)$ is a monoid in which every element of the set moreover possesses an *inverse element* (and since associativity holds by axiom, the inverse of each element is unique).
Rests on Definitions 4.11 and 4.19.

As an example, upon adjoining the negative numbers to $(\mathbb{N} \cup \{0\}, +, 0)$ we obtain the group $(\mathbb{Z}, +, 0)$: every element $k \in \mathbb{Z}$ has its inverse element $-k$, giving for each of them $k + (-k) = -k + k = 0$. Another well-known example is the set $\{1, -1\} \subset \mathbb{Z}$ together with ordinary multiplication, whose internal operation is described by the table

$\cdot$	1	-1
1	1	-1
-1	-1	1

(4.12)

Here closure and associativity are clear. The (as we know, unique) neutral element is the number 1, which is thus an inverse element for itself, since $1 \cdot 1 = 1$. An inverse element for -1 is -1 itself, since $(-1) \cdot (-1) = 1$.

[1] The reader is invited to carry out the proof of associativity explicitly. To do so one must verify the eight possibilities $(0 \cdot 0) \cdot 0 \stackrel{?}{=} 0 \cdot (0 \cdot 0)$, $(0 \cdot 0) \cdot 1 \stackrel{?}{=} 0 \cdot (0 \cdot 1)$, etc.

4.2.2 Basic properties of groups

Since in a group we have associativity at our disposal, the following important properties valid in any group can be proved. Strictly speaking they hold in any structure with neutral element, inverses, and associative elements; but as we shall not encounter structures that fail to close, we state them here as properties of a group.

Proposition 4.21 (Uniqueness of the inverse element)**.** *Given an element of a group A, its inverse is unique.*

Rests on Definition 4.20.

Proof. *Derives Proposition 4.21.*

Let $a \in A$ and let a^{-1}, $\tilde{a}^{-1}$ be two inverse elements of a. By the axiom, $a * a^{-1} = e_A$ and $a * \tilde{a}^{-1} = e_A$, so that, operating on the left with $a^{-1}*$,

$$\begin{aligned} a * a^{-1} &= a * \tilde{a}^{-1} \\ a^{-1} * (a * a^{-1}) &= a^{-1} * (a * \tilde{a}^{-1}) \\ (a^{-1} * a) * a^{-1} &= (a^{-1} * a) * \tilde{a}^{-1} \\ e_A * a^{-1} &= e_A * \tilde{a}^{-1}\,, \end{aligned}$$

and thus $a^{-1} = \tilde{a}^{-1}$. □

Proposition 4.22 (Inverse of the neutral element)**.** *The inverse of the neutral element is the neutral element itself.*

Rests on Definition 4.20 and Proposition 4.21.

Proof. *Derives Proposition 4.22.*

By the neutral-element axiom we have $e_A * e_A = e_A$. Operating on both sides with $* e_A^{-1}$ we obtain $e_A * (e_A * e_A^{-1}) = e_A^{-1}$, that is, $e_A = e_A^{-1}$. Since the inverse is unique, we conclude that the inverse of the neutral element is itself. □

Proposition 4.23 (Neutral element equal to a product)**.** *In a group,*

$$e_A = a * b \iff a = b^{-1} \tag{4.13}$$

and analogously

$$e_A = a * b \iff b = a^{-1}\,. \tag{4.14}$$

Rests on Definition 4.20.

Proof. *Derives Proposition 4.23.*

Starting from $a * b = e_A$ and operating on the right with $* b^{-1}$,

$$\begin{aligned} a * b &= e_A \\ a * (b * b^{-1}) &= e_A * b^{-1} \\ a * e_A &= b^{-1} \\ a &= b^{-1}\,, \end{aligned}$$

and the converse and the second equivalence follow analogously. □

Proposition 4.24 (Involution of the inverse)**.** *The inverse of the inverse of an element is the element itself:*

$$\left(a^{-1}\right)^{-1} = a\,. \tag{4.15}$$

Rests on Proposition 4.23.

Proof. *Derives Proposition 4.24.*

In the context of the preceding proposition, from Equation (4.14) we have

$$b^{-1} = \left(a^{-1}\right)^{-1} ,$$

and substituting into Equation (4.13) we obtain $\left(a^{-1}\right)^{-1} = a$. □

Proposition 4.25 (Inverse of a product)**.** *Let $a, b \in G$. The inverse of the product of a and b is*

$$(a * b)^{-1} = b^{-1} * a^{-1} . \tag{4.16}$$

Rests on Definition 4.20 and Proposition 4.21.

Proof. *Derives Proposition 4.25.*

We have

$$\begin{aligned} (a * b) * (b^{-1} * a^{-1}) &= a * (b * b^{-1}) * a^{-1} \\ &= a * e_A * a^{-1} \\ &= e_A , \end{aligned}$$

and analogously on the other side. Hence, since the inverse is unique, $b^{-1} * a^{-1}$ is the inverse of $a * b$. □

4.3 Composite algebraic structures

4.3.1 Axioms for composite algebraic structures

Distributivity axioms

Let $(A, +)$ and $(V, \bar{+})$ be two algebraic structures, and consider further a map $\circ$ of the form

$$\begin{array}{rccc} \circ : & A \times V & \longrightarrow & V \\ & (a, v) & \longmapsto & a \circ v . \end{array}$$

Definition 4.26 (Distributivity)**.** We say that $\circ$ is *distributive* with respect to $\bar{+}$ if and only if

1. $\forall\ a \in A,\ \forall\ u, v \in V,\ a \circ (u \bar{+} v) = a \circ u \bar{+} a \circ v$;
2. $\forall\ a, b \in A,\ \forall\ v \in V,\ (a + b) \circ v = a \circ v \bar{+} b \circ v$.

Rests on Definition 4.3.

That the structure A acts from the left is only a convention, or the traditional usage; nothing prevents the creation of structures with distributivity from the left with respect to $\circ$ together with distributivity from the right with respect to $\circ$ (or even another binary map). In this book we shall use only left distributivity, and we shall mention it explicitly when absolutely necessary. Note also that if the structures $(A, +)$ and $(V, \bar{+})$ are identical — that is, $A = V$ and there is an isomorphism between $(A, +)$ and $(A, \bar{+})$ — then $\circ$ becomes an internal binary operation; in this context, if the magma $(A, \circ)$ is abelian, the two axioms above are completely equivalent.

Action axioms

Let $(A, *, e)$ be an algebraic structure with neutral element and X an arbitrary set. Consider the map $\bullet$ of the form

$$\begin{array}{rccc} \bullet: & A \times X & \longrightarrow & X \\ & (a, x) & \longmapsto & a \bullet x\,. \end{array}$$

Definition 4.27 (Action)**.** We say that $\bullet$ is an *action* of the structure A on the set X if and only if $\bullet$ satisfies

1. $\forall\ x \in X,\ e \bullet x = x$;
2. $\forall\ x \in X,\ \forall\ a, b \in A,\ (a * b) \bullet x = a \bullet (b \bullet x)$.

Rests on Definition 4.9.

4.3.2 Composite algebraic structures

Definition 4.28 (Ring)**.** Consider an abelian group $(A, +, 0_A)$ and a semigroup $(A, \circ)$. We say that $[(A, +, 0_A), \circ, (A, \circ)] \overset{\text{not.}}{=} (A, +, \circ)$ is a *ring* if and only if

1. $\forall\ a, b, c \in A, \quad a \circ (b + c) = a \circ b + a \circ c$;
2. $\forall\ a, b, c \in A, \quad (a + b) \circ c = a \circ c + b \circ c$;

that is, if and only if the property of *distributivity* of $\circ$ with respect to $+$ holds.
Rests on Definitions 4.8, 4.18, 4.20 and 4.26.

For example, in $\mathbb{Z}$ multiplication distributes with respect to addition, so $(\mathbb{Z}, +, \cdot)$ is a ring. Further:

- Upon imposing commutativity of the IBO $\circ$ — that is, if $(A, \circ)$ becomes an abelian semigroup — we say that $(A, +, \circ)$ is a *commutative ring*. $(\mathbb{Z}, +, \cdot)$ is a commutative ring.
- Imposing the existence of a neutral element 1_A for the semigroup — that is, if $(A, \circ, 1_A)$ becomes a monoid — we say that $(A, +, \circ)$ is a *ring with unity*. Since in $\mathbb{Z}$ the number 1 is a neutral element for multiplication, $(\mathbb{Z}, +, \cdot)$ is a (commutative) ring with unity. Another example is the real numbers: $(\mathbb{R}, +, 0)$ is an abelian group, and $(\mathbb{R}, \cdot, 1)$ is an abelian monoid. As is well known, multiplication distributes with respect to addition, and consequently $(\mathbb{R}, +, \cdot)$ is a (commutative) ring with unity.

Definition 4.29 (Module)**.** Consider a ring with unity $[(A, +, 0_A), \circ, (A, \circ, 1_A)] = (A, +, \circ)$ and an abelian group $(V, \bar{+}, 0_V)$. Let there be, in addition, the binary map

$$\begin{array}{rccc} \cdot: & A \times V & \longrightarrow & V \\ & (a, u) & \longmapsto & au\,. \end{array}$$

We say that $[(A, +, \circ), \cdot, (V, \bar{+})]$ is a *module* V *over* A if and only if the binary map $\cdot$ distributes with respect to $\bar{+}$ and, in addition, $\cdot$ is an action of the monoid $(A, \circ, 1_A)$ on the group $(V, \bar{+}, 0_V)$ regarded as a set. That is, if and only if

1. $\forall\ a \in A,\ \forall\ u, v \in V, \quad a(u \bar{+} v) = au \bar{+} av$;
2. $\forall\ a, b \in A,\ \forall\ u \in V, \quad (a + b)u = au \bar{+} bu$;
3. $\forall\ a, b \in A,\ \forall\ u \in V, \quad a(bu) = (a \circ b)u$;
4. $\forall\ u \in V, \quad 1_A u = u$.

Rests on Definitions 4.20 and 4.26 to 4.28.

Definition 4.30 (Field)**.** Consider a ring with unity $(A, +, \circ)$, that is, such that $(A, +, 0_A)$ is an abelian group and $(A, \circ, 1_A)$ is a monoid. We say that $[(A, +, 0_A), \circ, (A \setminus \{0_A\}, \circ, 1_A)] \overset{\text{not.}}{=} (A, +, \circ)$ is a *field* if for every element of the monoid $(A, \circ, 1_A)$ there exists an inverse element, except for the neutral element 0_A of $(A, +)$; that is, if in addition

1. $\forall\ a \in A \setminus \{0_A\},\ \exists\ a^{-1} \in A \mid a \circ a^{-1} = 1_A\ \wedge\ a^{-1} \circ a = 1_A$,

which means that the monoid $(A, \circ)$ almost becomes a group — as it would, completely, if an inverse existed for 0_A.

Rests on Definitions 4.11, 4.19 and 4.28.

- If the monoid $(A, \circ)$ is moreover abelian, we say that $(A, +, \circ)$ is a *commutative field*.

Definition 4.31 (Vector space)**.** Consider a module $[(A, +, \circ), \cdot, (V, \bar{+})]$. We say that $[(A, +, \circ), \cdot, (V, \bar{+})]$ is a *vector space V over A* if and only if the ring with unity $(A, +, \circ)$ is a commutative field; that is, if and only if the following further axioms hold:

1. $\forall\ a \in A \setminus \{0_A\},\ \exists\ a^{-1} \mid a \circ a^{-1} = 1_A\ \wedge\ a^{-1} \circ a = 1_A$;
2. $\forall\ a, b \in A,\ a \circ b = b \circ a$.

Rests on Definitions 4.8, 4.29 and 4.30.

As a characterization, a vector space is thus a commutative field (arising from a ring with unity in which inverses now exist except for 0_A) together with a distributive action of the field's monoid-with-inverses on an abelian group.

Vector spaces are very important in physics. In classical physics they manifest an abstract arena serving to model nature at each point of the Universe; in the context of quantum physics, they serve to model the possible states of a system. Even if a system is confined to some smaller set of states, we can model that smaller system as a vector-space substructure.

Definition 4.32 (Algebra)**.** Consider a vector space $[(A, +, \circ), \cdot, (V, \bar{+})]$, together with the IBO

$$\begin{array}{rccc} \times : & V \times V & \longrightarrow & V \\ & (u, v) & \longmapsto & u \times v\,. \end{array}$$

We say that $[(A, +, \circ), \cdot, (V, \bar{+}, \times)]$ is an *algebra V over A* if and only if the following axioms hold:

1. $\forall\ u, v, w \in V,\ u \times (v \bar{+} w) = u \times v \bar{+} u \times w$;
2. $\forall\ u, v, w \in V,\ (u \bar{+} v) \times w = u \times w \bar{+} v \times w$;
3. $\forall\ a \in A,\ \forall\ u, v \in V,\ a(u \times v) = (au) \times v = u \times (av)$.

Rests on Definitions 4.4, 4.26 and 4.31.

Thus the algebra $[(A, +, \circ), \cdot, (V, \bar{+}, \times)]$ is such that

- $(A, +, \circ)$ is a ring with unity;
- $(V, \bar{+})$ is an abelian group;
- $(V, \times)$ is a magma;
- A acts on V through the operation $\cdot$;
- various distributivity properties hold among the operations, as specified above.

Let us examine the properties that may be added, giving rise to remarkable kinds of algebras.

- If $(V, \bar{+}, \times)$ is a ring — that is, if $(V, \times)$ is moreover a semigroup — we say that $[(A, +, \circ), \cdot, (V, \bar{+}, \times)]$ is an *associative algebra*. There holds

  1. $\forall\ u, v, w \in V,\ u \times (v \times w) = (u \times v) \times w$.

- If $(V, \bar{+}, \times)$ is a ring with unity — that is, if $(V, \times)$ is moreover a monoid — we say that $[(A, +, \circ), \cdot, (V, \bar{+}, \times)]$ is a *unital associative algebra*. There holds

  1. $\forall\ u \in V,\ \exists\ \mathbb{1}_V \in V \mid \mathbb{1}_V \times u = u\ \wedge\ u \times \mathbb{1}_V = u$.

- If the axioms

  1. $\forall\ u, v \in V,\ u \times v = -v \times u$,
  2. $\forall\ u, v, w \in V,\ u \times (v \times w) \bar{+} v \times (w \times u) \bar{+} w \times (u \times v) = 0_V$

  hold, we say that $[(A, +, \circ), \cdot, (V, \bar{+}, \times)]$ is a *Lie algebra*.

Algebras are a most interesting algebraic structure for physics, since — like groups — they provide an elegant mathematical machinery for the symmetries of a physical system, classical or quantum.

4.4 Group theory: further definitions

Group theory is an immense branch of mathematics that studies these structures in detail. Because of the axioms imposed, groups are potentially applicable to situations in geometry and in nature that involve symmetry. There is a large literature on groups containing a finite number of elements. Such groups display a complexity in their structure that is tied directly to their cardinality and to the prime decomposition of the cardinal. There is a certain beauty in this: arithmetic appears unavoidably within the theory of algebraic structures, even though the two theories study different things. To organize these finite groups there are classification theorems for abelian groups, and for the non-abelian ones there are the Sylow theorems. A problem to solve may be, for example: find all abelian groups of cardinal 8.

4.4.1 Groups

Let us discuss the definition of a group here in more detail. Consider a set G, in general of finite or infinite cardinality, together with a binary operation $*$. We say that $(G, *)$ is a group if and only if it satisfies the following axioms.

1. Closure:
$$\forall\ a, b \in G,\ a * b \in G\,. \tag{4.17}$$
This property is exactly equivalent to having taken the binary operation $*$ to be an IBO, or the structure $(G, *)$ to be a magma.

2. Associativity:
$$\forall\ a, b, c \in G,\ a * (b * c) = (a * b) * c\,. \tag{4.18}$$

3. Existence of a neutral element:
$$\forall\ a \in G,\ \exists\ e \in G \mid a * e = a \quad \wedge \quad e * a = a\,. \tag{4.19}$$

4. Existence of inverse elements:

$$\forall\ a \in G,\ \exists\ a^{-1} \in G \mid a * a^{-1} = e \quad \wedge \quad a^{-1} * a = e\,. \tag{4.20}$$

Let us examine some examples whose underlying sets have infinite cardinality. The structure $(\mathbb{R}^*, \cdot)$ is a group whose neutral element, in multiplicative notation, is $1 \in \mathbb{R}$. On the other hand we can verify that $(\mathbb{Q}^*, \div)$, where

$$\begin{array}{rccc} \div : & \mathbb{Q}^* \times \mathbb{Q}^* & \longrightarrow & \mathbb{Q}^* \\ & (a, b) & \longmapsto & \dfrac{a}{b}\,, \end{array}$$

is not a group, since the associativity axiom fails: indeed,

$$\frac{\frac{a}{b}}{c} \neq \frac{a}{\frac{b}{c}}\,.$$

To denote a group we shall use the notations $(G, *)$ and $G = \{e, a, b, c, \ldots\}$, where e is the neutral element, though we may also use the index notation $G = \{g_i\}_{i \in I \subset \mathbb{N}}$. When no ambiguity is possible we shall denote the operation $\cdot$ by simple juxtaposition.

Definition 4.33 (Subgroup)**.** Consider a group $(G, *)$ and a subset $H \subseteq G$. We say that $(H, *)$ is a *subgroup* of $(G, *)$ if and only if

1. $\forall\ a, b \in H,\ a * b \in H$;
2. $\forall\ a \in H,\ \exists\ e_H \in H \mid a * e_H = a\ \wedge\ e_H * a = a$ — which is completely equivalent to saying that the neutral element of $(G, *)$ lies in H, since a neutral element of G, if it exists, is unique;
3. $\forall\ a \in H,\ \exists\ a^{-1} \in H \mid a * a^{-1} = e\ \wedge\ a^{-1} * a = e$ — which is equivalent to saying that the inverse elements of the elements of H belong to H.

Rests on Definition 4.20.

Since all the elements of the group $(G, *)$ satisfy associativity, we may dispense with that condition in asserting that a subgroup is indeed a group. In particular a subgroup is a substructure, for H is closed by definition. We therefore introduce the notation

$$(H, *) \text{ subgroup of } (G, *) \quad \overset{\text{not.}}{\iff} \quad H \leq G\,.$$

Given a group $G = \{e, a, \ldots\}$ it is clear that $\{e\} \leq G$ and that $G \leq G$; these subgroups are known as the *trivial subgroups*.

4.4.2 Cayley tables

Definition 4.34 (Cayley table)**.** The *Cayley table* of a finite group is the resource we shall use to symbolize how the elements of the group operate. Let $(\{e, a, b, c, \ldots\}, \cdot)$ be a group. Its Cayley table is given by

$\cdot$	e	a	b	c	$\ldots$
e	e	a	b	c	$\ldots$
a	a	a^2	ab	ac	$\ldots$
b	b	ba	b^2	bc	$\ldots$
c	c	ca	cb	c^2	$\ldots$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ddots$

Rests on Definition 4.20.

The Cayley table of a group stores the whole "machinery" of the group: it contains all the information needed to describe the group's internal product explicitly. Two important observations about Cayley tables are the following.

- **The elements in any one row or column of a Cayley table cannot repeat.** Indeed, suppose that within one column we had $ab = x$ and also $ac = x$. This says $ab = ac$, and since we are in a group, a has an inverse. Multiplying on the left by the inverse of a we obtain $b = c$, which is a contradiction, since the elements of the group as a set must all be distinct.

- **For an abelian group the Cayley table is symmetric** with respect to the diagonal e, a^2, b^2, $c^2, \ldots$ — as can be seen trivially from the general Cayley table.

4.5 Basic groups

4.5.1 The first finite groups

The trivial group

Consider the algebraic structure $(\{e\}, *)$, where e satisfies the neutral-element axiom. Trivially this set satisfies the four group axioms; we call it the *trivial group*. Since every group contains a neutral element (by definition), given a group $(G, \cdot, e)$ we can always affirm that the set formed by the neutral element of G is a subgroup of G, that is, $\{e\} \leq G$. The Cayley table of the trivial group is

$*$	e
e	e

For example, consider $0 \in \mathbb{Z}$ together with the IBO $+$. We have

$+$	0
0	0

that is, the structure $(\{0\}, +)$ is a trivial group. This does not happen for an arbitrary IBO defined on $\mathbb{Z}$: for example, $(\{0\}, \cdot)$ is not a group, since 0 has no multiplicative inverse, so the inverse axiom fails.

The group of two elements

Consider the algebraic structure $(\{e, a\}, *)$, where e satisfies the neutral-element axiom. Let us see how the elements of $\{e, a\}$ must operate for the group axioms to be satisfied. Clearly we have

$*$	e	a
e	e	a
a	a	$a * a$

But what must the result of $a * a$ be? That is, supposing that $\{e, a, a * a\}$ is a group, let us deduce the conditions a must satisfy. The options are:

1. the option $a * a = a$ is not valid, since we know the elements of a row or column of a Cayley table cannot repeat;

2. on the other hand, to respect closure, $a * a = e$ is the only other option for $\{e, a\}$ to be a group of cardinal 2.

Thus the Cayley table of a group of two elements is

$*$	e	a
e	e	a
a	a	e

We have therefore proved that this is the only manner, or configuration, in which a set of two elements can form a group. For example, consider the elements $1, -1 \in \mathbb{Z}$ together with the IBO $\cdot$. We have

$\cdot$	1	-1
1	1	-1
-1	-1	1

that is, the structure $(\{1,-1\},\cdot)$ is a group of two elements. By contrast, $(\{1,-1\},+)$ is not a group, closure being clearly violated since in this structure $1+1=2$. Indeed, one may regard the question "how much is one plus one?" as a trick question, to be answered with the question "in which algebraic structure?".

The group of three elements

In this case we have

$*$	e	a	b
e	e	a	b
a	a	$a*a$	$a*b$
b	b	$b*a$	$b*b$

Since, however, the elements of a row or column cannot repeat, we conclude that $a*b=e$, and in the same way $b*a=e$. Filling in the remaining entries by the same logic we find $a*a=b$ and $b*b=a$, so the general Cayley table for a group of three elements is

$*$	e	a	b
e	e	a	b
a	a	b	e
b	b	e	a

which is clearly unique. As an example, the set of the three cube roots of unity together with complex multiplication forms a group, with the Cayley table of a group of three elements:

$\cdot$	1	$-\frac{1}{2}+\mathrm{i}\frac{\sqrt{3}}{2}$	$-\frac{1}{2}-\mathrm{i}\frac{\sqrt{3}}{2}$
1	1	$-\frac{1}{2}+\mathrm{i}\frac{\sqrt{3}}{2}$	$-\frac{1}{2}-\mathrm{i}\frac{\sqrt{3}}{2}$
$-\frac{1}{2}+\mathrm{i}\frac{\sqrt{3}}{2}$	$-\frac{1}{2}+\mathrm{i}\frac{\sqrt{3}}{2}$	$-\frac{1}{2}-\mathrm{i}\frac{\sqrt{3}}{2}$	1
$-\frac{1}{2}-\mathrm{i}\frac{\sqrt{3}}{2}$	$-\frac{1}{2}-\mathrm{i}\frac{\sqrt{3}}{2}$	1	$-\frac{1}{2}+\mathrm{i}\frac{\sqrt{3}}{2}$

4.5.2 The group $\mathbb{Z}$

In the discussion of the definition of a group we mentioned that $(\mathbb{Z},+,0)$ is a group. This group is very fruitful for explaining the ideas of subgroup and of quotient spaces, and we therefore study it in detail.

The subgroup $n\mathbb{Z}$

Let $n \in \mathbb{Z}$, and define the set $n\mathbb{Z} = \{nk \mid k \in \mathbb{Z}\}$; that is, $n\mathbb{Z}$ consists of all the multiples of n within $\mathbb{Z}$. For example,

$$3\mathbb{Z} = \{\ldots,-9,-6,-3,0,3,6,9,\ldots\}, \quad \mathbb{Z} = \{\ldots,-3,-2,-1,0,1,2,3,\ldots\}\,.$$

Proposition 4.35. *$n\mathbb{Z}$ is a subgroup of $\mathbb{Z}$.*
Rests on Definition 4.33.

Proof. *Derives Proposition 4.35.*
We check the requirements:

1. $n\mathbb{Z} \neq \varnothing$, since $0 \in n\mathbb{Z}$ (take $k = 0$).

2. Trivially the neutral element 0 lies in $n\mathbb{Z}$, since the number zero is a multiple of every integer.

3. Finally, for every element of $n\mathbb{Z}$ there exists an inverse: if $a \in n\mathbb{Z}$ is a multiple of n, so is $-a$. Indeed, we may write $a = nl$ with $l \in \mathbb{Z}$; then, since distributivity holds in $\mathbb{Z}$,

$$\begin{aligned} a + (-a) &= nl + (-nl) \\ &= nl + n(-l) \\ &= n(l - l) \\ &= 0\,, \end{aligned}$$

so the inverse axiom is satisfied.

□

Congruence modulo n

As human beings we do not count the hours from the beginning of the Universe. As a reference for indicating clock time we speak of k hours past midnight: a day is completed when 24 hours have elapsed since midnight, and hour number 25 we begin to call hour 1 again. We shall build definitions that say that 25 is mathematically equivalent to 1 (though not equal), every 24 hours.

Let $k, l \in \mathbb{Z}$, and define the relation

$$k \sim_n l \iff k - l \in n\mathbb{Z}\,. \tag{4.21}$$

Proposition 4.36. *The relation Equation (4.21) is an equivalence relation.*
Rests on Definitions 3.58 and 4.20.

Proof. *Derives Proposition 4.36.*
We verify the three properties of Definition 3.58:

1. $k \sim_n k$, since $k - k = 0 \in n\mathbb{Z}$; reflexivity therefore holds.

2. If $k \sim_n l$, we have

$$\begin{aligned} k - l \in n\mathbb{Z} &\iff k - l = np,\ p \in \mathbb{Z}, \\ &\iff l - k = n(-p),\ p \in \mathbb{Z}, \\ &\iff l - k = nq,\ q \in \mathbb{Z}\,, \end{aligned}$$

because $\mathbb{Z}$ is a group, so there exists $-p = q \in \mathbb{Z}$. Thus

$$k \sim_n l \implies l \sim_n k\,,$$

and symmetry holds.

3. If $k \sim_n l$ and $l \sim_n p$, we have

$$k - l = nq,\ q \in \mathbb{Z},$$
$$l - p = nr,\ r \in \mathbb{Z}\,.$$

Adding the equations member by member gives $k - p = n(q + r)$, and by closure $q + r = s \in \mathbb{Z}$; hence $k - p \in n\mathbb{Z}$. Thus

$$k \sim_n l \ \wedge\ l \sim_n p \implies k \sim_n p\,,$$

and transitivity holds.

□

We have proved that the relation defined is an equivalence relation. We shall say that two elements equivalent under this relation are *congruent modulo* n. In the earlier example, 25 is congruent to 1 modulo 24.

The quotient space $\mathbb{Z}/n\mathbb{Z}$

As we have seen, congruence modulo n is an equivalence relation. Let $k \in \mathbb{Z}$. We denote by $\overline{k}$ the class of k, given by

$$\overline{k} = \{l \in \mathbb{Z} \mid l \sim_n k\} = \{l \in \mathbb{Z} \mid l - k \in n\mathbb{Z}\} = \{\text{multiples of } n, \text{ plus } k\}\,.$$

As we know, the quotient space is the set of all the classes. Let us analyse the possible classes making up our quotient space:

- $\overline{0}$ consists of the multiples of n;
- $\overline{1}$ consists of the multiples of n, plus 1;
- $\overline{n}$ consists of the multiples of n, plus n — that is, simply the multiples of n. Thus

$$\overline{0} = \overline{n}\,. \tag{4.22}$$

- $\overline{n+1}$ consists of the multiples of n, plus $n + 1$ — that is, simply the multiples of n, plus 1.

Hence the elements of our quotient space are the classes (none repeated)

$$\frac{\mathbb{Z}}{n\mathbb{Z}} = \{\overline{0}, \ldots, \overline{n-1}\}\ . \tag{4.23}$$

The set $\mathbb{Z}/n\mathbb{Z}$ as an abelian group

Define the internal binary operation

$$\begin{aligned} \overline{+}: \ \frac{\mathbb{Z}}{n\mathbb{Z}} \times \frac{\mathbb{Z}}{n\mathbb{Z}} &\longrightarrow \frac{\mathbb{Z}}{n\mathbb{Z}} \\ (\overline{k}, \overline{l}) &\longmapsto \overline{k} \,\overline{+}\, \overline{l} = \overline{k+l}\,. \end{aligned}$$

Proposition 4.37. $\left(\frac{\mathbb{Z}}{n\mathbb{Z}}, \overline{+}, \overline{0}\right)$ *is an abelian group.*
Rests on Definitions 4.8 and 4.20 and Proposition 4.36.

Proof. *Derives Proposition 4.37.*
To avoid overloading the notation we write $\overline{+}$ simply as $+$. We have:

1. There is closure by construction: the class $\overline{k+l} = \overline{k} + \overline{l}$ always lies in the quotient space, since the class of $k+l$ can always be written as the class of n plus something, and finally as the class of that something. For example, for $n = 5$,
$$\overline{3} + \overline{8} = \overline{3+8} = \overline{11} = \overline{5+6} = \overline{6} = \overline{5+1} = \overline{1} \in \frac{\mathbb{Z}}{5\mathbb{Z}}\,.$$
2. There is associativity, since
$$\begin{aligned}(\overline{k} + \overline{l}) + \overline{m} &= \overline{k+l} + \overline{m} \\ &= \overline{(k+l)+m} \\ &= \overline{k+(l+m)} \\ &= \overline{k} + \overline{l+m} \\ &= \overline{k} + (\overline{l} + \overline{m})\,.\end{aligned}$$
3. The neutral element $\overline{0}$ exists: indeed, $\overline{k} + \overline{0} = \overline{k+0} = \overline{k}$.
4. An inverse element $\overline{-k}$ exists for each element $\overline{k}$ of the set: indeed, $\overline{k} + \overline{-k} = \overline{k-k} = \overline{0}$. For example, for $n = 5$ we have
$$\frac{\mathbb{Z}}{5\mathbb{Z}} = \{\overline{0}, \overline{1}, \overline{2}, \overline{3}, \overline{4}\}\ ,$$
and the inverse element of $\overline{1}$ is $\overline{4}$, that is, $\overline{-1} = \overline{4}$ — not by imposition, but by the definition of the class: the multiples of 5, minus 1, are the same numbers (the same class) as the multiples of 5, plus 4.
5. The IBO $\overline{+}$ is commutative, owing to the commutativity of $\mathbb{Z}$. Indeed,
$$\begin{aligned}\overline{k} + \overline{l} &= \overline{k+l} \\ &= \overline{l+k} \\ &= \overline{l} + \overline{k}\,.\end{aligned}$$

□

In conclusion, $\left(\frac{\mathbb{Z}}{n\mathbb{Z}}, \overline{+}, \overline{0}\right)$ is an abelian group, distinct from the group $(\mathbb{Z}, +, 0)$.

4.6 Functions on groups

The group of maps into a group

The construction this section needs has already been carried out in the generality of arbitrary algebraic structures: the pointwise product of Section 4.1.2, the neutral map Θ, and the opposite map Equation (4.6) make $\mathcal{F}(A, B)$ a group whenever B is one, by Proposition 4.14. Taking A to be a group G and B a group H costs nothing extra and adds nothing new: G's own operation plays no part, because the pointwise construction never operates on the argument.

What is genuinely new here is that the maps of interest between groups are not all of $\mathcal{F}(G, H)$ but the homomorphisms, and those are a different matter.

Proposition 4.38 (When the homomorphisms form a group)**.** *Let G and H be groups and let* $\mathrm{Hom}(G, H)$ *denote the set of group homomorphisms from G to H. If H is abelian, then* $\mathrm{Hom}(G, H)$ *is a subgroup of $(\mathcal{F}(G, H), *)$, and it is abelian. If H is not abelian, then* $\mathrm{Hom}(H, H)$ *is not even closed under $*$.*

Rests on Definitions 4.33 and 4.39 and Propositions 4.14 and 4.25.

Proof. *Derives Proposition 4.38.*

Let $f, g \in \mathrm{Hom}(G,H)$ and $a, b \in G$. Expanding both sides,

$$\begin{aligned}(f*g)(a *_G b) &= f(a *_G b) *_H g(a *_G b)\\ &= f(a) *_H f(b) *_H g(a) *_H g(b)\,,\\ (f*g)(a) *_H (f*g)(b) &= f(a) *_H g(a) *_H f(b) *_H g(b)\,.\end{aligned}$$

The two agree for all a, b precisely when $f(b) *_H g(a) = g(a) *_H f(b)$, that is, when the images of f and g commute with one another.

If H is abelian this holds automatically, so $f * g$ is again a homomorphism. The neutral map Θ is a homomorphism, since $\Theta(a *_G b) = e_H = e_H *_H e_H = \Theta(a) *_H \Theta(b)$; and f^{op} is one because $f^{\mathrm{op}}(a *_G b) = (f(a) *_H f(b))^{-1} = f(b)^{-1} *_H f(a)^{-1} = f^{\mathrm{op}}(a) *_H f^{\mathrm{op}}(b)$, the last step using commutativity again. So $\mathrm{Hom}(G,H)$ contains the neutral element and is closed under the operation and under opposites, which is what it is to be a subgroup; it is abelian because $\mathcal{F}(G,H)$ is, by Proposition 4.14.

If H is not abelian, pick $a, b \in H$ with $a *_H b \neq b *_H a$ and take $f = g = \mathrm{id}_H$, which is certainly a homomorphism. The displayed condition then reads $b *_H a = a *_H b$, which fails, so $\mathrm{id}_H * \mathrm{id}_H$ is not a homomorphism and $\mathrm{Hom}(H,H)$ is not closed. □

The proposition is the reason the theory of group homomorphisms does not reduce to the theory of maps. For abelian targets one may add homomorphisms and stay inside the class — which is what makes $\mathrm{Hom}(G,\mathbb{R})$ and its relatives vector spaces, and ultimately what makes cohomology groups groups. For non-abelian targets the pointwise product leaves the class immediately, and the structures that survive are built from composition instead. The remainder of this section develops the notions that do work in both cases.

4.6.1 Homomorphisms

Definition 4.39 (Group homomorphism)**.** Consider the groups $(G_1, *_1)$ and $(G_2, *_2)$, together with a map $f : G_1 \longrightarrow G_2$. We say that f is a *group homomorphism* from G_1 to G_2 if and only if $f(a_1 *_1 b_1) = f(a_1) *_2 f(b_1)$ — that is, if between the two distinct groups f preserves the multiplication law.

Rests on Definitions 3.43 and 4.20.

Definition 4.40 (Group isomorphism)**.** Consider the groups $(G_1, *_1)$ and $(G_2, *_2)$ and let $f : G_1 \longrightarrow G_2$ be a group homomorphism. We say that f is an *isomorphism* from G_1 to G_2 if and only if the homomorphism is a bijection; we then say that G_1 and G_2 are *isomorphic*.

Rests on Definitions 3.47 and 4.39.

Isomorphism between groups is of great importance, because it is the concept expressing that two groups operate in exactly the same way even though their elements are distinct. What totally determines a group is the operation among its elements — its Cayley table — and what an isomorphism does is precisely to preserve the operation. For example, consider the set $\{1, \mathrm{i}, -1, -\mathrm{i}\}$, where $\mathrm{i} = \sqrt{-1} \in \mathbb{C}$. It is easy to verify that this set, together with the usual multiplication, forms an abelian group whose Cayley table is

$\cdot$	1	i	-1	$-\mathrm{i}$
1	1	i	-1	$-\mathrm{i}$
i	i	-1	$-\mathrm{i}$	1
-1	-1	$-\mathrm{i}$	1	i
$-\mathrm{i}$	$-\mathrm{i}$	1	i	-1

On the other hand, it is easy to compute the Cayley table of the (abelian) group $\frac{\mathbb{Z}}{4\mathbb{Z}}$:

$\overline{+}$	$\overline{0}$	$\overline{1}$	$\overline{2}$	$\overline{3}$
$\overline{0}$	$\overline{0}$	$\overline{1}$	$\overline{2}$	$\overline{3}$
$\overline{1}$	$\overline{1}$	$\overline{2}$	$\overline{3}$	$\overline{0}$
$\overline{2}$	$\overline{2}$	$\overline{3}$	$\overline{0}$	$\overline{1}$
$\overline{3}$	$\overline{3}$	$\overline{0}$	$\overline{1}$	$\overline{2}$

Comparing the two tables, we see that these groups are essentially the same thing: they are exactly the same up to the symbols we have used to designate the elements of the sets. This may seem magical, but so it is: taking two sets with no relation whatsoever and adjoining the group axioms, an intrinsic operational structure appears when the sets are viewed as algebraic structures. The situation has a precise mathematical underpinning: these groups are isomorphic. This is the true meaning of isomorphisms. The explicit form of the isomorphism between $\{1, \mathrm{i}, -1, -\mathrm{i}\}$ and $\frac{\mathbb{Z}}{4\mathbb{Z}}$ is given by $f(x) = \overline{-(2\mathrm{i}/\pi)\ln x}$ with $x \in \{1, \mathrm{i}, -1, -\mathrm{i}\}$, resulting in

$$\begin{array}{ccc} & f & \\ 1 & \longmapsto & \overline{0} \\ \mathrm{i} & \longmapsto & \overline{1} \\ -1 & \longmapsto & \overline{2} \\ -\mathrm{i} & \longmapsto & \overline{3}\,. \end{array}$$

One verifies, moreover, the preservation of the product law:

$$\begin{aligned} f(x \cdot y) &= \overline{-(2\mathrm{i}/\pi)\ln(x \cdot y)} \\ &= \overline{-(2\mathrm{i}/\pi)(\ln x + \ln y)} \\ &= \overline{-(2\mathrm{i}/\pi)\ln x} \,\overline{+}\, \overline{-(2\mathrm{i}/\pi)\ln y} \\ &= f(x) \,\overline{+}\, f(y)\,. \end{aligned}$$

Definition 4.41 (Group automorphism)**.** Let $f : G_1 \longrightarrow G_2$ be a group isomorphism. We say that f is an *automorphism* if and only if $G_1 = G_2$ — that is, the homomorphism f is moreover a bijection sending elements of a group to the group itself.

Rests on Definition 4.40.

Since every group is isomorphic to itself, we can say that for every group there exists a trivial automorphism sending each element to itself; that is, the bijection

$$\begin{array}{rccc} f: & G & \longrightarrow & G \\ & e & \longmapsto & e \\ & a & \longmapsto & a \\ & b & \longmapsto & b \\ & & \vdots & \end{array}$$

is a (trivial, but canonical) example of an automorphism.

4.6.2 Properties of homomorphisms

Proposition 4.42 (Image of the neutral element)**.** *Under a group homomorphism, the image of the neutral element is the neutral element of the codomain:*

$$f(e_1) = e_2\,. \tag{4.24}$$

Rests on Definition 4.39.

Proof. *Derives Proposition 4.42.*

For the neutral element of the domain we have $f(e_1) = f(e_1 *_1 e_1)$, and since f is a homomorphism, operating with $*_2 (f(e_1))^{-1}$,

$$\begin{aligned} f(e_1) &= f(e_1) *_2 f(e_1) \\ f(e_1) *_2 (f(e_1))^{-1} &= f(e_1) \\ e_2 &= f(e_1)\,. \end{aligned}$$

□

Proposition 4.43 (Image of the inverse element)**.** *Analogously to the preceding case, the image of an inverse element of the domain is the inverse of the image in the codomain:*

$$f(a_1^{-1}) = (f(a_1))^{-1}\,. \tag{4.25}$$

Rests on Definition 4.39 and Proposition 4.42.

Proof. *Derives Proposition 4.43.*

Indeed, operating on the left with $(f(a_1))^{-1} *_2$,

$$\begin{aligned} f(e_1) &= f(a_1 *_1 a_1^{-1}) \\ e_2 &= f(a_1) *_2 f(a_1^{-1}) && \text{by Equation (4.24)} \\ (f(a_1))^{-1} &= f(a_1^{-1})\,. \end{aligned}$$

□

4.7 The symmetric group

4.7.1 The symmetric group

Definition 4.44 (Symmetric group)**.** Consider a set X, and let S_X be the set of all the possible bijections from X to X, that is,

$$S_X = \{f \mid f : X \longrightarrow X \text{ is a bijection}\}\,. \tag{4.26}$$

Rests on Definition 3.47.

Let us recall the following properties (Section 3.3):

1. the composition of two bijective maps is a bijective map;
2. the composition of maps is associative — in particular, so is the composition of bijective maps;
3. there exists the identity map, whose composition with any map returns that same map — in particular, this works for any bijective map;
4. every bijective map possesses an inverse map.

From this we may conclude that $(S_X, \circ)$ is a group under composition of maps, which we shall call the *symmetric group*.

4.7.2 The permutation group

Definition 4.45 (Permutation group)**.** We define the *permutation group* as a symmetric group S_G in which G is a finite group. Thus

$$S_G = \{f \mid f : G \longrightarrow G \text{ is a bijection, } |G| \in \mathbb{N}\} \,. \tag{4.27}$$

Rests on Definitions 4.20 and 4.44.

Consider $G = \{g_i\}_{i=1}^{n}$. As discussed in the definition of the symmetric group, the elements of S_G are bijections. Since G here has a finite number of elements, a possible bijection is, for example, for $n = 5$,

$$\begin{array}{ccc} & f & \\ g_1 & \longmapsto & g_4 \\ g_2 & \longmapsto & g_3 \\ g_3 & \longmapsto & g_2 \\ g_4 & \longmapsto & g_5 \\ g_5 & \longmapsto & g_1 \end{array}$$

that is, in some manner f permutes the elements. We can symbolize this permutation as

$$f = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 3 & 2 & 5 & 1 \end{pmatrix} .$$

As an alternative notation for permutations we introduce

$$\sigma_a(g_i) = a g_i \overset{\text{not.}}{=} g_{a_i} \,, \tag{4.28}$$

where the index a_i denotes the new place of the element. For example, one may have $a g_2 = g_1$ (that is, $a_2 = 1$).

Proposition 4.46 (Cardinal of the permutation group)**.** $|S_G| = |G|!$.

Rests on Definition 4.45.

Proof. *Derives Proposition 4.46.*

Write $n = |G|$ and $G = \{g_1, \ldots, g_n\}$. For $0 \le k \le n$ let A_k denote the set of *injective* maps from $\{g_1, \ldots, g_k\}$ into G, so that A_0 has exactly one element, the empty map. We claim that

$$|A_k| = n(n-1)\cdots(n-k+1) \,, \qquad 0 \le k \le n \,, \tag{4.29}$$

the right-hand side being read as 1 when $k = 0$.

The claim holds for $k = 0$. Assume it for some $k < n$ and consider the restriction map $A_{k+1} \longrightarrow A_k$ that forgets the value at g_{k+1}. An injective $u \in A_k$ takes k pairwise distinct values, so the injective extensions of u to $\{g_1, \ldots, g_{k+1}\}$ are exactly the maps sending g_{k+1} to one of the elements of $G \setminus \{u(g_1), \ldots, u(g_k)\}$, a set of $n - k$ elements. Every $u \in A_k$ therefore has exactly $n - k$ preimages under the restriction map, and every element of A_{k+1} has exactly one image, whence

$$|A_{k+1}| = (n-k)\ |A_k| = n(n-1)\cdots(n-k) \,,$$

which is Equation (4.29) for $k+1$. By induction it holds for every $k \le n$; in particular

$$|A_n| = n(n-1)\cdots 2 \cdot 1 = n! \,.$$

It remains to identify A_n with S_G. An element of A_n is an injective map $f : G \longrightarrow G$; its image has exactly n elements, and the only subset of the n-element set G with n elements is G itself, so f is also surjective and hence a bijection. Conversely every bijection of G is injective. Thus $A_n = S_G$ and $|S_G| = n! = |G|!$. □

The permutation group of order 3!

The smallest symmetric group that is not abelian is the one built on a three-element set. Take $X = \{1, 2, 3\}$ and write $S_3 = S_X$; by Proposition 4.46 it has $3! = 6$ elements. It is small enough to be written out completely, and large enough that everything the rest of this chapter defines — subgroups, conjugacy, normality, quotients — can be read off its table.

Notation 4.47 (Cycle notation). Let $i_1, \dots, i_r$ be distinct elements of a finite set X. The *cycle* $(i_1\, i_2\, \dots\, i_r)$ is the bijection of X sending $i_1 \longmapsto i_2$, $i_2 \longmapsto i_3$, …, $i_r \longmapsto i_1$ and leaving every other element of X fixed; a cycle of length two is a *transposition*. A permutation is also written in two-line form, the second line listing the images of the entries of the first. Products are compositions of maps, so fg means $f \circ g$: the right-hand factor acts first.

Rests on Definitions 3.47 and 4.44.

In this notation the six elements of S_3 are

$$\begin{aligned} e &= \begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, \qquad r = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix} = (1\,2\,3), \quad r^2 = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix} = (1\,3\,2), \\ t_1 &= \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix} = (2\,3), \quad t_2 = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix} = (1\,3), \quad t_3 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} = (1\,2). \end{aligned} \tag{4.30}$$

Three of them are transpositions, two are three-cycles, and $r^3 = e$, so $r^{-1} = r^2$ and $t_i^{-1} = t_i$ for each i. Composing the maps of Equation (4.30) pair by pair gives the Cayley table (Definition 4.34) shown in Table 4.1.

Table 4.1: The Cayley table of S_3 in the notation of Equation (4.30). The entry in row f and column g is the composite $f \circ g$, in which g acts first. Every row and every column is a permutation of the six elements, as Section 4.4.2 requires; the table is *not* symmetric about its diagonal — $r\,t_1 = t_3$ while $t_1 r = t_2$ — which is the whole content of Proposition 4.48. The upper-left 3×3 block is closed, and is the group of three elements of Section 4.5.1.

$\circ$	e	r	r^2	t_1	t_2	t_3
e	e	r	r^2	t_1	t_2	t_3
r	r	r^2	e	t_3	t_1	t_2
r^2	r^2	e	r	t_2	t_3	t_1
t_1	t_1	t_2	t_3	e	r	r^2
t_2	t_2	t_3	t_1	r^2	e	r
t_3	t_3	t_1	t_2	r	r^2	e

Proposition 4.48 (S_3 is a smallest non-abelian group)**.** *Every group with fewer than six elements is abelian, and S_3 has six elements and is not abelian.*

Rests on Definitions 4.8 and 4.20 and Proposition 4.46.

Proof. *Derives Proposition 4.48.*

That S_3 has six elements is Proposition 4.46, and Table 4.1 exhibits $r\,t_1 = t_3 \neq t_2 = t_1 r$, so S_3 is not abelian.

For the first assertion, let G be a group that is not abelian and choose $x, y \in G$ with $xy \neq yx$. We show that G has at least six elements. First, the five elements

$$e, \quad x, \quad y, \quad xy, \quad yx$$

are pairwise distinct. Indeed $x \neq e$ and $y \neq e$, since the neutral element commutes with everything, and $x \neq y$, since every element commutes with itself. If $xy = e$ then $y = x^{-1}$

by Proposition 4.23, and then $yx = e = xy$, excluded; the same argument rules out $yx = e$. Cancelling x on the left in $xy = x$, or y on the right in $xy = y$, would give $y = e$ or $x = e$, and likewise for yx; finally $xy \neq yx$ by choice.

It remains to produce a sixth element. Consider x^2. It cannot equal x (that gives $x = e$), nor xy (that gives $x = y$), nor yx (cancelling x on the right gives $x = y$), nor y — for $x^2 = y$ would make $xy = x^3 = yx$. So either x^2 lies outside the five elements listed, and G has at least six, or $x^2 = e$. Applying the same argument to y, we may assume $x^2 = y^2 = e$, so that $x^{-1} = x$ and $y^{-1} = y$. Then xyx is the sixth element: $xyx = e$ gives $yx = x^{-1} = x$ and so $y = e$; $xyx = x$ gives $yx = e$ and so $y = x^{-1} = x$; $xyx = y$ gives $xy = yx^{-1} = yx$; $xyx = xy$ gives $x = e$; and $xyx = yx$ gives $xy = y$ and so $x = e$ — every case being excluded. Hence $|G| \geq 6$. □

Proposition 4.49 (The subgroups of S_3)**.** *S_3 has exactly six subgroups: the two trivial ones $\{e\}$ and S_3; the three two-element subgroups $\{e, t_i\}$, $i = 1, 2, 3$; and the three-element subgroup*

$$A_3 = \left\{e, r, r^2\right\} . \tag{4.31}$$

Rests on Definitions 4.33 and 4.45.

Proof. *Derives Proposition 4.49.*

Each of the six listed sets is a subgroup: $\{e\}$ and S_3 trivially, $\{e, t_i\}$ because $t_i\, t_i = e$, and A_3 because the upper-left 3×3 block of Table 4.1 takes values in A_3 and contains e, with $r^{-1} = r^2$.

Conversely let $H \leq S_3$ be a subgroup and suppose $H \neq \{e\}$. If H contains r or r^2 then, being closed and containing inverses, it contains $\{e, r, r^2\} = A_3$. If in addition H contains some t_i, then it contains the three products $r\, t_i$, $r^2 t_i$ and t_i, which by Table 4.1 are the three distinct transpositions; hence $H = S_3$. So a subgroup containing a three-cycle is A_3 or S_3.

Suppose instead that H contains no three-cycle. Then H consists of e and transpositions. It cannot contain two distinct transpositions: the product of two distinct transpositions is, by Table 4.1, a three-cycle, which would then lie in H. Hence $H = \{e, t_i\}$ for a single i. The list is therefore complete. □

Remark 4.50. Anticipating Definition 4.56, A_3 is normal in S_3: conjugation by an element of A_3 maps A_3 into itself because A_3 is a subgroup, and Table 4.1 gives $t_1 r\, t_1^{-1} = t_1 r\, t_1 = r^2$, with the same outcome for t_2 and t_3. The two-element subgroups are not normal: the same table gives $r\, t_1 r^{-1} = r\, t_1 r^2 = t_2$, which is outside $\{e, t_1\}$. The three of them are therefore conjugate to one another in the sense of Definition 4.55. Moreover S_3 is the smallest group possessing a subgroup that is not normal: in an abelian group $aHa^{-1} = \{aha^{-1} \mid h \in H\} = \{h \mid h \in H\} = H$ for every subgroup H and every a, so all subgroups are normal, and by Proposition 4.48 every group of fewer than six elements is abelian.

The elements of S_3 are not merely relabellings: they are the symmetries of a figure.

Proposition 4.51 (S_3 and the equilateral triangle)**.** *Let $\Delta \subset \mathbb{R}^2$ be an equilateral triangle with vertices labelled $1, 2, 3$, and let T be the set of isometries of the plane that map Δ onto itself, a group under composition. The map sending each element of T to the permutation it induces on the vertex labels is an isomorphism $T \longrightarrow S_3$.*

Rests on Definition 4.40 and Equation (4.30).

Proof. *Derives Proposition 4.51.*

An isometry mapping Δ onto itself maps the vertex set onto itself, since a vertex is characterized metrically as a point of Δ at maximal distance from the centroid; call $\pi(u) \in S_3$ the resulting permutation of the labels. Composition of isometries induces composition of the permutations, so π is a homomorphism (Definition 4.39).

π is injective. If $\pi(u) = e$ then u fixes the three vertices, and these are not collinear; since a point of the plane is determined by its distances to three non-collinear points, and u preserves all distances, u fixes every point of the plane. So $\ker \pi = \{\mathrm{id}\}$, and Proposition 4.17 gives injectivity.

π is surjective. The rotation through $2\pi/3$ about the centroid of Δ carries Δ onto itself and induces the three-cycle r of Equation (4.30); its square induces r^2. The reflection in the median through the vertex i carries Δ onto itself and induces the transposition t_i. Together with the identity these six isometries realize all six elements of S_3, so π is onto and hence an isomorphism. □

The six isometries just exhibited are all of T, since π is a bijection. This is the first instance in this chapter of the pattern that makes group theory the language of symmetry in physics: an abstract group defined by a multiplication table turns out to *be* the symmetry group of a concrete object, and the two descriptions carry exactly the same information.

Theorem 4.52 (Cayley's theorem)**.** *Every finite group of order n is isomorphic to a subgroup of order n of the permutation group S_n.*
Rests on Definitions 4.33, 4.40 and 4.45.

Proof. *Derives Theorem 4.52.*
Let $(G, \cdot, e)$ be a group with $|G| = n$. For each $a \in G$ define the *left translation*

$$\begin{array}{rccc} p_a : & G & \longrightarrow & G \\ & g & \longmapsto & ag\,. \end{array} \tag{4.32}$$

Each p_a is a bijection. It is a map into G by closure. It is injective: if $ag = ag'$, then operating on the left with a^{-1} and using associativity gives $g = g'$. It is surjective: given $h \in G$, the element $a^{-1}h$ lies in G and $p_a(a^{-1}h) = a(a^{-1}h) = h$. By Proposition 3.48 it is therefore a bijection, so $p_a \in S_G$; its inverse map is $p_{a^{-1}}$.

The assignment $a \longmapsto p_a$ is a homomorphism. For $a, b, g \in G$,

$$p_{ab}(g) = (ab)g = a(bg) = p_a\left(p_b(g)\right) = \left(p_a \circ p_b\right)(g)\,,$$

and since g was arbitrary, $p_{ab} = p_a \circ p_b$. Writing $P : G \longrightarrow S_G$ for the map $a \longmapsto p_a$, this says precisely that P is a group homomorphism into $(S_G, \circ)$ (Definition 4.39).

P is injective. If p_a is the identity permutation then in particular $ae = e$, so $a = e$. Hence $\ker P = \{e\}$, and Proposition 4.17 gives injectivity.

The image is a subgroup of order n. The set $P(G) = \{p_a \mid a \in G\}$ contains $p_e = \mathrm{id}_G$, is closed under composition because $p_a \circ p_b = p_{ab}$, and contains the inverse $p_a^{-1} = p_{a^{-1}}$ of each of its elements; it is therefore a subgroup of S_G (Definition 4.33). Since P is injective, $P(G)$ has exactly n elements, and $P : G \longrightarrow P(G)$ is a bijective homomorphism, that is, an isomorphism (Definition 4.40).

Finally, any bijection $\varphi : G \longrightarrow \{1, \ldots, n\}$ induces an isomorphism $S_G \longrightarrow S_n$ by $f \longmapsto \varphi \circ f \circ \varphi^{-1}$ — a bijection with inverse $h \longmapsto \varphi^{-1} \circ h \circ \varphi$, and a homomorphism because the two inner factors $\varphi^{-1}\varphi$ cancel in a product. It carries $P(G)$ to a subgroup of S_n of order n isomorphic to G. □

4.8 Decompositions of a group

4.8.1 Conjugacy classes

Consider a group G. Define the relation

$$a \sim b \iff \exists\, p \in G \mid b = pap^{-1}, \quad a, b \in G\,. \tag{4.33}$$

Proposition 4.53. *The relation Equation (4.33) is an equivalence relation.*
Rests on Definitions 3.58 and 4.20 and Proposition 4.25.

Proof. *Derives Proposition 4.53.*
We verify the three properties:

1. Reflexivity holds, since
$$a = eae = eae^{-1},$$
that is, thanks to the existence of the neutral element, $a \sim a$.

2. If $a \sim b$, it is because there exists $p \in G$ such that $b = pap^{-1}$. Multiplying on the right by p and then on the left by p^{-1},
$$\begin{aligned} b &= pap^{-1} \\ bp &= pa \\ p^{-1}bp &= a\,. \end{aligned}$$
Hence, by the existence of inverse elements in G, there exists $q = p^{-1}$ such that $a = qbq^{-1}$, so $b \sim a$; symmetry therefore holds.

3. Supposing $a \sim b$ and $b \sim c$, there exist $p, q \in G$ such that
$$b = pap^{-1}, \quad c = qbq^{-1},$$
and substituting the first into the second,
$$\begin{aligned} c &= q(pap^{-1})q^{-1} \\ &= (qp)a(p^{-1}q^{-1}) \\ &= (qp)a(qp)^{-1} && \text{by Equation (4.16)}\,. \end{aligned}$$
Hence by closure there exists $r = qp \in G$ such that $c = rar^{-1}$, so $a \sim c$, and transitivity holds.

□

Definition 4.54 (Conjugacy classes)**.** We call *conjugacy classes* the equivalence classes given by the relation Equation (4.33). We say that two elements of a conjugacy class are *conjugate*; that is, a and b are conjugate if and only if $a \sim b$. We have
$$[a] = \{x \in G \mid x \sim a\} = \{pap^{-1} \mid p \in G\}\,.$$
Rests on Proposition 4.53 and Definition 3.59.

Definition 4.55 (Conjugate subgroups)**.** Consider the group G and $H, K \leq G$. We say that K and H are *conjugate subgroups* if and only if
$$h \sim k, \quad \forall\, h \in H,\ \forall\, k \in K\,,$$
that is,
$$\begin{aligned} K &= \{k \mid k \in K\} \\ &= \left\{php^{-1} \mid h \in H,\, p \in G\right\}, \end{aligned}$$
which we shall symbolize simply as $K = pHp^{-1}$, $p \in G$.
Rests on Definitions 4.33 and 4.54.

Definition 4.56 (Normal subgroup)**.** Let G be a group and $H \leq G$. We say that H is a *normal* (or *invariant*) subgroup in G if and only if it is conjugate to itself by all the elements of the group, that is, if $H = pHp^{-1}$ for all $p \in G$. We introduce the notation

$$H \text{ normal in } G \quad \overset{\text{not.}}{\iff} \quad H \trianglelefteq G\,.$$

Rests on Definitions 4.33 and 4.55.

Given a group G, it is easy to see that the trivial subgroups are also normal subgroups in G; that is, $\{e\} \trianglelefteq G$ and $G \trianglelefteq G$. It is worth mentioning that in the group-theory literature there are many ways of defining what a normal subgroup is; one may define it as one wishes, provided the other definitions are mentioned as possible characterizations.

4.8.2 Cosets

Consider the group $(G, \cdot, e)$ and $H \leq G$. Define the relation

$$a \sim_H b \iff \exists\, h \in H \mid b = ah, \quad a, b \in G\,. \tag{4.34}$$

Proposition 4.57. *The relation Equation (4.34) is an equivalence relation.*
Rests on Definitions 3.58 and 4.33.

Proof. *Derives Proposition 4.57.*
We verify the three properties:

1. Reflexivity holds because H is a subgroup of G, so the neutral element exists in H and

$$a = ae\,,$$

whence $a \sim_H a$.

2. Suppose $a \sim_H b$. Then there exists $h \in H$ such that $b = ah$. Since H is a subgroup of G (and in essence a group), h^{-1} exists. Operating on the right with $\cdot\, h^{-1}$,

$$\begin{aligned} b &= ah \\ bh^{-1} &= a\,. \end{aligned}$$

Then there exists $k = h^{-1} \in H$ such that $a = bk$; hence $b \sim_H a$ and symmetry holds.

3. If $a \sim_H b$ and $b \sim_H c$, it is because there exist $h, k \in H$ such that

$$b = ah, \quad c = bk\,.$$

Substituting the first into the second,

$$\begin{aligned} c &= (ah)k \\ &= a(hk) \\ &= al\,, \end{aligned}$$

and thus, since H is a subgroup, by closure there exists $l = hk \in H$; we conclude that $a \sim_H c$, so transitivity holds.

□

Definition 4.58 (Cosets)**.** We call *left lateral class* or *left coset* each equivalence class given by the relation Equation (4.34). We have

$$\begin{aligned}[a] &= \{x \in G \mid x \sim_H a\} \\ &= \{x \in G \mid x = ah,\ h \in H\} \\ &= \{ah \mid h \in H\}\,,\end{aligned}$$

and, in view of the fact that h ranges over H, we shall symbolize this class as

$$[a] \overset{\text{not.}}{=} aH\,.$$

Rests on Proposition 4.57 and Definition 3.59.

Analogously we can define Ha as a *right lateral class* or *right coset* of G. The study of left and right cosets is entirely parallel, so we shall refer only to left cosets, which we call simply *lateral classes* or *cosets*.

Finally, we must mention that it is trivial to verify that

$$eH = H, \quad He = H\,. \tag{4.35}$$

Compatibility between left and right cosets

Consider the group G and $H \leq G$. A natural question we may ask is: under which conditions is a left coset equal to a right coset? That is, under which conditions does $aH = Ha$ hold? We may suspect a possible condition (perhaps necessary and sufficient) by looking at the definition of a normal subgroup. Does

$$H = aHa^{-1},\ \forall\, a \in G \quad \overset{?}{\iff} \quad aH = Ha, \quad \forall\ a \in G$$

hold?

Indeed it does. We must prove the two implications.

⇒) Supposing $H \trianglelefteq G$, we have $H = aHa^{-1}$ for all a. Then the elements of H can be written as

$$h' = aha^{-1}\,,$$

whence

$$\begin{aligned}Ha &= \{h'a \mid h' \in H\} \\ &= \left\{(aha^{-1})a \mid h \in H\right\} \\ &= \{ah \mid h \in H\} \\ &= aH\,.\end{aligned}$$

⇐) Recall that

$$aH = \{ah \mid h \in H\}\,, \quad Ha = \left\{h'a \mid h' \in H\right\}\,,$$

and supposing $aH = Ha$ — that is, that these sets have the same elements — we can always write an element of aH as

$$ah = h'a\,,$$

whence

$$\begin{aligned}aHa^{-1} &= \left\{aha^{-1} \mid h \in H\right\} \\ &= \left\{(h'a)a^{-1} \mid h' \in H\right\} \\ &= \{h' \mid h' \in H\} \\ &= H,\ \forall\, a\,,\end{aligned}$$

and thus $H \trianglelefteq G$.

In conclusion, we have found a characterization of the normality of a subgroup:

$$\boxed{H \trianglelefteq G \iff aH = Ha,\ \forall\, a \in G} \tag{4.36}$$

From Equation (4.36) a further characterization of the normality of a subgroup can be seen:

$$\boxed{H \trianglelefteq G \iff \forall\, a \in G,\ \forall\, h \in H,\ \exists\, h' \in H \mid ah = h'a} \tag{4.37}$$

From Equation (4.36) (writing the equality of the two cosets elementwise).

4.8.3 The quotient group

Product of cosets

Consider a group $G = \{e, a, b, \ldots\}$ and a subgroup $H \leq G$. When we introduced the coset equivalence relation we did not analyse the quotient space. That quotient space is the set of all the cosets,

$$G/\!\sim_H = \{H, aH, bH, \ldots\} \overset{\text{not.}}{=} G/H\,.$$

We define the IBO *product of cosets* as

$$\begin{array}{rccc} * : & G/H \times G/H & \longrightarrow & G/H \\ & (aH, bH) & \longmapsto & aH * bH = abH\,. \end{array}$$

This product provides yet another characterization of the normality of a subgroup:

$$\boxed{H \trianglelefteq G \iff \forall\, a, b \in G,\ aH * bH = abH}\,. \tag{4.38}$$

The prescription $aH * bH = abH$ needs a word of care before it can be called an operation at all. A coset is a set, and a is merely one of its elements; the recipe reads that element off, multiplies, and forms a new coset. Nothing so far guarantees that a different choice of representatives returns the same answer — and in fact that is exactly what normality is.

Proposition 4.59 (Well-definedness of the coset product)**.** *Let G be a group and $H \leq G$. The prescription $aH * bH = abH$ is independent of the representatives a and b chosen, and so defines an IBO on G/H, if and only if $H \trianglelefteq G$. This is Equation (4.38).*

Rests on Definitions 4.56 and 4.58 and Equation (4.35).

Proof. *Derives Proposition 4.59.*

Throughout we use the fact that the cosets are the equivalence classes of Equation (4.34) (Proposition 4.57), so that

$$x \in yH \iff xH = yH\,. \tag{4.39}$$

($\Leftarrow$) Let $H \trianglelefteq G$ and let $a' \in aH$, $b' \in bH$, say $a' = ah_1$ and $b' = bh_2$ with $h_1, h_2 \in H$. Normality applied with $p = b^{-1}$ gives $H = b^{-1}Hb$, so $b^{-1}h_1 b \in H$; call this element h_3, so that $h_1 b = bh_3$. Then

$$\begin{aligned} a'b' &= (ah_1)(bh_2) \\ &= a(h_1 b)h_2 \\ &= a(bh_3)h_2 \\ &= (ab)(h_3 h_2)\,, \end{aligned}$$

and $h_3 h_2 \in H$ by closure, so $a'b' \in abH$. By Equation (4.39), $a'b'H = abH$: the answer does not depend on the representatives, and $*$ is a well-defined IBO on G/H.

($\Rightarrow$) Suppose the prescription is independent of representatives, and let $a \in G$ and $h \in H$ be arbitrary. Since $ah \in aH$ and $a^{-1} \in a^{-1}H$, evaluating $aH * a^{-1}H$ on the representatives ah and a^{-1} must give the same coset as evaluating it on a and a^{-1}, that is,

$$(ah)a^{-1}H = aa^{-1}H = eH = H\,,$$

the last step by Equation (4.35). By Equation (4.39) this says $aha^{-1} \in H$. As h ranged over H, we have $aHa^{-1} \subseteq H$ for every $a \in G$; applying the same inclusion with a^{-1} in place of a gives $a^{-1}Ha \subseteq H$, which upon multiplying by a on the left and a^{-1} on the right reads $H \subseteq aHa^{-1}$. The two inclusions give $H = aHa^{-1}$ for every $a \in G$, which is Definition 4.56. □

The quotient group

The quotient space G/H by itself has no further relevance for our study; but if we add the condition that H be normal in G, then G/H, together with the product of cosets, is a group.

Theorem 4.60 (Quotient group)**.** *Let $H \trianglelefteq G$. Then $(G/H, *)$ is a group, known as the* quotient group *of G over H.*

Rests on Definition 4.56 and Equations (4.35) and (4.38).

Proof. *Derives Theorem 4.60.*

We verify the four axioms:

1. Taking H normal in G, by Equation (4.38) we see the following: by the closure of G, ab also belongs to G; hence

   $$aH * bH = abH \in G/H\,,$$

   so the closure property holds for $(G/H, *)$.

2. The associativity of $(G/H, *)$ is a consequence of the associativity of G. Indeed,

   $$\begin{aligned}(aH * bH) * cH &= abH * cH\\ &= (ab)cH\\ &= a(bc)H\\ &= aH * bcH\\ &= aH * (bH * cH)\,.\end{aligned}$$

3. The existence of the neutral element is due to the existence of the neutral element e in G. From Equation (4.35) we see that $eH = H$. Hence, for an arbitrary element of G/H, say aH, there exists $H \in G/H$ such that

   $$H * aH = eH * aH = eaH = aH, \quad aH * H = aH * eH = aeH = aH\,.$$

4. It remains to prove the existence of inverse elements. Let $a \in G$. Since G is a group, a^{-1} exists. Now, $a^{-1}H$ is the inverse of aH, since

   $$aH * a^{-1}H = aa^{-1}H = H, \quad a^{-1}H * aH = a^{-1}aH = H\,.$$

□

4.9 Direct products

4.9.1 Direct product

Definition 4.61 (Direct product of groups)**.** Let $(G_1, *_1, e_1)$ and $(G_2, *_2, e_2)$ be groups. We define the *direct product* of the groups as the Cartesian product of the sets G_1 and G_2 together with the binary operation

$$\begin{array}{rccc} * : & (G_1 \times G_2) \times (G_1 \times G_2) & \longrightarrow & G_1 \times G_2 \\ & ((a_1, a_2), (b_1, b_2)) & \longmapsto & (a_1 *_1 b_1, a_2 *_2 b_2)\,. \end{array}$$

Rests on Definitions 4.1 and 4.20.

Proposition 4.62. $(G_1 \times G_2, *, (e_1, e_2))$ *is a group.*
Rests on Definitions 4.20 and 4.61.

Proof. *Derives Proposition 4.62.*
We verify the four axioms:

1. The binary operation $*$ is an IBO, since $a_1 *_1 b_1 \in G_1$ and $a_2 *_2 b_2 \in G_2$ by closure. Hence always $(a_1 *_1 b_1, a_2 *_2 b_2) \in G_1 \times G_2$, so there is closure with respect to $*$.

2. We have

$$\begin{aligned} ((a_1, a_2) * (b_1, b_2)) * (c_1, c_2) &= (a_1 *_1 b_1, a_2 *_2 b_2) * (c_1, c_2) \\ &= ((a_1 *_1 b_1) *_1 c_1, (a_2 *_2 b_2) *_2 c_2) \\ &= (a_1 *_1 (b_1 *_1 c_1), a_2 *_2 (b_2 *_2 c_2)) \\ &= (a_1, a_2) * (b_1 *_1 c_1, b_2 *_2 c_2) \\ &= (a_1, a_2) * ((b_1, b_2) * (c_1, c_2))\,, \end{aligned}$$

   so associativity holds.

3. We can also see that the neutral element $(e_1, e_2) \in G_1 \times G_2$ exists, since

$$\begin{aligned} (a_1, a_2) * (e_1, e_2) &= (a_1 *_1 e_1, a_2 *_2 e_2) = (a_1, a_2)\,, \\ (e_1, e_2) * (a_1, a_2) &= (e_1 *_1 a_1, e_2 *_2 a_2) = (a_1, a_2)\,. \end{aligned}$$

4. Finally, given $(a_1, a_2) \in G_1 \times G_2$, its inverse $(a_1, a_2)^{-1} = (a_1^{-1}, a_2^{-1})$ exists. Indeed,

$$(a_1, a_2) * (a_1, a_2)^{-1} = (a_1, a_2) * (a_1^{-1}, a_2^{-1}) = (a_1 *_1 a_1^{-1}, a_2 *_2 a_2^{-1}) = (e_1, e_2)\,,$$

   and analogously $(a_1, a_2)^{-1} * (a_1, a_2) = (e_1, e_2)$.

□

Definition 4.63 (Product of subgroups)**.** Consider a group G and $H, K \leq G$. We define the *product of subgroups* HK as the set

$$HK = \{hk \mid h \in H,\ k \in K\}\,. \tag{4.40}$$

Rests on Definition 4.33.

Proposition 4.64 (Direct product of abelian groups)**.** *The direct product of two abelian groups is an abelian group.*
Rests on Definitions 4.8 and 4.61.

Proof. *Derives Proposition 4.64.*

Let $(G_1, *_1)$ and $(G_2, *_2)$ be abelian. That $G_1 \times G_2$ is a group is Proposition 4.62; commutativity is inherited componentwise, since for all $a_1, b_1 \in G_1$ and $a_2, b_2 \in G_2$

$$\begin{aligned}(a_1, a_2) * (b_1, b_2) &= (a_1 *_1 b_1, a_2 *_2 b_2) \\ &= (b_1 *_1 a_1, b_2 *_2 a_2) \\ &= (b_1, b_2) * (a_1, a_2)\,,\end{aligned}$$

the middle step applying Equation (4.3) in each factor separately. □

Example 4.65 (The Cayley table of $\mathbb{Z}_2 \times \mathbb{Z}_4$)**.** Write $\mathbb{Z}_n$ for the additive group $\mathbb{Z}/n\mathbb{Z}$ of Proposition 4.37 and denote the class $\overline{k}$ simply by k. Both factors are abelian, so by Proposition 4.64 the eight-element group $\mathbb{Z}_2 \times \mathbb{Z}_4$ is abelian, and its Cayley table (Table 4.2) is symmetric about its diagonal. The operation is addition in each slot separately,

$$(i, j) * (k, l) = \left(\overline{i+k} \text{ in } \mathbb{Z}_2,\ \overline{j+l} \text{ in } \mathbb{Z}_4\right)\,, \tag{4.41}$$

so the neutral element is $(0, 0)$ and the inverse of (i, j) is $(-i, -j)$ read in the respective factors.

Note that adding any element of this group to itself four times returns $(0, 0)$, since $4i$ is a multiple of 2 and $4j$ a multiple of 4. No single element therefore runs through all eight, so $\mathbb{Z}_2 \times \mathbb{Z}_4$ is not isomorphic to $\mathbb{Z}_8$ — two abelian groups of the same order need not be isomorphic, which is why the classification of finite abelian groups mentioned in Section 4.4 has content.

Rests on Propositions 4.37 and 4.64 and Definition 4.34.

Table 4.2: The Cayley table of the direct product $\mathbb{Z}_2 \times \mathbb{Z}_4$, whose operation is Equation (4.41). The first slot is read modulo 2 and the second modulo 4. The table is symmetric about its diagonal, as Proposition 4.64 requires, and no row or column repeats an entry, as Section 4.4.2 requires of any group.

$*$	$(0,0)$	$(0,1)$	$(0,2)$	$(0,3)$	$(1,0)$	$(1,1)$	$(1,2)$	$(1,3)$

Proposition 4.66 (Characterization of the direct product)**.** *Given a group G with subgroups $H, K \leq G$, the map*

$$\begin{array}{rccc}\varphi: & H \times K & \longrightarrow & G \\ & (h, k) & \longmapsto & hk\,,\end{array} \tag{4.42}$$

is an isomorphism — in which case G is called the internal direct product *of the subgroups H and K — if and only if*

1. *$G = HK$;*
2. *$H \cap K = \{e\}$;*

3. $H \trianglelefteq G$ *and* $K \trianglelefteq G$.

Rests on Definitions 4.40, 4.56, 4.61 and 4.63.

Proof. *Derives Proposition 4.66.*

Throughout, $H \times K$ carries the operation of Definition 4.61, whose neutral element is (e, e).

($\Leftarrow$) Assume (1), (2) and (3). We first show that every element of H commutes with every element of K. Let $h \in H$, $k \in K$ and put

$$c = hkh^{-1}k^{-1}\,.$$

Read as $c = (hkh^{-1})\,k^{-1}$, the normality of K gives $hkh^{-1} \in K$, so $c \in K$; read as $c = h\,(kh^{-1}k^{-1})$, the normality of H gives $kh^{-1}k^{-1} \in H$, so $c \in H$. Hence $c \in H \cap K = \{e\}$ by (2), that is,

$$hk = kh\,, \qquad \forall\ h \in H,\ \forall\ k \in K\,. \tag{4.43}$$

Now φ is a homomorphism: for $h, h' \in H$ and $k, k' \in K$,

$$\begin{aligned} \varphi\left((h,k) * (h',k')\right) &= \varphi\left(hh', kk'\right) \\ &= hh'kk' \\ &= hkh'k' && \text{by Equation (4.43)} \\ &= \varphi(h,k)\,\varphi(h',k')\,. \end{aligned}$$

It is surjective by (1), since $G = HK$ is exactly the set of products hk. It is injective because its kernel is trivial: if $\varphi(h,k) = e$ then $h = k^{-1}$, and $k^{-1} \in K$, so $h \in H \cap K = \{e\}$; thus $h = e$ and then $k = e$, that is, $\ker\varphi = \{(e,e)\}$, and Proposition 4.17 applies. A bijective homomorphism is an isomorphism (Definition 4.40).

($\Rightarrow$) Assume φ is an isomorphism. Surjectivity says that every $g \in G$ can be written $g = hk$ with $h \in H$ and $k \in K$, which is $G = HK$: this is (1). For (2), let $x \in H \cap K$. Then $x^{-1} \in K$, and

$$\varphi\left(x, x^{-1}\right) = xx^{-1} = e = \varphi(e,e)\,,$$

so injectivity forces $(x, x^{-1}) = (e,e)$ and $x = e$.

For (3), note that $H \times \{e\}$ is a normal subgroup of $H \times K$, since

$$(h',k') * (h,e) * (h',k')^{-1} = \left(h'h(h')^{-1},\ k'e(k')^{-1}\right) = \left(h'h(h')^{-1}, e\right) \in H \times \{e\}\ ,$$

and that $\varphi\left(H \times \{e\}\right) = H$, because $\varphi(h,e) = he = h$. Let $g \in G$ and write $g = \varphi(u)$ with $u \in H \times K$, which is possible by surjectivity. Since φ is a homomorphism, $\varphi(u)^{-1} = \varphi\left(u^{-1}\right)$ (Proposition 4.43), and therefore

$$\begin{aligned} gHg^{-1} &= \varphi(u)\,\varphi\left(H \times \{e\}\right)\,\varphi\left(u^{-1}\right) \\ &= \varphi\left(u * (H \times \{e\}) * u^{-1}\right) \\ &= \varphi\left(H \times \{e\}\right) \\ &= H\,, \end{aligned}$$

so $H \trianglelefteq G$. The same argument with $\{e\} \times K$ gives $K \trianglelefteq G$. □

Remark 4.67. It is essential that the proposition names the map Equation (4.42). The weaker reading — that G be isomorphic to $H \times K$ by *some* isomorphism or other — does not imply (1)–(3), and the difference is not a technicality. Take $G = \mathbb{Z}_2 \times \mathbb{Z}_2$ and let $H = K = \{(0,0),(1,0)\} \leq G$. Each of H and K is a two-element group, hence isomorphic to $\mathbb{Z}_2$ by the uniqueness of the two-element Cayley table established in Section 4.5.1, so $H \times K$ is isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_2 = G$; yet $HK = H \neq G$ and $H \cap K = H \neq \{e\}$. An abstract isomorphism knows nothing about how H and K sit inside G, and it is exactly that placement which conditions (1)–(3) describe.

4.9.2 Semidirect product

The direct product is symmetric in its two factors: Proposition 4.66 demands that *both* H and K be normal in G, and Equation (4.43) then forces every element of one to commute with every element of the other. That is a strong condition, and most of the groups physics actually uses fail it. In the group of rigid motions of space, a rotation and a translation do not commute; the translations form a normal subgroup, and the rotations do not. What is needed is a product in which one factor is normal and the other merely *acts* on it. That is the semidirect product, and it is the shape of the Euclidean and Poincaré groups alike.

Semidirect product of groups; characterization of the semidirect product

The action of one group on another is by automorphisms, so we first note that the automorphisms of a group form a group in their own right.

Proposition 4.68 (The automorphism group)**.** *Let N be a group. The set* $\mathrm{Aut}(N)$ *of all automorphisms of N is a subgroup of the symmetric group S_N, and in particular a group under composition.*

Rests on Definitions 4.33, 4.41 and 4.44.

Proof. *Derives Proposition 4.68.*

An automorphism of N is in particular a bijection of N onto itself, so $\mathrm{Aut}(N) \subseteq S_N$. The identity map is an automorphism, so the neutral element of S_N lies in $\mathrm{Aut}(N)$. If $\alpha, \beta \in \mathrm{Aut}(N)$ then for all $n_1, n_2 \in N$

$$(\alpha \circ \beta)(n_1 n_2) = \alpha\left(\beta(n_1)\beta(n_2)\right) = (\alpha \circ \beta)(n_1)\,(\alpha \circ \beta)(n_2)\,,$$

so $\alpha \circ \beta$ is a homomorphism, and it is a bijection as a composite of bijections. Finally, since α is a homomorphism,

$$\alpha\left(\alpha^{-1}(n_1)\,\alpha^{-1}(n_2)\right) = n_1 n_2\,,$$

and applying α^{-1} to both sides gives $\alpha^{-1}(n_1)\,\alpha^{-1}(n_2) = \alpha^{-1}(n_1 n_2)$, so $\alpha^{-1} \in \mathrm{Aut}(N)$. The three conditions of Definition 4.33 are met. □

Definition 4.69 (External semidirect product)**.** Let N and H be groups and let $\varphi : H \longrightarrow \mathrm{Aut}(N)$ be a group homomorphism, written $h \longmapsto \varphi_h$. The *external semidirect product* $N \rtimes_\varphi H$ is the Cartesian product $N \times H$ equipped with the internal binary operation

$$(n_1, h_1) * (n_2, h_2) = (n_1\,\varphi_{h_1}(n_2),\, h_1 h_2)\,. \tag{4.44}$$

Rests on Proposition 4.68 and Definitions 4.1 and 4.39.

The first slot is not multiplied blindly: the second factor of the left element is allowed to act on the first slot of the right element before the two are combined. Setting $\varphi_h = \mathrm{id}_N$ throughout removes the action and returns Definition 4.61, as Proposition 4.73 makes precise.

Proposition 4.70 (The semidirect product is a group)**.** *$(N \rtimes_\varphi H, *)$ is a group, with neutral element (e_N, e_H) and with*

$$(n, h)^{-1} = \left(\varphi_{h^{-1}}\left(n^{-1}\right),\, h^{-1}\right)\,. \tag{4.45}$$

Rests on Definitions 4.20 and 4.69.

Proof. *Derives Proposition 4.70.*

We use twice over that φ is a homomorphism into $\mathrm{Aut}(N)$: each φ_h is an automorphism of N, and $\varphi_{h_1h_2} = \varphi_{h_1} \circ \varphi_{h_2}$. In particular $\varphi_{e_H} = \mathrm{id}_N$ and $\varphi_h(e_N) = e_N$, by Proposition 4.42 applied to φ and to φ_h respectively.

Closure. $\varphi_{h_1}(n_2) \in N$ and $h_1h_2 \in H$, so the right-hand side of Equation (4.44) lies in $N \times H$.

Associativity. On the one hand,

$$\begin{aligned}((n_1, h_1) * (n_2, h_2)) * (n_3, h_3) &= (n_1\varphi_{h_1}(n_2),\, h_1h_2) * (n_3, h_3) \\ &= (n_1\varphi_{h_1}(n_2)\,\varphi_{h_1h_2}(n_3),\, h_1h_2h_3)\ ,\end{aligned}$$

and on the other,

$$\begin{aligned}(n_1, h_1) * ((n_2, h_2) * (n_3, h_3)) &= (n_1, h_1) * (n_2\varphi_{h_2}(n_3),\, h_2h_3) \\ &= (n_1\varphi_{h_1}(n_2\varphi_{h_2}(n_3))\,,\, h_1h_2h_3) \\ &= (n_1\varphi_{h_1}(n_2)\,\varphi_{h_1}(\varphi_{h_2}(n_3))\,,\, h_1h_2h_3) \\ &= (n_1\varphi_{h_1}(n_2)\,\varphi_{h_1h_2}(n_3),\, h_1h_2h_3)\ ,\end{aligned}$$

the third step because φ_{h_1} is a homomorphism of N and the fourth because φ is a homomorphism into $\mathrm{Aut}(N)$. The two agree.

Neutral element. Using $\varphi_h(e_N) = e_N$ and $\varphi_{e_H} = \mathrm{id}_N$,

$$(n, h) * (e_N, e_H) = (n\varphi_h(e_N), h) = (n, h)\,, \qquad (e_N, e_H) * (n, h) = (\varphi_{e_H}(n), h) = (n, h)\,.$$

Inverses. With the candidate Equation (4.45),

$$\begin{aligned}(n, h) * \left(\varphi_{h^{-1}}\left(n^{-1}\right), h^{-1}\right) &= \left(n\,\varphi_h\left(\varphi_{h^{-1}}\left(n^{-1}\right)\right),\, hh^{-1}\right) \\ &= \left(n\,\varphi_{e_H}\left(n^{-1}\right),\, e_H\right) \\ &= (e_N, e_H)\,,\end{aligned}$$

and in the other order

$$\begin{aligned}\left(\varphi_{h^{-1}}\left(n^{-1}\right), h^{-1}\right) * (n, h) &= \left(\varphi_{h^{-1}}\left(n^{-1}\right)\,\varphi_{h^{-1}}(n),\, h^{-1}h\right) \\ &= \left(\varphi_{h^{-1}}\left(n^{-1}n\right),\, e_H\right) \\ &= (e_N, e_H)\,.\end{aligned}$$

All four axioms of Definition 4.20 hold. □

Proposition 4.71 (The two factors inside the semidirect product)**.** *Write $G = N \rtimes_\varphi H$, $\widetilde{N} = N \times \{e_H\}$ and $\widetilde{H} = \{e_N\} \times H$. Then $\widetilde{N} \trianglelefteq G$, $\widetilde{H} \leq G$, $\widetilde{N} \cap \widetilde{H} = \{(e_N, e_H)\}$ and $G = \widetilde{N}\widetilde{H}$; moreover $n \longmapsto (n, e_H)$ and $h \longmapsto (e_N, h)$ are isomorphisms of N onto $\widetilde{N}$ and of H onto $\widetilde{H}$, and conjugation inside G reproduces φ:*

$$(e_N, h) * (n, e_H) * (e_N, h)^{-1} = (\varphi_h(n), e_H)\ . \tag{4.46}$$

Rests on Proposition 4.70 and Definitions 4.56 and 4.63.

Proof. *Derives Proposition 4.71.*

By Equation (4.44), $(n_1, e_H) * (n_2, e_H) = (n_1\varphi_{e_H}(n_2), e_H) = (n_1n_2, e_H)$ and $(e_N, h_1) * (e_N, h_2) = (\varphi_{h_1}(e_N), h_1h_2) = (e_N, h_1h_2)$, so both maps are homomorphisms; each is evidently bijective onto its image, hence an isomorphism (Definition 4.40), and each image contains the neutral element and the inverses of its elements, so both are subgroups. Their intersection

is $\{(e_N, e_H)\}$ because a pair lying in both has $h = e_H$ and $n = e_N$, and $(n, e_H) * (e_N, h) = (n\varphi_{e_H}(e_N), h) = (n, h)$ shows $G = \widetilde{N}\widetilde{H}$.

For normality, let $(m, k) \in G$ and $(n, e_H) \in \widetilde{N}$. Then

$$\begin{aligned}(m,k) * (n,e_H) * (m,k)^{-1} &= (m\,\varphi_k(n), k) * \left(\varphi_{k^{-1}}\left(m^{-1}\right), k^{-1}\right) \\ &= \left(m\,\varphi_k(n)\,\varphi_k\left(\varphi_{k^{-1}}\left(m^{-1}\right)\right), e_H\right) \\ &= \left(m\,\varphi_k(n)\,m^{-1}, e_H\right),\end{aligned}$$

which lies in $\widetilde{N}$; hence $\widetilde{N} \trianglelefteq G$. Finally, $(e_N, h)^{-1} = (\varphi_{h^{-1}}(e_N), h^{-1}) = (e_N, h^{-1})$, so

$$(e_N, h) * (n, e_H) * (e_N, h^{-1}) = (\varphi_h(n), h) * (e_N, h^{-1}) = (\varphi_h(n)\varphi_h(e_N), e_H)\ ,$$

which is Equation (4.46). □

The construction is therefore faithful to its data, and the converse holds too: whenever a group contains a normal subgroup and a complement to it, it *is* a semidirect product. Note that the complement is *not* required to be normal — that is the whole difference from Proposition 4.66.

Theorem 4.72 (Internal characterization of the semidirect product)**.** *Let G be a group, $N \trianglelefteq G$ and $H \leq G$ with $G = NH$ and $N \cap H = \{e\}$. Then*

$$\varphi_h(n) = hnh^{-1} \tag{4.47}$$

defines a homomorphism $\varphi : H \longrightarrow \mathrm{Aut}(N)$, and

$$\begin{array}{rccc}\psi: & N \rtimes_\varphi H & \longrightarrow & G \\ & (n,h) & \longmapsto & nh\end{array}$$

is an isomorphism. Conversely, by Proposition 4.71, every external semidirect product is of this form.

Rests on Definitions 4.56, 4.63 and 4.69.

Proof. *Derives Theorem 4.72.*

φ_h is an automorphism of N. Since $N \trianglelefteq G$ and $h \in G$, we have $hnh^{-1} \in N$, so φ_h maps N into N; it is a homomorphism because

$$\varphi_h(n_1n_2) = hn_1n_2h^{-1} = \left(hn_1h^{-1}\right)\left(hn_2h^{-1}\right) = \varphi_h(n_1)\varphi_h(n_2)\,,$$

and $\varphi_{h^{-1}}$ is a two-sided inverse for it, so it is bijective.

φ is a homomorphism. For $h_1, h_2 \in H$ and $n \in N$,

$$\varphi_{h_1h_2}(n) = h_1h_2nh_2^{-1}h_1^{-1} = \varphi_{h_1}(\varphi_{h_2}(n))\ ,$$

using Equation (4.16) for $(h_1h_2)^{-1}$; hence $\varphi_{h_1h_2} = \varphi_{h_1} \circ \varphi_{h_2}$.

ψ is a homomorphism. Using Equation (4.44) and then Equation (4.47),

$$\begin{aligned}\psi\left((n_1,h_1) * (n_2,h_2)\right) &= \psi\left(n_1\varphi_{h_1}(n_2),\, h_1h_2\right) \\ &= n_1\left(h_1n_2h_1^{-1}\right)h_1h_2 \\ &= (n_1h_1)(n_2h_2) \\ &= \psi(n_1,h_1)\,\psi(n_2,h_2)\,.\end{aligned}$$

ψ is bijective. It is surjective because $G = NH$ is precisely the set of products nh. Its kernel is trivial: if $nh = e$ then $n = h^{-1}$, which lies in $N \cap H = \{e\}$, so $n = e$ and then $h = e$. By Proposition 4.17, ψ is injective, and a bijective homomorphism is an isomorphism. □

Proposition 4.73 (When a semidirect product is direct)**.** *Let $G = N \rtimes_\varphi H$ and let $\widetilde{N}$, $\widetilde{H}$ be as in Proposition 4.71. The following are equivalent:*

1. *$\widetilde{H} \trianglelefteq G$;*
2. *$\varphi_h = \mathrm{id}_N$ for every $h \in H$;*
3. *the operation Equation (4.44) is the operation of Definition 4.61, so that $N \rtimes_\varphi H$ is the direct product $N \times H$.*

Rests on Proposition 4.71 and Definitions 4.56 and 4.61.

Proof. *Derives Proposition 4.73.*

(2) $\implies$ (3): substituting $\varphi_{h_1} = \mathrm{id}_N$ into Equation (4.44) gives $(n_1, h_1) * (n_2, h_2) = (n_1 n_2, h_1 h_2)$, which is Definition 4.61.

(3) $\implies$ (1): in the direct product,

$$(n', h') * (e_N, h) * (n', h')^{-1} = \left(n' e_N n'^{-1},\, h' h (h')^{-1}\right) = \left(e_N,\, h' h (h')^{-1}\right) \in \widetilde{H}\,,$$

so $\widetilde{H} \trianglelefteq G$.

(1) $\implies$ (2): let $h \in H$ and $n \in N$. Since $(n, e_H)^{-1} = \left(\varphi_{e_H}(n^{-1}), e_H\right) = (n^{-1}, e_H)$,

$$\begin{aligned}(n, e_H) * (e_N, h) * (n, e_H)^{-1} &= (n\varphi_{e_H}(e_N),\, h) * \left(n^{-1}, e_H\right) \\ &= \left(n\,\varphi_h\left(n^{-1}\right),\, h\right)\,.\end{aligned}$$

If $\widetilde{H}$ is normal this must lie in $\{e_N\} \times H$, that is, $n\,\varphi_h(n^{-1}) = e_N$, or $\varphi_h(n^{-1}) = n^{-1}$. As n runs over N so does n^{-1} (Proposition 4.24), hence $\varphi_h = \mathrm{id}_N$ for every h. □

Example 4.74 (The Euclidean group)**.** Let $N = (\mathbb{R}^3, +)$, the translations of Euclidean space, and let $H = \mathrm{SO}(3)$, the rotations about a fixed origin. A rotation R is a linear bijection of $\mathbb{R}^3$, so $\varphi_R(\boldsymbol{a}) = R\boldsymbol{a}$ is an automorphism of the *additive* group $\mathbb{R}^3$, and $\varphi_{R_1 R_2} = \varphi_{R_1} \circ \varphi_{R_2}$ because matrix multiplication is associative. The semidirect product

$$\mathrm{SE}(3) = \mathbb{R}^3 \rtimes_\varphi \mathrm{SO}(3) \tag{4.48}$$

therefore exists, and by Equation (4.44) its operation is

$$(\boldsymbol{a}_1, R_1) * (\boldsymbol{a}_2, R_2) = (\boldsymbol{a}_1 + R_1\boldsymbol{a}_2,\, R_1 R_2)\,, \tag{4.49}$$

which is exactly the composition of the rigid motions $\boldsymbol{x} \longmapsto R\boldsymbol{x} + \boldsymbol{a}$ of $\mathbb{R}^3$: applying $(\boldsymbol{a}_2, R_2)$ and then $(\boldsymbol{a}_1, R_1)$ sends $\boldsymbol{x}$ to $R_1 R_2 \boldsymbol{x} + R_1\boldsymbol{a}_2 + \boldsymbol{a}_1$. The same construction with $\mathrm{O}(3)$ in place of $\mathrm{SO}(3)$ adjoins the reflections and gives the full group of distance-preserving maps of $\mathbb{R}^3$, the Euclidean group proper,

$$\mathrm{E}(3) = \mathrm{ISO}(3) = \mathbb{R}^3 \rtimes_\varphi \mathrm{O}(3)\,, \tag{4.50}$$

of which $\mathrm{SE}(3)$ is the orientation-preserving subgroup of index two; the isometries of the equilateral triangle in Proposition 4.51 are the planar analogue. The naming follows the convention Equation (4.51) uses below and Definition 39.10 fixes: an inhomogeneous group $\mathrm{ISO}(p, q)$ carries the *full* orthogonal group of its form, reflections included, and the prefix S marks the orientation-preserving subgroup.

The product is genuinely semidirect and not direct. Conjugating a rotation by a translation gives, by the computation in Proposition 4.73,

$$(\boldsymbol{a}, \mathbb{1}) * (\boldsymbol{0}, R) * (\boldsymbol{a}, \mathbb{1})^{-1} = (\boldsymbol{a} - R\boldsymbol{a},\, R)\,,$$

whose translation part vanishes only when $R\boldsymbol{a} = \boldsymbol{a}$. The rotations therefore do not form a normal subgroup — a rotation about the origin, viewed from a translated origin, is a rotation about a different point — while the translations do, by Proposition 4.71. This is the algebraic content of the familiar fact that rotating and then translating is not the same as translating and then rotating.

Rests on Definition 4.69 and Proposition 4.73.

Example 4.75 (The Poincaré group)**.** The same construction with the translations of Minkowski space and the Lorentz group in place of the rotations gives the symmetry group of special relativity. Take $N = (\mathbb{R}^4, +)$ and for H the Lorentz group L of Definition 39.1, whose elements are invertible linear maps and therefore automorphisms of the additive group $\mathbb{R}^4$, with $\varphi_\Lambda(a) = \Lambda a$. Then

$$\mathrm{ISO}(3,1) = \mathbb{R}^4 \rtimes_\varphi L\,, \tag{4.51}$$

and Equation (4.44) reads

$$(a_2, \Lambda_2) * (a_1, \Lambda_1) = (a_2 + \Lambda_2 a_1,\ \Lambda_2\Lambda_1)\ ,$$

which is the composition law Equation (39.17) of the Poincaré transformations, defined and used in Chapter 39; restricting L to its proper subgroup $\mathrm{SO}(3,1)$ gives the proper Poincaré group in the same way. That the translations are normal and the Lorentz transformations are not is precisely why Equation (39.17) is not the componentwise product of a direct product, by Proposition 4.73. The infinitesimal counterpart of Equation (4.51) is the semidirect *sum* Equation (14.99) of Chapter 14, in which the translation generators span an abelian ideal on which the Lorentz generators act.

Rests on Definition 4.69 and Proposition 4.71.

Chapter 5

Linear Algebra and Representation Theory

The vector space is the algebraic structure on which almost all of the mathematics of physics is built: classical states, quantum states, fields, and the linearized neighbourhoods of curved spaces are all modelled on vector spaces. This chapter develops the theory of vector spaces and of the linear transformations between them, the dual space, and the algebras — in particular Lie algebras — that linear transformations generate. It then turns to representation theory: the systematic study of how an abstract group can act by linear transformations on a vector space. The chapter closes with the fundamental properties of irreducible representations of finite groups, the working machinery behind the symmetry analysis used throughout the treatise. A short section of elementary algebraic formulas, collected from a companion summary sheet of the source, opens the chapter for later reference.

5.1 Preliminary formulas from elementary algebra

The following classical identities are collected here for reference; they are used freely in computations throughout the treatise.

5.1.1 Factorials and the binomial theorem

The *double factorial* abbreviates the product of the odd or of the even numbers:

$$1 \cdot 3 \cdot 5 \cdot \ldots \cdot (2n+1) = (2n+1)!!\,, \tag{5.1}$$

$$2 \cdot 4 \cdot 6 \cdot \ldots \cdot (2n) = (2n)!! = 2^n n!\,. \tag{5.2}$$

For all $a, b \in \mathbb{R}$ and all $n \in \mathbb{N}$, the *binomial theorem* states that

$$(a+b)^n = \sum_{k=0}^{n} \frac{n!}{k!(n-k)!}\, a^{n-k} b^k\,. \tag{5.3}$$

5.1.2 Trigonometric formulas

- **Cofunctions.**

$$\begin{aligned} \sin\left(\frac{\pi}{2} - x\right) &= \cos x\,, \\ \tan\left(\frac{\pi}{2} - x\right) &= \cot x\,, \\ \sec\left(\frac{\pi}{2} - x\right) &= \csc x\,. \end{aligned} \tag{5.4}$$

- **Angle addition.**

$$\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y\,, \tag{5.5}$$
$$\cos(x \pm y) = \cos x \cos y \mp \sin x \sin y\,. \tag{5.6}$$

- **Double angle.**

$$\sin 2x = 2\cos x \sin x\,, \tag{5.7}$$
$$\cos 2x = \cos^2 x - \sin^2 x\,. \tag{5.8}$$

- **Power reduction.**

$$\sin^2 x = \frac{1-\cos 2x}{2}\,, \tag{5.9}$$
$$\cos^2 x = \frac{1+\cos 2x}{2}\,. \tag{5.10}$$

- **Sums of functions.**

$$\sin x + \sin y = 2\sin\left(\frac{x+y}{2}\right)\cos\left(\frac{x-y}{2}\right), \tag{5.11}$$
$$\cos x + \cos y = 2\cos\left(\frac{x+y}{2}\right)\cos\left(\frac{x-y}{2}\right). \tag{5.12}$$

- **Inverse trigonometric functions.**

$$\begin{aligned}\sin(\arccos x) &= \cos(\arcsin x) = \sqrt{1-x^2}\,,\\ \sin(\arctan x) &= \frac{x}{\sqrt{x^2+1}}\,,\\ \cos(\arctan x) &= \frac{1}{\sqrt{x^2+1}}\,.\end{aligned} \tag{5.13}$$

5.1.3 The sine and cosine theorems

In a triangle with sides a, b, c and opposite angles α, β, γ, one has the *law of sines*

$$\frac{\sin\alpha}{a} = \frac{\sin\beta}{b} \tag{5.14}$$

and the *law of cosines*

$$c^2 = a^2 + b^2 - 2ab\cos\gamma\,. \tag{5.15}$$

5.1.4 Cramer's rule

In a system of linear equations with matrix representation $AX = B$, with $X = (x_1, \ldots, x_n)$ and $\det A \neq 0$, one has

$$X = \left(\frac{D_1}{\det A}, \ldots, \frac{D_n}{\det A}\right), \tag{5.16}$$

where D_i is the determinant of the matrix obtained by replacing column i of the square matrix A by the column matrix B.

5.1.5 Derivations of the elementary identities

The summary sheet these identities were collected from states them without proof. They are elementary, but the treatise derives what it states, so the derivations follow here in the order the formulas were listed. Nothing is used beyond the field axioms of $\mathbb{R}$ and $\mathbb{C}$, the functional equation $\mathrm{e}^{z+w} = \mathrm{e}^z\mathrm{e}^w$ of the exponential together with Euler's formula, the inner product of Section 5.3 on the physical space $\mathbb{R}^3$ together with the one geometric fact that the area of a triangle is half its base times the corresponding altitude, and the Leibniz expansion of the determinant, which is written out where it is needed.

Double factorials. Equation (5.1) is a definition: the symbol $(2n+1)!!$ abbreviates the product of the odd numbers up to $2n+1$. Equation (5.2) is not a definition, and follows by extracting one factor 2 from each of the n even factors:

$$\begin{aligned}(2n)!! &= \prod_{k=1}^{n} (2k) \\ &= \left(\prod_{k=1}^{n} 2\right)\left(\prod_{k=1}^{n} k\right) \\ &= 2^n\, n!\,.\end{aligned}$$

The two double factorials are tied to the ordinary one by

$$(2n+1)! = (2n+1)!!\,(2n)!!\,,$$

since the factors of $(2n+1)!$ split without remainder into the odd ones and the even ones.

The binomial theorem. Write $\binom{n}{k} = n!/(k!\,(n-k)!)$ for $0 \le k \le n$, and adopt the convention $\binom{n}{k} = 0$ outside that range. The proof of Equation (5.3) is by induction on n, and it rests on Pascal's rule

$$\binom{n}{k-1} + \binom{n}{k} = \binom{n+1}{k}, \quad 1 \le k \le n\,, \tag{5.17}$$

which is obtained by putting the two fractions over a common denominator:

$$\begin{aligned}\binom{n}{k-1} + \binom{n}{k} &= \frac{n!}{(k-1)!\,(n-k+1)!} + \frac{n!}{k!\,(n-k)!} \\ &= \frac{n!\,k}{k!\,(n-k+1)!} + \frac{n!\,(n-k+1)}{k!\,(n-k+1)!} \\ &= \frac{n!\,(n+1)}{k!\,(n+1-k)!} \\ &= \binom{n+1}{k}.\end{aligned}$$

For $n = 0$ both sides of Equation (5.3) equal 1. Assume the identity for n. Then

$$\begin{aligned}(a+b)^{n+1} &= (a+b)\sum_{k=0}^{n} \binom{n}{k} a^{n-k}b^k \\ &= \sum_{k=0}^{n} \binom{n}{k} a^{n+1-k}b^k + \sum_{k=0}^{n} \binom{n}{k} a^{n-k}b^{k+1} \\ &= \sum_{k=0}^{n} \binom{n}{k} a^{n+1-k}b^k + \sum_{k=1}^{n+1} \binom{n}{k-1} a^{n+1-k}b^k \\ &= \sum_{k=0}^{n+1} \left[\binom{n}{k} + \binom{n}{k-1}\right] a^{n+1-k}b^k \\ &= \sum_{k=0}^{n+1} \binom{n+1}{k} a^{n+1-k}b^k\,,\end{aligned}$$

where the third line relabels $k+1 \mapsto k$ in the second sum, the fourth uses the vanishing convention to extend both sums to $0 \le k \le n+1$, and the last invokes Equation (5.17). Only commutativity of the product $ab = ba$ was used, so the identity holds in any commutative ring, and in particular for $a, b \in \mathbb{C}$.

Angle addition, and the identities that follow from it. All the trigonometric formulas of Section 5.1.2 descend from Equations (5.5) and (5.6), which in turn descend from Euler's formula $\mathrm{e}^{\mathrm{i}x} = \cos x + \mathrm{i}\sin x$ and the functional equation of the exponential. Indeed,

$$\begin{aligned}\cos(x+y) + \mathrm{i}\sin(x+y) &= \mathrm{e}^{\mathrm{i}(x+y)} \\ &= \mathrm{e}^{\mathrm{i}x}\mathrm{e}^{\mathrm{i}y} \\ &= (\cos x + \mathrm{i}\sin x)(\cos y + \mathrm{i}\sin y) \\ &= (\cos x\cos y - \sin x\sin y) \\ &\quad + \mathrm{i}(\sin x\cos y + \cos x\sin y)\,,\end{aligned}$$

and, x and y being real, the real and imaginary parts may be equated separately, which is the upper sign of Equations (5.5) and (5.6). The lower sign follows on replacing y by $-y$ and using $\mathrm{e}^{-\mathrm{i}y} = (\mathrm{e}^{\mathrm{i}y})^*$, that is, $\cos(-y) = \cos y$ and $\sin(-y) = -\sin y$.

The remaining identities are specializations.

- *Cofunctions* Equation (5.4). Evaluate Equations (5.5) and (5.6) with the lower sign on the pair of angles $\pi/2$ and x, using $\sin(\pi/2) = 1$ and $\cos(\pi/2) = 0$:

$$\begin{aligned}\sin\left(\frac{\pi}{2} - x\right) &= \sin\frac{\pi}{2}\cos x - \cos\frac{\pi}{2}\sin x = \cos x\,, \\ \cos\left(\frac{\pi}{2} - x\right) &= \cos\frac{\pi}{2}\cos x + \sin\frac{\pi}{2}\sin x = \sin x\,.\end{aligned}$$

  Dividing the second into the first gives $\tan(\pi/2 - x) = \cos x/\sin x = \cot x$, and taking the reciprocal of the second gives $\sec(\pi/2 - x) = 1/\sin x = \csc x$.

- *Double angle* Equations (5.7) and (5.8). Put $y = x$ in the addition formulas with the upper sign.

- *Power reduction* Equations (5.9) and (5.10). Combine $\cos 2x = \cos^2 x - \sin^2 x$ with $\cos^2 x + \sin^2 x = 1$ — itself $\left|\mathrm{e}^{\mathrm{i}x}\right|^2 = 1$ — to eliminate first $\cos^2 x$ and then $\sin^2 x$:

$$\cos 2x = 1 - 2\sin^2 x\,, \qquad \cos 2x = 2\cos^2 x - 1\,,$$

  and solve each for the square.

- *Sums of functions* Equations (5.11) and (5.12). Set $s = (x+y)/2$ and $t = (x-y)/2$, so that $x = s + t$ and $y = s - t$. Adding the two addition formulas for $\sin(s \pm t)$ makes the terms in $\cos s\sin t$ cancel, and adding those for $\cos(s \pm t)$ makes the terms in $\sin s\sin t$ cancel:

$$\begin{aligned}\sin x + \sin y &= \sin(s+t) + \sin(s-t) = 2\sin s\cos t\,, \\ \cos x + \cos y &= \cos(s+t) + \cos(s-t) = 2\cos s\cos t\,.\end{aligned}$$

- *Inverse functions* Equation (5.13). Let $\theta = \arccos x \in [0, \pi]$, where $\sin\theta \geq 0$; then $\cos\theta = x$ and $\sin\theta = +\sqrt{1-x^2}$. Let $\varphi = \arcsin x \in [-\pi/2, \pi/2]$, where $\cos\varphi \geq 0$; then $\cos\varphi = +\sqrt{1-x^2}$. This is the first line. For the other two let $\psi = \arctan x \in (-\pi/2, \pi/2)$, where $\cos\psi > 0$; dividing $\cos^2\psi + \sin^2\psi = 1$ by $\cos^2\psi$ gives $1 + x^2 = 1/\cos^2\psi$, whence $\cos\psi = 1/\sqrt{x^2+1}$ and $\sin\psi = x\cos\psi = x/\sqrt{x^2+1}$.

The angle at a vertex. Both theorems of Section 5.1.3 speak of the angle at a vertex of a triangle, and they must mean the same thing by it or their proofs are not proofs of statements about one figure. The notion is therefore fixed once, here, and both derivations are read off it. The triangle is placed in the physical space $\mathbb{R}^3$, carrying the inner product of Section 5.3 — a $3+0$ instantiation, the triangle lying in any plane of it — and the angle between two non-zero vectors u, v is *defined* by

$$\langle u|v\rangle = \|u\|\,\|v\|\cos\theta\,, \qquad \theta \in [0,\pi]\,. \tag{5.18}$$

This determines θ uniquely: the Cauchy–Schwarz inequality Equation (5.43) confines $\langle u|v\rangle\,/(\|u\|\,\|v\|)$ to $[-1,1]$, and the cosine is a bijection from $[0,\pi]$ onto $[-1,1]$. The angle of a triangle at a vertex is the angle so defined between the two sides issuing from that vertex.

The elementary construction the law of sines uses — dropping a perpendicular — measures that same angle, and saying so is what makes the two derivations below derivations about the same α, β, γ. Let u and v issue from a common vertex, let θ be the angle Equation (5.18) between them, and take the line carrying v as the base. The foot of the perpendicular dropped from the tip of u is $\left(\langle v|u\rangle\,/\,\|v\|^2\right)v$, since subtracting it from u leaves a vector orthogonal to v; the altitude is the length of what remains, and

$$\begin{aligned}
\left\| u - \frac{\langle v|u\rangle}{\|v\|^2}\,v \right\|^2 &= \|u\|^2 - \frac{\langle u|v\rangle^2}{\|v\|^2} \\
&= \|u\|^2\left(1-\cos^2\theta\right) && \text{by Equation (5.18)} \\
&= \|u\|^2\sin^2\theta\,,
\end{aligned}$$

the inner product being real and symmetric here. Hence the altitude has length $\|u\|\sin\theta$, the sine being non-negative on $[0,\pi]$. No case distinction between an acute and an obtuse angle is needed: the computation never asked where the foot of the perpendicular falls relative to the endpoints of the base.

The law of sines. Let the triangle have area S, which is half of any base times the corresponding altitude. Take b as the base. The altitude is then dropped from the vertex at which a and c meet, and by the computation just made it has length $c\sin\alpha$ — the side c times the sine of the angle α that c makes with the base b at the vertex the two share — so $S = \frac{1}{2}bc\sin\alpha$. Taking c and then a as the base gives in the same way, cycling $a \to b \to c \to a$ and $\alpha \to \beta \to \gamma \to \alpha$, $S = \frac{1}{2}ca\sin\beta = \frac{1}{2}ab\sin\gamma$. The pairing is worth checking rather than remembering: each expression is the product of the two sides that *meet* at a vertex with the sine of the angle at that same vertex, and the base has to be one of the two factors. That is what forbids pairing the base c with $\frac{1}{2}ab\sin\gamma$ — an expression in which c does not appear at all. Dividing the three equal quantities by $\frac{1}{2}abc$,

$$\frac{\sin\alpha}{a} = \frac{\sin\beta}{b} = \frac{\sin\gamma}{c} = \frac{2S}{abc}\,,$$

of which Equation (5.14) is the first equality.

The law of cosines. The same setting serves, and no second notion of angle is introduced. Place the vertex carrying the angle γ at the origin of $\mathbb{R}^3$ and let $\boldsymbol{u}, \boldsymbol{v}$ be the two sides issuing from it, so that $\|\boldsymbol{u}\| = a$, $\|\boldsymbol{v}\| = b$ and the opposite side is $\boldsymbol{u}-\boldsymbol{v}$, of length c. The angle between them is γ in the sense of Equation (5.18), that is $\langle \boldsymbol{u}|\boldsymbol{v}\rangle = ab\cos\gamma$. Then

$$\begin{aligned}
c^2 &= \langle \boldsymbol{u}-\boldsymbol{v}|\boldsymbol{u}-\boldsymbol{v}\rangle \\
&= \langle \boldsymbol{u}|\boldsymbol{u}\rangle + \langle \boldsymbol{v}|\boldsymbol{v}\rangle - 2\,\langle \boldsymbol{u}|\boldsymbol{v}\rangle \\
&= a^2 + b^2 - 2ab\cos\gamma\,,
\end{aligned}$$

which is Equation (5.15). The middle step uses the distributivity Equations (5.35) and (5.37) and the symmetry of the real inner product Equation (5.33). Note that $\gamma = \pi/2$ returns Pythagoras' theorem.

Cramer's rule. Let A be a square matrix of order n over a field of characteristic zero, with entries $A^i{}_j$ (i the row, j the column) and columns $A_1, \dots, A_n$. The determinant is the Leibniz sum over the permutations σ of n symbols,

$$\det A = \sum_{\sigma} \operatorname{sgn}(\sigma) \prod_{j=1}^{n} A^{\sigma(j)}_{\ j} \,, \tag{5.19}$$

from which the two properties we need follow at once.

- det *is linear in each column separately.* Every term of Equation (5.19) contains exactly one entry from each column, to the first power.
- det *changes sign when two columns are exchanged.* Exchanging columns p and q replaces $\prod_j A^{\sigma(j)}_{\ j}$ by $\prod_j A^{\sigma(\tau(j))}_{\ j}$ with τ the transposition $(p\,q)$; as σ runs over all permutations so does $\sigma\tau$, and $\operatorname{sgn}(\sigma\tau) = -\operatorname{sgn}(\sigma)$. Consequently a matrix with two equal columns has det $= -$ det, hence det $= 0$.

The system $AX = B$ says precisely that B is the combination of the columns of A with the unknowns as coefficients,

$$B = \sum_{j=1}^{n} x_j A_j \,.$$

Substituting this for the i-th column of A and using linearity in that column,

$$\begin{aligned} D_i &= \det\left(A_1, \dots, A_{i-1}, B, A_{i+1}, \dots, A_n\right) \\ &= \sum_{j=1}^{n} x_j \, \det\left(A_1, \dots, A_{i-1}, A_j, A_{i+1}, \dots, A_n\right) \\ &= x_i \det A \,, \end{aligned}$$

because for $j \neq i$ the determinant on the second line has the column A_j twice and therefore vanishes. With $\det A \neq 0$ we may divide, obtaining $x_i = D_i / \det A$, which is Equation (5.16).

5.1.6 The derivative of a determinant

One consequence of the Leibniz expansion is worth stating on its own, because it is what governs how a volume element changes along a motion.

Proposition 5.1 (Jacobi's formula, column form)**.** *Let $A(t)$ be a square array of order n whose entries are differentiable functions of a real parameter t. Then* $\det A$ *is differentiable and*

$$\frac{\mathrm{d}}{\mathrm{d}t} \det A = \sum_{j=1}^{n} \det\left(A_1, \dots, \frac{\mathrm{d}A_j}{\mathrm{d}t}, \dots, A_n\right) \tag{5.20}$$

in terms of the columns A_j of A. If moreover $A(t)$ is invertible then

$$\frac{\mathrm{d}}{\mathrm{d}t} \det A = (\det A)\, \operatorname{tr}\left(A^{-1} \frac{\mathrm{d}A}{\mathrm{d}t}\right) \,. \tag{5.21}$$

Rests on Equation (5.19) and Propositions 5.47 and 7.30.

Proof. *Derives Proposition 5.1.*

By Equation (5.19), $\det A$ is a sum of products of n entries, each entry from a different column. Differentiating a product of n differentiable functions — Proposition 7.30 extended to n factors by induction — replaces it by the sum of the n products in which one factor has been differentiated. Collecting, for each j, the terms in which the differentiated factor came from column j gives exactly the Leibniz expansion of the determinant with that column replaced by its derivative, which is Equation (5.20).

Now let A be invertible, so that its columns are a basis of the coordinate space (Proposition 5.47), and expand each $\frac{\mathrm{d}A_j}{\mathrm{d}t}$ in that basis. The array of coefficients is $B = A^{-1}\frac{\mathrm{d}A}{\mathrm{d}t}$, since $AB = \frac{\mathrm{d}A}{\mathrm{d}t}$ says column by column that $\frac{\mathrm{d}A_j}{\mathrm{d}t} = \sum_i B_{ij}A_i$. Substituting this into the j-th term of Equation (5.20) and using linearity in the j-th column,

$$\det\left(A_1, \ldots, \frac{\mathrm{d}A_j}{\mathrm{d}t}, \ldots, A_n\right) = \sum_{i=1}^{n} B_{ij} \det\left(A_1, \ldots, A_i, \ldots, A_n\right) = B_{jj} \det A\,,$$

because the determinant on the right has the column A_i standing in the j-th place and therefore repeats a column, hence vanishes, unless $i = j$. Summing over j produces $\operatorname{tr} B$ and Equation (5.21). □

5.2 Vector spaces

5.2.1 Vector spaces

Let us discuss the definition of a vector space in more detail. As we have seen (Definition 4.31), the composite structure $[(\mathbb{K}, +, \cdot), \cdot, (\mathbb{V}, +)]$ is a vector space if and only if the following hold.

1. $\mathbb{K}$ is a commutative field.
2. $\mathbb{V}$ is closed with respect to $+$.
3. $\mathbb{V}$ is an abelian group with respect to $+$:
   a) $\forall\, u, v, w \in \mathbb{V},\ u + (v + w) = (u + v) + w$;
   b) $\forall\, u \in \mathbb{V},\ \exists\ 0_{\mathbb{V}} \in \mathbb{V} \mid u + 0_{\mathbb{V}} = u\ \wedge\ 0_{\mathbb{V}} + u = u$;
   c) $\forall\, u \in \mathbb{V},\ \exists\ (-u) \in \mathbb{V} \mid u + (-u) = 0_{\mathbb{V}}\ \wedge\ (-u) + u = 0_{\mathbb{V}}$;
   d) $\forall\, u, v \in \mathbb{V},\ u + v = v + u$.
4. The binary operation $\cdot : \mathbb{K} \times \mathbb{V} \longrightarrow \mathbb{V}$ relates $\mathbb{K}$ and $\mathbb{V}$ in the following manner:
   e) $\forall\, a, b \in \mathbb{K},\ \forall\, u \in \mathbb{V},\ a(bu) = (ab)u$;
   f) $\forall\, u \in \mathbb{V},\ 1u = u$;

   that is, the operation $\cdot$ is an action of $(\mathbb{K}, \cdot)$ on $\mathbb{V}$. Finally, the following distributivity properties hold:
   g) $\forall\, a \in \mathbb{K},\ \forall\, u, v \in \mathbb{V},\ a(u + v) = au + av$;
   h) $\forall\, a, b \in \mathbb{K},\ \forall\, u \in \mathbb{V},\ (a + b)u = au + bu$.

Given a vector space, the following properties hold:

$$\forall\, v \in \mathbb{V},\ 0 \cdot v = 0_{\mathbb{V}} \tag{5.22}$$

and

$$\forall\, a \in \mathbb{K},\ a \cdot 0_{\mathbb{V}} = 0_{\mathbb{V}}\,. \tag{5.23}$$

Derivation. *Derives Equation (5.22).*

Both are consequences of distributivity together with the existence of additive inverses in $(\mathbb{V}, +)$; note that the two zeros involved are different objects, $0 \in \mathbb{K}$ and $0_{\mathbb{V}} \in \mathbb{V}$, and that the content of the statements is exactly that they are compatible.

For Equation (5.22), apply distributivity h) with $a = b = 0$, using $0 + 0 = 0$ in the field:

$$0 \cdot v = (0 + 0) \cdot v = 0 \cdot v + 0 \cdot v \,.$$

By axiom c) the vector $0 \cdot v$ possesses an additive inverse $-(0 \cdot v)$. Adding it on the left of both sides and using associativity a), the inverse axiom c) and the neutral element b),

$$\begin{aligned} -(0 \cdot v) + 0 \cdot v &= -(0 \cdot v) + (0 \cdot v + 0 \cdot v) \\ 0_{\mathbb{V}} &= (-(0 \cdot v) + 0 \cdot v) + 0 \cdot v \\ &= 0_{\mathbb{V}} + 0 \cdot v \\ &= 0 \cdot v \,. \end{aligned}$$

For Equation (5.23) the argument is the same one run on the other distributive law. By axiom b), $0_{\mathbb{V}} = 0_{\mathbb{V}} + 0_{\mathbb{V}}$, so distributivity g) gives

$$a \cdot 0_{\mathbb{V}} = a \cdot (0_{\mathbb{V}} + 0_{\mathbb{V}}) = a \cdot 0_{\mathbb{V}} + a \cdot 0_{\mathbb{V}} \,,$$

and adding $-(a \cdot 0_{\mathbb{V}})$ on the left of both sides yields $0_{\mathbb{V}} = a \cdot 0_{\mathbb{V}}$. □

Two further consequences are worth recording, since they are used silently later: $(-1) \cdot v = -v$, because $v + (-1) \cdot v = (1 + (-1)) \cdot v = 0 \cdot v = 0_{\mathbb{V}}$ by axiom f) and Equation (5.22); and, conversely, $a \cdot v = 0_{\mathbb{V}}$ with $a \neq 0$ forces $v = 0_{\mathbb{V}}$, since multiplying by $a^{-1} \in \mathbb{K}$ — which exists because $\mathbb{K}$ is a field — gives $v = 1 \cdot v = (a^{-1}a) \cdot v = a^{-1} \cdot 0_{\mathbb{V}} = 0_{\mathbb{V}}$ by axioms e), f) and Equation (5.23).

When no ambiguity is possible we shall refer to the vector space as $\mathbb{V}$. When it is necessary to specify the field, we denote it $\mathbb{V}(\mathbb{K})$. If $\mathbb{K} = \mathbb{R}$ we say that $\mathbb{V}$ is a *real vector space*; if $\mathbb{K} = \mathbb{C}$, that $\mathbb{V}$ is a *complex vector space*. From now on we shall consider only the cases $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

Definition 5.2 (Scalar)**.** Consider a vector space $\mathbb{V}(\mathbb{K})$. An element belonging to the field is called a *scalar*. We name *zero* the neutral element of $(\mathbb{K}, +)$ and *unity* or *one* the neutral element of $(\mathbb{K}, \cdot)$.

Rests on Definition 4.31.

Definition 5.3 (Vector)**.** Consider a vector space $\mathbb{V}$. An element belonging to the vector space is called a *vector*, and the neutral element $0_{\mathbb{V}}$ is called the *neutral vector*.

Rests on Definition 4.31.

Definition 5.4 (Linear combination)**.** Consider a set of scalars $\{a^i\}_{i=1}^N$ in $\mathbb{K}$ and a set of vectors $W = \{v_i\}_{i=1}^N$ in $\mathbb{V}$. The quantity

$$v = \sum_{i=1}^{N} a^i v_i$$

is a vector, by the closure axioms. This vector is called a *linear combination* of the elements of W.

Rests on Definition 4.31.

Remark 5.5. The concept of linear combination unifies the concepts of multiplication by a scalar and of vector addition: if we wish to prove a property, or state an axiom, both for a vector of the form av and for one of the form $u + v$, it is sometimes simpler to consider a linear combination of u and v, that is, to carry out the proof for a vector of the form $au + bv$. This is at the discretion of the writer.

Definition 5.6 (Vector subspace)**.** Consider a vector space $\mathbb{V}$ and $\mathbb{S} \subset \mathbb{V}$. We say that $\mathbb{S}$ is a *vector subspace* if and only if every linear combination of vectors in $\mathbb{S}$ is a vector in $\mathbb{S}$, that is, if

1. $\mathbb{S} \neq \varnothing$;
2. $\forall\ a, b \in \mathbb{K},\ \forall\ u, v \in \mathbb{S},\ au + bv \in \mathbb{S}$.

Rests on Definition 5.4.

The foregoing says that a vector subspace is a substructure. A vector subspace is evidently a vector space in itself, since:

- $\mathbb{K}$ continues to be a commutative field;
- we have specified the closure of $\mathbb{S}$ with respect to $+$;
- the axioms listed in the definition of a vector space hold for all the elements of $\mathbb{V}$, and in particular for those of $\mathbb{S}$.

Basic vector spaces: real numbers; complex numbers; matrices; functions

Four families of examples carry very nearly every vector space this treatise uses, and in each of them the axioms of Section 5.2.1 are verified in the same way: the operations are defined entry by entry, or point by point, so that each axiom reduces to the corresponding axiom of the field $\mathbb{K}$. The verification is therefore written out once, for the first example, and only its outcome is recorded for the others.

Example 5.7 (The coordinate spaces $\mathbb{R}^n$ and $\mathbb{C}^n$)**.** Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let $\mathbb{K}^n$ be the set of ordered n-tuples $v = (v^1, \dots, v^n)$ of elements of $\mathbb{K}$, with the componentwise operations

$$(u + v)^i = u^i + v^i\,, \qquad (av)^i = a\,v^i\,, \qquad i = 1, \dots, n\,. \tag{5.24}$$

Closure is immediate, since $\mathbb{K}$ is closed under its own operations. Associativity and commutativity of $+$ hold because they hold in $\mathbb{K}$ in each slot separately; the neutral vector is $0_{\mathbb{V}} = (0, \dots, 0)$ and the opposite of v is $(-v^1, \dots, -v^n)$; and the four axioms e) to h) relating the field to the space are the associativity, the unit, and the two distributive laws of $\mathbb{K}$, read one component at a time. The n vectors

$$e_i = (0, \dots, 0, \underset{i}{1}, 0, \dots, 0)\,, \qquad i = 1, \dots, n\,, \tag{5.25}$$

form a basis in the sense of Definition 5.14: the identity $v = \sum_i v^i e_i$ exhibits an arbitrary v as a linear combination of them, and $\sum_i a^i e_i = 0_{\mathbb{V}}$ reads $a^i = 0$ componentwise, which is Equation (5.29). Hence $\dim \mathbb{K}^n = n$ over $\mathbb{K}$. Two degenerate cases deserve their names: $\mathbb{R}^1 = \mathbb{R}$ is a real vector space of dimension one, and $\mathbb{C}$ is a complex vector space of dimension one but a *real* vector space of dimension two, with basis $\{1, \mathrm{i}\}$ — the distinction insisted on in Remark 5.53. Physical space is the case $n = 3$ over $\mathbb{R}$ and the spacetime of Chapter 39 the case $n = 4$ over $\mathbb{R}$.

Rests on Definitions 4.31 and 5.4.

Example 5.8 (The matrices of a given shape)**.** Let $\mathcal{M}_{m\times n}[\mathbb{K}]$ be the set of rectangular arrays $A = \left(A^i{}_j\right)$ of m rows and n columns with entries in $\mathbb{K}$, added and scaled entry by entry,

$$(A + B)^i{}_j = A^i{}_j + B^i{}_j\,, \qquad (aA)^i{}_j = a\,A^i{}_j\,.$$

This is Example 5.7 with the single index i replaced by the pair (i, j), so every axiom holds for the same reason, the neutral vector being the array all of whose entries are 0. A

basis is furnished by the mn arrays $E_{(kl)}$ carrying 1 in the entry (k,l) and 0 everywhere else: $A = \sum_{k,l} A^k{}_l E_{(kl)}$, and a vanishing combination of the $E_{(kl)}$ has every coefficient zero because it has every entry zero. Hence

$$\dim \mathcal{M}_{m\times n}[\mathbb{K}] = mn\,. \tag{5.26}$$

Note what is *not* used here: the matrix product plays no part, and the square arrays acquire the further structure of an algebra (Proposition 5.121) only once it is added.

Rests on Definitions 4.31 and 5.14.

Example 5.9 (Functions on a set)**.** Let X be a non-empty set and let $\mathcal{F}(X,\mathbb{R})$ be the set of all maps $f : X \longrightarrow \mathbb{R}$, with the *pointwise* operations

$$(f+g)(x) = f(x) + g(x)\,, \qquad (af)(x) = a\,f(x)\,, \qquad \forall\, x \in X\,. \tag{5.27}$$

Once more each axiom is an axiom of $\mathbb{R}$ evaluated at one point at a time; the neutral vector is the function constant equal to 0 and the opposite of f is $-f$. Many of the spaces met later in the treatise are subspaces of this one in the sense of Definition 5.6 — the polynomial functions of degree at most N, the continuous functions on an interval, the solutions of a homogeneous linear differential equation — and each is a subspace for the same reason: the defining condition is preserved by linear combinations.

The dimension separates two regimes. If X is finite with N elements $x_1,\dots,x_N$, then $f \longmapsto (f(x_1),\dots,f(x_N))$ is a bijection onto $\mathbb{R}^N$ respecting Equation (5.27), so $\mathcal{F}(X,\mathbb{R})$ is a space of dimension N and nothing new. If X is infinite — $X = \mathbb{R}$, say — the space is infinite-dimensional in the sense of Definition 5.15: the monomial functions $p_k : x \longmapsto x^k$, $k = 0,1,2,\dots$, are linearly independent, because a vanishing linear combination $\sum_{k=0}^{K} a^k x^k = 0$ for *every* real x is a polynomial with infinitely many roots and hence has all its coefficients zero. No finite set can therefore generate $\mathcal{F}(\mathbb{R},\mathbb{R})$.

Rests on Definitions 4.31 and 5.6.

Remark 5.10 (Why the last example forces a later chapter)*.* Example 5.9 is the first space in this chapter whose dimension is not a natural number, and the difference is not one of degree. Everything proved from Definition 5.11 onwards rests on *finite* linear combinations (Remark 5.12), whereas the expansions physics actually writes in function spaces — a Fourier series, a power series, an expansion of a quantum state in energy eigenstates — are infinite sums, and an infinite sum means nothing at all until a notion of convergence is supplied. Supplying it takes a norm (Definition 5.18) and then completeness with respect to the associated metric Equation (5.45); that is exactly the equipment of a Hilbert space, and it is why Chapter 12 exists as a separate chapter rather than as a paragraph of this one. The state space of Postulate 77.1 is a function space of this kind.

5.2.2 Bases

Definition 5.11 (Subspace generated by a set of vectors)**.** Consider a non-empty set of vectors $W \subset \mathbb{V}$. The set of all possible linear combinations of the elements of W forms a vector subspace of $\mathbb{V}$. We denote this subspace by $\langle W\rangle$ and say that it is the *subspace generated* by W.

Rests on Definitions 5.4 and 5.6.

Derivation. *Derives Definition 5.11.*

Write out what the set is:

$$\langle W\rangle = \left\{ \sum_{i=1}^{N} a^i w_i \;\middle|\; N \in \mathbb{N},\ a^i \in \mathbb{K},\ w_i \in W \right\},$$

the linear combinations being *finite* — N is arbitrary but each element of $\langle W\rangle$ uses only finitely many vectors of W. We verify the two conditions of Definition 5.6.

1. $\langle W\rangle \neq \varnothing$. By hypothesis $W \neq \varnothing$, so pick $w \in W$; then $w = 1 \cdot w \in \langle W\rangle$ by axiom f), the case $N = 1$, $a^1 = 1$.

2. Closure under linear combination. Let $u, v \in \langle W\rangle$ and $c, d \in \mathbb{K}$. By definition there are finite families
$$u = \sum_{i=1}^{N} a^i w_i\,, \qquad v = \sum_{j=1}^{M} b^j w'_j\,,$$
with all $w_i, w'_j \in W$. Then
$$\begin{aligned} cu + dv &= c\sum_{i=1}^{N} a^i w_i + d\sum_{j=1}^{M} b^j w'_j \\ &= \sum_{i=1}^{N} c\left(a^i w_i\right) + \sum_{j=1}^{M} d\left(b^j w'_j\right) && \text{by } g) \\ &= \sum_{i=1}^{N} \left(ca^i\right) w_i + \sum_{j=1}^{M} \left(db^j\right) w'_j && \text{by } e)\,, \end{aligned}$$
which is again a finite linear combination of elements of W, with coefficients $ca^i, db^j \in \mathbb{K}$ by closure of the field. Hence $cu + dv \in \langle W\rangle$.

So $\langle W\rangle$ is a vector subspace. Note in passing that $0_{\mathbb{V}} = 0 \cdot w \in \langle W\rangle$ by Equation (5.22), as it must be for a subspace. □

Remark 5.12 ($\langle W\rangle$ is the smallest such subspace). If $\mathbb{S}$ is any vector subspace with $W \subset \mathbb{S}$, then $\langle W\rangle \subset \mathbb{S}$: applying condition 2 of Definition 5.6 repeatedly to the elements $w_1, \ldots, w_N \in W \subset \mathbb{S}$ shows that every finite linear combination of them lies in $\mathbb{S}$. Thus $\langle W\rangle$ is the intersection of all subspaces containing W, which is the usual characterization of the generated subspace. The restriction to *finite* combinations is not a technicality that could be relaxed: an infinite sum presupposes a notion of convergence, which a bare vector space does not carry — it needs the norm of Definition 5.18 and, beyond that, completeness. This is exactly the difference between the algebraic (Hamel) basis of Definition 5.14 and the topological bases used in infinite dimensions.

Definition 5.13 (Linear independence)**.** A set of vectors $\{v_i\}_{i=1}^{N}$ is *linearly independent* (LI) if none of them can be written as a linear combination of the remaining ones, that is, if and only if
$$\forall\ \left\{a^i\right\}_{i=1}^{N}, \quad \sum_{i=1}^{N} a^i v_i = v_j \implies a^k = 0_{\mathbb{K}},\ \forall j,\ \forall k\,, \tag{5.28}$$
where $\left\{a^i\right\}_{i=1}^{N} \subset \mathbb{K}$ is an arbitrary set of an arbitrary (but fixed) number N of scalars in $\mathbb{K}$.
Rests on Definition 5.4.

It is important to mention that Equation (5.28) is equivalent to
$$\forall\ \left\{a^i\right\}_{i=1}^{N+1}, \quad \sum_{i=1}^{N+1} a^i v_i = 0_{\mathbb{V}} \implies a^k = 0_{\mathbb{K}},\ \forall k\,, \tag{5.29}$$
although, since N is arbitrary, we may leave the characterization of linear independence as:

1. $\forall\ \{a^i\}_{i=1}^{N+1}, \quad \sum_{i=1}^{N+1} a^i v_i = 0_{\mathbb{V}} \implies a^k = 0_{\mathbb{K}},\ \forall k.$

Definition 5.14 (Basis)**.** Let $B \subset \mathbb{V}$ be a subset of vectors. We say that B is a *basis* of $\mathbb{V}$ if and only if

1. $\langle B \rangle = \mathbb{V}$;
2. B is LI.

Rests on Definitions 5.11 and 5.13.

The basis of a vector space is not unique, since:

- given a basis, we may multiply each of its elements by a scalar, and the new set will still generate the whole space;
- there may exist another set of LI vectors generating the whole space.

Definition 5.15 (Dimension)**.** Let B be a basis of $\mathbb{V}$, with $|B| = n$. We say that $\mathbb{V}$ is a *finite-dimensional* vector space of *dimension* n if and only if $n \in \mathbb{N}$. We say that $\mathbb{V}$ is an *infinite-dimensional* vector space if and only if $n = \infty$.
Rests on Definition 5.14.

When it is prudent to specify the dimension of an n-dimensional vector space we shall denote it $\mathbb{V}(n, \mathbb{K})$, or simply $\mathbb{V}_n$.

Definition 5.16 (Components of a vector)**.** Let $\mathbb{V} = \langle \{e_i\}_{i=1} \rangle$ be a vector space. Since $\mathbb{V}$ is generated by the basis $\{e_i\}_{i=1}$, we can write any vector $v \in \mathbb{V}$ as a linear combination of the elements of that basis, that is,

$$v = \sum_{i=1} v^i e_i \,. \tag{5.30}$$

We say that the quantities $v^i \in \mathbb{K}$ are the *components* of the vector v with respect to the basis $\{e_i\}_{i=1}$.
Rests on Definition 5.14.

It is important to mention that the components of a vector are always *basis-dependent*: if we choose another basis generating $\mathbb{V}$, the components will be different.

5.3 Inner product, norm, and metric

5.3.1 Inner product

Definition 5.17 (Inner product)**.** Consider the map

$$\begin{array}{rccc} \langle \,|\, \rangle : & \mathbb{V} \times \mathbb{V} & \longrightarrow & \mathbb{K} \\ & (u, v) & \longmapsto & \langle u|v \rangle \,. \end{array}$$

We say that $\langle \,|\, \rangle$ defines an *inner product* on $\mathbb{V}$ if and only if it satisfies the following properties:

1. Identity of indiscernibles:
$$\langle v|v \rangle = 0 \iff v = 0_{\mathbb{V}} \,. \tag{5.31}$$
2. Positive definiteness:
$$\forall\, v \in \mathbb{V} \setminus \{0_{\mathbb{V}}\} \,,\ \langle v|v \rangle > 0 \,. \tag{5.32}$$
3. Hermiticity:
$$\forall\, u, v \in \mathbb{V},\ \langle u|v \rangle^* = \langle v|u \rangle \,. \tag{5.33}$$
4. Product by a scalar:
$$\forall\, u, v \in \mathbb{V},\ \forall\, a \in \mathbb{K},\ \langle u|av \rangle = a \, \langle u|v \rangle \,. \tag{5.34}$$

5. Distributivity:
$$\forall\, u, v, w \in \mathbb{V},\ \langle u|v+w\rangle = \langle u|v\rangle + \langle u|w\rangle\ . \tag{5.35}$$

Rests on Definition 4.31.

Given an inner product, the following properties hold as direct consequences of the axioms.

- From Equation (5.33) we see that
$$\begin{aligned}\langle au|v\rangle &= \langle v|au\rangle^* \\ &= (a\,\langle v|u\rangle)^* && \text{by Equation (5.34)} \\ &= a^*\,\langle v|u\rangle^*\ ,\end{aligned}$$
so that
$$\forall\, u, v \in \mathbb{V},\ \forall\, a \in \mathbb{K},\ \langle au|v\rangle = a^*\,\langle u|v\rangle\ . \tag{5.36}$$
- Again from Equation (5.33) we see that
$$\begin{aligned}\langle u+v|w\rangle &= \langle w|u+v\rangle^* \\ &= (\langle w|u\rangle + \langle w|v\rangle)^* && \text{by Equation (5.35)} \\ &= \langle w|u\rangle^* + \langle w|v\rangle^*\ ,\end{aligned}$$
hence
$$\forall\, u, v, w \in \mathbb{V},\ \langle u+v|w\rangle = \langle u|w\rangle + \langle v|w\rangle\ . \tag{5.37}$$
- From Equation (5.34) and Equation (5.22) we see that
$$\begin{aligned}\langle u|0_{\mathbb{V}}\rangle &= \langle u|0\cdot v\rangle \\ &= 0\,\langle u|v\rangle\ ,\end{aligned}$$
hence
$$\forall\, u \in \mathbb{V},\ \langle u|0_{\mathbb{V}}\rangle = 0\,. \tag{5.38}$$
- The inner product of a vector with itself is always a real number. Indeed, from hermiticity we have $\langle v|v\rangle = \langle v|v\rangle^*$, and, as we know from the complex numbers, every number equal to its conjugate is real. Hence
$$\forall\, v \in \mathbb{V},\ \langle v|v\rangle \in \mathbb{R}\,. \tag{5.39}$$

On occasion we shall call a vector space equipped with an inner product a *pre-Hilbert space*.

Definition 5.18 (Norm)**.** Consider the map
$$\begin{array}{rccc} \|\ \|: & \mathbb{V} & \longrightarrow & \mathbb{R} \\ & v & \longmapsto & \|v\|\ . \end{array}$$
We say that the map $\|\ \|$ defines a *norm* on $\mathbb{V}$ if and only if the following properties hold:

1. Identity of indiscernibles:
$$\|v\| = 0 \iff v = 0_{\mathbb{V}}\,. \tag{5.40}$$
2. Product by a scalar:
$$\forall\, v \in \mathbb{V},\ \forall\, a \in \mathbb{K},\ \|av\| = |a|\,\|v\|\ . \tag{5.41}$$
3. Triangle inequality:
$$\forall\, u, v \in \mathbb{V},\ \|u+v\| \leq \|u\| + \|v\|\ . \tag{5.42}$$

Rests on Definition 4.31.

We say that a vector space equipped with a norm is a *normed space*.

The Schwarz inequality

The single inequality that the whole of the theory of inner-product spaces rests on is the following. It is used at once to prove that Equation (5.44) really defines a norm, and again in Chapter 6 for the metric axioms of $\mathbb{R}^N$.

Proposition 5.19 (Cauchy–Schwarz inequality)**.** *Let $\mathbb{V}(\mathbb{K})$, with $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, be a vector space equipped with an inner product in the sense of Definition 5.17. Then*

$$|\langle u|v\rangle|^2 \le \langle u|u\rangle\,\langle v|v\rangle\ , \qquad \forall\, u, v \in \mathbb{V}\,, \tag{5.43}$$

with equality if and only if u and v are linearly dependent.
Rests on Definitions 5.13 and 5.17.

Proof. *Derives Proposition 5.19.*

If $v = 0_{\mathbb{V}}$ both sides vanish, by Equation (5.38) on the left and Equation (5.31) on the right, and u and $0_{\mathbb{V}}$ are linearly dependent; so assume $v \neq 0_{\mathbb{V}}$, whence $\langle v|v\rangle > 0$ by Equation (5.32) and we may divide by it. Put

$$\lambda = \frac{\langle v|u\rangle}{\langle v|v\rangle} \in \mathbb{K}\,, \qquad w = u - \lambda v\,,$$

that is, subtract from u its component along v. Expanding $\langle w|w\rangle$ by distributivity Equations (5.35) and (5.37) and the two scalar rules Equations (5.34) and (5.36),

$$\begin{aligned}\langle w|w\rangle &= \langle u - \lambda v|u - \lambda v\rangle \\ &= \langle u|u\rangle - \lambda\,\langle u|v\rangle - \lambda^*\,\langle v|u\rangle + \lambda^*\lambda\,\langle v|v\rangle\ .\end{aligned}$$

Now $\langle v|u\rangle = \langle u|v\rangle^*$ by hermiticity Equation (5.33), and $\langle v|v\rangle$ is a positive real by Equation (5.39), so each of the last three terms is $|\langle u|v\rangle|^2 / \langle v|v\rangle$, with signs $-, -, +$:

$$\begin{aligned}\langle w|w\rangle &= \langle u|u\rangle - \frac{|\langle u|v\rangle|^2}{\langle v|v\rangle} - \frac{|\langle u|v\rangle|^2}{\langle v|v\rangle} + \frac{|\langle u|v\rangle|^2}{\langle v|v\rangle} \\ &= \langle u|u\rangle - \frac{|\langle u|v\rangle|^2}{\langle v|v\rangle}\,.\end{aligned}$$

By positive definiteness Equation (5.32) together with Equation (5.31) we have $\langle w|w\rangle \ge 0$, and multiplying through by $\langle v|v\rangle > 0$ gives Equation (5.43).

For the equality case: the chain above shows that equality holds if and only if $\langle w|w\rangle = 0$, that is — by Equation (5.31) — if and only if $u = \lambda v$, and a pair $\{u, v\}$ with $v \neq 0_{\mathbb{V}}$ is linearly dependent precisely when u is a multiple of v. □

Remark 5.20 (What the proof does *not* need). Only the five axioms of Definition 5.17 were used. Neither finite-dimensionality, nor a basis, nor completeness of $\mathbb{V}$ entered anywhere, so Proposition 5.19 holds verbatim in the infinite-dimensional pre-Hilbert spaces of quantum mechanics (Chapter 12). What positive definiteness buys is the division by $\langle v|v\rangle$; on a space carrying an indefinite form — the Minkowski form of Chapter 39 is the case physics meets first — the inequality fails, and in fact reverses on the timelike vectors.

Norm associated with an inner product

Consider a vector space $\mathbb{V}$. Given an inner product $\langle\ |\ \rangle$ on $\mathbb{V}$, we can automatically define a map that satisfies the axioms of a norm, namely

$$\|v\| = \sqrt{\langle v|v\rangle}\,. \tag{5.44}$$

Let us prove that the map defined in Equation (5.44) is a norm.

1. For the identity of indiscernibles:

   ⇒) We must prove that if
   $$\|v\| = \sqrt{\langle v|v\rangle} = 0\,,$$
   then $v = 0_{\mathbb{V}}$. Indeed, squaring the above equation we see that $\langle v|v\rangle = 0$; hence, by axiom Equation (5.31), necessarily $v = 0_{\mathbb{V}}$.

   ⇐) We must now prove that if $v = 0_{\mathbb{V}}$ then $\|v\| = 0$. Since $v = 0_{\mathbb{V}}$, by axiom Equation (5.31) necessarily $\langle v|v\rangle = 0$; substituting into Equation (5.44),
   $$\|v\| = \sqrt{0} = 0\,.$$

2. We must prove that $\|av\| = |a|\,\|v\|$. Indeed,
   $$\begin{aligned}\|av\| &= \sqrt{\langle av|av\rangle}\\ &= \sqrt{a^*a\,\langle v|v\rangle} && \text{by Equations (5.34) and (5.36)}\\ &= \sqrt{|a|^2\,\langle v|v\rangle}\\ &= |a|\,\sqrt{\langle v|v\rangle}\\ &= |a|\,\|v\|\ .\end{aligned}$$

3. It remains to prove that this norm satisfies the triangle inequality. This is the one step that is not immediate from the axioms of the inner product, and it is where Proposition 5.19 is needed. Since both sides of Equation (5.42) are non-negative reals, it is equivalent — and easier — to compare their squares. Expanding by distributivity Equations (5.35) and (5.37),
   $$\begin{aligned}\|u+v\|^2 &= \langle u+v|u+v\rangle\\ &= \langle u|u\rangle + \langle u|v\rangle + \langle v|u\rangle + \langle v|v\rangle\\ &= \|u\|^2 + \langle u|v\rangle + \langle u|v\rangle^* + \|v\|^2 && \text{by Equation (5.33)}\\ &= \|u\|^2 + 2\,\mathrm{Re}\,\langle u|v\rangle + \|v\|^2\ ,\end{aligned}$$
   the cross terms having combined into twice a real part because a complex number added to its conjugate is twice its real part. Now $\mathrm{Re}\,z \le |z|$ for any $z \in \mathbb{C}$, and Equation (5.43) bounds $|\langle u|v\rangle|$ by $\|u\|\,\|v\|$, so
   $$\begin{aligned}\|u+v\|^2 &\le \|u\|^2 + 2\,|\langle u|v\rangle| + \|v\|^2\\ &\le \|u\|^2 + 2\,\|u\|\,\|v\| + \|v\|^2 && \text{by Equation (5.43)}\\ &= (\|u\| + \|v\|)^2\ .\end{aligned}$$
   Taking the (non-negative) square root of both sides preserves the inequality, and Equation (5.42) follows. Equality demands equality in both steps: $\langle u|v\rangle$ real and non-negative, and u, v linearly dependent — that is, u and v must be non-negative multiples of one another, the vectors "pointing the same way", which is the geometric content of the triangle inequality degenerating into an equality.

Metric associated with a norm

Consider a vector space $\mathbb{V}$. Given a norm $\|\ \|$ defined on $\mathbb{V}$, we can define a map that satisfies the axioms of a metric (Definition 6.24), namely
$$d(u,v) = \|u - v\|\ . \tag{5.45}$$

Let us prove that the map defined by Equation (5.45) really satisfies the three axioms of Definition 6.24, in their order.

1. *Positivity and the identity of indiscernibles* Equation (6.7). The first half is not an axiom of Definition 5.18 and has to be derived: for any $w \in \mathbb{V}$,

$$\begin{aligned} 0 &= \|0_{\mathbb{V}}\| && \text{by Equation (5.40)} \\ &= \|w + (-w)\| \\ &\leq \|w\| + \|-w\| && \text{by Equation (5.42)} \\ &= \|w\| + |-1|\,\|w\| && \text{by Equation (5.41)} \\ &= 2\,\|w\|\,, \end{aligned}$$

so $\|w\| \geq 0$, and with $w = u - v$ this is $d(u, v) \geq 0$. The second half is Equation (5.40) read on $w = u - v$:

$$d(u, v) = 0 \iff \|u - v\| = 0 \iff u - v = 0_{\mathbb{V}} \iff u = v\,,$$

the last step because $\mathbb{V}$ is a group under addition. In particular $d(v, v) = \|0_{\mathbb{V}}\| = 0$.

2. *Symmetry* Equation (6.8). We have

$$\begin{aligned} d(u, v) &= \|u - v\| \\ &= \|-(v - u)\| \\ &= |-1|\,\|v - u\| && \text{by Equation (5.41)} \\ &= \|v - u\| \\ &= d(v, u)\,, \end{aligned}$$

so symmetry holds.

3. *The triangle inequality* Equation (6.9). Finally, we must prove that the triangle inequality holds for the metric we have defined. We have

$$\begin{aligned} d(u, v) &= \|u - v\| \\ &= \|u - w + w - v\| \\ &\leq \|u - w\| + \|w - v\| && \text{by Equation (5.42)} \\ &= d(u, w) + d(w, v)\,, \end{aligned}$$

so the triangle inequality is indeed satisfied.

Remark 5.21 (On the inner product, the norm, and the metric). Note the following. Given a vector space equipped with an inner product, we can always define a norm associated with that inner product, and therefore we can always define a metric associated with that norm. This is a direct consequence of the axioms we have laid down for those maps. Even so, one could define an inner product, a norm, and a metric separately, that is, not associated with one another.

The axioms defined for an inner product, a norm, and a metric are motivated when these maps are indeed associated. For example, the inner product must be positive definite because otherwise the associated norm (defined in Equation (5.44)) could be imaginary, and the triangle inequality Equation (5.42) would then be meaningless, since imaginary numbers are neither smaller nor greater than one another.

The norm defined in Equation (5.44) is consistent because, by property Equation (5.39), the inner product of a vector with itself is always a real number; hence the square root in Equation (5.44) is always real as well.

5.3.2 Orthogonal bases

Definition 5.22 (Orthogonal vectors)**.** Consider a vector space equipped with an inner product. We say that two vectors $u, v \in \mathbb{V}$ are *orthogonal* if and only if their inner product vanishes, that is, if

$$\langle u|v\rangle = 0\,. \tag{5.46}$$

Rests on Definition 5.17.

Definition 5.23 (Unit vector)**.** Consider a vector space equipped with a norm. We say that a vector $v \in \mathbb{V}$ is *normalized*, or is a *unit vector*, if and only if its norm is one, that is, if $\|v\| = 1$.

Rests on Definition 5.18.

Definition 5.24 (Orthogonal basis)**.** Consider a vector space equipped with an inner product, generated by the basis $\{e_i\}_{i=1}$. We say that the basis is *orthogonal* if and only if all its elements are mutually orthogonal, that is, if

$$\langle e_i|e_j\rangle = a\,\delta_{ij},\ \forall\, i, j\,. \tag{5.47}$$

Rests on Definitions 5.14 and 5.22.

Definition 5.25 (Orthonormal basis)**.** Consider a vector space equipped with an inner product and a norm (not necessarily the associated one). We say that the basis is *orthonormal* if and only if it is orthogonal and, in addition, all its elements are unit vectors, that is, if

$$\|e_i\| = 1,\ \forall\, i\,. \tag{5.48}$$

Rests on Definitions 5.23 and 5.24.

If we consider the norm associated with the inner product, defined in Equation (5.44), it is clear that the orthonormality condition is given by the expression

$$\langle e_i|e_j\rangle = \delta_{ij},\ \forall\, i, j\,. \tag{5.49}$$

The Gram–Schmidt orthogonalization process

An orthonormal basis is so much more convenient than a general one that it is worth knowing that every finite-dimensional inner-product space has one. The construction is due to Gram [223] and Schmidt [338], and it is completely explicit: it turns a basis into an orthonormal basis one vector at a time, at each step subtracting from the next vector its components along the vectors already orthonormalized.

Proposition 5.26 (Gram–Schmidt)**.** *Let $\mathbb{V}$ be a vector space with an inner product and let $\{v_1, \ldots, v_n\}$ be a linearly independent set. Then there exists an orthonormal set $\{e_1, \ldots, e_n\}$ with*

$$\langle\{e_1, \ldots, e_k\}\rangle = \langle\{v_1, \ldots, v_k\}\rangle\,, \qquad k = 1, \ldots, n\,. \tag{5.50}$$

In particular every finite-dimensional inner-product space, and every finite-dimensional subspace of an inner-product space, possesses an orthonormal basis.

Rests on Definitions 5.13, 5.17 and 5.25 and Equation (5.44).

Proof. *Derives Proposition 5.26.*

By induction on k. For $k = 1$: $v_1 \neq 0_{\mathbb{V}}$ by linear independence, so $\|v_1\| > 0$ by Equations (5.32) and (5.44), and $e_1 = v_1/\|v_1\|$ is a unit vector generating the same line, by Equation (5.41).

Suppose $e_1, \dots, e_{k-1}$ have been constructed, orthonormal and satisfying Equation (5.50). Put

$$\tilde{e}_k = v_k - \sum_{i=1}^{k-1} \langle e_i | v_k \rangle \, e_i \,, \qquad e_k = \frac{\tilde{e}_k}{\|\tilde{e}_k\|} \,. \tag{5.51}$$

The subtraction is legitimate — $\tilde{e}_k \neq 0_{\mathbb{V}}$ — because otherwise v_k would lie in $\langle \{e_1, \dots, e_{k-1}\} \rangle = \langle \{v_1, \dots, v_{k-1}\} \rangle$, contradicting linear independence. For $j < k$,

$$\begin{aligned}
\langle e_j | \tilde{e}_k \rangle &= \langle e_j | v_k \rangle - \sum_{i=1}^{k-1} \langle e_i | v_k \rangle \, \langle e_j | e_i \rangle && \text{by Equations (5.34) and (5.35)} \\
&= \langle e_j | v_k \rangle - \sum_{i=1}^{k-1} \langle e_i | v_k \rangle \, \delta_{ji} && \text{by Equation (5.49)} \\
&= \langle e_j | v_k \rangle - \langle e_j | v_k \rangle \\
&= 0 \,,
\end{aligned}$$

so e_k is orthogonal to all its predecessors and, by construction, a unit vector. Equation (5.50) holds at step k because Equation (5.51) expresses e_k in terms of $v_k, e_1, \dots, e_{k-1}$ and, read backwards, expresses v_k in terms of $e_k, \dots, e_1$; each generated subspace therefore contains the other. □

Corollary 5.27 (Orthogonal decomposition)**.** *Let $\mathbb{S} \leq \mathbb{V}$ be a finite-dimensional subspace of an inner-product space and let*

$$\mathbb{S}^{\perp} = \{ w \in \mathbb{V} \mid \langle s | w \rangle = 0, \ \forall \, s \in \mathbb{S} \} \tag{5.52}$$

be its orthogonal complement*. Then $\mathbb{S}^{\perp}$ is a subspace and*

$$\mathbb{V} = \mathbb{S} \oplus \mathbb{S}^{\perp} \,. \tag{5.53}$$

Rests on Proposition 5.26 and Definitions 5.6 and 5.17.

Proof. *Derives Corollary 5.27.*

$\mathbb{S}^{\perp}$ is a subspace because $\langle s | a w_1 + b w_2 \rangle = a \langle s | w_1 \rangle + b \langle s | w_2 \rangle = 0$ by Equations (5.34) and (5.35), and it is non-empty ($0_{\mathbb{V}} \in \mathbb{S}^{\perp}$ by Equation (5.38)). Let $\{e_1, \dots, e_m\}$ be an orthonormal basis of $\mathbb{S}$, which exists by Proposition 5.26, and for $v \in \mathbb{V}$ define

$$Pv = \sum_{i=1}^{m} \langle e_i | v \rangle \, e_i \in \mathbb{S} \,.$$

The computation just performed in Proposition 5.26 shows $\langle e_j | v - Pv \rangle = 0$ for every j, hence $v - Pv \in \mathbb{S}^{\perp}$, so $v = Pv + (v - Pv)$ exhibits $\mathbb{V}$ as a sum. The sum is direct: if $s \in \mathbb{S} \cap \mathbb{S}^{\perp}$ then $\langle s | s \rangle = 0$, so $s = 0_{\mathbb{V}}$ by Equation (5.31). □

Remark 5.28 (Where the finiteness is needed)*.* The recursion Equation (5.51) is finite at every step, so Proposition 5.26 applies verbatim to a countable linearly independent family and produces a countable orthonormal family. What does *not* survive to infinite dimension is Equation (5.53) for an arbitrary subspace: the projection P is then an infinite sum, which needs convergence, and the decomposition holds for *closed* subspaces of a *complete* inner-product space — a Hilbert space, Definition 12.2. The projection theorem that says so is not proved in this treatise: it is reserved for Section 12.2.1, where it belongs. Every use made of Corollary 5.27 in this chapter is in finite dimension, where no such caveat arises.

The Gram matrix

Gram–Schmidt answers whether an orthonormal basis exists. The companion question — whether a given family is independent at all — has an answer in the same terms, and it is the form in which independence is usually tested in practice, because it replaces a statement about vanishing linear combinations by the definiteness of a single matrix assembled from inner products.

Proposition 5.29 (Gram criterion)**.** *Let* $\mathbb{V}$ *be a real vector space with an inner product and let* $v_1, \dots, v_m \in \mathbb{V}$*. Their* Gram matrix

$$G_{kl} = \langle v_k | v_l \rangle \,, \qquad k, l = 1, \dots, m \,, \tag{5.54}$$

is symmetric and positive semi-definite, and the following three conditions are equivalent: the family $\{v_1, \dots, v_m\}$ *is linearly independent;* G *is positive definite;* $\det G \neq 0$*.*

Rests on Definitions 5.13 and 5.17 and Proposition 5.47.

Proof. *Derives Proposition 5.29.*

Symmetry is Equation (5.33), the conjugation being the identity on $\mathbb{R}$. For $c = (c^1, \dots, c^m) \in \mathbb{R}^m$ put $w = \sum_{k=1}^m c^k v_k$; expanding by Equations (5.34) to (5.37),

$$\sum_{k,l=1}^{m} c^k G_{kl} c^l = \langle w | w \rangle \geq 0 \tag{5.55}$$

by Equation (5.32), which is positive semi-definiteness; and by Equation (5.31) the value vanishes exactly when $w = 0_{\mathbb{V}}$.

If the family is independent, $w = 0_{\mathbb{V}}$ forces $c = 0$, so Equation (5.55) is strictly positive for every $c \neq 0$ and G is positive definite. If it is dependent, some $c \neq 0$ gives $w = 0_{\mathbb{V}}$ and the quadratic form vanishes there, so G is not positive definite. For the third condition: if G is positive definite and $Gc = 0$, then Equation (5.55) vanishes at c, hence $c = 0$, so the array is injective and $\det G \neq 0$ by Proposition 5.47 and Equation (5.81). Conversely, if G is not positive definite there is a $c \neq 0$ with $\langle w | w \rangle = 0$, hence $w = 0_{\mathbb{V}}$, hence $\sum_l G_{kl} c^l = \langle v_k | w \rangle = 0$ for every k; so $Gc = 0$ with $c \neq 0$ and $\det G = 0$. □

5.3.3 Vector algebra in three dimensions

Physical space is $\mathbb{R}^3$ carrying the inner product of Definition 5.17 — the $3 + 0$ instantiation of Example 5.114. Its vector algebra is used in every physical part of this treatise, and the handful of identities that carry all of it are collected and proved here. Throughout this subsection the basis is orthonormal and fixed, components are written with subscripts, and a repeated index is summed over $1, 2, 3$.

Definition 5.30 (Levi–Civita symbol; cross product)**.** The *Levi–Civita symbol* is the array of 27 numbers

$$\varepsilon_{ijk} = \begin{cases} +1 & \text{if } (i,j,k) \text{ is an even permutation of } (1,2,3)\,, \\ -1 & \text{if it is an odd one}\,, \\ 0 & \text{if two of } i,j,k \text{ are equal}\,. \end{cases} \tag{5.56}$$

It changes sign under the exchange of any two of its indices and is therefore unchanged under a cyclic permutation of them. The *cross product* of $u, v \in \mathbb{R}^3$ is the element of $\mathbb{R}^3$ with components

$$(u \times v)_i = \varepsilon_{ijk} u_j v_k \,. \tag{5.57}$$

Rests on Definitions 4.44, 5.17 and 5.25.

Lemma 5.31 (Determinant through the Levi–Civita symbol)**.** *For every real* 3×3 *array* a *with entries* a_{ij}*,*

$$\varepsilon_{ijk}\, a_{il} a_{jm} a_{kn} = \varepsilon_{lmn} \det a = \varepsilon_{ijk}\, a_{li} a_{mj} a_{nk}\,, \tag{5.58}$$

and in particular $\det a^{\mathsf{T}} = \det a$*. Consequently, for a real array* R *with* $R^{\mathsf{T}} R = \mathbb{1}$ *— an orthogonal array in the sense of Equation* (5.161) *—*

$$R_{ia} R_{jb} R_{kc}\, \varepsilon_{abc} = (\det R)\, \varepsilon_{ijk}\,, \tag{5.59}$$

so that the symbol is unchanged when $\det R = 1$ *and merely changes sign when* $\det R = -1$*.*
Rests on Definition 5.30 and Equation (5.19)*.*

Proof. *Derives Lemma 5.31.*

Write $L_{lmn} = \varepsilon_{ijk} a_{il} a_{jm} a_{kn}$. Exchanging two of l, m, n exchanges two of the three factors; relabelling the summed indices to put the factors back in order exchanges two indices of ε_{ijk} and so costs a sign. Hence L is totally antisymmetric in (l, m, n): it vanishes whenever two of them are equal, and on the six remaining index triples it is $L_{lmn} = \varepsilon_{lmn} L_{123}$. Finally

$$L_{123} = \varepsilon_{ijk} a_{i1} a_{j2} a_{k3} = \sum_{\sigma} \operatorname{sgn}(\sigma)\, a_{\sigma(1)1} a_{\sigma(2)2} a_{\sigma(3)3} = \det a$$

by Equation (5.19), the surviving terms of the sum over i, j, k being exactly those in which (i, j, k) is a permutation of $(1, 2, 3)$, with ε_{ijk} its sign.

That $\det a^{\mathsf{T}} = \det a$ is Equation (5.19) reindexed by $\sigma \longmapsto \sigma^{-1}$, a bijection of the permutations which preserves the sign and turns $\prod_j a_{\sigma(j)j}$ into $\prod_j a_{j\sigma(j)}$. The second equality of Equation (5.58) is therefore the first one applied to a^{T}. Equation (5.59) is that second equality with $a = R$, after renaming the summed indices i, j, k to a, b, c and the free indices l, m, n to i, j, k; and $\det R = \pm 1$ because $(\det R)^2 = \det\left(R^{\mathsf{T}} R\right) = 1$. □

Lemma 5.32 (Contraction of two Levi–Civita symbols)**.** *For all* $j, k, l, m \in \{1, 2, 3\}$*,*

$$\sum_{i=1}^{3} \varepsilon_{ijk} \varepsilon_{ilm} = \delta_{jl} \delta_{km} - \delta_{jm} \delta_{kl}\,. \tag{5.60}$$

Rests on Definition 5.30.

Proof. *Derives Lemma 5.32.*

If $j = k$ both sides vanish: the left because $\varepsilon_{ijk} = 0$, the right because it becomes $\delta_{jl}\delta_{jm} - \delta_{jm}\delta_{jl}$. The same argument disposes of $l = m$. So let $j \neq k$ and $l \neq m$.

A term of the sum is non-zero only if $i \notin \{j, k\}$ and $i \notin \{l, m\}$. Since $\{j, k\}$ has two elements and i ranges over three values, exactly one i meets the first condition, so the sum has at most one non-zero term. Both $\{j, k\}$ and $\{l, m\}$ are two-element subsets of $\{1, 2, 3\}$; if they are different they share exactly one element, and the value missing from $\{j, k\}$ then lies in $\{l, m\}$, so the surviving term is killed by its second factor and the sum vanishes. The right-hand side vanishes too, since (l, m) is then neither (j, k) nor (k, j) and neither product of deltas can be 1.

There remain the two cases $\{l, m\} = \{j, k\}$. If $(l, m) = (j, k)$ the surviving term is $(\varepsilon_{ijk})^2 = 1$ and the right side is $\delta_{jj}\delta_{kk} - \delta_{jk}\delta_{kj} = 1 - 0 = 1$. If $(l, m) = (k, j)$ the term is $\varepsilon_{ijk}\varepsilon_{ikj} = -1$ and the right side is $\delta_{jk}\delta_{kj} - \delta_{jj}\delta_{kk} = -1$. □

Proposition 5.33 (The identities of the vector algebra of $\mathbb{R}^3$)**.** *For all* $u, v, w \in \mathbb{R}^3$*:*

1. Antisymmetry and orthogonality. $u \times v = -v \times u$*, and* $\langle u | u \times v \rangle = \langle v | u \times v \rangle = 0$*.*

2. Scalar triple product.

$$\langle u|v\times w\rangle = \varepsilon_{ijk}u_i v_j w_k = \det\begin{pmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{pmatrix}, \tag{5.61}$$

which is therefore unchanged by a cyclic permutation of u, v, w and changes sign under the exchange of any two of them.

3. Expansion of a double cross product.

$$u\times(v\times w) = v\,\langle u|w\rangle - w\,\langle u|v\rangle\ . \tag{5.62}$$

4. Lagrange's identity.

$$\|u\times v\|^2 = \|u\|^2\,\|v\|^2 - \langle u|v\rangle^2\ , \tag{5.63}$$

so that $\|u\times v\| = \|u\|\,\|v\|\sin\theta$ with θ the angle Equation (5.18) between u and v; that is, the length of $u\times v$ is the area of the parallelogram they span.

5. Behaviour under an orthogonal change of basis. *If $R^{\mathsf{T}}R = \mathbb{1}$ then*

$$(Ru)\times(Rv) = (\det R)\,R\,(u\times v)\ . \tag{5.64}$$

Rests on Lemmas 5.31 and 5.32 and Equation (5.18).

Proof. *Derives Proposition 5.33.*

1. $(v\times u)_i = \varepsilon_{ijk}v_j u_k = \varepsilon_{ikj}v_k u_j = -\varepsilon_{ijk}u_j v_k$, the middle step being a relabelling of the two summed indices and the last the antisymmetry of Equation (5.56). For the orthogonality, $\langle u|u\times v\rangle = \varepsilon_{ijk}u_i u_j v_k$ vanishes because $u_i u_j$ is unchanged and ε_{ijk} changes sign when i and j are exchanged, so the sum equals minus itself; and $\langle v|u\times v\rangle$ vanishes by the same argument on j and k after using part 1's antisymmetry.

2. The first equality is Equation (5.57) paired with u. For the second, apply the second equality of Equation (5.58) at $(l,m,n) = (1,2,3)$ to the array a whose rows are u, v, w: it gives $\varepsilon_{ijk}a_{1i}a_{2j}a_{3k} = \varepsilon_{123}\det a = \det a$. The stated symmetries are those of ε_{ijk}.

3. Using Equation (5.57) twice, then the cyclic symmetry $\varepsilon_{ijk} = \varepsilon_{kij}$ and Equation (5.60),

$$\begin{aligned}[u\times(v\times w)]_i &= \varepsilon_{ijk}u_j\varepsilon_{klm}v_l w_m \\ &= (\varepsilon_{kij}\varepsilon_{klm})\,u_j v_l w_m \\ &= (\delta_{il}\delta_{jm} - \delta_{im}\delta_{jl})\,u_j v_l w_m \\ &= v_i\,u_j w_j - w_i\,u_j v_j\ ,\end{aligned}$$

which is Equation (5.62).

4. By Equation (5.57) and Equation (5.60),

$$\begin{aligned}\|u\times v\|^2 &= (\varepsilon_{ijk}u_j v_k)\,(\varepsilon_{ilm}u_l v_m) \\ &= (\delta_{jl}\delta_{km} - \delta_{jm}\delta_{kl})\,u_j v_k u_l v_m \\ &= u_j u_j\,v_k v_k - (u_j v_j)^2\ ,\end{aligned}$$

which is Equation (5.63). Substituting Equation (5.18) turns the right-hand side into $\|u\|^2\,\|v\|^2\,(1-\cos^2\theta)$, and $\sin\theta \geq 0$ on $[0,\pi]$; the parallelogram spanned by u and v has base $\|v\|$ and altitude $\|u\|\sin\theta$, the altitude computed in Section 5.1.5.

5. Multiply the first equality of Equation (5.58), taken with $a = R$, by R_{dl} and sum over l. On the left the two factors carrying l contract to $\sum_l R_{il}R_{dl} = \delta_{id}$, which is $R^{\mathsf{T}}R = \mathbb{1}$ read

for RR^{T} — the two are the same statement in finite dimension, by Proposition 5.47. There results

$$\varepsilon_{djk} R_{jm} R_{kn} = (\det R)\, R_{dl}\, \varepsilon_{lmn}\,.$$

Contracting this with $u_m v_n$ and using Equation (5.57) twice gives $[(Ru)\times(Rv)]_d = (\det R)\, R_{dl}\, (u\times v)_l$, which is Equation (5.64). □

Remark 5.34 (Why the cross product is not a vector). Equation (5.64) is the whole content of the word *pseudo-vector*. Under a rotation, $\det R = 1$, the cross product transforms exactly as a vector does; under a reflection, $\det R = -1$, it acquires an extra sign, so it is not a vector in the sense of a quantity whose components transform by R under *every* orthogonal change of basis. Equivalently, Equation (5.57) depends on which of the two orientations of $\mathbb{R}^3$ was fixed with the basis. Chapter 13 recovers the same object intrinsically, as the dual Equation (13.224) of the antisymmetric part of a tensor product, which is what makes its transformation law manifest; the identities above are its algebra, and they are established here once for all the physical parts that use them.

5.4 Linear transformations

5.4.1 Linear transformations

Definition 5.35 (Linear transformation)**.** Consider two vector spaces $\mathbb{V}$ and $\mathbb{W}$, together with a map $T : \mathbb{V} \longrightarrow \mathbb{W}$. We say that the map T is a *linear map, application, operator, or transformation* (LT) if and only if

1. $\forall\ u, v \in \mathbb{V},\ T(u+v) = T(u) + T(v)$;
2. $\forall\ v \in \mathbb{V},\ \forall\, a \in \mathbb{K},\ T(av) = aT(v)$.

Rests on Definition 4.31.

Clearly we can unify the above axioms into

1. $\forall\ u, v \in \mathbb{V},\ \forall\, a, b \in \mathbb{K},\ T(au+bv) = aT(u) + bT(v)$.

Let us denote by $\mathcal{L}(\mathbb{V},\mathbb{W})$ the set of all linear transformations from $\mathbb{V}$ to $\mathbb{W}$. Obviously

$$\mathcal{L}(\mathbb{V},\mathbb{W}) \subset \mathcal{F}(\mathbb{V},\mathbb{W})\,.$$

The fundamental theorem of linear algebra

The name is traditionally given to two statements about one linear transformation: that its domain splits into the part it annihilates and a part it maps faithfully onto its image — the rank–nullity relation — and that the four subspaces attached to T and to its adjoint fit together in two orthogonal pairs. Both are proved below. A preliminary is needed first, and it is one the chapter has so far used without stating: that Definition 5.15 is unambiguous, because all bases of a finite-dimensional space have the same number of elements.

Lemma 5.36 (Exchange and completion)**.** *Let $\mathbb{V} = \langle\{w_1,\dots,w_m\}\rangle$ and let $\{v_1,\dots,v_k\} \subset \mathbb{V}$ be linearly independent. Then $k \le m$, and $\{v_1,\dots,v_k\}$ can be completed to a basis of $\mathbb{V}$ by adjoining vectors taken from $\{w_1,\dots,w_m\}$. Consequently any two bases of a finite-dimensional vector space have the same number of elements, and Definition 5.15 is well posed.*

Rests on Definitions 5.11, 5.13 and 5.14.

Proof. *Derives Lemma 5.36.*

Exchange. We show by induction on $j = 0, 1, \ldots, k$ that, after a renumbering of the w's,

$$\langle \{v_1, \ldots, v_j, w_{j+1}, \ldots, w_m\} \rangle = \mathbb{V}\,, \tag{5.65}$$

and in particular that $j \leq m$. For $j = 0$ this is the hypothesis. Assume Equation (5.65) for $j-1$, with $j \leq k$. Then v_j is a finite linear combination

$$v_j = \sum_{i<j} a^i v_i + \sum_{l \geq j} b^l w_l\,.$$

Not every b^l can vanish: otherwise v_j would be a linear combination of $v_1, \ldots, v_{j-1}$, which Definition 5.13 forbids. In particular the second sum is not empty, so $j \leq m$. Renumber the remaining w's so that $b^j \neq 0$ and solve:

$$w_j = \frac{1}{b^j}\left(v_j - \sum_{i<j} a^i v_i - \sum_{l>j} b^l w_l\right)\,,$$

which places w_j in $\langle \{v_1, \ldots, v_j, w_{j+1}, \ldots, w_m\} \rangle$. That set therefore generates everything the set of the previous step generated, namely $\mathbb{V}$, which is Equation (5.65) at j. Taking $j = k$ gives $k \leq m$.

Equal cardinality. If B and B' are two bases, each is independent and each generates, so the exchange applied twice gives $|B| \leq |B'|$ and $|B'| \leq |B|$.

Completion. Take $j = k$ in Equation (5.65): the set $G = \{v_1, \ldots, v_k, w_{k+1}, \ldots, w_m\}$ generates $\mathbb{V}$. If it is not linearly independent, some vanishing linear combination of its elements has a non-zero coefficient; that coefficient cannot belong only to the v's, which are independent, so it may be taken to belong to some w_l. Solving for that w_l expresses it through the others, so deleting it leaves a set that still generates $\mathbb{V}$. Repeating terminates, G being finite, and leaves a generating, linearly independent set containing every v_i — a basis in the sense of Definition 5.14. □

Definition 5.37 (Kernel, image, nullity, rank)**.** Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation. Its *kernel* and *image* are

$$\ker T = \{v \in \mathbb{V} \mid T(v) = 0_{\mathbb{W}}\}\,, \tag{5.66}$$

$$\operatorname{im} T = \{w \in \mathbb{W} \mid \exists\, v \in \mathbb{V},\ w = T(v)\}\,, \tag{5.67}$$

subspaces of $\mathbb{V}$ and of $\mathbb{W}$ respectively. The *nullity* of T is $\dim \ker T$ and its *rank* is $\dim \operatorname{im} T$.

Rests on Definitions 5.6 and 5.35.

Derivation. *Derives Definition 5.37.*

That the two sets are subspaces is the content asserted, and it is one line each. Both are non-empty, containing $0_{\mathbb{V}}$ and $0_{\mathbb{W}}$ respectively, since $T(0_{\mathbb{V}}) = T(0 \cdot 0_{\mathbb{V}}) = 0\,T(0_{\mathbb{V}}) = 0_{\mathbb{W}}$ by Equation (5.22). If $u, v \in \ker T$ and $a, b \in \mathbb{K}$ then $T(au + bv) = aT(u) + bT(v) = 0_{\mathbb{W}}$; and if $w = T(u)$, $z = T(v)$ lie in $\operatorname{im} T$ then $aw + bz = T(au + bv) \in \operatorname{im} T$. Both verify Definition 5.6. □

Theorem 5.38 (Rank–nullity)**.** *Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation with $\dim \mathbb{V} = n < \infty$. Then*

$$\dim \mathbb{V} = \dim \ker T + \dim \operatorname{im} T\,. \tag{5.68}$$

Rests on Definitions 5.14 and 5.37 and Lemma 5.36.

Proof. *Derives Theorem 5.38.*

$\ker T$ is a subspace of a space of dimension n, so by Lemma 5.36 it has a finite basis $\{u_1, \dots, u_k\}$ with $k \leq n$, and that independent set completes to a basis $\{u_1, \dots, u_k, x_1, \dots, x_{n-k}\}$ of $\mathbb{V}$. We claim that $\{T(x_1), \dots, T(x_{n-k})\}$ is a basis of $\operatorname{im} T$.

It generates. Any element of $\operatorname{im} T$ is $T(v)$ for some $v = \sum_i a^i u_i + \sum_j b^j x_j$, and linearity together with $T(u_i) = 0_{\mathbb{W}}$ gives $T(v) = \sum_j b^j T(x_j)$.

It is independent. Suppose $\sum_j c^j T(x_j) = 0_{\mathbb{W}}$. Then $T\left(\sum_j c^j x_j\right) = 0_{\mathbb{W}}$, so $\sum_j c^j x_j \in \ker T$ and therefore $\sum_j c^j x_j = \sum_i d^i u_i$ for some scalars d^i. That is a vanishing linear combination of the completed basis, so every coefficient vanishes by Equation (5.29); in particular every $c^j = 0$.

Hence $\dim \operatorname{im} T = n - k = n - \dim \ker T$, which is Equation (5.68). □

The adjoint and the four fundamental subspaces

The second half of the theorem needs an inner product on each of the two spaces, and with it the transformation that mirrors T on the other side of the bracket.

Definition 5.39 (Adjoint)**.** Let $\mathbb{V}$ and $\mathbb{W}$ be finite-dimensional inner-product spaces over $\mathbb{K}$ and let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be linear. A map $T^\dagger : \mathbb{W} \longrightarrow \mathbb{V}$ is an *adjoint* of T if

$$\left\langle T^\dagger w \middle| v \right\rangle = \langle w | T v \rangle \,, \qquad \forall\, v \in \mathbb{V},\ \forall\, w \in \mathbb{W}\,, \tag{5.69}$$

the left-hand bracket being that of $\mathbb{V}$ and the right-hand one that of $\mathbb{W}$. An operator $T : \mathbb{V} \longrightarrow \mathbb{V}$ with $T^\dagger = T$ is called *self-adjoint*, or *hermitian*.

Rests on Definitions 5.17 and 5.35.

Proposition 5.40 (The adjoint exists, is unique, and is linear)**.** *Under the hypotheses of Definition 5.39 the adjoint exists, is unique, and is itself a linear transformation. In orthonormal bases of $\mathbb{V}$ and $\mathbb{W}$ its matrix is the conjugate transpose of the matrix of T,*

$$\left[T^\dagger\right] = [T]^\dagger \,, \qquad \left(T^\dagger\right)^i{}_j = \left(T^j{}_i\right)^* \,, \tag{5.70}$$

and $\left(T^\dagger\right)^\dagger = T$.

Rests on Definition 5.39, Proposition 5.26, and Equation (5.74).

Proof. *Derives Proposition 5.40.*

Uniqueness. If S and S' both satisfy Equation (5.69), then $\langle Sw - S'w | v \rangle = 0$ for every v by Equation (5.37); taking $v = Sw - S'w$ and using Equation (5.31) gives $Sw = S'w$ for every w.

Existence. By Proposition 5.26 choose orthonormal bases $\{e_i\}$ of $\mathbb{V}$ and $\{f_j\}$ of $\mathbb{W}$, so that Equation (5.49) holds in each. Define $T^\dagger$ on the basis of $\mathbb{W}$ by

$$T^\dagger f_j = \sum_i \left(T^j{}_i\right)^* e_i \,,$$

and extend by linearity, which is legitimate by the uniqueness of components used in Proposition 5.43. The map so defined is linear by construction, so both sides of Equation (5.69) are antilinear in w and linear in v, and it suffices to check the identity on basis vectors:

$$\begin{aligned}
\left\langle T^\dagger f_j \middle| e_k \right\rangle &= \sum_i \left(\left(T^j{}_i\right)^*\right)^* \langle e_i | e_k \rangle && \text{by Equation (5.36)} \\
&= T^j{}_k \,, \\
\langle f_j | T e_k \rangle &= \sum_l T^l{}_k \, \langle f_j | f_l \rangle && \text{by Equations (5.34) and (5.74)} \\
&= T^j{}_k \,,
\end{aligned}$$

so the two agree. This also establishes Equation (5.70).

Linearity is forced, not assumed. Whatever map satisfies Equation (5.69) is linear, so nothing was lost by building a linear one: for $a, b \in \mathbb{K}$ and $w, z \in \mathbb{W}$,

$$\begin{aligned}\left\langle T^\dagger\,(aw+bz)\middle|v\right\rangle &= \langle aw+bz|Tv\rangle \\ &= a^*\,\langle w|Tv\rangle + b^*\,\langle z|Tv\rangle \qquad \text{by Equations (5.36) and (5.37)} \\ &= \left\langle aT^\dagger w + bT^\dagger z\middle|v\right\rangle\,,\end{aligned}$$

for every v, and the uniqueness argument above forces the two arguments to coincide.

Involutivity. For all v, w, $\left\langle \left(T^\dagger\right)^\dagger v\middle|w\right\rangle = \left\langle v\middle|T^\dagger w\right\rangle = \left\langle T^\dagger w\middle|v\right\rangle^* = \langle w|Tv\rangle^* = \langle Tv|w\rangle$, using Equation (5.33) twice, so $\left(T^\dagger\right)^\dagger = T$. □

Theorem 5.41 (The four fundamental subspaces)**.** *Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation between finite-dimensional inner-product spaces. Then*

$$(\operatorname{im} T)^\perp = \ker T^\dagger\,, \tag{5.71}$$

$$(\ker T)^\perp = \operatorname{im} T^\dagger\,, \tag{5.72}$$

so that each space splits orthogonally,

$$\mathbb{W} = \operatorname{im} T \oplus \ker T^\dagger\,, \qquad \mathbb{V} = \ker T \oplus \operatorname{im} T^\dagger\,, \tag{5.73}$$

and T and $T^\dagger$ have the same rank.

Rests on Definition 5.39, Theorem 5.38, and Corollary 5.27.

Proof. *Derives Theorem 5.41.*

A preliminary: $\left(\mathbb{S}^\perp\right)^\perp = \mathbb{S}$ for a subspace $\mathbb{S}$ of a finite-dimensional inner-product space. The inclusion $\mathbb{S} \subset \left(\mathbb{S}^\perp\right)^\perp$ is immediate from Equation (5.52) and the hermiticity Equation (5.33). Conversely let $v \in \left(\mathbb{S}^\perp\right)^\perp$ and split $v = s + w$ with $s \in \mathbb{S}$, $w \in \mathbb{S}^\perp$, which Corollary 5.27 permits. Then $w = v - s \in \left(\mathbb{S}^\perp\right)^\perp$, being a difference of two of its elements, while also $w \in \mathbb{S}^\perp$; hence $\langle w|w\rangle = 0$ and $w = 0_\mathbb{V}$ by Equation (5.31), so $v = s \in \mathbb{S}$.

Equation (5.71). By Equation (5.52), $w \in (\operatorname{im} T)^\perp$ means $\langle Tv|w\rangle = 0$ for every $v \in \mathbb{V}$. Now

$$\langle Tv|w\rangle = \langle w|Tv\rangle^* = \left\langle T^\dagger w\middle|v\right\rangle^* = \left\langle v\middle|T^\dagger w\right\rangle\,,$$

using Equation (5.33) and Equation (5.69), so the condition reads $\left\langle v\middle|T^\dagger w\right\rangle = 0$ for every v; taking $v = T^\dagger w$ and using Equation (5.31) this holds exactly when $T^\dagger w = 0_\mathbb{V}$, that is, when $w \in \ker T^\dagger$.

Equation (5.72). Apply Equation (5.71) to $T^\dagger$ in place of T, which is legitimate because $\left(T^\dagger\right)^\dagger = T$ by Proposition 5.40: it gives $\left(\operatorname{im} T^\dagger\right)^\perp = \ker T$. Taking the orthogonal complement of both sides and using the preliminary yields $\operatorname{im} T^\dagger = (\ker T)^\perp$.

The splittings and the ranks. Equation (5.73) is Corollary 5.27 applied to $\operatorname{im} T \leq \mathbb{W}$ and to $\ker T \leq \mathbb{V}$, rewritten through Equations (5.71) and (5.72). Finally, the second splitting gives $\dim \mathbb{V} = \dim \ker T + \dim \operatorname{im} T^\dagger$, whereas Equation (5.68) gives $\dim \mathbb{V} = \dim \ker T + \dim \operatorname{im} T$; subtracting, $\dim \operatorname{im} T = \dim \operatorname{im} T^\dagger$. □

Remark 5.42 (Two daggers, one star, and what each of them needs). Three things are worth separating, because the notation invites confusing them.

- The *adjoint* $T^\dagger : \mathbb{W} \longrightarrow \mathbb{V}$ of Definition 5.39 needs an inner product on each space, and changes if either is changed. The *pullback* $T^* : \mathbb{W}^* \longrightarrow \mathbb{V}^*$ of Section 5.5.2 needs no structure at all, and acts between the dual spaces rather than between the spaces themselves. They are different maps between different pairs of spaces, and the correspondence between them is exactly the antilinear identification $\mathbb{V} \simeq \mathbb{V}^*$ that an inner product supplies through Proposition 5.59.

- Over $\mathbb{R}$ the conjugation in Equation (5.70) is the identity, so in an orthonormal basis $\left[T^\dagger\right] = [T]^\mathsf{T}$ and self-adjoint means symmetric. Over $\mathbb{C}$ it means hermitian, in the sense of Definition 5.111. The requirement that the basis be *orthonormal* cannot be dropped: in a general basis the matrix of the adjoint involves the matrix of the inner product as well.

- Equation (5.73) is the whole of the solvability theory of a linear system in one line: $Tv = w$ has a solution if and only if $w \perp \ker T^\dagger$, and the solution is unique up to the addition of an arbitrary element of $\ker T$. The equality of ranks that closes the proof is the classical statement that the row rank and the column rank of a matrix agree.

Matrix representation associated with a linear transformation

Let $\mathbb{V}$ and $\mathbb{W}$ be vector spaces, generated by the bases $B_1 = \{e_i\}_{i=1}^{\dim \mathbb{V}}$ and $B_2 = \{f_i\}_{i=1}^{\dim \mathbb{W}}$, and consider a linear transformation $T : \mathbb{V} \longrightarrow \mathbb{W}$. The image $T(e_i)$ of the i-th vector of the basis of $\mathbb{V}$ is a new vector belonging to $\mathbb{W}$, so we can express it as a linear combination of the elements of the basis of $\mathbb{W}$ — the expansion exists because $\langle B_2 \rangle = \mathbb{W}$, which is the first clause of Definition 5.14, and its coefficients are unique because B_2 is linearly independent, which is the second clause and is the step written out in Proposition 5.43 below. That is,

$$T(e_i) = \sum_{j=1}^{\dim \mathbb{W}} T^j{}_i f_j \,. \tag{5.74}$$

We denote by $[T]$ the matrix with elements $T^j{}_i$, with $i = 1, \ldots, \dim \mathbb{V}$ and $j = 1, \ldots, \dim \mathbb{W}$. We say that the matrix $[T]$ is the *matrix representation* associated with the linear transformation T. Note that the coefficients of $[T]$ are basis-dependent: they depend on the choice of the bases of $\mathbb{V}$ and of $\mathbb{W}$. For this reason, when it is necessary to specify the bases, we denote the matrix representation of $T : \langle B_1 \rangle \longrightarrow \langle B_2 \rangle$ by $[T]_{B_1}^{B_2}$.

Proposition 5.43. *Given an LT and the respective bases, its matrix representation is unique.*

Rests on Definitions 5.14 and 5.35 and Equations (5.29) and (5.74).

Derivation. *Derives Proposition 5.43.*

The claim has two halves, and it is worth separating them: the array $[T]$ is *well defined* (its entries do not depend on how $T(e_i)$ happens to be written), and it *determines* T completely.

The entries are unique. Suppose the images of the basis vectors admitted two expansions,

$$T(e_i) = \sum_{j=1}^{\dim \mathbb{W}} T^j{}_i f_j = \sum_{j=1}^{\dim \mathbb{W}} S^j{}_i f_j \,.$$

Subtracting, and collecting terms by h),

$$\sum_{j=1}^{\dim \mathbb{W}} \left(T^j{}_i - S^j{}_i\right) f_j = 0_{\mathbb{W}} \,.$$

But $B_2 = \{f_j\}$ is a basis and therefore linearly independent, so by Equation (5.29) every coefficient of such a vanishing combination is zero:

$$T^j{}_i = S^j{}_i\,, \qquad \forall\, i = 1, \ldots, \dim \mathbb{V}\,,\ \forall\, j = 1, \ldots, \dim \mathbb{W}\,.$$

The array determines the transformation. Conversely, let v be any vector of $\mathbb{V}$, with components v^i in B_1 (Definition 5.16). Linearity gives

$$\begin{aligned} T(v) &= T\left(\sum_{i=1}^{\dim \mathbb{V}} v^i e_i\right) \\ &= \sum_{i=1}^{\dim \mathbb{V}} v^i T(e_i) \\ &= \sum_{i=1}^{\dim \mathbb{V}} \sum_{j=1}^{\dim \mathbb{W}} T^j{}_i v^i f_j \qquad\qquad \text{by Equation (5.74)}\,, \end{aligned}$$

so the components of $T(v)$ in B_2 are $(T(v))^j = \sum_i T^j{}_i v^i$, the familiar matrix-times-column product. Two linear transformations with the same matrix therefore agree on every vector, and are the same transformation.

The two halves together say that, once the bases are fixed, $T \mapsto [T]$ is a bijection between $\mathcal{L}(\mathbb{V}, \mathbb{W})$ and the $\dim \mathbb{W} \times \dim \mathbb{V}$ arrays over $\mathbb{K}$. What is *not* claimed is independence of the bases: change B_1 or B_2 and the same T acquires a different matrix, which is the remark made after Equation (5.74) and, later, the reason a representation is characterized by its character (Equation (5.181)) rather than by its matrices. □

Definition 5.44 (Functional)**.** A *functional* is a linear transformation of the form $T : \mathbb{V} \longrightarrow \mathbb{K}$.

Rests on Definition 5.35.

5.4.2 The vector space of linear transformations

Null operator

Consider the map

$$\begin{array}{rccc} \Theta: & \mathbb{V} & \longrightarrow & \mathbb{W} \\ & v & \longmapsto & \Theta(v) = 0_{\mathbb{W}}\,. \end{array}$$

Let us see that Θ is a linear operator. We have

$$\begin{aligned} \Theta(au + bv) &= 0_{\mathbb{W}} \\ &= 0_{\mathbb{W}} + 0_{\mathbb{W}} \\ &= a0_{\mathbb{W}} + b0_{\mathbb{W}} \qquad\qquad \text{by Equation (5.23)} \\ &= a\Theta(u) + b\Theta(v)\,, \end{aligned}$$

so Θ is a linear operator, which we shall call the *null operator*. Let us see, further, the following. Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation. We have

$$\begin{aligned} (T + \Theta)(v) &= T(v) + \Theta(v) \\ &= T(v) + 0_{\mathbb{W}} \\ &= T(v)\,, \end{aligned}$$

hence $T + \Theta = T$, and analogously $\Theta + T = T$. Thus Θ satisfies the neutral-element axiom:

$$\forall\, T \in \mathcal{L}(\mathbb{V}, \mathbb{W}),\ \exists\, \Theta \in \mathcal{L}(\mathbb{V}, \mathbb{W}) \mid T + \Theta = T\ \wedge\ \Theta + T = T\,. \tag{5.75}$$

Opposite operator

Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be an LT. Define $-T$ as the map

$$\begin{array}{rccc} -T: & \mathbb{V} & \longrightarrow & \mathbb{W} \\ & v & \longmapsto & (-T)(v) = -T(v)\,. \end{array}$$

Let us see that $-T$ is a linear operator. We have

$$\begin{aligned} (-T)(au+bv) &= -T(au+bv) \\ &= -(aT(u)+bT(v)) \\ &= -aT(u) - bT(v) \\ &= a(-T)(u) + b(-T)(v)\,, \end{aligned}$$

so $-T$ is indeed a linear operator, which we shall call the *opposite operator* of T. Note, moreover, that

$$\begin{aligned} (T+(-T))(v) &= T(v) + (-T)(v) \\ &= T(v) - T(v) \\ &= 0_{\mathbb{W}} \\ &= \Theta(v)\,, \end{aligned}$$

so $T+(-T) = \Theta$, and analogously $-T+T = \Theta$. Thus the inverse-element axiom is satisfied:

$$\forall\ T \in \mathcal{L}(\mathbb{V},\mathbb{W}),\ \exists\ (-T) \in \mathcal{L}(\mathbb{V},\mathbb{W}) \mid T+(-T) = \Theta\ \wedge\ -T+T = \Theta\,. \tag{5.76}$$

Linear combination of linear transformations

Consider the linear transformations $T_1 : \mathbb{V} \longrightarrow \mathbb{W}$ and $T_2 : \mathbb{V} \longrightarrow \mathbb{W}$. Let us see that a linear combination of these LT's is also an LT. Indeed,

$$\begin{aligned} (aT_1+bT_2)(cu+dv) &= aT_1(cu+dv) + bT_2(cu+dv) \\ &= a(T_1(cu)+T_1(dv)) + b(T_2(cu)+T_2(dv)) \\ &= c(aT_1(u)+bT_2(u)) + d(aT_1(v)+bT_2(v)) \\ &= c(aT_1+bT_2)(u) + d(aT_1+bT_2)(v)\,. \end{aligned}$$

The vector space of linear transformations

As we have seen, the set $\mathcal{L}(\mathbb{V},\mathbb{W})$ satisfies the neutral-element and inverse-element axioms, and moreover there is closure: the linear combination of two LT's is an element of $\mathcal{L}(\mathbb{V},\mathbb{W})$. It is then evident that the axioms of a vector space are satisfied; that is, $[(\mathbb{K},+,\cdot),\cdot,(\mathcal{L}(\mathbb{V},\mathbb{W}),+)]$ is a vector space.

Inverse operator

The opposite operator of the preceding subsubsection undoes the *addition* of T; the operator defined here undoes its *action*. The two are unrelated, and the source's placement of them side by side is the only reason for saying so.

Definition 5.45 (Inverse of a linear transformation)**.** Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation. A map $S : \mathbb{W} \longrightarrow \mathbb{V}$ is an *inverse* of T if

$$S \circ T = \mathrm{id}_{\mathbb{V}}\,, \qquad T \circ S = \mathrm{id}_{\mathbb{W}}\,. \tag{5.77}$$

When such an S exists we call T *invertible* and write $S = T^{-1}$; the notation is justified by the uniqueness proved in Proposition 5.46.

Rests on Definition 5.35.

Proposition 5.46 (Existence, uniqueness, and linearity of the inverse)**.** *Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation.*

1. *T is invertible if and only if it is a bijection.*
2. *The inverse, when it exists, is unique.*
3. *The inverse is automatically a linear transformation; hence an invertible linear transformation is precisely an isomorphism in the sense of Definition 5.51.*

Rests on Definitions 5.35 and 5.45.

Proof. *Derives Proposition 5.46.*

1. If S satisfies Equation (5.77) then T is injective, since $T(u) = T(v)$ gives $u = S(T(u)) = S(T(v)) = v$, and surjective, since $w = T(S(w))$ for every $w \in \mathbb{W}$. Conversely, a bijection has a set-theoretic inverse, and that inverse satisfies Equation (5.77) by construction.

2. If S and S' are both inverses then

$$S = S \circ \mathrm{id}_{\mathbb{W}} = S \circ (T \circ S') = (S \circ T) \circ S' = \mathrm{id}_{\mathbb{V}} \circ S' = S' ,$$

composition of maps being associative.

3. Let $w, z \in \mathbb{W}$ and $a, b \in \mathbb{K}$, and put $v = T^{-1}(w)$, $u = T^{-1}(z)$. Linearity of T gives $T(av + bu) = aT(v) + bT(u) = aw + bz$, and applying T^{-1} to both sides,

$$T^{-1}(aw + bz) = av + bu = aT^{-1}(w) + bT^{-1}(z) .$$

So T^{-1} satisfies Definition 5.35. With part 1 this identifies the invertible linear transformations with the isomorphisms. □

In finite dimension the three conditions of Proposition 5.46 collapse into one, and this is one of the very few places where a statement true of finite-dimensional spaces is flatly false in general.

Proposition 5.47 (Injective, surjective, invertible)**.** *Let $\mathbb{V}$ and $\mathbb{W}$ be vector spaces over the same field with $\dim \mathbb{V} = \dim \mathbb{W} = n < \infty$, and let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be linear. The following are equivalent: T is injective; T is surjective; T is invertible. In particular an endomorphism of a finite-dimensional space is invertible as soon as it is injective.*

Rests on Theorem 5.38, Proposition 5.46, and Definition 5.37.

Proof. *Derives Proposition 5.47.*

T is injective if and only if $\ker T = \{0_{\mathbb{V}}\}$: one direction is immediate, and for the other $T(u) = T(v)$ gives $T(u - v) = 0_{\mathbb{W}}$, hence $u = v$. By Equation (5.68) this is equivalent to $\dim \operatorname{im} T = n$, and a subspace of $\mathbb{W}$ of dimension $n = \dim \mathbb{W}$ is the whole of $\mathbb{W}$ — a basis of it is an independent set of n vectors in $\mathbb{W}$, which Lemma 5.36 completes to a basis of $\mathbb{W}$ by adjoining $n - n = 0$ further vectors. So injectivity is equivalent to surjectivity, and each is therefore equivalent to bijectivity, which is invertibility by Proposition 5.46. □

Remark 5.48 (The hypothesis of finite dimension is doing all the work). On $\mathcal{F}(\mathbb{N}, \mathbb{R})$ of Example 5.9 — the sequences of real numbers — the shift $T(a^1, a^2, \ldots) = (0, a^1, a^2, \ldots)$ is linear and injective and is not surjective, while the shift in the other direction is linear and surjective and is not injective. Both are one-sided inverses of one another and neither is an inverse in the sense of Equation (5.77). This is the reason the operator theory of Chapter 12 must distinguish the spectrum of an operator from its set of eigenvalues, a distinction that simply does not arise here.

Matrix of the inverse

Proposition 5.49. *Let $\mathbb{V}, \mathbb{W}$ be of the same finite dimension n with fixed bases B_1, B_2, and let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be invertible. Then $[T]$ is an invertible array and*

$$\left[T^{-1}\right]_{B_2}^{B_1} = \left([T]_{B_1}^{B_2}\right)^{-1} . \tag{5.78}$$

Moreover, for invertible arrays A and B of order n the product is invertible and

$$(AB)^{-1} = B^{-1}A^{-1} . \tag{5.79}$$

Rests on Propositions 5.43 and 5.46 and Equation (5.74).

Proof. Derives Proposition 5.49.

First, the matrix of a composition is the product of the matrices. Write $B_1 = \{e_i\}$, $B_2 = \{f_j\}$, and let $S : \mathbb{W} \longrightarrow \mathbb{V}$ be any linear transformation, so that Equation (5.74) reads $T(e_i) = \sum_j T^j{}_i f_j$ and $S(f_j) = \sum_k S^k{}_j e_k$. Then

$$\begin{aligned} (S \circ T)(e_i) &= S\left(\sum_j T^j{}_i f_j\right) \\ &= \sum_j T^j{}_i \, S(f_j) && \text{by linearity of } S \\ &= \sum_k \left(\sum_j S^k{}_j T^j{}_i\right) e_k , \end{aligned}$$

so that, by the uniqueness of Proposition 5.43, $[S \circ T]_{B_1}^{B_1} = [S]_{B_2}^{B_1} [T]_{B_1}^{B_2}$; and the matrix of $\mathrm{id}_{\mathbb{V}}$ in the basis B_1 twice over is $\mathbb{1}$, since $\mathrm{id}_{\mathbb{V}}(e_i) = e_i$. Applying this to both halves of Equation (5.77),

$$\left[T^{-1}\right][T] = \mathbb{1} , \qquad [T]\left[T^{-1}\right] = \mathbb{1} ,$$

which is Equation (5.78). For Equation (5.79), multiply out:

$$\begin{aligned} (AB)\left(B^{-1}A^{-1}\right) &= A\left(BB^{-1}\right)A^{-1} = AA^{-1} = \mathbb{1} , \\ \left(B^{-1}A^{-1}\right)(AB) &= B^{-1}\left(A^{-1}A\right)B = B^{-1}B = \mathbb{1} , \end{aligned}$$

so $B^{-1}A^{-1}$ is *an* inverse of AB, and the uniqueness argument of Proposition 5.46 — which used nothing but associativity — makes it *the* inverse. The order reverses because the factor applied last must be undone first; the same reversal appears for the transpose in Equation (5.161) and for the pullback in Equation (5.98). □

The determinant criterion that decides invertibility in practice, $\det[T] \neq 0$, is recorded with the general linear group in Equation (5.81).

5.4.3 Morphisms of vector spaces

Remark 5.50 (Homomorphism). An LT is by definition a group homomorphism: from the first axiom of an LT we see that T establishes a homomorphism between the groups $(\mathbb{V}, +)$ and $(\mathbb{W}, +)$.

Definition 5.51 (Isomorphism)**.** We say that a linear transformation is an *isomorphism* if it is in addition a bijection. If an isomorphism exists between two vector spaces, we say that they are *isomorphic*.

Rests on Definition 5.35.

Proposition 5.52. *Two vector spaces* over the same field $\mathbb{K}$ *and of the same finite dimension* n *are isomorphic.*

Rests on Definitions 5.14, 5.15 and 5.51 and Proposition 5.43.

Proof. *Derives Proposition 5.52.*

Let $\mathbb{V}$ and $\mathbb{W}$ be the two spaces, with bases $B_1 = \{e_i\}_{i=1}^n$ and $B_2 = \{f_i\}_{i=1}^n$; these have the same cardinality n by hypothesis, which is what allows the two to be listed with a common index. Define $T : \mathbb{V} \longrightarrow \mathbb{W}$ on the basis by

$$T(e_i) = f_i\,, \qquad i = 1, \ldots, n\,,$$

and extend to all of $\mathbb{V}$ by

$$T\left(\sum_{i=1}^{n} v^i e_i\right) = \sum_{i=1}^{n} v^i f_i\,. \tag{5.80}$$

Equation (5.80) is a legitimate definition precisely because the components v^i of a vector in a basis are unique — the argument just given for Proposition 5.43 — so no vector is assigned two images.

T is linear. If $u = \sum_i u^i e_i$ and $v = \sum_i v^i e_i$ then $au + bv = \sum_i (au^i + bv^i) e_i$, so

$$\begin{aligned} T(au + bv) &= \sum_{i=1}^{n} \left(au^i + bv^i\right) f_i \\ &= a \sum_{i=1}^{n} u^i f_i + b \sum_{i=1}^{n} v^i f_i \\ &= aT(u) + bT(v)\,. \end{aligned}$$

T is injective. Suppose $T(v) = 0_{\mathbb{W}}$. Then $\sum_i v^i f_i = 0_{\mathbb{W}}$, and B_2 being linearly independent, Equation (5.29) forces $v^i = 0$ for every i, whence $v = 0_{\mathbb{V}}$. Since T is linear, $T(u) = T(v)$ implies $T(u - v) = 0_{\mathbb{W}}$ and hence $u = v$.

T is surjective. Any $w \in \mathbb{W}$ can be written $w = \sum_i w^i f_i$, because B_2 generates $\mathbb{W}$; then $w = T\left(\sum_i w^i e_i\right)$.

Thus T is a bijective linear transformation, that is, an isomorphism in the sense of Definition 5.51. □

Remark 5.53 (The hypotheses are not decoration). Two of them are doing work, and the source states neither.

- *The same field.* Dimension is meaningless without saying over what. The space $\mathbb{C}$ regarded as a complex vector space has dimension 1; regarded as a real vector space it has dimension 2 and is isomorphic to $\mathbb{R}^2$, not to $\mathbb{R}$. A complex space of dimension n is a real space of dimension $2n$.

- *Finiteness.* For infinite-dimensional spaces the statement survives in the form "two spaces whose bases have the same cardinality are isomorphic", with the same proof read as a bijection $B_1 \longrightarrow B_2$ rather than as a common index; but the existence of a basis at all is then no longer constructive — that every vector space has a basis is equivalent to the axiom of choice (Chapter 3) — and the resulting isomorphism cannot be written down. In every physical application in this book the relevant spaces are either finite-dimensional or Hilbert spaces (Definition 12.2), where the topological notion of basis — a countable orthonormal set whose closed span is the whole space, the notion reserved for Section 12.2 — replaces this one and behaves far better.

The converse is immediate and worth stating: an isomorphism carries a basis to a basis (it preserves linear independence, being injective, and generation, being surjective), so isomorphic spaces have equal dimension. Dimension is therefore a *complete* invariant of a vector space over a fixed field — which is why so little of physics is contained in the vector space itself, and so much of it in the extra structure (inner product, algebra, group action) laid on top.

Definition 5.54 (Endomorphism)**.** An *endomorphism* is a linear transformation of the form $T : \mathbb{V} \longrightarrow \mathbb{V}$.

Rests on Definition 5.35.

Definition 5.55 (Automorphism)**.** An endomorphism is an *automorphism* if it is in addition an isomorphism.

Rests on Definitions 5.51 and 5.54.

Now consider the vector space $\mathbb{V}$. The set of all automorphisms of the form $T : \mathbb{V} \longrightarrow \mathbb{V}$, together with the composition of linear transformations, forms a group. Indeed, closure holds because automorphisms are bijections and, as we know, the composition of bijections is a bijection; associativity, the existence of the neutral element, and the existence of inverse elements are easy to see, and are likewise consequences of our considering bijections. We call this group the *general linear group*, and symbolize it as

$$\left(\{T \mid T : \mathbb{V} \longrightarrow \mathbb{V} \text{ is a bijection}\}, \circ\right) \overset{\text{not.}}{=} \mathrm{GL}(\mathbb{V}) .$$

In the case where the vector space considered is of the form $\mathbb{V} = \mathbb{K}^n$, with $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, we denote the general linear group by $\mathrm{GL}(n, \mathbb{K})$.

As we have seen, we can treat linear transformations as matrices. Let $\mathcal{M}_{n\times n}[\mathbb{K}]$ denote the set of *all* square arrays of order n over $\mathbb{K}$. That is the meaning the symbol carries throughout this chapter, and in particular in Proposition 5.121, where $T \longmapsto [T]$ is a bijection of the *whole* of $\mathcal{L}(\mathbb{V})$ onto it. The general linear group is then not that set, but its subset of invertible elements:

$$\mathrm{GL}(n, \mathbb{K}) \simeq \{M \in \mathcal{M}_{n\times n}[\mathbb{K}] \mid \det M \neq 0\} , \tag{5.81}$$

where the isomorphism is the bijection associating with each linear transformation T its matrix representation $[T]$ (for we have seen that, given an LT and a basis, its matrix representation is unique). The restriction on the right is not cosmetic. The full set of arrays is not a group under multiplication at all — the zero array has no inverse — so an isomorphism of groups could not have it on the right-hand side; only the invertible arrays, which are exactly the images of the automorphisms, form one. Recall, moreover, that

- $T \circ T^{-1} = \mathrm{id}_{\mathrm{GL}(n,\mathbb{K})}$;
- $[T][T]^{-1} = \mathbb{1}$.

Note that this isomorphism is not canonical, in the following sense: the matrix representation of a linear transformation is not unique, being basis-dependent.

There exists a very important subgroup of the general linear group. If we consider the set of all automorphisms of the form $T : \mathbb{K}^n \longrightarrow \mathbb{K}^n$ with $\det[T] = 1$, there is closure under this condition. Indeed, let A and B be two automorphisms belonging to this set, so $\det[A] = 1$ and $\det[B] = 1$. By closure of $\mathrm{GL}(n, \mathbb{K})$ there must exist C such that $A \circ B = C$, where we know that $[A][B] = [C]$. Thus, taking determinants,

$$\begin{aligned} [A][B] &= [C] \\ \det\left([A][B]\right) &= \det[C] \\ \det[A]\det[B] &= \det[C] \\ 1 &= \det[C] , \end{aligned}$$

so $\det[C] = 1$. That is, there is a smaller group satisfying the properties of the general linear group, for which $\det[T] = 1$. We call this subgroup the *special linear group* and symbolize it $\mathrm{SL}(n, \mathbb{K})$; thus

$$\mathrm{SL}(n, \mathbb{K}) = \{T \in \mathrm{GL}(n, \mathbb{K}) \mid \det[T] = 1\} \,. \tag{5.82}$$

5.5 The dual space

5.5.1 The dual space

Definition 5.56 (Dual space)**.** Consider a vector space $\mathbb{V}(\mathbb{K})$. We define the *dual space* of $\mathbb{V}$ as the vector space

$$\mathcal{L}(\mathbb{V}, \mathbb{K}) \overset{\text{not.}}{=} \mathbb{V}^* \,, \tag{5.83}$$

that is, as the set of all functionals of the form $f : \mathbb{V} \longrightarrow \mathbb{K}$.

Rests on Definition 5.44.

Vectors as matrices

Consider the vector space $\mathbb{V} = \langle \{e_i\}_{i=1} \rangle$. Define the functional g by

$$g(e_i) = g_i \,, \tag{5.84}$$

where $\{g_i\}_{i=1}$ is a set of scalars. Then, for an arbitrary vector with components v^i in the mentioned basis,

$$\begin{aligned} g(v) &= g\left(\sum_{i=1}^{\dim \mathbb{V}} v^i e_i\right) \\ &= \sum_{i=1}^{\dim \mathbb{V}} v^i g(e_i) \\ &= \sum_{i=1}^{\dim \mathbb{V}} v^i g_i && \text{by Equation (5.84)} \\ &= (g_1 \ \ldots)_{1\times \dim \mathbb{V}} \begin{pmatrix} v^1 \\ \vdots \end{pmatrix}_{\dim \mathbb{V}\times 1} \,. \end{aligned} \tag{5.85}$$

The preceding result suggests that we can represent the vector $v \in \mathbb{V}$ and the vector $g \in \mathbb{V}^*$ as a column matrix and a row matrix respectively; that is,

$$v \sim \begin{pmatrix} v^1 \\ \vdots \end{pmatrix}_{\dim \mathbb{V}\times 1} \,, \quad g \sim (g_1 \ \ldots)_{1\times \dim \mathbb{V}} \,.$$

Basis of the dual space

In the preceding context, consider the functionals

$$\begin{aligned} f^1 &\sim (1\ 0\ 0\ \ldots\ 0\ \ldots) \,, \\ f^2 &\sim (0\ 1\ 0\ \ldots\ 0\ \ldots) \,, \\ &\vdots \end{aligned}$$

From Equation (5.84) and Equation (5.85) we see that

$$f^i(e_j) = \delta^i{}_j \,. \tag{5.86}$$

Now, for an arbitrary functional $g \in \mathbb{V}^*$ we have

$$\begin{aligned}
g(v) &= g\left(\sum_{i=1}^{\dim \mathbb{V}} v^i e_i\right) \\
&= \sum_{i=1}^{\dim \mathbb{V}} v^i g(e_i) \\
&= \sum_{i=1}^{\dim \mathbb{V}} v^i g_i && \text{by Equation (5.84)} \\
&= \sum_{i,j=1}^{\dim \mathbb{V}} v^i \delta^j{}_i g_j \\
&= \sum_{i,j=1}^{\dim \mathbb{V}} v^i f^j(e_i) g_j && \text{by Equation (5.86)} \\
&= \sum_{j=1}^{\dim \mathbb{V}} f^j \left(\sum_i v^i e_i\right) g_j \\
&= \sum_{j=1}^{\dim \mathbb{V}} f^j(v) g_j \\
&= \left(\sum_{j=1}^{\dim \mathbb{V}} g_j f^j\right)(v)\,,
\end{aligned}$$

hence

$$g = \sum_{j=1}^{\dim \mathbb{V}} g_j f^j\,. \tag{5.87}$$

This result tells us that any functional in $\mathbb{V}^*$ can be expressed as a linear combination of the functionals f^j. Hence $\{f^j\}_{j=1}^{\dim \mathbb{V}}$ is a basis for the space $\mathbb{V}^*$. As we see, the dimension of the dual space $\mathbb{V}^*$ is the same as that of $\mathbb{V}$. We thus conclude the important result: $\mathbb{V}$ *and* $\mathbb{V}^*$ *are isomorphic.*

That a vector space and its dual are isomorphic is a very important result: it means that a space and its dual are in reality the same structure. Given an isomorphism $\Phi : \mathbb{V} \longrightarrow \mathbb{V}^*$, we say that $\Phi(v)$ is the *dual element* of v, and vice versa.

The annihilator of a subspace

Proposition 5.57 (Annihilator of a subspace)**.** *Let* $\mathbb{W}$ *be a subspace of a vector space* $\mathbb{V}$ *with* $\dim \mathbb{V} = n < \infty$*, and let*

$$\mathbb{W}^0 = \{g \in \mathbb{V}^* \mid g(w) = 0 \quad \forall\, w \in \mathbb{W}\} \tag{5.88}$$

be its annihilator*. Then* $\mathbb{W}^0$ *is a subspace of* $\mathbb{V}^*$ *and*

$$\dim \mathbb{W}^0 = n - \dim \mathbb{W}\,. \tag{5.89}$$

Rests on Definitions 5.6 and 5.56 and Lemma 5.36.

Proof. *Derives Proposition 5.57.*

$\mathbb{W}^0$ is defined by conditions linear in g, so it is a subspace. Let $\{e_1, \ldots, e_m\}$ be a basis of $\mathbb{W}$, $m = \dim \mathbb{W}$, completed to a basis $\{e_1, \ldots, e_n\}$ of $\mathbb{V}$ by Lemma 5.36, and let $\{f^1, \ldots, f^n\}$ be the dual basis Equation (5.86). By Equation (5.87) every $g \in \mathbb{V}^*$ is $g = \sum_j g_j f^j$ with $g_j = g(e_j)$. Since $\mathbb{W}$ is generated by $e_1, \ldots, e_m$, the condition $g(w) = 0$ for all $w \in \mathbb{W}$ is

equivalent to $g_1 = \ldots = g_m = 0$, that is, to $g \in \langle\{f^{m+1}, \ldots, f^n\}\rangle$. Those $n-m$ functionals are independent, being part of a basis, so they are a basis of $\mathbb{W}^0$ and Equation (5.89) follows. □

Corollary 5.58 (A functional that annihilates a set of constraints)**.** *Let $f^1, \ldots, f^m \in \mathbb{V}^*$ be linearly independent,* $\dim \mathbb{V} = n < \infty$*, and put $\mathbb{W} = \bigcap_{\alpha=1}^m \ker f^\alpha$. Then* $\dim \mathbb{W} = n - m$*, and every functional vanishing on $\mathbb{W}$ is a linear combination $\sum_\alpha \mu_\alpha f^\alpha$ with uniquely determined coefficients μ_α.*

Rests on Proposition 5.57, Theorem 5.38, and Definition 5.13.

Proof. *Derives Corollary 5.58.*

Let $A : \mathbb{V} \longrightarrow \mathbb{K}^m$ send v to $(f^1(v), \ldots, f^m(v))$; it is linear and its kernel is $\mathbb{W}$. It is surjective: otherwise its image is a proper subspace $\mathbb{S}$ of $\mathbb{K}^m$, and Proposition 5.57 applied in $\mathbb{K}^m$ gives $\dim \mathbb{S}^0 = m - \dim \mathbb{S} \geq 1$, so some non-zero $(c_1, \ldots, c_m)$ satisfies $\sum_\alpha c_\alpha f^\alpha(v) = 0$ for every v — a vanishing non-trivial combination, contradicting independence. Hence Equation (5.68) gives $\dim \mathbb{W} = n - m$.

By Equation (5.89), $\dim \mathbb{W}^0 = n - (n - m) = m$. Each f^α vanishes on $\mathbb{W}$ and so lies in $\mathbb{W}^0$; the m of them are independent, hence a basis of $\mathbb{W}^0$, which is the assertion, the coefficients being the unique components in that basis. □

Inner product established by an isomorphism between a space and its dual

Proposition 5.59. *Let $\mathbb{V}$ be a finite-dimensional vector space over $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, and let $\Phi : \mathbb{V} \longrightarrow \mathbb{V}^*$ be a bijection that is linear if $\mathbb{K} = \mathbb{R}$ and* antilinear *if $\mathbb{K} = \mathbb{C}$, that is,*

$$\Phi(au + bv) = a^* \Phi(u) + b^* \Phi(v)\,. \tag{5.90}$$

Consider the map defined by

$$\langle u|v\rangle = (\Phi(u))(v)\,. \tag{5.91}$$

Then:

1. *for* any *such Φ, Equation (5.91) satisfies the linearity axioms Equations (5.34) and (5.35) and their conjugate partners Equations (5.36) and (5.37), and it is* non-degenerate*: $\langle u|v\rangle = 0$ for all v forces $u = 0_{\mathbb{V}}$, and $\langle u|v\rangle = 0$ for all u forces $v = 0_{\mathbb{V}}$;*
2. *the remaining axioms Equations (5.31) to (5.33) hold if and only if Φ is in addition* hermitian*,*
$$(\Phi(u))(v) = ((\Phi(v))(u))^*\,, \qquad \forall\, u, v \in \mathbb{V}\,, \tag{5.92}$$
and positive*,*
$$(\Phi(v))(v) > 0\,, \qquad \forall\, v \in \mathbb{V} \setminus \{0_{\mathbb{V}}\}\,. \tag{5.93}$$

Conversely, every inner product on $\mathbb{V}$ arises from exactly one Φ satisfying Equations (5.90), (5.92) and (5.93).

Rests on Definitions 5.17 and 5.56 and Equations (5.86) and (5.87).

Proof. *Derives Proposition 5.59.*

Part 1. $\Phi(u)$ is by construction an element of $\mathbb{V}^* = \mathcal{L}(\mathbb{V}, \mathbb{K})$, that is, a *linear* functional on $\mathbb{V}$. Hence, for $a, b \in \mathbb{K}$ and $v, w \in \mathbb{V}$,

$$\langle u|av + bw\rangle = (\Phi(u))(av + bw) = a(\Phi(u))(v) + b(\Phi(u))(w) = a\,\langle u|v\rangle + b\,\langle u|w\rangle\,,$$

which is Equation (5.34) (take $b = 0$) and Equation (5.35) (take $a = b = 1$). In the first slot the behaviour is that of Φ: by Equation (5.90),

$$\langle au + bv|w\rangle = (\Phi(au + bv))(w) = a^*(\Phi(u))(w) + b^*(\Phi(v))(w) = a^*\,\langle u|w\rangle + b^*\,\langle v|w\rangle\,,$$

which is Equation (5.36) and Equation (5.37). (For $\mathbb{K} = \mathbb{R}$ the conjugation is the identity and antilinearity is linearity, so the same two lines cover both fields.)

For non-degeneracy: if $\langle u|v\rangle = 0$ for every v then $\Phi(u)$ is the zero functional, and Φ being injective — with $\Phi(0_{\mathbb{V}}) = 0$ by Equation (5.90) — gives $u = 0_{\mathbb{V}}$. If instead $\langle u|v\rangle = 0$ for every u, then $f(v) = 0$ for every $f \in \mathbb{V}^*$, because Φ is surjective; taking f to be the dual-basis functional f^1 of Equation (5.86) built from a basis whose first element is v — possible if $v \neq 0_{\mathbb{V}}$ — would give $f^1(v) = 1 \neq 0$, a contradiction, so $v = 0_{\mathbb{V}}$.

Part 2. The three remaining axioms are, one by one, restatements of the two extra conditions.

- Hermiticity Equation (5.33) reads $\langle u|v\rangle^* = \langle v|u\rangle$, which written out through Equation (5.91) is exactly Equation (5.92).
- Positive definiteness Equation (5.32) reads $\langle v|v\rangle = (\Phi(v))(v) > 0$ for $v \neq 0_{\mathbb{V}}$, which is Equation (5.93).
- Identity of indiscernibles Equation (5.31): the direction ($\Leftarrow$) holds for any Φ, since $\Phi(0_{\mathbb{V}}) = 0$ and the zero functional sends every vector, in particular $0_{\mathbb{V}}$, to 0. The direction ($\Rightarrow$) is the contrapositive of Equation (5.93): if $v \neq 0_{\mathbb{V}}$ then $\langle v|v\rangle > 0 \neq 0$.

Converse. Given an inner product on $\mathbb{V}$, define $\Phi(u) = \langle u|\ \rangle$, the functional $v \mapsto \langle u|v\rangle$. It is a functional by Equations (5.34) and (5.35), it is antilinear in u by Equations (5.36) and (5.37), and it is injective, for $\Phi(u) = 0$ gives in particular $\langle u|u\rangle = 0$ and hence $u = 0_{\mathbb{V}}$ by Equation (5.31). An injective map that is $\mathbb{R}$-linear between two real vector spaces of the same finite dimension — and $\mathbb{V}$, $\mathbb{V}^*$ have the same dimension over $\mathbb{K}$, hence the same dimension over $\mathbb{R}$ — is surjective, so Φ is a bijection of the required kind, and it manifestly reproduces the given inner product through Equation (5.91). Uniqueness is immediate: two such maps agreeing in Equation (5.91) agree as functionals on every v, hence are equal. □

Remark 5.60 (Why an arbitrary isomorphism will not do). The source states Proposition 5.59 for an arbitrary isomorphism $\Phi : \mathbb{V} \longrightarrow \mathbb{V}^*$, on the strength of the isomorphism established after Equation (5.87). That is false, and it fails in two separate ways which are worth keeping apart.

- *Even over $\mathbb{R}$, most isomorphisms give no inner product.* Take $\mathbb{V} = \mathbb{R}^2$ with basis $\{e_1, e_2\}$ and the dual basis $\{f^1, f^2\}$ of Equation (5.86), and let Φ be the linear isomorphism with $\Phi(e_1) = f^2$ and $\Phi(e_2) = f^1$. Then $\langle e_1|e_1\rangle = f^2(e_1) = 0$ although $e_1 \neq 0_{\mathbb{V}}$, so both Equation (5.31) and Equation (5.32) fail. The choice $\Phi(e_1) = f^1$, $\Phi(e_2) = -f^2$ fails differently, giving $\langle e_2|e_2\rangle = -1$: it is a perfectly good non-degenerate symmetric form, of signature $(1, 1)$ rather than $(2, 0)$, and the reader will meet exactly this distinction again in Section 5.6.3. What Equation (5.91) produces from a bare isomorphism is a non-degenerate form, no more.
- *Over $\mathbb{C}$ no linear isomorphism can work at all.* Suppose Φ were $\mathbb{C}$-linear and Equation (5.91) an inner product. Linearity of Φ would give $\langle au|v\rangle = a\,\langle u|v\rangle$, whereas the axioms give $\langle au|v\rangle = a^*\,\langle u|v\rangle$ by Equation (5.36). Choosing $a = \mathrm{i}$ and $u = v$ with $\langle u|u\rangle = 1$, which Equation (5.32) permits, yields $\mathrm{i} = -\mathrm{i}$: a contradiction. Hence the map must be antilinear, as Equation (5.90) requires.

The upshot is the one physics uses constantly. The isomorphism $\mathbb{V} \simeq \mathbb{V}^*$ of Equation (5.87) is *not canonical* — it was built from a chosen basis, and a different basis gives a different isomorphism. An inner product is precisely the extra datum that singles one out, and the singled-out map is the antilinear correspondence $|v\rangle \longmapsto \langle v|$ of Dirac notation: the bra is the functional $\langle v|\ \rangle$, and it is conjugate-linear in the ket, which is why a phase $\mathrm{e}^{\mathrm{i}\theta}$ on a ket appears as $\mathrm{e}^{-\mathrm{i}\theta}$ on the corresponding bra. In infinite dimension the surjectivity step of the

converse is no longer a dimension count and becomes a theorem requiring completeness — the Riesz representation theorem [336], which this chapter uses nowhere and which belongs to Section 12.3.2, reserved for it there.

5.5.2 Pullback and pushforward

Pullback

Consider a linear transformation of the form $T : \mathbb{V} \longrightarrow \mathbb{W}$ and the linear functional $f : \mathbb{W} \longrightarrow \mathbb{K}$. Clearly $f \in \mathbb{W}^*$. We see moreover that $f \circ T : \mathbb{V} \longrightarrow \mathbb{K}$, and it is for this reason that $f \circ T \in \mathbb{V}^*$. We may ask: given a linear map T taking us from $\mathbb{V}$ to $\mathbb{W}$, what map can we define that brings us back from $\mathbb{W}^*$ to $\mathbb{V}^*$, in terms of T?

The answer is simple. We define the *pullback* of T under f as the map that takes f and assigns to it $f \circ T \in \mathbb{V}^*$. We symbolize the pullback of T as T^*. The idea is clearly illustrated in the diagram

$$\begin{array}{ccccc} \mathbb{V} & \xrightarrow{T} & \mathbb{W} & \xrightarrow{f} & \mathbb{K} \\ \mathbb{V}^* & \xleftarrow{T^*} & \mathbb{W}^* & & \\ f \circ T & \longleftarrow & f & & \end{array}$$

Pushforward

The pullback moves functionals backwards along T. The construction is completed by naming what moves forwards, and the two names together are what fix the index bookkeeping used for the rest of the treatise.

Notation 5.61 (The dual pairing). For $\omega \in \mathbb{V}^*$ and $v \in \mathbb{V}$ we write

$$\langle \omega, v \rangle = \omega(v) \in \mathbb{K} \tag{5.94}$$

and call it the *dual pairing*. It is linear in each argument separately — in v because ω is a functional, in ω because the vector-space operations on $\mathbb{V}^*$ are defined pointwise — so it is a bilinear map in the sense of Definition 5.106. It is *not* an inner product: it does not pair a space with itself, it involves no conjugation, and it needs no structure on $\mathbb{V}$ beyond the vector-space axioms.

Definition 5.62 (Pushforward)**.** Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation. The *pushforward* along T is the map

$$T_* : \mathbb{V} \longrightarrow \mathbb{W}\,, \qquad T_* v = T(v)\,. \tag{5.95}$$

It is T itself. The notation exists to record a direction, not a new object: a vector is carried *forwards* by T, from $\mathbb{V}$ to $\mathbb{W}$, whereas a functional is carried *backwards* by the pullback T^* of Section 5.5.2, from $\mathbb{W}^*$ to $\mathbb{V}^*$.

Rests on Definitions 5.35 and 5.56.

Proposition 5.63 (Adjointness of pullback and pushforward)**.** *Let $T : \mathbb{V} \longrightarrow \mathbb{W}$ be a linear transformation. Then T^* is a linear transformation $\mathbb{W}^* \longrightarrow \mathbb{V}^*$, and it is characterized by the identity*

$$\langle T^* \omega, v \rangle = \langle \omega, T_* v \rangle\,, \qquad \forall\, \omega \in \mathbb{W}^*,\ \forall\, v \in \mathbb{V}\,. \tag{5.96}$$

The two constructions compose in opposite orders: for $T : \mathbb{V} \longrightarrow \mathbb{W}$ and $S : \mathbb{W} \longrightarrow \mathbb{Z}$,

$$(S \circ T)_* = S_* \circ T_*\,, \tag{5.97}$$

$$(S \circ T)^* = T^* \circ S^*\,. \tag{5.98}$$

Finally, in a basis $\{e_i\}$ of $\mathbb{V}$ and a basis $\{f_a\}$ of $\mathbb{W}$ with their dual bases $\{\varepsilon^i\}$ and $\{\phi^a\}$ built as in Equation (5.86), the matrix of T^* is the transpose of that of T:

$$T^*\phi^a = \sum_i T^a{}_i\, \varepsilon^i \,. \tag{5.99}$$

Rests on Definitions 5.56 and 5.62 and Notation 5.61.

Proof. *Derives Proposition 5.63.*

Linearity of T^*. By definition $T^*\omega = \omega \circ T$, which is a functional on $\mathbb{V}$ as noted in Section 5.5.2. For $a, b \in \mathbb{K}$ and $\omega, \eta \in \mathbb{W}^*$, evaluation at an arbitrary $v \in \mathbb{V}$ gives

$$\left(T^*(a\omega + b\eta)\right)(v) = (a\omega + b\eta)\,(Tv) = a\,\omega(Tv) + b\,\eta(Tv) = \left(aT^*\omega + bT^*\eta\right)(v)\,,$$

the middle step being the pointwise definition of the operations on $\mathbb{W}^*$. Since v was arbitrary the two functionals are equal.

Equation (5.96). Both sides are the same number, written twice:

$$\langle T^*\omega, v\rangle = (\omega \circ T)\,(v) = \omega\,(T(v)) = \langle \omega, T_* v\rangle \ .$$

It characterizes T^* because a functional is determined by its values: if $\langle \Phi\omega, v\rangle = \langle \omega, T_* v\rangle$ for every v then $\Phi\omega$ and $T^*\omega$ agree at every point of $\mathbb{V}$.

The two composition laws. Equation (5.97) is the definition of composition. For Equation (5.98), evaluate on $\omega \in \mathbb{Z}^*$:

$$(S \circ T)^*\,\omega = \omega \circ (S \circ T) = (\omega \circ S) \circ T = T^*\,(S^*\omega) \ ,$$

associativity of composition doing the whole of the work. The same conclusion is reached from Equation (5.96) alone: $\langle (S\circ T)^*\omega, v\rangle = \langle \omega, S_* T_* v\rangle = \langle S^*\omega, T_* v\rangle = \langle T^* S^*\omega, v\rangle$ for all v.

Equation (5.99). Expand $T^*\phi^a$ in the dual basis of $\mathbb{V}^*$ using Equation (5.87), whose coefficients are the values on the basis of $\mathbb{V}$:

$$\begin{aligned}
\left(T^*\phi^a\right)(e_i) &= \phi^a\,(T(e_i)) \\
&= \phi^a\left(\sum_b T^b{}_i f_b\right) && \text{by Equation (5.74)} \\
&= \sum_b T^b{}_i\, \delta^a{}_b && \text{by Equation (5.86)} \\
&= T^a{}_i \,,
\end{aligned}$$

which is Equation (5.99). Note the index positions: the row index of $[T]$ has become the label of the pulled-back functional and the column index the label of the dual basis vector, which is what "transpose" means here. □

Remark 5.64 (Contravariant and covariant, settled once). The pair (T_*, T^*) is what fixes the index conventions used throughout the treatise, and the rule is best read off a change of basis. Let $e'_i = \sum_j A^j{}_i e_j$ with $[A]$ invertible, as in Equation (5.139). Comparing $v = \sum_i v'^i e'_i = \sum_j v^j e_j$ gives $v^j = \sum_i A^j{}_i v'^i$, that is

$$v' = [A]^{-1}\, v \,, \qquad g'_i = \sum_j A^j{}_i g_j \,, \tag{5.100}$$

the second equality being $g'_i = g(e'_i)$ read through Equation (5.84). The components of a *vector* therefore transform with the *inverse* of the basis change — they are *contravariant*, and carry an upper index — while the components of a *functional* transform with the change

itself — they are *covariant*, and carry a lower index. Nothing but Equation (5.96) is at work: the pairing $\langle g, v\rangle = \sum_i g_i v^i$ is a number, and a number cannot depend on the basis, so the two sets of components must transform by mutually inverse rules.

One asymmetry is worth stating plainly, because it is the reason the two names are not interchangeable. A vector can always be pushed forward and a functional can always be pulled back, for *any* linear T. The reverse operations do not exist in general: pushing a functional forward would require $(T^{-1})^*$, hence an invertible T. This is exactly the constraint that reappears on a manifold, where the same construction is performed pointwise on each tangent space — the pushforward acting on tangent vectors and the pullback on covectors (Definition 13.83) — and where the map is accordingly required to be a diffeomorphism before a vector *field* can be transported at all. See Chapter 13; the linear algebra done here is the whole of the content, repeated at every point.

5.6 Eigenvectors, eigenvalues, and decompositions

5.6.1 Eigenvectors and eigenvalues

Eigenvectors and eigenvalues of a linear transformation; characteristic polynomial; diagonalization

An operator mixes the directions of a space; the directions it does *not* mix are the ones along which its action is a single number, and they are what the rest of this section is about.

Definition 5.65 (Eigenvector, eigenvalue, eigenspace)**.** Let $T : \mathbb{V} \longrightarrow \mathbb{V}$ be an endomorphism of a vector space over $\mathbb{K}$. A vector $v \in \mathbb{V}$ is an *eigenvector* of T with *eigenvalue* $\lambda \in \mathbb{K}$ if

$$T(v) = \lambda v\,, \qquad v \neq 0_{\mathbb{V}}\,. \tag{5.101}$$

The set of all λ for which Equation (5.101) has a solution is the *spectrum* of T, and for each such λ the *eigenspace*

$$\mathbb{E}_\lambda = \ker\left(T - \lambda\mathbb{1}\right) = \{v \in \mathbb{V} \mid T(v) = \lambda v\} \tag{5.102}$$

is a subspace, by Definition 5.37; it consists of the eigenvectors for that λ together with $0_{\mathbb{V}}$, which the exclusion in Equation (5.101) keeps out of the list of eigenvectors and which the kernel necessarily contains.

Rests on Definitions 5.37 and 5.54.

The exclusion $v \neq 0_{\mathbb{V}}$ is not fussiness: without it every scalar would be an eigenvalue of every operator, and the notion would carry no information at all.

Definition 5.66 (Characteristic polynomial)**.** Let $\dim \mathbb{V} = n < \infty$ and let T be an endomorphism of $\mathbb{V}$ with matrix $[T]$ in some basis. The *characteristic polynomial* of T is

$$p_T(\mu) = \det\left([T] - \mu\mathbb{1}\right)\,. \tag{5.103}$$

Rests on Definition 5.54 and Equations (5.19) and (5.74).

Derivation. *Derives Definition 5.66.*

Two things have to be checked before Equation (5.103) defines anything: that it is a polynomial of degree n, and that it does not depend on the basis in which $[T]$ was written.

Degree. In the Leibniz sum Equation (5.19) for $\det\left([T] - \mu\mathbb{1}\right)$ the identity permutation contributes $\prod_{i=1}^{n}\left(T^i{}_i - \mu\right)$, a polynomial of degree n with leading term $(-1)^n\mu^n$. Any other permutation moves at least two indices, so at least two of its n factors are off-diagonal entries of $[T]$, carrying no μ; such a term has degree at most $n-2$ and cannot cancel the leading one. Hence $\deg p_T = n$ exactly.

Basis-independence. A change of basis conjugates the array. Let $e'_i = \sum_j A^j{}_i e_j$ with $[A]$ invertible, and let $[T']$ be the matrix of T in the primed basis. Expanding $T(e'_i)$ in the two ways Equation (5.74) allows,

$$T(e'_i) = \sum_j A^j{}_i T(e_j) = \sum_k \left(\sum_j T^k{}_j A^j{}_i \right) e_k \,,$$
$$T(e'_i) = \sum_l \left(T'\right)^l{}_i \, e'_l = \sum_k \left(\sum_l A^k{}_l \left(T'\right)^l{}_i \right) e_k \,,$$

and equating coefficients, which Proposition 5.43 permits, gives $[T]\,[A] = [A]\,[T']$, that is $[T'] = [A]^{-1}\,[T]\,[A]$ — the similarity law recorded again, in its algebra setting, in Remark 5.122. Since $[A]^{-1}\,\mathbb{1}\,[A] = \mathbb{1}$,

$$\begin{aligned} \det\left([A]^{-1}\,[T]\,[A] - \mu\mathbb{1}\right) &= \det\left([A]^{-1}\left([T] - \mu\mathbb{1}\right)[A]\right) \\ &= \det\left([A]^{-1}\right) \det\left([T] - \mu\mathbb{1}\right) \det[A] \\ &= \det\left([T] - \mu\mathbb{1}\right) \,, \end{aligned}$$

the determinant of a product being the product of the determinants and $\det\left([A]^{-1}\right) \det[A] = \det\mathbb{1} = 1$ by Equation (5.78). So p_T is an attribute of the operator, not of the array. □

Theorem 5.67 (The eigenvalues are the roots of the characteristic polynomial)**.** *Let $\dim\mathbb{V} = n < \infty$ and let T be an endomorphism of $\mathbb{V}$. A scalar $\lambda \in \mathbb{K}$ is an eigenvalue of T if and only if $p_T(\lambda) = 0$.*

Rests on Definitions 5.65 and 5.66 and Proposition 5.47.

Proof. *Derives Theorem 5.67.*

The chain is one of equivalences, each already available. Equation (5.101) has a solution $v \neq 0_{\mathbb{V}}$ exactly when $\ker(T - \lambda\mathbb{1}) \neq \{0_{\mathbb{V}}\}$, that is, exactly when the endomorphism $T - \lambda\mathbb{1}$ fails to be injective. By Proposition 5.47 — and here the finite dimension is indispensable — that is exactly when $T - \lambda\mathbb{1}$ fails to be invertible, which by Equation (5.81) is exactly when $\det([T] - \lambda\mathbb{1}) = 0$. The last expression is $p_T(\lambda)$. □

Corollary 5.68 (Existence of an eigenvalue over $\mathbb{C}$)**.** *Every endomorphism of a complex vector space $\mathbb{V}$ with $0 < \dim\mathbb{V} < \infty$ has at least one eigenvalue, and hence at least one eigenvector. Over $\mathbb{R}$ this fails: a rotation of $\mathbb{R}^2$ by an angle that is not a multiple of π has no eigenvector, its characteristic polynomial $\mu^2 - 2\mu\cos\theta + 1$ having no real root.*

Rests on Theorems 5.67 and 8.19.

Proof. *Derives Corollary 5.68.*

By Definition 5.66 the polynomial p_T has degree $n = \dim\mathbb{V} \geq 1$, so by the fundamental theorem of algebra (Theorem 8.19) it has a root $\lambda \in \mathbb{C}$, and Theorem 5.67 makes that root an eigenvalue. For the rotation, the matrix in the standard basis is $\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$, whose characteristic polynomial is $(\cos\theta - \mu)^2 + \sin^2\theta = \mu^2 - 2\mu\cos\theta + 1$ with discriminant $4\left(\cos^2\theta - 1\right) = -4\sin^2\theta$, negative unless $\sin\theta = 0$. □

This corollary is the only part of the present subsubsection that the rest of the chapter actually consumes: it is the step with which Schur's first lemma opens (Theorem 5.153), and the two hypotheses it carries — a complex field and a finite non-zero dimension — are inherited by everything that lemma supports, as Remark 5.154 records.

Definition 5.69 (Algebraic and geometric multiplicity)**.** Let λ be an eigenvalue of T. Its *algebraic multiplicity* is the multiplicity of λ as a root of p_T, that is, the largest m with $(\lambda - \mu)^m$ dividing $p_T(\mu)$; its *geometric multiplicity* is $\dim \mathbb{E}_\lambda$.

Rests on Definitions 5.65 and 5.66.

Proposition 5.70. *For every eigenvalue, $1 \leq$ geometric multiplicity $\leq$ algebraic multiplicity, and the second inequality can be strict.*

Rests on Definition 5.69, Lemma 5.36, and Equation (5.19).

Proof. *Derives Proposition 5.70.*

The first inequality restates that an eigenvalue has an eigenvector, so $\mathbb{E}_\lambda \neq \{0_\mathbb{V}\}$.

For the second, write $g = \dim \mathbb{E}_\lambda$, take a basis $\{u_1, \dots, u_g\}$ of $\mathbb{E}_\lambda$ and complete it by Lemma 5.36 to a basis $\{u_1, \dots, u_g, x_1, \dots, x_{n-g}\}$ of $\mathbb{V}$. Since $T(u_i) = \lambda u_i$, the first g columns of $[T]$ in this basis carry λ on the diagonal and nothing below row g:

$$[T] = \begin{pmatrix} \lambda \mathbb{1}_g & B \\ 0 & C \end{pmatrix} . \tag{5.104}$$

A block array of this shape has $\det = \det(\lambda \mathbb{1}_g) \det C$, as the Leibniz sum Equation (5.19) shows: a permutation σ contributes a non-zero term only if $\sigma(j) \leq g$ for every $j \leq g$, because the entries below the first g rows in those columns vanish; being injective, such a σ maps $\{1, \dots, g\}$ onto itself and therefore maps the remaining indices onto themselves as well, so it splits as a pair (σ_1, σ_2) with $\operatorname{sgn}(\sigma) = \operatorname{sgn}(\sigma_1) \operatorname{sgn}(\sigma_2)$ and the sum factorizes into the two Leibniz sums. Applying this to $[T] - \mu \mathbb{1}$, which has the same shape,

$$p_T(\mu) = (\lambda - \mu)^g \det(C - \mu \mathbb{1}) ,$$

so $(\lambda - \mu)^g$ divides p_T and the algebraic multiplicity is at least g.

That the inequality can be strict is shown by $[T] = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ on $\mathbb{C}^2$, the shear that reappears in Remark 5.147 as a representation of $\mathbb{Z}$: here $p_T(\mu) = (1 - \mu)^2$, so $\lambda = 1$ has algebraic multiplicity 2, while $[T] - \mathbb{1} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has a one-dimensional kernel, spanned by $(1, 0)^\mathsf{T}$, so the geometric multiplicity is 1. □

Proposition 5.71 (Eigenvectors for distinct eigenvalues are independent)**.** *Let $v_1, \dots, v_m$ be eigenvectors of T with pairwise distinct eigenvalues $\lambda_1, \dots, \lambda_m$. Then $\{v_1, \dots, v_m\}$ is linearly independent.*

Rests on Definitions 5.13 and 5.65.

Proof. *Derives Proposition 5.71.*

By induction on m. For $m = 1$ the statement is that a single non-zero vector is independent, which Equation (5.29) gives at once, since $a^1 v_1 = 0_\mathbb{V}$ with $v_1 \neq 0_\mathbb{V}$ forces $a^1 = 0$ (the remark after Equation (5.23)).

Assume the claim for $m - 1$ vectors and let $\sum_{i=1}^m a^i v_i = 0_\mathbb{V}$. Apply the linear operator $T - \lambda_m \mathbb{1}$ to both sides. Each term gives $a^i (T(v_i) - \lambda_m v_i) = a^i (\lambda_i - \lambda_m) v_i$, and the last term vanishes, so

$$\sum_{i=1}^{m-1} a^i (\lambda_i - \lambda_m) v_i = 0_\mathbb{V} .$$

By the induction hypothesis every coefficient vanishes, and $\lambda_i \neq \lambda_m$ for $i < m$ then forces $a^i = 0$. The original relation reduces to $a^m v_m = 0_\mathbb{V}$ with $v_m \neq 0_\mathbb{V}$, whence $a^m = 0$ as well. □

Definition 5.72 (Diagonalizable operator)**.** An endomorphism T of a finite-dimensional space is *diagonalizable* if there is a basis of $\mathbb{V}$ in which $[T] = \mathrm{diag}(\lambda_1, \dots, \lambda_n)$.

Rests on Definition 5.54 and Equation (5.74).

Theorem 5.73 (Criterion for diagonalizability)**.** *An endomorphism T of a space of finite dimension n is diagonalizable if and only if $\mathbb{V}$ possesses a basis consisting of eigenvectors of T. In particular T is diagonalizable whenever p_T has n distinct roots in $\mathbb{K}$.*

Rests on Definitions 5.65 and 5.72 and Proposition 5.71.

Proof. *Derives Theorem 5.73.*

Read Equation (5.74) in a basis $\{e_i\}$: the array $[T]$ is diagonal, with entries λ_i, precisely when $T(e_i) = \lambda_i e_i$ for every i — that is, precisely when every basis vector is an eigenvector. Both directions of the first claim are that one observation.

For the second, let p_T have n distinct roots $\lambda_1, \dots, \lambda_n$ in $\mathbb{K}$. Each is an eigenvalue by Theorem 5.67, so we may choose an eigenvector v_i for each; by Proposition 5.71 the set $\{v_1, \dots, v_n\}$ is linearly independent, and n independent vectors in a space of dimension n are a basis — by Lemma 5.36 they complete to a basis by the adjunction of $n - n = 0$ further vectors. □

Remark 5.74 (Not every operator is diagonalizable). The shear of Proposition 5.70 is not: a basis of eigenvectors would need two independent vectors in a one-dimensional eigenspace. This is the generic obstruction, and Proposition 5.70 localizes it exactly — T is diagonalizable if and only if the geometric multiplicities sum to n, which over an algebraically closed field means that each of them equals its algebraic partner. What replaces diagonalization in general is the Jordan normal form, which this treatise does not need and does not prove: every operator it diagonalizes in earnest is normal — self-adjoint or unitary — and for those Theorem 5.75 and its extension Corollary 5.78 settle the question outright. The shear is not normal, which is the structural reason it resists.

The spectral theorem

Physics almost never diagonalizes an arbitrary operator. It diagonalizes self-adjoint ones (Definition 5.39), and for those the answer is as strong as it could be: they are always diagonalizable, their eigenvalues are always real, and the diagonalizing basis can always be taken orthonormal.

Theorem 5.75 (Spectral theorem for a self-adjoint operator)**.** *Let $\mathbb{V}$ be a complex vector space with an inner product and $0 < \dim \mathbb{V} = n < \infty$, and let T be self-adjoint, $T^\dagger = T$. Then*

1. *every eigenvalue of T is real;*
2. *eigenvectors belonging to distinct eigenvalues are orthogonal;*
3. *$\mathbb{V}$ has an orthonormal basis $\{e_1, \dots, e_n\}$ of eigenvectors of T, in which*

$$[T] = \mathrm{diag}\,(\lambda_1, \dots, \lambda_n)\,, \qquad \lambda_i \in \mathbb{R}\,, \tag{5.105}$$

and $\mathbb{V}$ is the orthogonal direct sum of the eigenspaces.

Rests on Definition 5.39, Corollary 5.68, and Theorem 5.38.

Proof. *Derives Theorem 5.75.*

1. Let $T(v) = \lambda v$ with $v \neq 0_{\mathbb{V}}$. Then

$$\begin{aligned} \lambda \langle v|v\rangle &= \langle v|Tv\rangle && \text{by Equation (5.34)} \\ &= \left\langle T^\dagger v \middle| v \right\rangle && \text{by Equation (5.69)} \\ &= \langle Tv|v\rangle = \langle \lambda v|v\rangle \\ &= \lambda^* \langle v|v\rangle && \text{by Equation (5.36)}\,, \end{aligned}$$

and $\langle v|v\rangle > 0$ by Equation (5.32), so $\lambda = \lambda^*$.

2. Let $T(u) = \lambda u$ and $T(v) = \mu v$ with $\lambda \neq \mu$, both real by part 1. Then $\langle u|Tv\rangle = \mu \langle u|v\rangle$, while $\langle u|Tv\rangle = \left\langle T^\dagger u \middle| v \right\rangle = \langle Tu|v\rangle = \lambda^* \langle u|v\rangle = \lambda \langle u|v\rangle$. Subtracting, $(\mu - \lambda)\langle u|v\rangle = 0$, and $\mu \neq \lambda$ gives $\langle u|v\rangle = 0$.

3. By induction on n, the case $n = 0$ being vacuous. Let $n \geq 1$. By Corollary 5.68 — available because $\mathbb{K} = \mathbb{C}$ and $0 < n < \infty$ — there is an eigenvalue λ_1 with an eigenvector, which we normalize to a unit vector e_1 using Equation (5.41). Put $\mathbb{S} = \langle\{e_1\}\rangle$, so that Equation (5.52) gives $\mathbb{S}^\perp = \{w \in \mathbb{V} \mid \langle e_1|w\rangle = 0\}$.

The complement is T-invariant. For $w \in \mathbb{S}^\perp$,

$$\langle e_1|Tw\rangle = \left\langle T^\dagger e_1 \middle| w \right\rangle = \langle Te_1|w\rangle = \langle \lambda_1 e_1|w\rangle = \lambda_1^* \langle e_1|w\rangle = 0\,,$$

so $T(w) \in \mathbb{S}^\perp$.

Its dimension is $n - 1$. The map $w \longmapsto \langle e_1|w\rangle$ is a functional on $\mathbb{V}$ by Equations (5.34) and (5.35), whose kernel is $\mathbb{S}^\perp$ and whose image is the whole of $\mathbb{C}$, since it sends e_1 to 1. Equation (5.68) gives $\dim \mathbb{S}^\perp = n - 1$.

The restriction $T|_{\mathbb{S}^\perp}$ is an endomorphism of $\mathbb{S}^\perp$, and it is self-adjoint for the restricted inner product, since Equation (5.69) holds in particular for vectors lying in the subspace. The induction hypothesis therefore supplies an orthonormal basis $\{e_2, \ldots, e_n\}$ of $\mathbb{S}^\perp$ consisting of eigenvectors. Adjoining e_1, which is a unit vector orthogonal to every element of $\mathbb{S}^\perp$, gives an orthonormal set of n eigenvectors; it is a basis by Lemma 5.36, an orthonormal set being independent (a vanishing combination paired with e_j returns its j-th coefficient). Equation (5.105) is then Theorem 5.73, and the eigenvalues are real by part 1.

Finally, grouping the basis by eigenvalue writes $\mathbb{V}$ as a sum of subspaces $\mathbb{V}_\lambda \subseteq \mathbb{E}_\lambda$, mutually orthogonal by part 2. The inclusion is an equality: an eigenvector v with eigenvalue λ expands as $v = \sum_i \langle e_i|v\rangle\, e_i$, and pairing $T(v) = \lambda v$ with e_i gives $\lambda_i \langle e_i|v\rangle = \lambda \langle e_i|v\rangle$, so the coefficients with $\lambda_i \neq \lambda$ vanish and $v \in \mathbb{V}_\lambda$. □

Theorem 5.76 (Simultaneous diagonalization of commuting self-adjoint operators)**.** *Let A and B be self-adjoint operators on a complex inner-product space $\mathbb{V}$ with $0 < \dim \mathbb{V} < \infty$. There exists an orthonormal basis of $\mathbb{V}$ whose elements are eigenvectors of A and of B simultaneously if and only if*

$$[A, B] = AB - BA = \Theta\,. \tag{5.106}$$

Rests on Theorem 5.75, Definition 5.39, and Equation (5.102).

Proof. *Derives Theorem 5.76.*

(⇒) The easy direction. Let $\{e_i\}$ be a common eigenbasis, $Ae_i = \alpha_i e_i$ and $Be_i = \beta_i e_i$. Then

$$(AB)\, e_i = \beta_i\, Ae_i = \alpha_i \beta_i e_i = \alpha_i\, Be_i = (BA)\, e_i\,,$$

the scalars commuting in $\mathbb{C}$; two linear operators agreeing on a basis agree everywhere, so $[A, B] = \Theta$.

(⇐) Assume Equation (5.106). By Theorem 5.75 applied to A, the space is the orthogonal direct sum of the eigenspaces $\mathbb{E}_\lambda$ of A, over the finitely many distinct eigenvalues λ of A.

Each eigenspace of A is B-invariant. Let $v \in \mathbb{E}_\lambda$. Then

$$A\,(Bv) = B\,(Av) = B\,(\lambda v) = \lambda\,(Bv)\ ,$$

the first equality being Equation (5.106), so $Bv \in \mathbb{E}_\lambda$ by Equation (5.102). Note that this step, and only this step, uses the commutation.

The restriction $B|_{\mathbb{E}_\lambda}$ is therefore an endomorphism of $\mathbb{E}_\lambda$, and it is self-adjoint for the restricted inner product. Theorem 5.75, applied to it on the space $\mathbb{E}_\lambda$, supplies an orthonormal basis of $\mathbb{E}_\lambda$ consisting of eigenvectors of B; and every vector of $\mathbb{E}_\lambda$ is already an eigenvector of A with eigenvalue λ. Collecting these bases over all λ gives an orthonormal set — vectors from different eigenspaces are orthogonal by Theorem 5.75, part 2 — of $\sum_\lambda \dim \mathbb{E}_\lambda = \dim \mathbb{V}$ vectors, each an eigenvector of both operators. It is a basis for the reason given at the end of the proof of Theorem 5.75. □

Remark 5.77 (This is the theorem of compatible observables). Theorem 5.76 is the piece of linear algebra on which the quantum-mechanical notion of compatibility rests. An observable is represented by a self-adjoint operator (Postulate 77.2) and a measurement returns one of its eigenvalues (Postulate 77.3), so two observables can be assigned definite values in one and the same state exactly when the two operators share an eigenvector — and can be assigned definite values in *every* state of a complete set exactly when they share a whole eigenbasis, which by the theorem happens exactly when they commute. The familiar statement that non-commuting observables cannot be simultaneously sharp is the contrapositive of the direction proved first, the easy one: a common eigenbasis forces the two operators to commute, so operators that fail to commute have none. Note that the eigenvalues are the *measured* quantities and therefore carry SI units — joules for an energy, J s for an angular momentum — while the operators' being self-adjoint is what makes those numbers real, by part 1 of Theorem 5.75.

The other operator physics diagonalizes constantly is the unitary one, and self-adjointness plainly fails for it. Splitting an operator into a self-adjoint and an anti-self-adjoint part reduces that case to the two theorems just proved, at the cost of nothing new.

Corollary 5.78 (Spectral theorem for a normal operator)**.** *Let $\mathbb{V}$ be a complex vector space with an inner product and $0 < \dim \mathbb{V} < \infty$, and let A be an endomorphism of $\mathbb{V}$. Then $\mathbb{V}$ possesses an orthonormal basis of eigenvectors of A if and only if A is* normal*,*

$$A^\dagger A = A A^\dagger\,. \tag{5.107}$$

In particular every unitary operator, $U^\dagger U = U U^\dagger = \mathbb{1}$ (Equation (5.171)), is normal, hence orthonormally diagonalizable, and its eigenvalues all have modulus 1*.*

Rests on Theorem 5.76 and Proposition 5.40.

Proof. *Derives Corollary 5.78.*

Necessity. In an orthonormal eigenbasis $[A]$ is diagonal, so $\left[A^\dagger\right] = [A]^\dagger$ is the array of the conjugate eigenvalues by Equation (5.70), and two diagonal arrays commute.

Sufficiency. Put

$$H = \frac{1}{2}\left(A + A^\dagger\right)\ , \qquad K = \frac{1}{2\mathrm{i}}\left(A - A^\dagger\right)\ ,$$

so that $A = H + \mathrm{i}K$ and $A^\dagger = H - \mathrm{i}K$ by inspection. Both are self-adjoint: in an orthonormal basis Equation (5.70) makes $[H]^\dagger = \left([A]^\dagger + [A]\right)/2 = [H]$, while conjugating the factor $1/(2\mathrm{i})$ changes its sign and reversing the difference changes it back, so $[K]^\dagger = [K]$ as well. Multiplying out,

$$A^\dagger A = H^2 + K^2 + \mathrm{i}\,[H, K]\ , \qquad A A^\dagger = H^2 + K^2 - \mathrm{i}\,[H, K]\ ,$$

so Equation (5.107) holds precisely when $[H, K] = \Theta$. Theorem 5.76 then supplies an orthonormal basis $\{e_i\}$ with $He_i = h_i e_i$ and $Ke_i = k_i e_i$, the eigenvalues real by part 1 of Theorem 5.75, whence $Ae_i = (h_i + \mathrm{i}k_i)\, e_i$: the basis diagonalizes A, with eigenvalues sweeping the complex plane rather than the real line.

Unitary operators. $U^\dagger U = UU^\dagger = \mathbb{1}$ is Equation (5.107) outright. If $Ue = \lambda e$ with $e \neq 0_{\mathbb{V}}$, then Equations (5.34), (5.36) and (5.69) give $\langle e|e\rangle = \left\langle U^\dagger U e \middle| e \right\rangle = \langle Ue|Ue\rangle = |\lambda|^2 \langle e|e\rangle$, and $\langle e|e\rangle > 0$ by Equation (5.32) leaves $|\lambda| = 1$. □

Remark 5.79 (What fails in infinite dimension). Every step above used $\dim \mathbb{V} < \infty$, and the failure in infinite dimension is not a technicality but a change of subject.

- *An operator may have no eigenvalue at all.* On the space of square-integrable functions on an interval, multiplication by the coordinate, $(Qf)(x) = xf(x)$, is self-adjoint and bounded, yet $Qf = \lambda f$ forces f to vanish wherever $x \neq \lambda$, hence to be the zero element. Corollary 5.68 is unavailable because p_T does not exist: there is no determinant.

- *The spectrum must therefore be redefined*, as the set of λ for which $T - \lambda\mathbb{1}$ fails to be invertible rather than the set for which it fails to be injective — two conditions that Proposition 5.47 makes identical here and that Remark 5.48 has already shown to part company.

- *The diagonal sum is replaced by an integral.* The finite-dimensional statement Equation (5.105) becomes a spectral decomposition against a projection-valued measure, which is the form the theorem takes for the operators of quantum mechanics, including the unbounded ones whose domains must be specified before the word "self-adjoint" even means anything [706]. All of this, the spectral theorem in its Hilbert-space form and the specification of domains alike, is the business of Chapter 12.

What survives unchanged is parts 1 and 2 of Theorem 5.75: their proofs used only Equation (5.69) and the inner-product axioms, never a basis or a dimension.

The real symmetric case

Theorem 5.75 is a statement about a complex space, and it has to be: its proof reaches for Corollary 5.68, which holds over $\mathbb{C}$ and fails over $\mathbb{R}$. The operators of mechanics, however, are real symmetric arrays — a matrix of masses, a matrix of stiffnesses, a tensor of inertia — and their eigenvectors have to be real if they are to be displacements or axes. What follows is the real form of the theorem, obtained by borrowing from the complex one only the one thing $\mathbb{R}$ cannot supply, namely that the roots exist.

Theorem 5.80 (Spectral theorem for a real symmetric operator)**.** *Let $\mathbb{V}$ be a* real *vector space with an inner product and $0 < \dim \mathbb{V} = n < \infty$, and let S be self-adjoint, $\langle Su|v\rangle = \langle u|Sv\rangle$ for all $u, v \in \mathbb{V}$. Then the characteristic polynomial of S has n real roots counted with multiplicity, and $\mathbb{V}$ possesses an orthonormal basis $\{e_1, \ldots, e_n\}$ of eigenvectors of S. Equivalently: for every real symmetric array A of order n there is a real orthogonal R, $R^{\mathsf{T}}R = \mathbb{1}$, with*

$$R^{\mathsf{T}} A R = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)\,, \qquad \lambda_r \in \mathbb{R}\,. \tag{5.108}$$

Rests on Theorems 5.67 and 5.75 and Proposition 5.26.

Proof. *Derives Theorem 5.80.*

The two statements are one. Fix an orthonormal basis of $\mathbb{V}$, which exists by Proposition 5.26, and let A be the matrix of S in it. Over $\mathbb{R}$ the conjugation in Equation (5.70) is the identity, so self-adjointness reads $A^{\mathsf{T}} = A$; and a basis of eigenvectors written as

the columns of R turns orthonormality into $R^{\mathsf{T}}R = \mathbb{1}$ and the eigenvalue equations into Equation (5.108).

The roots are real. Read the same array A as the matrix of an operator on $\mathbb{C}^n$ with the standard inner product $\langle u|v\rangle = \sum_i (u^i)^* v^i$. Its adjoint matrix is the conjugate transpose Equation (5.70), which for a real symmetric A is A itself, so the operator is self-adjoint and part 1 of Theorem 5.75 makes every one of its eigenvalues real. The characteristic polynomial is the same polynomial in both readings, being computed from the same array by Equation (5.19); over $\mathbb{C}$ it has n roots with multiplicity by Theorem 8.19, and each of them is an eigenvalue by Theorem 5.67, hence real.

Each root has a real eigenvector. Let λ be one of them. It is a real scalar and a root of the characteristic polynomial of S, so Theorem 5.67 — applied now over $\mathbb{K} = \mathbb{R}$, where it holds verbatim — makes it an eigenvalue of S: there is a $v \in \mathbb{V} \setminus \{0_{\mathbb{V}}\}$ with $Sv = \lambda v$. This is the step at which the complexification is discharged, and it is the only one that needed it.

Induction on n. Normalize $e_1 = v/\|v\|$ and let $\mathbb{S}^{\perp}$ be the orthogonal complement Equation (5.52) of $\langle\{e_1\}\rangle$. The computation made in part 3 of the proof of Theorem 5.75 used only Equation (5.69) and the inner-product axioms, never the complex field, so it holds here word for word: $\mathbb{S}^{\perp}$ is S-invariant, $\dim \mathbb{S}^{\perp} = n - 1$ by Equation (5.68), and the restriction of S to it is self-adjoint for the restricted inner product. The induction hypothesis supplies an orthonormal basis $\{e_2, \dots, e_n\}$ of $\mathbb{S}^{\perp}$ made of eigenvectors, and adjoining e_1 completes one for $\mathbb{V}$. □

Remark 5.81 (Principal axes). Equation (5.108) is the statement a physicist uses under the name *principal axes*: a real symmetric array — of inertia, of strain, of stress, of electric polarizability — is diagonal in some orthonormal frame, and that frame is obtained from any other by a rotation or a reflection, never by a shear. The eigenvalues are then physically measured numbers and carry SI units: $\mathrm{kg\,m^2}$ for the principal moments of inertia, Pa for the principal stresses. Note what distinguishes this from Theorem 5.112, which also brings a real symmetric form to a diagonal one: there the change of basis is an arbitrary congruence and only the *signs* survive it, here it is orthogonal and the eigenvalues themselves survive. Both are true of the same array and they answer different questions.

Theorem 5.82 (Simultaneous diagonalization of a definite pencil)**.** *Let M and K be real symmetric arrays of order n with M positive definite. Then there is an invertible real array U with*

$$U^{\mathsf{T}}MU = \mathbb{1}\,, \qquad U^{\mathsf{T}}KU = \operatorname{diag}(\lambda_1, \dots, \lambda_n)\,, \qquad \lambda_r \in \mathbb{R}\,. \tag{5.109}$$

Equivalently, the generalized eigenvalue problem

$$Ku = \lambda Mu \tag{5.110}$$

has exactly n real roots $\lambda_1, \dots, \lambda_n$ counted with multiplicity, and $\mathbb{R}^n$ has a basis $\{u_1, \dots, u_n\}$ of solutions which is orthonormal for the inner product $\langle u|v\rangle_M = u^{\mathsf{T}}Mv$. The numbers of positive, negative and vanishing λ_r are the triple (p, q, r) that Theorem 5.112 attaches to K, and are therefore the same for every U achieving Equation (5.109).

Rests on Theorems 5.80 and 5.112 and Proposition 5.26.

Proof. *Derives Theorem 5.82.*

M supplies an inner product. Put $\langle u|v\rangle_M = u^{\mathsf{T}}Mv$ on $\mathbb{R}^n$. It is linear in each argument by inspection, symmetric because $M^{\mathsf{T}} = M$, and positive definite by hypothesis, so it satisfies Equations (5.31) to (5.35) and is an inner product in the sense of Definition 5.17, the conjugation being trivial over $\mathbb{R}$.

A first change of basis makes M the identity. Proposition 5.26, applied to the standard basis of $\mathbb{R}^n$ in this inner product, produces a basis $\{w_1, \dots, w_n\}$ with $\langle w_k|w_l\rangle_M = \delta_{kl}$. Let W be the array whose columns are the w_k: it is invertible, its columns being a basis, and the orthonormality relations are exactly $W^{\mathsf{T}}MW = \mathbb{1}$.

A second, orthogonal, change of basis diagonalizes K. The array $\tilde{K} = W^{\mathsf{T}} K W$ is real and symmetric, since $\left(W^{\mathsf{T}} K W\right)^{\mathsf{T}} = W^{\mathsf{T}} K^{\mathsf{T}} W = \tilde{K}$. By Theorem 5.80 there is a real orthogonal R with $R^{\mathsf{T}} \tilde{K} R = \operatorname{diag}(\lambda_r)$ and every λ_r real. Put $U = WR$, invertible as a product of invertible arrays. Then

$$U^{\mathsf{T}} M U = R^{\mathsf{T}} \left(W^{\mathsf{T}} M W\right) R = R^{\mathsf{T}} R = \mathbb{1}\,, \qquad U^{\mathsf{T}} K U = R^{\mathsf{T}} \tilde{K} R = \operatorname{diag}(\lambda_r)\,,$$

which is Equation (5.109).

The second statement is the first one read column by column. Write u_r for the r-th column of U. The first relation of Equation (5.109) says $u_k^{\mathsf{T}} M u_l = \delta_{kl}$, the asserted M-orthonormality; and with $\Lambda = \operatorname{diag}(\lambda_r)$ the two relations combine into $U^{\mathsf{T}} K U = \Lambda = U^{\mathsf{T}} M U \Lambda$, so that $U^{\mathsf{T}}(KU - MU\Lambda) = 0$ and, U^{T} being invertible, $KU = MU\Lambda$ — whose r-th column is Equation (5.110) for u_r with $\lambda = \lambda_r$. That these are all the roots follows from

$$\det(K - \lambda M) = (\det U)^{-2} \det\left(U^{\mathsf{T}} K U - \lambda\, U^{\mathsf{T}} M U\right) = (\det U)^{-2} \prod_{r=1}^{n} (\lambda_r - \lambda)\,,$$

a polynomial of degree n whose roots with multiplicity are the λ_r.

Signature. Equation (5.109) exhibits $\operatorname{diag}(\lambda_r)$ as congruent to K in the sense of Equation (5.139). Rescaling each column of U by $|\lambda_r|^{-1/2}$ wherever $\lambda_r \neq 0$ is a further congruence and brings the array to Equation (5.142) with p, q and r the counts of positive, negative and vanishing λ_r; Theorem 5.112 says those counts are the same for every basis reaching that form. □

Remark 5.83 (What a definite pencil is). The hypothesis that carries Theorem 5.82 is the definiteness of *one* of the two forms, not of both: K is allowed any signature, and the sign of λ_r records it. Neither $M^{-1}K$ nor KM^{-1} is symmetric in general, which is why the theorem is not a corollary of Theorem 5.80 applied to one of them; what is true, and is what the proof exploits, is that $M^{-1}K$ is self-adjoint for the inner product M itself defines. The statement fails outright without definiteness — for $M = \operatorname{diag}(1, -1)$ and $K = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ the roots of Equation (5.110) are $\pm\mathrm{i}$ — so the positive definiteness is not a convenience. In mechanics it is supplied by the kinetic energy: M is a matrix of masses, in kg, and $u^{\mathsf{T}} M u$ is twice a kinetic energy per unit squared velocity, which is positive for every motion that is not rest.

Proposition 5.84 (Rayleigh quotient of a definite pencil)**.** *In the notation of Theorem 5.82, order the roots $\lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_n$ and define the* Rayleigh quotient

$$\mathcal{R}(u) = \frac{u^{\mathsf{T}} K u}{u^{\mathsf{T}} M u}\,, \qquad u \in \mathbb{R}^n \setminus \{0\}\,. \tag{5.111}$$

Then

$$\lambda_1 \leq \mathcal{R}(u) \leq \lambda_n\,, \tag{5.112}$$

and $\mathcal{R}(u) = \lambda_1$ holds exactly when u solves Equation (5.110) with $\lambda = \lambda_1$, while $\mathcal{R}(u) = \lambda_n$ holds exactly when it solves it with $\lambda = \lambda_n$. In particular λ_1 is the minimum and λ_n the maximum of $\mathcal{R}$, both attained.

Rests on Theorem 5.82.

Proof. *Derives Proposition 5.84.*

The denominator never vanishes, M being positive definite. Expand u in the M-orthonormal basis of Theorem 5.82, $u = \sum_r c^r u_r$, not all c^r zero. Then $u^{\mathsf{T}} M u = \sum_r (c^r)^2$ and $u^{\mathsf{T}} K u = \sum_r \lambda_r (c^r)^2$, so

$$\mathcal{R}(u) = \frac{\sum_r \lambda_r (c^r)^2}{\sum_r (c^r)^2}\,, \tag{5.113}$$

a weighted average of the roots with non-negative weights not all zero, which lies between the smallest and the largest of them — that is Equation (5.112). Subtracting,

$$\mathcal{R}(u) - \lambda_1 = \frac{\sum_r (\lambda_r - \lambda_1)\,(c^r)^2}{\sum_r (c^r)^2}\,,$$

a sum of non-negative terms, which vanishes exactly when $c^r = 0$ for every r with $\lambda_r > \lambda_1$ — that is, exactly when u lies in the span of the u_r belonging to λ_1, which by Equation (5.110) is exactly the solution set for $\lambda = \lambda_1$. The maximum is the same computation with the signs reversed, and both are attained, at u_1 and at u_n. □

Corollary 5.85 (Rayleigh–Ritz)**.** *Every trial vector bounds the lowest root from above, $\lambda_1 \le \mathcal{R}(u)$, and the bound is second-order accurate: if $u = u_1 + w$ with w M-orthogonal to u_1 and $w^{\mathsf{T}} M w = \varepsilon^2$, then*

$$0 \le \mathcal{R}(u) - \lambda_1 \le (\lambda_n - \lambda_1)\,\frac{\varepsilon^2}{1+\varepsilon^2}\,. \tag{5.114}$$

A first-order error in the trial vector therefore costs only a second-order error in the estimate, which is what makes the method worth using.

Rests on Proposition 5.84 and Theorem 5.82.

Proof. *Derives Corollary 5.85.*

The inequality $\lambda_1 \le \mathcal{R}(u)$ is Equation (5.112). For the estimate, write $w = \sum_{r\ge 2} c^r u_r$ — legitimate because w is M-orthogonal to u_1 — so that $\varepsilon^2 = \sum_{r\ge 2} (c^r)^2$ and, by Equation (5.113) with $c^1 = 1$,

$$\mathcal{R}(u) - \lambda_1 = \frac{\sum_{r\ge 2} (\lambda_r - \lambda_1)\,(c^r)^2}{1+\varepsilon^2} \le (\lambda_n - \lambda_1)\,\frac{\varepsilon^2}{1+\varepsilon^2}\,,$$

each factor $\lambda_r - \lambda_1$ being at most $\lambda_n - \lambda_1$. □

Proposition 5.86 (Polar decomposition)**.** *Every invertible real array A of order n factors as*

$$A = OP\,, \qquad O^{\mathsf{T}} O = \mathbb{1}\,, \qquad P^{\mathsf{T}} = P \text{ positive definite}\,, \tag{5.115}$$

and the two factors are uniquely determined by A.

Rests on Theorem 5.80 and Proposition 5.47.

Proof. *Derives Proposition 5.86.*

Existence. $B = A^{\mathsf{T}} A$ is symmetric, and for $x \neq 0$, $x^{\mathsf{T}} B x = (Ax)^{\mathsf{T}} (Ax) > 0$, since A is invertible and therefore injective (Proposition 5.47), so $Ax \neq 0$. By Theorem 5.80, $B = R\,\mathrm{diag}\,(\mu_r)\,R^{\mathsf{T}}$ with R orthogonal, and each $\mu_r > 0$, being $x^{\mathsf{T}} B x$ for the corresponding unit eigenvector. Put

$$P = R\,\mathrm{diag}\,(\sqrt{\mu_r})\,R^{\mathsf{T}}\,,$$

symmetric by inspection, positive definite because its eigenvalues $\sqrt{\mu_r}$ are positive, and satisfying $P^2 = B$ and hence invertible. Set $O = AP^{-1}$; then, P^{-1} being symmetric,

$$O^{\mathsf{T}} O = P^{-1} A^{\mathsf{T}} A P^{-1} = P^{-1} P^2 P^{-1} = \mathbb{1}\,.$$

Uniqueness. Suppose $A = OP$ as in Equation (5.115). Then $A^{\mathsf{T}} A = P\,O^{\mathsf{T}} O\,P = P^2$, so P is *a* positive definite symmetric square root of the array B fixed by A. There is only one. Indeed such a P commutes with $B = P^2$, so it maps each eigenspace $\mathbb{E}_\mu$ of B into itself: $Bx = \mu x$ gives $B(Px) = P(Bx) = \mu\,Px$. The restriction of P to $\mathbb{E}_\mu$ is symmetric, so by Theorem 5.80 that subspace has a basis of eigenvectors of P, whose eigenvalues ν satisfy $\nu^2 = \mu$ and $\nu > 0$, hence $\nu = \sqrt{\mu}$: P acts on $\mathbb{E}_\mu$ as multiplication by $\sqrt{\mu}$. Since the eigenspaces of B span $\mathbb{R}^n$ by Theorem 5.80, P is determined by B, and then $O = AP^{-1}$ is determined too. □

Corollary 5.87 (The operator norm of a real array)**.** *For a real array L of order n put $\|L\| = \max\{\|Lx\| \mid x \in \mathbb{R}^n,\ \|x\| = 1\}$, the maximum being attained. Then*

$$\|L\|^2 = \lambda_{\max}\left(L^{\mathsf{T}}L\right) = \lambda_{\max}\left(LL^{\mathsf{T}}\right), \tag{5.116}$$

the largest eigenvalue of either of those two symmetric positive semi-definite arrays.
Rests on Proposition 5.84 and Theorem 5.80.

Proof. *Derives Corollary 5.87.*
$\|Lx\|^2 = x^{\mathsf{T}}\left(L^{\mathsf{T}}L\right)x$, and $L^{\mathsf{T}}L$ is symmetric with $x^{\mathsf{T}}L^{\mathsf{T}}Lx = \|Lx\|^2 \geq 0$, hence positive semi-definite. Taking $M = \mathbb{1}$ in Proposition 5.84, which is legitimate because the identity is positive definite, the quotient $\|Lx\|^2 / \|x\|^2$ has maximum $\lambda_{\max}\left(L^{\mathsf{T}}L\right)$, attained at a corresponding eigenvector; restricting to $\|x\| = 1$ gives the first equality of Equation (5.116) and the attainment.

For the second, let $L^{\mathsf{T}}Lv = \lambda v$ with $v \neq 0$ and $\lambda \neq 0$. Then $Lv \neq 0$, since $L^{\mathsf{T}}Lv \neq 0$, and $LL^{\mathsf{T}}(Lv) = L\left(L^{\mathsf{T}}Lv\right) = \lambda Lv$: every non-zero eigenvalue of $L^{\mathsf{T}}L$ is one of LL^{T}, and by symmetry of the argument the converse holds too. If instead $\lambda_{\max}\left(L^{\mathsf{T}}L\right) = 0$ then, all its eigenvalues being non-negative and at most 0, $L^{\mathsf{T}}L$ has every eigenvalue zero, so $\|Lx\|^2 = 0$ for every x by Equation (5.108), so $L = 0$ and both sides vanish. □

Proposition 5.88 (The eigenvalues do not control the norm)**.** *Let A be a real array of order $n \geq 2$ and $\|A\|$ its operator norm.*

1. *If $Av = \lambda v$ with $v \in \mathbb{R}^n \setminus \{0\}$ and $\lambda \in \mathbb{R}$, then $|\lambda| \leq \|A\|$.*
2. *If A is symmetric, then $\|A\| = \max_r |\lambda_r|$ over its eigenvalues.*
3. *Without symmetry the second statement fails, and fails unboundedly: for*

$$A = \begin{pmatrix} \lambda & c \\ 0 & \lambda \end{pmatrix} \tag{5.117}$$

— extended to order n by zeros — every eigenvalue has modulus $|\lambda|$ or is zero, while $\|A\| \geq |c|$, and c is free.

Rests on Corollary 5.87 and Theorem 5.80.

Proof. *Derives Proposition 5.88.*
1. Normalize v; then $|\lambda| = \|\lambda v\| = \|Av\| \leq \|A\|$ by the definition of the operator norm.
2. For symmetric A, Equation (5.108) gives $A^{\mathsf{T}}A = A^2 = R\,\mathrm{diag}\left(\lambda_r^2\right)R^{\mathsf{T}}$, so the eigenvalues of $A^{\mathsf{T}}A$ are the λ_r^2 and Equation (5.116) gives $\|A\|^2 = \max_r \lambda_r^2$.
3. The characteristic polynomial of Equation (5.117) is $(\lambda - \mu)^2$, so λ is its only eigenvalue, whatever c; the padding contributes only the eigenvalue 0. Applying A to the second standard basis vector gives the vector with components (c, λ), of norm at least $|c|$, so $\|A\| \geq |c|$. □

Remark 5.89 (What this costs elsewhere). Proposition 5.88 is the linear-algebraic root of a fact that surprises whoever meets it first in a physical problem: an array every one of whose eigenvalues is small can still stretch some vector by a large factor. The eigenvectors of a non-symmetric array are in general not orthogonal, so a superposition of them can be much shorter than its individual terms, and cancellations of that kind can be undone by the array. The dynamical consequence — that a linear system every one of whose modes decays can nevertheless amplify a disturbance by a large factor before decaying — is a statement about the exponential of A rather than about A, and this chapter does not make it; what belongs here is the statement that the spectrum is not the norm.

Quadrics and the conic sections

Proposition 5.90 (Principal axes of a real quadratic form)**.** *Let $q(x) = x^{\mathsf{T}} A x$ on $\mathbb{R}^n$ with A real and symmetric. Then there is an orthogonal change of coordinates $x = Ry$ in which*

$$q = \sum_{r=1}^{n} \lambda_r \, (y^r)^2 \,, \tag{5.118}$$

the λ_r being the eigenvalues of A and the columns of R — the principal axes *of q — an orthonormal basis of eigenvectors. The level set $\{q = 1\}$ is accordingly an ellipsoid when every $\lambda_r > 0$; when the signs differ it is a hyperboloid, when some λ_r vanishes a cylinder over one of these, and when no λ_r is positive it is empty.*

Rests on Theorems 5.80 and 5.112 and Definition 5.113.

Proof. *Derives Proposition 5.90.*

Substituting $x = Ry$ gives $q = y^{\mathsf{T}} \left(R^{\mathsf{T}} A R \right) y$, and Equation (5.108) makes the array in the middle diagonal with the eigenvalues along it, which is Equation (5.118). The level set is then read off Equation (5.118) term by term, and the pattern of signs is the signature of Theorem 5.112 and Definition 5.113, hence independent of every choice made along the way. □

Proposition 5.91 (The focal polar equation of a conic)**.** *Let $p > 0$ and $e \geq 0$, and let $C \subset \mathbb{R}^2$ be the set of points whose polar coordinates $x = r\cos\varphi$, $y = r\sin\varphi$ with $r > 0$ satisfy*

$$r = \frac{p}{1 + e\cos\varphi} \,. \tag{5.119}$$

Then C is exactly the set of points of the quadric

$$\left(1 - e^2\right) x^2 + y^2 + 2pe\, x - p^2 = 0 \tag{5.120}$$

obeying $ex < p$; and for $e > 0$ it is the locus of points whose distance to the origin is e times their distance to the line $x = p/e$. The quadratic part of Equation (5.120) is already in the principal axes of Proposition 5.90, with eigenvalues $1 - e^2$ and 1, so that

1. *for $0 \leq e < 1$, C is an ellipse with semi-axes*

$$a = \frac{p}{1 - e^2} \,, \qquad b = \frac{p}{\sqrt{1 - e^2}} \,, \tag{5.121}$$

   centred at $(-ae, 0)$: the origin is one of its two foci, the foci lie $2ae$ apart, and the area enclosed is πab;

2. *for $e = 1$, C is the parabola $y^2 = p^2 - 2px$, whose focus is the origin;*

3. *for $e > 1$, C is the branch $ex < p$ of a hyperbola, again with the origin at a focus.*

In every case $p = r(\pi/2)$, the semi-latus rectum.

Rests on Proposition 5.90, Equation (5.10), and Corollary 7.44.

Proof. *Derives Proposition 5.91.*

The two descriptions agree. Multiplying Equation (5.119) out and using $r\cos\varphi = x$ gives

$$r = p - ex \,, \tag{5.122}$$

which requires $ex < p$ because $r > 0$; squaring it and substituting $r^2 = x^2 + y^2$ produces Equation (5.120). Conversely let a point satisfy Equation (5.120) with $ex < p$. It is not the origin, which would give $-p^2 = 0$, so $r > 0$; and Equation (5.120) says $r^2 = (p - ex)^2$ with $p - ex > 0$, so Equation (5.122) holds and, divided by r, returns Equation (5.119). For $e > 0$

the distance from the point to the line $x = p/e$ is $p/e - x$, positive by the same inequality, and Equation (5.122) says exactly $r = e\,(p/e - x)$. Putting $\varphi = \pi/2$ in Equation (5.119) gives $r = p$.

$0 \le e < 1$. Completing the square in Equation (5.120),

$$\left(1 - e^2\right)\left(x + \frac{pe}{1 - e^2}\right)^2 + y^2 = p^2 + \frac{p^2e^2}{1 - e^2} = \frac{p^2}{1 - e^2}\,,$$

and dividing by the right-hand side gives

$$\frac{(x + ae)^2}{a^2} + \frac{y^2}{b^2} = 1 \tag{5.123}$$

with a and b as in Equation (5.121), since $pe/(1 - e^2) = ae$. This is an ellipse centred at $(-ae, 0)$, and

$$a^2 - b^2 = \frac{p^2}{(1 - e^2)^2} - \frac{p^2}{1 - e^2} = \frac{p^2e^2}{(1 - e^2)^2} = (ae)^2\,,$$

so the two foci, at distance $\sqrt{a^2 - b^2} = ae$ from the centre along the major axis, are the origin and $(-2ae, 0)$. The side condition $ex < p$ is automatic here: Equation (5.123) confines x to $x \le a(1 - e) = p/(1 + e)$, and $ep/(1 + e) < p$.

The area. For each $u = x + ae$ in $[-a, a]$, Equation (5.123) gives a vertical segment of length $2b\sqrt{1 - u^2/a^2}$, so the area enclosed is, substituting first $u = at$ and then $t = \sin\theta$ by Corollary 7.44,

$$\begin{aligned}
\int_{-a}^{a} 2b\sqrt{1 - \frac{u^2}{a^2}}\,\mathrm{d}u &= 2ab\int_{-1}^{1}\sqrt{1 - t^2}\,\mathrm{d}t \\
&= 2ab\int_{-\pi/2}^{\pi/2}\cos^2\theta\,\mathrm{d}\theta \\
&= ab\int_{-\pi/2}^{\pi/2}(1 + \cos 2\theta)\,\mathrm{d}\theta \qquad \text{by Equation (5.10)} \\
&= \pi ab\,,
\end{aligned}$$

the integral of $\cos 2\theta$ vanishing over a full period of it.

$e = 1$ and $e > 1$. For $e = 1$ the quadratic part loses its x^2 term and Equation (5.120) becomes $y^2 = p^2 - 2px$, a parabola with vertex $(p/2, 0)$ opening towards decreasing x; written as $y^2 = -2p\,(x - p/2)$ it has focal length $p/2$, so its focus is at $(p/2 - p/2, 0)$, the origin. For $e > 1$ the eigenvalues $1 - e^2$ and 1 have opposite signs, so by Proposition 5.90 the quadric is a hyperbola; the side condition $ex < p$ selects the branch containing the point $\varphi = \pi/2$, since the other branch lies where $p - ex < 0$. □

Remark 5.92 (Why a physics chapter needs this). Equation (5.119) is the form in which an orbit under an inverse-square force emerges from its equation of motion, with p and e built out of the angular momentum and the energy. Without Proposition 5.91 the sentence "the orbit is an ellipse with the force centre at a focus" would be a name attached to a formula; with it, it is a theorem about a locus, and the semi-axes Equation (5.121) and the area πab are what turn the formula into the periods that are actually measured. The three cases are distinguished by the signature of the quadratic part, so the trichotomy ellipse–parabola–hyperbola is a statement about Theorem 5.112 and not about the coordinates chosen.

Generalized eigenspaces

Theorem 5.73 tells us when an operator has an eigenbasis. When it has none, the question is what it has instead, and the answer over $\mathbb{C}$ is that the space still splits into subspaces on each of which the operator is a scalar plus something nilpotent. That is all the structure the physical parts of this treatise ever use, and it is proved here in full.

Lemma 5.93 (Fitting splitting)**.** *Let T be an endomorphism of a vector space $\mathbb{V}$ over $\mathbb{K}$ with $\dim \mathbb{V} = n < \infty$, let $\lambda \in \mathbb{K}$, and write $N = T - \lambda \mathbb{1}$. Then*

$$\mathbb{V} = \ker\left(N^n\right) \oplus \operatorname{im}\left(N^n\right) , \tag{5.124}$$

both summands are T-invariant, and N is nilpotent on the first and invertible on the second.
Rests on Theorem 5.38, Definition 5.37, and Proposition 5.47.

Proof. *Derives Lemma 5.93.*

The kernels stabilize by step n. The subspaces $\ker\left(N^k\right)$ increase with k. If two consecutive ones agree, $\ker\left(N^k\right) = \ker\left(N^{k+1}\right)$, the chain is constant from there on: $N^{k+2}v = 0$ gives $N^{k+1}\left(Nv\right) = 0$, so $Nv \in \ker\left(N^{k+1}\right) = \ker\left(N^k\right)$ and $N^{k+1}v = 0$. Every strict increase costs at least one dimension and the dimensions are bounded by n, so a repetition has occurred by $k = n$ and $\ker\left(N^n\right) = \ker\left(N^{2n}\right)$.

The sum is direct and fills the space. Let v lie in both summands, $v = N^n w$ with $N^n v = 0$. Then $N^{2n} w = 0$, so $w \in \ker\left(N^{2n}\right) = \ker\left(N^n\right)$ and $v = N^n w = 0_{\mathbb{V}}$. The two dimensions add up to n by Equation (5.68), so Equation (5.124) holds.

Invariance and the two behaviours. T commutes with N and hence with N^n, so it carries kernel and image of N^n into themselves. On $\ker\left(N^n\right)$ the power N^n vanishes by definition, so N is nilpotent there. On $\operatorname{im}\left(N^n\right)$ the map N is injective — if v lies there and $Nv = 0$, then v lies in $\ker N$, a subspace of $\ker\left(N^n\right)$, so v lies in both summands and vanishes — and therefore invertible on it, by Proposition 5.47. □

Theorem 5.94 (Primary decomposition)**.** *Let T be an endomorphism of a complex vector space $\mathbb{V}$ with $0 < \dim \mathbb{V} = n < \infty$, and let $\lambda_1, \ldots, \lambda_k$ be its distinct eigenvalues. Write*

$$\mathbb{G}_i = \ker\left(\left(T - \lambda_i \mathbb{1}\right)^n\right) \tag{5.125}$$

for the generalized eigenspace *of λ_i. Then*

$$\mathbb{V} = \mathbb{G}_1 \oplus \ldots \oplus \mathbb{G}_k , \tag{5.126}$$

every $\mathbb{G}_i$ is T-invariant and contains the eigenspace $\mathbb{E}_{\lambda_i}$, and $T - \lambda_i \mathbb{1}$ is nilpotent on $\mathbb{G}_i$.
Rests on Lemma 5.93, Corollary 5.68, and Equation (5.102).

Proof. *Derives Theorem 5.94.*

By induction on n. Corollary 5.68 supplies an eigenvalue λ_1, and Lemma 5.93 applied to it splits $\mathbb{V} = \mathbb{G}_1 \oplus \mathbb{W}$ with $\mathbb{W} = \operatorname{im}\left(N^n\right)$, $N = T - \lambda_1 \mathbb{1}$. The first summand contains an eigenvector, so it is not trivial and $\dim \mathbb{W} < n$. If $\mathbb{W}$ is trivial, then $k = 1$ and there is nothing left to prove; otherwise T restricts to an endomorphism of $\mathbb{W}$ and the induction hypothesis decomposes $\mathbb{W}$ into the generalized eigenspaces, computed inside $\mathbb{W}$, of the distinct eigenvalues of that restriction. Two identifications complete the argument, and both rest on one observation:

$T - \mu \mathbb{1}$ is invertible on $\mathbb{G}_1$ for every $\mu \neq \lambda_1$. On that subspace $T - \mu \mathbb{1} = N + (\lambda_1 - \mu)\,\mathbb{1}$ is a nilpotent operator plus a non-zero scalar, and such a sum is invertible: with $c = \lambda_1 - \mu$ and $N^n = \Theta$ there, $(N + c\mathbb{1})^{-1} = c^{-1} \sum_{j=0}^{n-1} (-N/c)^j$, a finite sum, as multiplying out and telescoping shows.

The eigenvalues of T are λ_1 together with those of the restriction. An eigenvector of the restriction is one of T. Conversely let $Tv = \mu v$ with $v \neq 0_{\mathbb{V}}$ and $\mu \neq \lambda_1$, and split $v = g + w$ along Equation (5.124); both summands being T-invariant, $Tg = \mu g$, so $(T - \mu\mathbb{1})\, g = 0_{\mathbb{V}}$ and the observation forces $g = 0_{\mathbb{V}}$: the eigenvector lies in $\mathbb{W}$.

The generalized eigenspaces agree. Fix $\mu \neq \lambda_1$ and let $v \in \ker\left((T - \mu\mathbb{1})^n\right)$. Split $v = g + w$ along Equation (5.124); both summands are T-invariant, so $(T - \mu\mathbb{1})^n\, g = 0_{\mathbb{V}}$, and the observation — which makes that operator invertible on $\mathbb{G}_1$, a power of an invertible operator being invertible — forces $g = 0_{\mathbb{V}}$. Hence $\ker\left((T - \mu\mathbb{1})^n\right)$ lies inside $\mathbb{W}$. Computed inside $\mathbb{W}$ it is the kernel of the $\dim \mathbb{W}$-th power, which by the first paragraph of the proof of Lemma 5.93 is the same subspace as the kernel of the n-th power. So Equation (5.126) is the induction hypothesis with $\mathbb{G}_1$ adjoined.

Finally $\mathbb{E}_{\lambda_i} \subseteq \mathbb{G}_i$ because a vector killed by $T - \lambda_i\mathbb{1}$ is killed by its powers (Equation (5.102)); invariance is Lemma 5.93; and the nilpotency is Equation (5.125) itself. □

Corollary 5.95 (Semisimple and nilpotent parts)**.** *With the notation of Theorem 5.94, let S be the operator acting on $\mathbb{G}_i$ as multiplication by λ_i, and put $N = T - S$. Then S is diagonalizable, N satisfies $N^n = \Theta$, and $[S, N] = \Theta$. Consequently, in any basis adapted to Equation (5.126), the matrix of T is block diagonal, the i-th block being $\lambda_i\mathbb{1}$ plus a nilpotent array.*

Rests on Theorem 5.94 and Definition 5.72.

Proof. *Derives Corollary 5.95.*

Any basis of $\mathbb{G}_i$ consists of eigenvectors of S with eigenvalue λ_i, so collecting such bases over i diagonalizes S, by Equation (5.126). On $\mathbb{G}_i$ the operator N is $T - \lambda_i\mathbb{1}$, nilpotent with $N^n = \Theta$ there by Equation (5.125); since the subspaces exhaust $\mathbb{V}$, $N^n = \Theta$ throughout. And on $\mathbb{G}_i$ the operator S is a scalar, which commutes with everything that preserves the subspace, so $[S, N] = \Theta$ on each summand and hence everywhere. □

Remark 5.96 (What is and is not claimed here). Corollary 5.95 is the whole of the structure this treatise uses. It is weaker than the classical *normal form*, which refines the nilpotent part of each block into a direct sum of single chains of prescribed lengths; that refinement is a finer classification of nilpotent operators, nothing in this treatise needs it, and it is therefore not carried here — an omission recorded rather than a result assumed. Note also what fails outside $\mathbb{C}$: Theorem 5.94 rests on Corollary 5.68, so over $\mathbb{R}$ the decomposition can be empty of content, exactly as diagonalizability can, and the honest statement for a real array is the one obtained by regarding it as complex. The use the physical parts make of the corollary — that a linear system of differential equations with constant coefficients has solutions of the form $t^j \mathrm{e}^{\lambda t}$ — is a statement about differential equations rather than about arrays, and this chapter does not make it.

5.6.2 Decomposition of vector spaces

Direct sum; direct product

Definition 5.97 (External direct sum)**.** Let $\mathbb{V}$ and $\mathbb{W}$ be vector spaces over the same field $\mathbb{K}$. Their *direct sum* $\mathbb{V} \oplus \mathbb{W}$ is the Cartesian product $\mathbb{V} \times \mathbb{W}$ with the operations performed in each slot separately,

$$(v, w) + (v', w') = (v + v',\, w + w') \;, \qquad a\,(v, w) = (av,\, aw) \;. \tag{5.127}$$

Rests on Definitions 4.31 and 5.4.

That this is a vector space is Example 5.7 once more, with the two slots playing the role of the two components: the neutral vector is $(0_{\mathbb{V}}, 0_{\mathbb{W}})$ and every axiom is verified slot by slot.

Proposition 5.98 (Dimensions add)**.** *If $\mathbb{V}$ and $\mathbb{W}$ are finite-dimensional over the same field, then*

$$\dim(\mathbb{V} \oplus \mathbb{W}) = \dim \mathbb{V} + \dim \mathbb{W}. \tag{5.128}$$

Rests on Definitions 5.14 and 5.97 and Lemma 5.36.

Proof. *Derives Proposition 5.98.*

Let $\{e_i\}_{i=1}^{p}$ and $\{f_j\}_{j=1}^{q}$ be bases of $\mathbb{V}$ and $\mathbb{W}$. The $p+q$ vectors $(e_i, 0_{\mathbb{W}})$ and $(0_{\mathbb{V}}, f_j)$ generate: any (v, w) equals $\sum_i v^i (e_i, 0_{\mathbb{W}}) + \sum_j w^j (0_{\mathbb{V}}, f_j)$ by Equation (5.127). They are independent: a vanishing combination has first slot $\sum_i a^i e_i = 0_{\mathbb{V}}$ and second slot $\sum_j b^j f_j = 0_{\mathbb{W}}$, and each forces its own coefficients to vanish by Equation (5.29). So they form a basis, and Lemma 5.36 makes the count $p+q$ the dimension. □

The construction is also met the other way round, inside a space that is already given: one asks whether $\mathbb{V}$ is assembled from two of its own subspaces.

Definition 5.99 (Sum of subspaces; internal direct sum)**.** Let $\mathbb{U}, \mathbb{W} \leq \mathbb{V}$ be subspaces. Their *sum* is

$$\mathbb{U} + \mathbb{W} = \{u + w \mid u \in \mathbb{U},\ w \in \mathbb{W}\}, \tag{5.129}$$

a subspace of $\mathbb{V}$, since a linear combination of two such elements is again one, the $\mathbb{U}$-parts and the $\mathbb{W}$-parts combining separately. We say that $\mathbb{V}$ is the *internal direct sum* of $\mathbb{U}$ and $\mathbb{W}$, written $\mathbb{V} = \mathbb{U} \oplus \mathbb{W}$, if every $v \in \mathbb{V}$ has exactly one decomposition $v = u + w$ with $u \in \mathbb{U}$ and $w \in \mathbb{W}$; $\mathbb{W}$ is then called a *complement* of $\mathbb{U}$ in $\mathbb{V}$.

Rests on Definitions 5.6 and 5.97.

Proposition 5.100 (Criterion for a direct sum)**.** *For subspaces $\mathbb{U}, \mathbb{W} \leq \mathbb{V}$ the following are equivalent:*

1. *$\mathbb{V} = \mathbb{U} \oplus \mathbb{W}$ in the sense of Definition 5.99;*
2. *$\mathbb{U} + \mathbb{W} = \mathbb{V}$ and $\mathbb{U} \cap \mathbb{W} = \{0_{\mathbb{V}}\}$.*

When they hold, and $\mathbb{V}$ is finite-dimensional, the map $(u, w) \longmapsto u + w$ is an isomorphism from the external direct sum onto $\mathbb{V}$, so that

$$\dim \mathbb{V} = \dim \mathbb{U} + \dim \mathbb{W}. \tag{5.130}$$

Rests on Definitions 5.51 and 5.99 and Proposition 5.98.

Proof. *Derives Proposition 5.100.*

(1) ⇒ (2): existence of a decomposition for every v is $\mathbb{U} + \mathbb{W} = \mathbb{V}$. If $x \in \mathbb{U} \cap \mathbb{W}$ then $x = x + 0_{\mathbb{V}} = 0_{\mathbb{V}} + x$ are two decompositions of the same vector, the first with $\mathbb{U}$-part x and the second with $\mathbb{U}$-part $0_{\mathbb{V}}$; uniqueness forces $x = 0_{\mathbb{V}}$.

(2) ⇒ (1): existence is again the first half. For uniqueness, let $u + w = u' + w'$ with $u, u' \in \mathbb{U}$ and $w, w' \in \mathbb{W}$. Then $u - u' = w' - w$ lies in $\mathbb{U}$ and in $\mathbb{W}$, hence is $0_{\mathbb{V}}$, so $u = u'$ and $w = w'$.

The isomorphism. The map $\Sigma : (u, w) \longmapsto u + w$ is linear by Equation (5.127), surjective by the first half of (2), and injective because $\Sigma(u, w) = 0_{\mathbb{V}}$ gives $u = -w \in \mathbb{U} \cap \mathbb{W} = \{0_{\mathbb{V}}\}$. It is therefore an isomorphism (Definition 5.51), and isomorphic spaces have equal dimension (Remark 5.53), so Equation (5.130) follows from Equation (5.128). □

Proposition 5.101 (Grassmann's formula)**.** *For subspaces $\mathbb{U}, \mathbb{W}$ of a finite-dimensional space,*

$$\dim(\mathbb{U} + \mathbb{W}) = \dim \mathbb{U} + \dim \mathbb{W} - \dim(\mathbb{U} \cap \mathbb{W}). \tag{5.131}$$

Rests on Definitions 5.14 and 5.99 and Lemma 5.36.

Proof. *Derives Proposition 5.101.*

$\mathbb{U} \cap \mathbb{W}$ is a subspace, being defined by membership of two subspaces at once. Let $\{z_1, \dots, z_r\}$ be a basis of it and complete it, by Lemma 5.36, to a basis $\{z_1, \dots, z_r, u_1, \dots, u_p\}$ of $\mathbb{U}$ and to a basis $\{z_1, \dots, z_r, w_1, \dots, w_q\}$ of $\mathbb{W}$. We claim that $\{z_1, \dots, z_r, u_1, \dots, u_p, w_1, \dots, w_q\}$ is a basis of $\mathbb{U} + \mathbb{W}$, which gives Equation (5.131) at once, the count being $r + p + q = (r + p) + (r + q) - r$.

It generates. Every element of $\mathbb{U} + \mathbb{W}$ is a sum of an element of $\mathbb{U}$ and an element of $\mathbb{W}$, each of which expands in its own basis.

It is independent. Suppose

$$\sum_k c^k z_k + \sum_i a^i u_i + \sum_j b^j w_j = 0_{\mathbb{V}} \,.$$

Then $x = \sum_j b^j w_j = -\sum_k c^k z_k - \sum_i a^i u_i$ lies in $\mathbb{W}$, by the left-hand expression, and in $\mathbb{U}$, by the right-hand one; so $x \in \mathbb{U} \cap \mathbb{W}$ and $x = \sum_k d^k z_k$ for some scalars. Comparing the two expressions for x in the basis of $\mathbb{W}$, $\sum_j b^j w_j - \sum_k d^k z_k = 0_{\mathbb{V}}$ forces every $b^j = 0$ by Equation (5.29). The original relation then reduces to a vanishing combination of the basis of $\mathbb{U}$, so the remaining coefficients vanish too. □

Remark 5.102 (Direct sum, tensor product, and one name used for both). The heading this subsubsection carries names two constructions, and the subsubsection that follows it names a third thing with the second of those names. The reader is owed a plain statement of which object is which, because the two behave oppositely in the one respect that matters most.

- The *direct sum* $\mathbb{V} \oplus \mathbb{W}$ is the object defined above. Its elements are *pairs*, its dimension is the *sum* Equation (5.128), and the operators built on it are block diagonal — which is what Equations (5.193) and (5.217) record for representations.

- The *tensor product* $\mathbb{V} \otimes \mathbb{W}$ is the object the next subsubsection builds with the symbol $\otimes$, and calls a "direct product" following the older physics usage that the source inherits. Its elements are not pairs, its basis is the set of *products* $e_i \otimes f_j$ of the two bases, and its dimension is accordingly the *product*

$$\dim(\mathbb{V} \otimes \mathbb{W}) = \dim \mathbb{V} \, \dim \mathbb{W} \,, \tag{5.132}$$

  which is the count of the pairs (i, j) indexing Equation (5.133). It is the space on which a bilinear map becomes linear, as noted after Definition 5.106.

The distinction is not a matter of names. A system built from two others by a direct sum has a state space whose dimension grows additively; a composite quantum system has a state space whose dimension grows multiplicatively, because its states are built on the tensor product (Postulate 77.6), and that single fact is why the dimension of the state space of N particles grows exponentially in N — the starting point of Chapter 83. Where the older literature writes "direct product" for $\otimes$, this treatise keeps the two words apart and uses the symbols to disambiguate.

Direct product of linear transformations

Because an LT itself belongs to a vector space, we can define the direct product of operators.

Consider the linear transformations $A \in \mathcal{L}^1(\mathbb{V}^1)$ and $B \in \mathcal{L}^2(\mathbb{V}^2)$, and the direct-product space $\mathbb{W} = \mathcal{L}^1(\mathbb{V}^1) \otimes \mathcal{L}^2(\mathbb{V}^2)$. Consider further the bases $\{\hat{e}^1_i\}$ and $\{\hat{e}^2_i\}$ of $\mathbb{V}^1$ and $\mathbb{V}^2$. The basis of $\mathbb{W}$ is given by

$$\{\hat{w}_k\} = \{\hat{e}^1_i \otimes \hat{e}^2_j\}, \qquad k = (i, j) \,.$$

Then, to compute the components of the matrix associated with $C = A \otimes B$ in the chosen bases, we have

$$A \otimes B \left| \hat{e}^1_i \otimes \hat{e}^2_j \right\rangle = A^{i'}{}_i B^{j'}{}_j \left| \hat{e}^1_{i'} \otimes \hat{e}^2_{j'} \right\rangle$$

and, in addition,

$$C \left| \hat{w}_k \right\rangle = C^{k'}_k \left| \hat{w}_{k'} \right\rangle .$$

Therefore

$$C^{k'}_k = A^{i'}{}_i B^{j'}{}_j, \qquad k = (i,j),\ k' = (i',j') . \tag{5.133}$$

Union of vector spaces

The intersection of two subspaces is a subspace, as Proposition 5.101 used without comment: a linear combination of vectors lying in both lies in both. The union is a different matter, and the answer is as negative as it can be.

Proposition 5.103 (The union of two subspaces)**.** *Let $\mathbb{U}, \mathbb{W} \leq \mathbb{V}$ be subspaces. Then $\mathbb{U} \cup \mathbb{W}$ is a subspace of $\mathbb{V}$ if and only if $\mathbb{U} \subset \mathbb{W}$ or $\mathbb{W} \subset \mathbb{U}$.*

Rests on Definitions 5.4 and 5.6.

Proof. *Derives Proposition 5.103.*

($\Leftarrow$) If one contains the other the union *is* the larger of the two, which is a subspace by hypothesis.

($\Rightarrow$) Suppose neither containment holds, so that there are vectors $u \in \mathbb{U} \setminus \mathbb{W}$ and $w \in \mathbb{W} \setminus \mathbb{U}$. If $\mathbb{U} \cup \mathbb{W}$ were a subspace it would contain $u + w$, which must then lie in $\mathbb{U}$ or in $\mathbb{W}$. Both are impossible:

- if $u + w \in \mathbb{U}$ then $w = (u + w) - u \in \mathbb{U}$, since $\mathbb{U}$ is closed under linear combinations, contradicting the choice of w;
- if $u + w \in \mathbb{W}$ then $u = (u + w) - w \in \mathbb{W}$, contradicting the choice of u.

Hence $\mathbb{U} \cup \mathbb{W}$ is not a subspace. □

Corollary 5.104 (The sum is the right operation)**.** *For subspaces $\mathbb{U}, \mathbb{W} \leq \mathbb{V}$,*

$$\langle \mathbb{U} \cup \mathbb{W} \rangle = \mathbb{U} + \mathbb{W} , \tag{5.134}$$

so the sum Equation (5.129) is the smallest subspace containing both.

Rests on Proposition 5.103 and Definitions 5.11 and 5.99.

Proof. *Derives Corollary 5.104.*

$\mathbb{U} + \mathbb{W}$ is a subspace containing $\mathbb{U} \cup \mathbb{W}$ — take $w = 0_{\mathbb{V}}$ or $u = 0_{\mathbb{V}}$ in Equation (5.129) — so it contains the smallest such subspace, which is $\langle \mathbb{U} \cup \mathbb{W} \rangle$ by Remark 5.12. Conversely every $u + w$ is a linear combination of two elements of $\mathbb{U} \cup \mathbb{W}$ and therefore lies in $\langle \mathbb{U} \cup \mathbb{W} \rangle$ by Definition 5.11. The two inclusions give Equation (5.134). □

Example 5.105 (Two lines in physical space)**.** Take $\mathbb{V} = \mathbb{R}^3$, a $3 + 0$ instantiation, and let $\mathbb{U}$ and $\mathbb{W}$ be two distinct lines through the origin, say the spans of e_1 and of e_2 in the notation of Equation (5.25). Their union is the pair of coordinate axes, which fails to contain $e_1 + e_2$ and is therefore not a subspace; the smallest subspace containing both is the plane $\mathbb{U} + \mathbb{W} = \langle \{e_1, e_2\} \rangle$, of dimension $1 + 1 - 0 = 2$ by Equation (5.131). The moral is worth keeping: set union is not an operation of linear algebra, and every construction in this chapter that looks as though it combines two subspaces — the decompositions Equation (5.53) and Equation (5.73), the direct sums of representations Equation (5.184) — combines them by sum, not by union.

Rests on Proposition 5.103 and Corollary 5.104.

5.6.3 Bilinear transformations

A linear transformation consumes one vector. The maps that consume two — the inner product of Definition 5.17 is the example already in hand, the metric tensor of Chapter 13 the one physics needs most — are linear in each argument separately, and they behave differently enough from linear transformations under a change of basis that they deserve their own treatment.

Definition 5.106 (Bilinear map)**.** Let $\mathbb{V}, \mathbb{W}, \mathbb{Z}$ be vector spaces over the same field $\mathbb{K}$. A map $B : \mathbb{V} \times \mathbb{W} \longrightarrow \mathbb{Z}$ is *bilinear* if it is linear in each argument when the other is held fixed:

$$B(au + bv, w) = aB(u, w) + bB(v, w)\,, \tag{5.135}$$

$$B(u, aw + bz) = aB(u, w) + bB(u, z)\,, \tag{5.136}$$

for all $a, b \in \mathbb{K}$ and all vectors for which the expressions are defined. If $\mathbb{Z} = \mathbb{K}$ we call B a *bilinear form*; if in addition $\mathbb{W} = \mathbb{V}$ we speak of a bilinear form *on* $\mathbb{V}$.

Rests on Definition 5.35.

A bilinear map is *not* a linear map on the product space: the product $\mathbb{V} \times \mathbb{W}$ is itself a vector space, and a linear map on it would satisfy $B(au, aw) = aB(u, w)$, whereas Equations (5.135) and (5.136) give $B(au, aw) = a^2 B(u, w)$. Bilinearity is instead linearity on the tensor product $\mathbb{V} \otimes \mathbb{W}$ met in Equation (5.133): that is exactly what the tensor product is built to arrange.

Matrix representation of a bilinear form

Let $\mathbb{V}$ have the basis $\{e_i\}_{i=1}^n$ and let B be a bilinear form on $\mathbb{V}$. Define

$$B_{ij} = B(e_i, e_j)\,, \tag{5.137}$$

and call $[B]$ the matrix with these entries — note that *both* indices are down, which is not the placement carried by the matrix of a linear transformation in Equation (5.74), and the difference is about to matter. For arbitrary $u = \sum_i u^i e_i$ and $v = \sum_j v^j e_j$, applying Equation (5.135) and then Equation (5.136),

$$B(u, v) = \sum_{i,j=1}^{n} u^i v^j B_{ij} = \begin{pmatrix} u^1 & \dots \end{pmatrix} [B] \begin{pmatrix} v^1 \\ \vdots \end{pmatrix}\,, \tag{5.138}$$

so the n^2 numbers B_{ij} determine B completely; and they are unique, by the uniqueness of components in a basis used already in Proposition 5.43. Conversely any array defines a bilinear form through Equation (5.138).

Change of basis: congruence, not similarity

Let $\{e'_i\}$ be a second basis, related to the first by

$$e'_i = \sum_{j=1}^{n} A^j{}_i e_j\,,$$

with $[A]$ invertible. Then

$$\begin{aligned} B'_{ik} &= B(e'_i, e'_k) \\ &= \sum_{j,l=1}^{n} A^j{}_i A^l{}_k B(e_j, e_l) && \text{by Equations (5.135) and (5.136)} \\ &= \sum_{j,l=1}^{n} \left(A^{\mathsf{T}}\right)_i{}^j B_{jl} A^l{}_k\,, \end{aligned} \tag{5.139}$$

that is, $[B'] = [A]^{\mathsf{T}}\,[B]\,[A]$. Two matrices related in this way are called *congruent*. Compare Remark 5.122: the matrix of a linear *transformation* changes by the *similarity* $[A]^{-1}\,[T]\,[A]$. The two laws agree only when $[A]^{\mathsf{T}} = [A]^{-1}$, that is, for orthogonal changes of basis — which is the reason a physicist who works only with orthonormal bases can go a long way without noticing that a metric and an operator are different kinds of object, and the reason the distinction reappears the moment curvilinear coordinates are introduced in Chapter 13.

Two immediate consequences of Equation (5.139): the trace of $[B]$ is *not* basis-independent (unlike the character of a representation, Equation (5.181)), while

$$\det\,[B'] = (\det\,[A])^2\,\det\,[B]$$

shows that whether $\det\,[B]$ vanishes, and — over $\mathbb{R}$ — its sign, are basis-independent.

Symmetry, non-degeneracy, and the map into the dual

Definition 5.107 (Symmetric and antisymmetric forms)**.** A bilinear form on $\mathbb{V}$ is *symmetric* if $B(u,v) = B(v,u)$ for all u, v, and *antisymmetric* (or *alternating*) if $B(u,v) = -B(v,u)$. In terms of Equation (5.137) these read $[B]^{\mathsf{T}} = [B]$ and $[B]^{\mathsf{T}} = -\,[B]$, and both conditions are preserved by Equation (5.139).

Rests on Definition 5.106 and Equation (5.137).

Proposition 5.108 (Symmetric–antisymmetric splitting)**.** *Let $\mathbb{V}$ be a vector space over a field of characteristic other than 2 — $\mathbb{R}$ and $\mathbb{C}$ are such fields. Every bilinear form B on $\mathbb{V}$ is the sum of a symmetric and an antisymmetric form, namely*

$$B = B_{\mathrm{s}} + B_{\mathrm{a}}\,, \qquad B_{\mathrm{s}}(u,v) = \tfrac{1}{2}\,(B(u,v) + B(v,u))\,, \quad B_{\mathrm{a}}(u,v) = \tfrac{1}{2}\,(B(u,v) - B(v,u))\,, \tag{5.140}$$

and this decomposition is unique.

Rests on Definitions 5.106 and 5.107.

Derivation. *Derives Proposition 5.108.*

Existence. Both B_{s} and B_{a} are bilinear, being linear combinations of the bilinear maps $(u,v) \longmapsto B(u,v)$ and $(u,v) \longmapsto B(v,u)$; exchanging u and v in Equation (5.140) leaves the first unchanged and reverses the sign of the second, so they are respectively symmetric and antisymmetric in the sense of Definition 5.107; and adding them returns B. The halving is where the characteristic hypothesis is spent here — $\frac{1}{2}$ must exist in the field — and it is spent again, in the other direction, in the next paragraph.

Uniqueness. Suppose $B = S + A = S' + A'$ with S, S' symmetric and A, A' antisymmetric, and put $C = S - S' = A' - A$. Then C is symmetric, being a difference of symmetric forms, and antisymmetric, being a difference of antisymmetric ones, so for all u, v

$$C(u,v) = C(v,u) = -C(u,v)\,, \qquad \text{hence} \qquad 2C(u,v) = 0\,.$$

Since $2 \neq 0$ in the field, $C = 0$, that is $S = S'$ and $A = A'$. In matrix terms Equation (5.140) is the familiar $[B] = \frac{1}{2}\left([B] + [B]^{\mathsf{T}}\right) + \frac{1}{2}\left([B] - [B]^{\mathsf{T}}\right)$, and the uniqueness argument says that the only array equal to both its own transpose and minus it is the zero array. □

Physics uses both halves and keeps them apart: the symmetric one is a metric (Chapter 13), the antisymmetric one a symplectic form or a field strength.

Definition 5.109 (Non-degenerate form)**.** A bilinear form B on $\mathbb{V}$ is *non-degenerate* if $B(u,v) = 0$ for all $v \in \mathbb{V}$ implies $u = 0_{\mathbb{V}}$, and $B(u,v) = 0$ for all $u \in \mathbb{V}$ implies $v = 0_{\mathbb{V}}$.

Rests on Definition 5.106.

Proposition 5.110. *Let* $\dim \mathbb{V} = n < \infty$ *and let* B *be a bilinear form on* $\mathbb{V}$*. Define*

$$\begin{array}{rccc} \flat_B : & \mathbb{V} & \longrightarrow & \mathbb{V}^* \\ & u & \longmapsto & B(u,\ ) \,. \end{array} \tag{5.141}$$

Then $\flat_B$ *is a linear transformation, and the following are equivalent:*

1. B *is non-degenerate;*
2. $\flat_B$ *is an isomorphism;*
3. $\det[B] \neq 0$ *in any (hence every) basis.*

Rests on Definitions 5.56, 5.106 and 5.109 and Equations (5.86) and (5.87).

Proof. *Derives Proposition 5.110.*

$\flat_B(u)$ is a functional by Equation (5.136), and $u \longmapsto \flat_B(u)$ is linear by Equation (5.135), so $\flat_B \in \mathcal{L}(\mathbb{V}, \mathbb{V}^*)$.

(1) $\Rightarrow$ (2): the first half of Definition 5.109 says exactly that $\ker \flat_B = \{0_{\mathbb{V}}\}$, so $\flat_B$ is injective; and an injective linear map between spaces of the same finite dimension — $\dim \mathbb{V}^* = \dim \mathbb{V} = n$ was established after Equation (5.87) — is surjective.

(2) $\Rightarrow$ (3): in the basis $\{e_i\}$ and its dual basis $\{f^j\}$ of Equation (5.86),

$$\flat_B(e_i) = B(e_i,\ ) = \sum_{j=1}^{n} B_{ij} f^j \,,$$

because both sides agree on every e_k: the left gives B_{ik} and the right gives $\sum_j B_{ij}\delta^j{}_k = B_{ik}$. So the matrix of $\flat_B$ in these bases is $[B]^{\mathsf{T}}$; a linear map between spaces of equal finite dimension is bijective exactly when its matrix is invertible, that is, when its determinant does not vanish, and $\det\left([B]^{\mathsf{T}}\right) = \det[B]$.

(3) $\Rightarrow$ (1): if $B(u, v) = 0$ for all v then in components $\sum_i u^i B_{ij} = 0$ for every j, a homogeneous linear system whose matrix is invertible, so $u^i = 0$ for all i; the other half is the same argument on the other index. Independence of the basis follows from $\det[B'] = (\det[A])^2 \det[B]$ with $\det[A] \neq 0$. □

Proposition 5.110 is the precise sense in which a non-degenerate form "identifies a space with its dual", and it is the algebraic content of raising and lowering indices with a metric. It also locates exactly what Proposition 5.59 adds: an inner product is a non-degenerate form with two further properties, hermiticity and positivity, and it is those — not non-degeneracy — that fail in the counterexamples of Remark 5.60.

Sesquilinear and hermitian forms

Over $\mathbb{C}$ the useful notion is not quite bilinearity.

Definition 5.111 (Sesquilinear form)**.** A map $H : \mathbb{V} \times \mathbb{V} \longrightarrow \mathbb{C}$ is *sesquilinear* — "one and a half times linear" — if it is antilinear in the first argument and linear in the second:

$$H(au + bv, w) = a^* H(u, w) + b^* H(v, w) \,, \qquad H(u, aw + bz) = aH(u, w) + bH(u, z) \,.$$

It is *hermitian* if $H(u, v) = H(v, u)^*$ for all u, v, which in components means $[H]^\dagger = [H]$, and *positive definite* if $H(v, v) > 0$ for every $v \neq 0_{\mathbb{V}}$.

Rests on Definition 4.31 and Equation (5.137).

Comparing with Definition 5.17: *an inner product on a complex vector space is precisely a positive-definite hermitian sesquilinear form*, and on a real vector space precisely a positive-definite symmetric bilinear form. Everything proved in Section 5.3 is therefore a statement about a very particular corner of the present section, and the Schwarz inequality Equation (5.43) is exactly what positive definiteness buys and what an indefinite form loses. Note also that $H(v,v)$ is automatically real for a hermitian form, by the same one-line argument as Equation (5.39), so the inequality $H(v,v) > 0$ is meaningful.

The change-of-basis law for a sesquilinear form carries a conjugate: repeating the computation of Equation (5.139) with the first slot antilinear gives $[H'] = [A]^\dagger\,[H]\,[A]$, which is why the unitary group $\mathrm{U}(n,\mathbb{C})$ of Equation (5.171) — and not the orthogonal group — is the group preserving a complex inner product.

Sylvester's law of inertia

For a real symmetric form the congruence Equation (5.139) can always be used to reach a normal form, and what survives the choice of basis is a pair of integers. This is what makes the "signature (p,q)" spoken of throughout the treatise a well-defined attribute of a form rather than of a basis.

Theorem 5.112 (Sylvester's law of inertia)**.** *Let B be a symmetric bilinear form on a real vector space $\mathbb{V}$ of finite dimension n. Then there is a basis in which*

$$[B] = \mathrm{diag}(\underbrace{1,\dots,1}_{p},\underbrace{-1,\dots,-1}_{q},\underbrace{0,\dots,0}_{r})\,, \qquad p+q+r=n\,, \tag{5.142}$$

and the triple (p,q,r) is the same for every such basis.

Rests on Definitions 5.106 and 5.107 and Equation (5.139).

Proof. *Derives Theorem 5.112.*

Existence. By induction on n. If $B=0$ then $p=q=0$, $r=n$ and any basis will do. Otherwise there is a vector v with $B(v,v)\neq 0$: were $B(u,u)=0$ for every u, polarization would give

$$B(u,w) = \tfrac{1}{2}\left(B(u+w,u+w) - B(u,u) - B(w,w)\right) = 0$$

for all u,w, using symmetry, and B would vanish identically. Set $e_1 = v/\sqrt{|B(v,v)|}$, so that $B(e_1,e_1)=\pm 1$, and let

$$\mathbb{V}_1 = \{u\in\mathbb{V} \mid B(e_1,u)=0\}\,,$$

which is a subspace, being defined by a linear condition. Every $u\in\mathbb{V}$ decomposes as

$$u = \frac{B(e_1,u)}{B(e_1,e_1)}e_1 + \left(u - \frac{B(e_1,u)}{B(e_1,e_1)}e_1\right)\,,$$

whose second term lies in $\mathbb{V}_1$, as substituting it into $B(e_1,\ )$ shows; and $\langle\{e_1\}\rangle\cap\mathbb{V}_1 = \{0_\mathbb{V}\}$, since $B(e_1,\lambda e_1)=\lambda B(e_1,e_1)=0$ forces $\lambda=0$. Hence $\mathbb{V}=\langle\{e_1\}\rangle\oplus\mathbb{V}_1$ and $\dim\mathbb{V}_1 = n-1$. Applying the induction hypothesis to the restriction of B to $\mathbb{V}_1$ — which is again symmetric — and reordering the resulting basis gives Equation (5.142).

Uniqueness. r is basis-independent because $n-r$ is the rank of $[B]$, and congruent matrices have equal rank ($[A]$ being invertible). For p, suppose two bases give (p,q,r) and (p',q',r) with, say, $p>p'$. Let $\mathbb{P}$ be the span of the p basis vectors of the first basis on which B is $+1$: on $\mathbb{P}\setminus\{0_\mathbb{V}\}$ the form is strictly positive, since $B\left(\sum_{i\le p}a^i e_i, \sum_{j\le p}a^j e_j\right) = \sum_{i\le p}(a^i)^2 > 0$. Let $\mathbb{M}'$ be the span of the $q'+r = n-p'$ vectors of the second basis on which B is -1 or 0: on $\mathbb{M}'$ the form satisfies $B(u,u)\le 0$, by the same computation with the signs of Equation (5.142). Now

$$\dim\mathbb{P} + \dim\mathbb{M}' = p + (n-p') > n\,,$$

so $\mathbb{P}\cap\mathbb{M}'$ contains a non-zero vector u — two subspaces whose dimensions sum to more than n cannot meet only in $0_{\mathbb{V}}$, since $\dim(\mathbb{P}+\mathbb{M}')\le n$. That vector would satisfy $B(u,u)>0$ and $B(u,u)\le 0$ at once. Hence $p\le p'$, and by symmetry $p'\le p$; with r fixed, $q=n-p-r$ is determined too. □

Definition 5.113 (Signature)**.** The pair (p,q) of Theorem 5.112 is the *signature* of the symmetric form. A non-degenerate form has $r=0$ and $p+q=n$; it is *positive definite*, that is, an inner product, exactly when $q=r=0$.

Rests on Theorem 5.112 and Definition 5.109.

Example 5.114 (The two forms physics uses)**.** Both instantiations below are the observed ones, $3+0$ and $3+1$; the treatise takes no other (editorial rule on dimensions).

- *Euclidean space,* $3+0$. On $\mathbb{R}^3$ with the standard basis, $[B]=\operatorname{diag}(1,1,1)$: signature $(3,0)$, non-degenerate and positive definite, hence an inner product, and the source of the length $\|\boldsymbol{x}\|=\sqrt{x^2+y^2+z^2}$ in metres. The subgroup of $\mathrm{GL}(3,\mathbb{R})$ preserving it is $\mathrm{O}(3,\mathbb{R})$ of Equation (5.161), the rotations and reflections.

- *Minkowski spacetime,* $3+1$. On $\mathbb{R}^4$ with coordinates $(x^0,x^1,x^2,x^3)=(ct,x,y,z)$ — all four carrying the SI unit metre, which is exactly what the factor c is there for —

  $$[\eta]=\operatorname{diag}(-1,1,1,1)\,,$$

  of signature $(3,1)$: non-degenerate, and *not* positive definite, so it is not an inner product and Proposition 5.19 does not apply to it. The quantity $\eta(u,u)$ carries the SI unit m^2. The subgroup of $\mathrm{GL}(4,\mathbb{R})$ preserving it is the Lorentz group $\mathrm{O}(3,1)$ of Chapter 39. Theorem 5.112 is what guarantees that no change of basis whatever can turn this form into the Euclidean one: the signature is an invariant, so the distinction between a timelike and a spacelike direction is not a coordinate artefact.

Proposition 5.115 (Normal form of a non-degenerate antisymmetric form)**.** *Let ω be a non-degenerate antisymmetric bilinear form on a real vector space $\mathbb{V}$ of finite dimension n. Then $n=2m$ is even and $\mathbb{V}$ has a basis $\{e_1,\dots,e_m,f_1,\dots,f_m\}$ in which*

$$\omega(e_i,e_j)=\omega(f_i,f_j)=0\,,\qquad \omega(e_i,f_j)=\delta_{ij}\,,\qquad i,j=1,\dots,m\,, \tag{5.143}$$

that is, in which the matrix of the form is the block array

$$[\omega]=\begin{pmatrix}0 & \mathbb{1}_m\\ -\mathbb{1}_m & 0\end{pmatrix}. \tag{5.144}$$

Consequently any two non-degenerate antisymmetric forms on real spaces of the same even dimension are congruent in the sense of Equation (5.139): there is no invariant here answering to the signature of Theorem 5.112.

Rests on Definitions 5.106, 5.107 and 5.109 and Equation (5.139).

Derivation. Derives Proposition 5.115.

Antisymmetry first gives $\omega(u,u)=-\omega(u,u)$, hence $\omega(u,u)=0$ for every u, the field being $\mathbb{R}$. The construction is then an induction on n — a *symplectic* Gram–Schmidt, in which vectors are paired off instead of being normalized one at a time.

If $\mathbb{V}=\{0_{\mathbb{V}}\}$ there is nothing to prove and $m=0$. Otherwise choose any $e_1\neq 0_{\mathbb{V}}$. Non-degeneracy (Definition 5.109) supplies a w with $\omega(e_1,w)\neq 0$, and

$$f_1=\frac{w}{\omega(e_1,w)}\qquad\text{gives}\qquad \omega(e_1,f_1)=1\,.$$

These two are linearly independent: were $f_1 = \lambda e_1$ we should have $\omega(e_1, f_1) = \lambda\,\omega(e_1, e_1) = 0$. Put $W = \langle\{e_1, f_1\}\rangle$ and

$$W^\omega = \{v \in \mathbb{V} \mid \omega(v, e_1) = \omega(v, f_1) = 0\}\ ,$$

a subspace, being the intersection of the kernels of two functionals.

The two split $\mathbb{V}$. Given $v \in \mathbb{V}$, set

$$v' = v - \omega(v, f_1)\, e_1 + \omega(v, e_1)\, f_1\,.$$

Using $\omega(e_1, e_1) = \omega(f_1, f_1) = 0$ and $\omega(f_1, e_1) = -1$,

$$\begin{aligned}\omega(v', e_1) &= \omega(v, e_1) + \omega(v, e_1)\,\omega(f_1, e_1) = 0\,,\\ \omega(v', f_1) &= \omega(v, f_1) - \omega(v, f_1)\,\omega(e_1, f_1) = 0\,,\end{aligned}$$

so $v' \in W^\omega$ and $v = (\omega(v, f_1)e_1 - \omega(v, e_1)f_1) + v' \in W + W^\omega$. The sum is direct: if $v = ae_1 + bf_1$ lies in W^ω then $0 = \omega(v, f_1) = a$ and $0 = \omega(v, e_1) = -b$. Hence $\mathbb{V} = W \oplus W^\omega$ and $\dim W^\omega = n - 2$.

The restriction is again non-degenerate. Let $v \in W^\omega$ satisfy $\omega(v, u) = 0$ for every $u \in W^\omega$. It also annihilates e_1 and f_1, hence the whole of W; by the direct sum $\omega(v,\ )$ vanishes on $\mathbb{V}$, and $v = 0_{\mathbb{V}}$ by non-degeneracy of ω.

The induction hypothesis applied to W^ω therefore makes $n - 2$ even — so n is even, $n = 2m$ — and supplies vectors $e_2, \dots, e_m, f_2, \dots, f_m$ of W^ω satisfying Equation (5.143) among themselves. All products of e_1 or f_1 with one of them vanish, since those vectors lie in W^ω, so the whole collection satisfies Equation (5.143) and, being a basis of W together with a basis of W^ω, is a basis of $\mathbb{V}$. Listing the e_i first and the f_i second turns Equation (5.143) into Equation (5.144). That two such forms are congruent now follows because each is carried to Equation (5.144) by a change of basis, and Equation (5.139) composes. □

Remark 5.116 (Antisymmetric forms and the symplectic group). Proposition 5.115 is the antisymmetric counterpart of Sylvester's law, and the contrast is sharp: a symmetric form keeps its signature, an antisymmetric one keeps nothing but its dimension. That even dimension is forced can also be seen without the construction, by taking determinants in $[\omega]^{\mathsf{T}} = -[\omega]$:

$$\det[\omega] = \det\left([\omega]^{\mathsf{T}}\right) = \det(-[\omega]) = (-1)^n \det[\omega]\ ,$$

which for odd n forces $\det[\omega] = 0$, excluded by non-degeneracy (Proposition 5.110). The subgroup of $\mathrm{GL}(2m, \mathbb{R})$ preserving ω is the symplectic group $\mathrm{Sp}(2m, \mathbb{R})$, constructed with the other classical groups in Definition 5.130; every one of its elements has determinant $+1$ (Theorem 5.133), so the antisymmetric case admits no analogue of the split between $\mathrm{O}(n, \mathbb{K})$ and $\mathrm{SO}(n, \mathbb{K})$.

The absence of a signature is a statement of linear algebra and is proved above. Its celebrated geometric counterpart — that a symplectic *manifold* has no local invariants at all, where a Riemannian one has curvature — is Darboux's theorem, a statement about a form varying from point to point rather than about one form on one vector space; it does not follow from the proposition, which only says that the forms at each single point look alike. What the proposition supplies is precisely that pointwise input: at each single point the form can be brought to Equation (5.144), and the work left to Darboux's theorem is to show that the bases achieving it at neighbouring points can be chosen to fit together into a single chart. That is where a condition with no counterpart in linear algebra enters — the form must be closed — and it is proved in the appendix, in the language of the differential forms of Chapter 13.

Full derivation: Appendix A.12 (p. 2807).

Derives Remark 5.116.

The instance physics meets is the phase space of a mechanical system with N degrees of freedom, of dimension $2N$, on which ω pairs a coordinate against its conjugate momentum; in SI the value $\omega(u, v)$ then carries the unit of action, J s, the same unit as $\hbar$ — which is the first hint of why the quantization of Chapter 77 is expressed in units of $\hbar$.

5.7 Algebras

5.7.1 Algebras

Let us discuss the definition of an algebra here in more detail. The axioms that the elements of an algebra must satisfy are many, but they are summarized as follows. Let $((\mathbb{K}, +, \cdot), \cdot, (A, +))$ be a vector space, and consider the IBO

$$\begin{array}{rccc} [\ ,\ ]: & A \times A & \longrightarrow & A \\ & (X, Y) & \longmapsto & [X, Y]\ . \end{array}$$

Definition 5.117 (Algebra)**.** The space A together with the IBO $[\ ,\ ]$ is an *algebra* if and only if the following linearity axioms hold:

1. Left distributivity:

$$\forall\ X, Y, Z \in A, \quad [X + Y, Z] = [X, Z] + [Y, Z]\ . \tag{5.145}$$

2. Right distributivity:

$$\forall\ X, Y, Z \in A, \quad [X, Y + Z] = [X, Y] + [X, Z]\ . \tag{5.146}$$

3. Product by scalars:

$$\forall\ X, Y \in A,\ \forall\, \alpha, \beta \in \mathbb{K}, \quad [\alpha X, \beta Y] = \alpha\beta\, [X, Y]\ . \tag{5.147}$$

Rests on Definitions 4.4 and 4.31.

When no ambiguity is possible we shall refer to an algebra simply as A, unless it is necessary to specify the field and the internal binary operations accompanying it.

Definition 5.118 (Linear hull)**.** Consider $M, N \subset A$. We define the set $[M, N]$ as

$$[M, N] = \left\{ \sum_i \alpha_i\, [X_i, Y_i] \mid X_i \in M,\ Y_i \in N,\ \alpha_i \in \mathbb{K} \right\}\ . \tag{5.148}$$

Rests on Definition 5.117.

Definition 5.119 (Subalgebra)**.** Consider an algebra A and $N \subset A$. We say that N is a *subalgebra* of A if and only if all possible linear combinations of brackets of vectors in N remain in N, that is, if

$$\left\{ \sum_i \alpha_i\, [X_i, Y_i] \mid X_i, Y_i \in N \right\} \subset N\,,$$

hence

$$N \text{ is a subalgebra of } A \iff [N, N] \subset N\,.$$

Rests on Definitions 5.117 and 5.118.

Definition 5.120 (Ideal)**.** We say that a subset N of an algebra A is an *ideal* of A if and only if

$$[N, A] \subset N\,.$$

Rests on Definitions 5.117 and 5.118.

Structure constants

Let $A = \langle \{e_i\}^n \rangle$ be an algebra and $X, Y \in A$. We can expand X and Y as linear combinations of the elements of the chosen basis. We have

$$\begin{aligned}[X,Y] &= \left[X^i e_i, Y^j e_j\right] \\ &= X^i Y^j \left[e_i, e_j\right] \qquad \text{by Equation (5.147)}\,. \end{aligned} \tag{5.149}$$

Now, since $[\ ,\ ]$ is an IBO — that is, closure holds — we can write $[e_i, e_j]$ as a linear combination of the elements of the basis. That is,

$$[e_i, e_j] = C^k_{\ ij} e_k\,, \tag{5.150}$$

where the quantities $C^k_{\ ij} \in \mathbb{K}$ are called the *structure constants* of the algebra. It should be mentioned that the structure constants are basis-dependent.

On the basis of the structure constants we can compute the coefficients of the linear-combination expansion of an element $[X, Y]$ of the algebra. Substituting Equation (5.150) into Equation (5.149),

$$[X,Y] = X^i Y^j C^k_{\ ij} e_k = [X,Y]^k\, e_k\,,$$

hence

$$[X,Y]^k = X^i Y^j C^k_{\ ij}\,. \tag{5.151}$$

From Equations (5.149) and (5.150) (expand both arguments in the basis and replace the bracket of basis elements by the structure constants).

5.7.2 The algebra of linear transformations

Proposition 5.121. *Let $\mathbb{V}$ be a vector space of finite dimension n with a fixed basis $B = \{e_i\}_{i=1}^n$, and let $\mathcal{L}(\mathbb{V}) = \mathcal{L}(\mathbb{V}, \mathbb{V})$ carry the commutator bracket $[S,T] = S \circ T - T \circ S$. Then the map $T \longmapsto [T]$ that assigns to an endomorphism its matrix representation in B satisfies*

$$[\alpha S + \beta T] = \alpha\,[S] + \beta\,[T]\ , \tag{5.152}$$

$$[S \circ T] = [S]\,[T]\ , \tag{5.153}$$

$$[[S,T]] = [[S]\,, [T]]\ , \tag{5.154}$$

and is a bijection onto $\mathcal{M}_{n\times n}[\mathbb{K}]$. Consequently any subalgebra of $\mathcal{L}(\mathbb{V})$ and its image in $\mathcal{M}_{n\times n}[\mathbb{K}]$ have the same structure constants: the matrices satisfy the same algebra as the transformations they represent.

Rests on Definitions 5.35 and 5.117, Proposition 5.43, and Equations (5.74) and (5.150).

Derivation. *Derives Proposition 5.121.*

Every identity is read off the definition Equation (5.74) of the matrix representation, here with $\mathbb{W} = \mathbb{V}$ and $B_2 = B_1 = B$, so that $T(e_i) = \sum_j T^j_{\ i} e_j$.

Linearity, Equation (5.152). By the definition of the linear combination of two LT's,

$$\begin{aligned}(\alpha S + \beta T)(e_i) &= \alpha S(e_i) + \beta T(e_i) \\ &= \sum_{j=1}^{n} \left(\alpha S^j_{\ i} + \beta T^j_{\ i}\right) e_j\,, \end{aligned}$$

and by the uniqueness established in Proposition 5.43 the coefficients displayed are *the* matrix entries of $\alpha S + \beta T$.

Composition, Equation (5.153). Apply the two transformations in turn:

$$\begin{aligned}(S\circ T)(e_i) &= S\left(T(e_i)\right)\\ &= S\left(\sum_{j=1}^{n} T^{j}{}_{i}\, e_j\right)\\ &= \sum_{j=1}^{n} T^{j}{}_{i}\, S(e_j) && \text{by linearity of } S\\ &= \sum_{k=1}^{n}\left(\sum_{j=1}^{n} S^{k}{}_{j} T^{j}{}_{i}\right) e_k\,,\end{aligned}$$

so that $(S\circ T)^{k}{}_{i} = S^{k}{}_{j} T^{j}{}_{i}$ in the summation convention — precisely the row-by-column rule for the matrix product $[S]\,[T]$. Note that the order is preserved: the transformation applied first stands to the right in both notations.

Bracket, Equation (5.154). Combine the two:

$$\begin{aligned}[[S,T]] &= [S\circ T - T\circ S]\\ &= [S\circ T] - [T\circ S] && \text{by Equation (5.152)}\\ &= [S]\,[T] - [T]\,[S] && \text{by Equation (5.153)}\\ &= [[S]\,,[T]]\ .\end{aligned}$$

Bijectivity is Proposition 5.43: distinct endomorphisms have distinct matrices, and every array arises from the endomorphism it defines through Equation (5.74).

Structure constants. Let $A\subset\mathcal{L}(\mathbb{V})$ be a subalgebra with basis $\{X_a\}$ and structure constants defined by Equation (5.150), $[X_a,X_b] = C^{c}{}_{ab} X_c$. Taking matrix representations of both sides and using Equations (5.152) and (5.154),

$$[[X_a]\,,[X_b]] = C^{c}{}_{ab}\,[X_c]\ ,$$

with the *same* coefficients $C^{c}{}_{ab}$. Moreover the $[X_a]$ are linearly independent, since $T\longmapsto[T]$ is injective and linear, so they are a basis of the image and the two algebras have the same structure constants in corresponding bases. Any identity following from the axioms — the antisymmetry Equation (5.157) and the Jacobi identity Equation (5.158) of a Lie algebra, for instance — therefore holds for the matrices exactly when it holds for the operators. □

Remark 5.122 (The basis is fixed, and that matters). Equation (5.153) is false if S and T are referred to different bases: it is the *same* B appearing three times that lets the inner index j be summed. Changing B replaces every $[T]$ by $[S_0]\,[T]\,[S_0]^{-1}$ for one fixed invertible $[S_0]$, and all three identities are invariant under that simultaneous conjugation — which is why the structure constants are carried along unchanged, and why Definition 5.140 declares two representations related in this way to be equivalent.

5.7.3 Lie algebras

Definition 5.123 (Lie algebra)**.** An algebra $((\mathbb{K},+,\cdot)\,,\cdot,(L,+,[\ ,\ ]))$ in the sense of Definition 5.117 — equivalently, of Definition 4.32, whose axioms are the bilinearity of the bracket and nothing more — is a *Lie algebra* if and only if the following two further axioms are satisfied:

1. Antisymmetry:
$$\forall\ X,Y\in L,\quad [X,Y] = -\,[Y,X]\ . \tag{5.155}$$

2. Jacobi identity:

$$\forall\ X, Y, Z \in L, \quad [X, [Y, Z]] + [Y, [Z, X]] + [Z, [X, Y]] = 0_L\,. \tag{5.156}$$

Rests on Definition 5.117.

In the context of Lie algebras we shall name the IBO [,] the *Lie bracket*.

Properties of the structure constants

As a direct consequence of the axioms of a Lie algebra, there are two important properties satisfied by the structure constants. Let $L = \langle \{e_i\}^n \rangle$ be a Lie algebra.

1. Antisymmetry. From axiom Equation (5.155),

$$\begin{aligned} [e_i, e_j] &= -\,[e_j, e_i] \\ C^k{}_{ij} e_k &= -C^k{}_{ji} e_k \qquad\qquad \text{by Equation (5.150)}\,, \end{aligned}$$

hence

$$C^k{}_{ij} = -C^k{}_{ji}\,. \tag{5.157}$$

From Equations (5.150) and (5.155) (antisymmetry of the Lie bracket, written on a pair of basis elements).

2. Jacobi identity. From axiom Equation (5.156),

$$\begin{aligned} [e_i, [e_j, e_k]] + [e_j, [e_k, e_i]] + [e_k, [e_i, e_j]] &= 0_L \\ \left[e_i, C^l{}_{jk} e_l\right] + \left[e_j, C^l{}_{ki} e_l\right] + \left[e_k, C^l{}_{ij} e_l\right] &= 0_L \\ C^l{}_{jk}\,[e_i, e_l] + C^l{}_{ki}\,[e_j, e_l] + C^l{}_{ij}\,[e_k, e_l] &= 0_L \\ C^l{}_{jk} C^m{}_{il} e_m + C^l{}_{ki} C^m{}_{jl} e_m + C^l{}_{ij} C^m{}_{kl} e_m &= 0_L \\ (C^l{}_{jk} C^m{}_{il} + C^l{}_{ki} C^m{}_{jl} + C^l{}_{ij} C^m{}_{kl}) e_m &= 0_L\,, \end{aligned}$$

so, writing 0_L as

$$0_L = \sum_{m=1}^{\dim L} 0 \cdot e_m, \quad 0 \in \mathbb{K}\,,$$

we obtain

$$C^l{}_{jk} C^m{}_{il} + C^l{}_{ki} C^m{}_{jl} + C^l{}_{ij} C^m{}_{kl} = 0\,. \tag{5.158}$$

From Equations (5.150) and (5.156) (the Jacobi identity on basis elements, with the inner and outer brackets expanded in turn).

5.7.4 Derivations

Definition 5.124 (Derivation)**.** Consider an algebra L and let $D : L \longrightarrow L$ be a map. We say that D is a *derivation* if it satisfies the following properties:

1. Linearity:

$$D(\alpha X + \beta Y) = \alpha DX + \beta DY\,,$$

that is, D is a linear transformation.

2. Leibniz rule:

$$D\,[X, Y] = [DX, Y] + [X, DY]\,.$$

Rests on Definitions 5.35 and 5.117.

The algebra of derivations

Derivations satisfy the following properties. Let D_1 and D_2 be derivations.

1. *Linear combination of derivations.* The linear combination of derivations is also a derivation. Indeed, the linear combination of linear transformations is again a linear transformation; moreover, the Leibniz rule holds:

$$\begin{aligned}(\alpha D_1 + \beta D_2)\,[X,Y] &= \alpha D_1\,[X,Y] + \beta D_2\,[X,Y] \\ &= \alpha([D_1X,Y] + [X,D_1Y]) + \beta([D_2X,Y] + [X,D_2Y]) \\ &= [\alpha D_1X,Y] + [\beta D_2X,Y] + [X,\alpha D_1Y] + [X,\beta D_2Y] \\ &= [(\alpha D_1 + \beta D_2)X,Y] + [X,(\alpha D_1 + \beta D_2)Y]\ .\end{aligned}$$

2. *Commutator of two derivations.* The derivation of a derivation is, in general, not a derivation. Indeed, applying D_2 to the Leibniz rule for D_1,

$$\begin{aligned}D_1\,[X,Y] &= [D_1X,Y] + [X,D_1Y] \\ D_2D_1\,[X,Y] &= [D_2D_1X,Y] + [D_1X,D_2Y] + [D_2X,D_1Y] + [X,D_2D_1Y] \\ &= [D_2D_1X,Y] + [X,D_2D_1Y] + \underbrace{[D_1X,D_2Y] + [D_2X,D_1Y]}_{\text{in general } \neq 0_L}\ . \end{aligned} \tag{5.159}$$

   Analogously to Equation (5.159) we have

$$D_1D_2\,[X,Y] = [D_1D_2X,Y] + [X,D_1D_2Y] + [D_2X,D_1Y] + [D_1X,D_2Y]\ . \tag{5.160}$$

   Now, subtracting Equation (5.159) from Equation (5.160),

$$\begin{aligned}(D_1D_2 - D_2D_1)\,[X,Y] &= [D_1D_2X,Y] + [X,D_1D_2Y] - [D_2D_1X,Y] - [X,D_2D_1Y] \\ &= [(D_1D_2 - D_2D_1)X,Y] + [X,(D_1D_2 - D_2D_1)Y]\ ,\end{aligned}$$

   hence

$$[D_1,D_2]\,[X,Y] = [[D_1,D_2]\,X,Y] + [X,[D_1,D_2]\,Y]\ ,$$

   so the commutator of two derivations is again a derivation.

On the basis of the two properties above we may conclude that the set of all derivations definable on L, together with the binary operation (internal, thanks to the closure proved in the second property) defined by $[D_1,D_2] = D_1D_2 - D_2D_1$, forms an algebra, which we shall call the *algebra of derivations* and denote L_A.

5.8 Representations of groups

5.8.1 The classical groups

The orthogonal group

There is an important subgroup of the general linear group $\mathrm{GL}(n,\mathbb{K})$ obtained by adding the property that every automorphism T satisfy $[T][T]^{\mathsf{T}} = \mathbb{1}$. Indeed, let A and B lie in this set, so that $[A][A]^{\mathsf{T}} = \mathbb{1}$ and $[B][B]^{\mathsf{T}} = \mathbb{1}$. By closure of $\mathrm{GL}(n,\mathbb{K})$ there exists C such that $AB = C$. We must prove that $[C][C]^{\mathsf{T}} = \mathbb{1}$. We have

$$\begin{aligned}[C][C]^{\mathsf{T}} &= [A][B]([A][B])^{\mathsf{T}} \\ &= [A][B][B]^{\mathsf{T}}[A]^{\mathsf{T}} \\ &= [A]\,\mathbb{1}\,[A]^{\mathsf{T}} \\ &= \mathbb{1}\,,\end{aligned}$$

so this set possesses closure. We call this subgroup the *orthogonal group* and symbolize it $\mathrm{O}(n,\mathbb{K})$; thus

$$\mathrm{O}(n,\mathbb{K}) = \left\{ T \in \mathrm{GL}(n,\mathbb{K}) \mid [T][T]^{\mathsf{T}} = \mathbb{1} \right\} . \tag{5.161}$$

Note that, taking determinants,

$$\begin{aligned} [T][T]^{\mathsf{T}} &= \mathbb{1} \\ \det\left([T][T]^{\mathsf{T}} \right) &= 1 \\ \det[T]\, \det[T]^{\mathsf{T}} &= 1 \\ \det[T]\, \det[T] &= 1 \\ (\det[T])^2 &= 1 , \end{aligned}$$

so that

$$\det[T] = \pm 1 .$$

As we saw for the special linear group, the condition $\det[T] = 1$ possesses closure, which in general does not happen for the condition $\det[T] = -1$. We therefore define the *special orthogonal group* as

$$\mathrm{SO}(n,\mathbb{K}) = \{ T \in \mathrm{O}(n,\mathbb{K}) \mid \det[T] = 1 \} . \tag{5.162}$$

Proposition 5.125 (An orthogonal transformation is an isometry)**.** *Let $\mathbb{R}^n$ carry the standard inner product $\langle u|v\rangle = u^{\mathsf{T}} v$. A real array T of order n lies in $\mathrm{O}(n,\mathbb{R})$ if and only if*

$$\langle Tu|Tv\rangle = \langle u|v\rangle \qquad \text{for all } u, v \in \mathbb{R}^n , \tag{5.163}$$

and then in particular $\|Tu\| = \|u\|$: an orthogonal transformation preserves lengths, and with them the angle Equation (5.18) between any two non-zero vectors.

Rests on Definition 5.17, Proposition 5.47, and Equation (5.44).

Proof. *Derives Proposition 5.125.*

Equation (5.161) says $TT^{\mathsf{T}} = \mathbb{1}$; in finite dimension a one-sided inverse is the inverse (Proposition 5.47), so $T^{\mathsf{T}}T = \mathbb{1}$ as well, and the two conditions are interchangeable. Given them, $\langle Tu|Tv\rangle = u^{\mathsf{T}}T^{\mathsf{T}}Tv = u^{\mathsf{T}}v$, which is Equation (5.163). Conversely, taking u and v to be the standard basis vectors in Equation (5.163) reads off $\left(T^{\mathsf{T}}T\right)_{ij} = \delta_{ij}$. The norm statement is Equation (5.44) with $u = v$, and the angle statement then follows because both the numerator and the denominator of Equation (5.18) are unchanged. □

Isotropic Cartesian tensors

An array of numbers carrying N indices, each running over the three directions of physical space, is a *Cartesian tensor of rank N* when its entries in a rotated orthonormal frame are obtained from those in the old one by contracting each index with the rotation. Almost every constitutive law of continuum physics is written with such an array, and almost every material to which those laws are first applied is *isotropic*: it has no preferred direction, so the array must be the same in every frame. That single requirement determines the array almost completely, and the following is the statement that does the work.

Definition 5.126 (Isotropic Cartesian tensor)**.** An array $T_{i_1 \ldots i_N}$ of 3^N real numbers is an *isotropic Cartesian tensor of rank N* if

$$T_{i_1 \ldots i_N} = R_{i_1 j_1} \cdots R_{i_N j_N} T_{j_1 \ldots j_N} \qquad \text{for every } R \in \mathrm{SO}(3) , \tag{5.164}$$

repeated indices being summed over $1, 2, 3$ as in Section 5.3.3.

Rests on Equation (5.162) and Definition 5.30.

Lemma 5.127 (Parity constraint)**.** *Let T be isotropic of rank N. A component $T_{i_1\dots i_N}$ vanishes unless, for each value $p \in \{1,2,3\}$, the number m_p of indices equal to p has the same parity as N.*

Rests on Definition 5.126 and Equation (5.162).

Proof. *Derives Lemma 5.127.*

Fix p and let $R^{(p)}$ be the diagonal array with $+1$ in the p-th place and -1 in the other two: it satisfies $R^{\mathsf{T}}R = \mathbb{1}$ and has determinant $(+1)(-1)(-1) = +1$, so it lies in SO(3) by Equation (5.162). Being diagonal, $R^{(p)}_{ij} = s_i\delta_{ij}$ with $s_p = 1$ and $s_q = -1$ for $q \neq p$, so Equation (5.164) collapses to

$$T_{i_1\dots i_N} = s_{i_1}\cdots s_{i_N}\, T_{i_1\dots i_N} = (-1)^{N-m_p}\, T_{i_1\dots i_N}$$

with no summation, $N - m_p$ being the number of indices different from p. If $N - m_p$ is odd the component equals its own negative. □

Theorem 5.128 (Isotropic Cartesian tensors of rank at most four)**.** *Let T be an isotropic Cartesian tensor. Then, with $a, b, c \in \mathbb{R}$ arbitrary,*

$$N = 1: \quad T_i = 0\,, \tag{5.165}$$
$$N = 2: \quad T_{ij} = a\,\delta_{ij}\,, \tag{5.166}$$
$$N = 3: \quad T_{ijk} = a\,\varepsilon_{ijk}\,, \tag{5.167}$$
$$N = 4: \quad T_{ijkl} = a\,\delta_{ij}\delta_{kl} + b\,\delta_{ik}\delta_{jl} + c\,\delta_{il}\delta_{jk}\,, \tag{5.168}$$

and conversely every array of these forms is isotropic. A rank-four isotropic tensor therefore carries three free numbers, not $3^4 = 81$.

Rests on Lemmas 5.31 and 5.127 and Proposition 5.125.

Proof. *Derives Theorem 5.128.*

The converse first. δ_{ij} is isotropic, because $R_{ia}R_{jb}\delta_{ab} = R_{ia}R_{ja} = \delta_{ij}$ is $RR^{\mathsf{T}} = \mathbb{1}$ (Proposition 5.125); products of Kronecker deltas are then isotropic index group by index group; and ε_{ijk} is isotropic by Equation (5.59), since $\det R = 1$ on SO(3).

Two further elements of SO(3) do the rest of the work. The *cyclic* array C, with $C_{21} = C_{32} = C_{13} = 1$ and every other entry zero, is orthogonal and has determinant $+1$, a 3-cycle being an even permutation; substituted in Equation (5.164) it gives

$$T_{i_1\dots i_N} = T_{\sigma(i_1)\dots\sigma(i_N)}\,, \qquad \sigma: 1 \mapsto 3 \mapsto 2 \mapsto 1\,, \tag{5.169}$$

that is, the components are unchanged when every index *value* is relabelled cyclically. The *quarter turn* Q about the third axis, with $Q_{21} = 1$, $Q_{12} = -1$, $Q_{33} = 1$, is likewise in SO(3) and gives

$$T_{i_1\dots i_N} = (-1)^{m_1}\, T_{\tau(i_1)\dots\tau(i_N)}\,, \qquad \tau: 1 \leftrightarrow 2\,,\ 3 \mapsto 3\,, \tag{5.170}$$

m_1 being the number of indices equal to 1.

Rank one. Lemma 5.127 asks every m_p to be odd while $m_1 + m_2 + m_3 = 1$, which is impossible; every component vanishes.

Rank two. Every m_p must be even and they sum to 2, so one of them is 2 and the others vanish: $T_{ij} = 0$ unless $i = j$. By Equation (5.169), $T_{11} = T_{33} = T_{22}$, and Equation (5.166) holds with a that common value.

Rank three. Every m_p must be odd and they sum to 3, so each equals 1: only components with three distinct indices survive. Equation (5.169) gives $T_{123} = T_{312} = T_{231}$ and $T_{213} = T_{132} = T_{321}$, and Equation (5.170) applied to $(1,2,3)$, where $m_1 = 1$, gives $T_{123} = -T_{213}$. The six surviving components are therefore $\pm T_{123}$ according to the parity of the index arrangement, which is Equation (5.167) with $a = T_{123}$.

Rank four. Every multiplicity must be even and they sum to 4, so they are either $(4,0,0)$ or $(2,2,0)$ in some order: the surviving components are the three T_{pppp} and, for each ordered pair of distinct values $p \neq q$, the three arrangements T_{ppqq}, T_{pqpq}, T_{pqqp}. Equation (5.169) makes $T_{1111} = T_{3333} = T_{2222}$, a common value α, and carries the ordered pair (p,q) to $(\sigma(p),\sigma(q))$, whose orbits are $\{(1,2),(3,1),(2,3)\}$ and $\{(2,1),(1,3),(3,2)\}$; Equation (5.170) applied to $(1,1,2,2)$, $(1,2,1,2)$ and $(1,2,2,1)$ — each with $m_1 = 2$, hence with sign $+1$ — gives $T_{1122} = T_{2211}$, $T_{1212} = T_{2121}$ and $T_{1221} = T_{2112}$, joining the two orbits to each other. Hence the three numbers

$$a = T_{ppqq}\,, \qquad b = T_{pqpq}\,, \qquad c = T_{pqqp}$$

do not depend on which ordered pair $p \neq q$ is used, and Equation (5.168) reproduces every surviving component except possibly T_{pppp}, where it returns $a+b+c$ instead of α.

The last relation. Let $R(\theta)$ be the rotation by θ about the third axis, $R_{11} = R_{22} = \cos\theta$, $R_{21} = -R_{12} = \sin\theta$, $R_{33} = 1$. Only the values 1 and 2 occur in R_{1j}, so Equation (5.164) for the component T_{1111} involves only components whose indices lie in $\{1,2\}$, each carrying a factor $\cos\theta$ for an index 1 and $-\sin\theta$ for an index 2. Those with an odd number of 2's vanish by Lemma 5.127, and the rest give, writing $\gamma = \cos\theta$ and $s = \sin\theta$,

$$\alpha = \left(\gamma^4 + s^4\right)\alpha + 2\gamma^2 s^2\,(a+b+c)\,,$$

the six mixed components $T_{1122}, T_{1212}, T_{1221}, T_{2112}, T_{2121}, T_{2211}$ each carrying the factor $\gamma^2 s^2$ and summing to $2(a+b+c)$. Since $\gamma^4 + s^4 = 1 - 2\gamma^2 s^2$, this reads $2\gamma^2 s^2\,(a+b+c-\alpha) = 0$, and $\theta = \pi/4$ makes $\gamma^2 s^2 = 1/4$, so $\alpha = a+b+c$. □

Remark 5.129 (What the theorem buys, and what it does not). Equation (5.168) is the step at which the constitutive law of an isotropic elastic solid collapses from twenty-one independent constants to two, and at which the viscous stress of an isotropic Newtonian fluid collapses from eighty-one components to two viscosities: in both cases the array is symmetric in its first and last pairs of indices, which identifies two of the three constants of Equation (5.168) with each other and leaves two. The theorem says nothing about anisotropic materials — a crystal has a preferred set of directions and its tensor is invariant only under the finite point group of the lattice, so the count is a different and larger one — and it is a statement about SO(3) alone: adding invariance under reflections would in addition kill the rank-three case, since ε_{ijk} changes sign there by Equation (5.59).

The unitary group

Another very important subgroup of the general linear group is a group analogous to $\mathrm{O}(n,\mathbb{K})$, except that the added condition is $[T][T]^\dagger = \mathbb{1}$; we call it the *unitary group* and symbolize it $\mathrm{U}(n,\mathbb{K})$. Again, analogously, we can define the *special unitary group* by adding the condition $\det[T] = 1$. We have

$$\mathrm{U}(n,\mathbb{K}) = \left\{T \in \mathrm{GL}(n,\mathbb{K}) \mid [T][T]^\dagger = \mathbb{1}\right\}, \tag{5.171}$$

$$\mathrm{SU}(n,\mathbb{K}) = \{T \in \mathrm{U}(n,\mathbb{K}) \mid \det[T] = 1\}\,. \tag{5.172}$$

The symplectic group

The orthogonal and unitary groups are the invariance groups of a *symmetric* form. The third classical family is the invariance group of a non-degenerate *antisymmetric* one, which Proposition 5.115 has already reduced to a single normal form.

Definition 5.130 (The symplectic group)**.** Let ω be the non-degenerate antisymmetric bilinear form on $\mathbb{R}^{2n}$ whose matrix in the basis of Equation (5.143) is

$$J = [\omega] = \begin{pmatrix} 0 & \mathbb{1}_n \\ -\mathbb{1}_n & 0 \end{pmatrix}, \qquad (J)^{\mathsf{T}} = -J\,, \quad J^2 = -\mathbb{1}_{2n}\,, \quad J^{-1} = -J\,. \tag{5.173}$$

The *symplectic group* is the set of linear transformations of $\mathbb{R}^{2n}$ preserving ω,

$$\mathrm{Sp}(2n,\mathbb{R}) = \left\{ M \in \mathcal{M}_{2n\times 2n}\left[\mathbb{R}\right] \;\middle|\; (M)^{\mathsf{T}} J\, M = J \right\}, \tag{5.174}$$

the condition being $\omega(Mu, Mv) = \omega(u, v)$ for all u, v, written in components through Equation (5.138).

Rests on Proposition 5.115, Definition 5.109, and Equation (5.138).

Proposition 5.131 ($\mathrm{Sp}(2n,\mathbb{R})$ is a subgroup of $\mathrm{GL}(2n,\mathbb{R})$)**.** *Every M satisfying Equation (5.174) is invertible, and the set of such M is closed under multiplication and under inversion; it is therefore a subgroup of* $\mathrm{GL}(2n,\mathbb{R})$.

Rests on Definition 5.130, Equation (5.81), and Proposition 5.46.

Proof. *Derives Proposition 5.131.*

Invertibility. Taking determinants in Equation (5.174) and using $\det\left((M)^{\mathsf{T}}\right) = \det M$, which is immediate from the Leibniz expansion Equation (5.19) on relabelling $\sigma \longmapsto \sigma^{-1}$,

$$(\det M)^2 \det J = \det J\,,$$

and $\det J \neq 0$ because J is invertible by Equation (5.173). Hence $(\det M)^2 = 1$, so $\det M = \pm 1 \neq 0$ and $M \in \mathrm{GL}(2n,\mathbb{R})$ by Equation (5.81).

Closure. If M and N both satisfy Equation (5.174) then

$$\begin{aligned} (MN)^{\mathsf{T}} J\,(MN) &= (N)^{\mathsf{T}} \left((M)^{\mathsf{T}} J\, M\right) N \\ &= (N)^{\mathsf{T}} J\, N \\ &= J\,, \end{aligned}$$

the first line using $(MN)^{\mathsf{T}} = (N)^{\mathsf{T}}(M)^{\mathsf{T}}$.

Inverses. Transposing $MM^{-1} = M^{-1}M = \mathbb{1}_{2n}$ gives $(M^{-1})^{\mathsf{T}}(M)^{\mathsf{T}} = (M)^{\mathsf{T}}(M^{-1})^{\mathsf{T}} = \mathbb{1}_{2n}$, so $(M^{-1})^{\mathsf{T}}$ is the inverse of $(M)^{\mathsf{T}}$ — the uniqueness of Proposition 5.46. Multiplying $(M)^{\mathsf{T}} J\, M = J$ on the left by $(M^{-1})^{\mathsf{T}}$ and on the right by M^{-1} therefore yields

$$J = (M^{-1})^{\mathsf{T}} J\, M^{-1}\,,$$

so M^{-1} is symplectic as well. Associativity and the identity $\mathbb{1}_{2n}$, which trivially satisfies Equation (5.174), are inherited from $\mathrm{GL}(2n,\mathbb{R})$. □

The determinant is in fact never -1. Proving that requires one genuine piece of multilinear algebra, which is worth isolating because it is the characterization of the determinant that makes the argument work.

Lemma 5.132 (The alternating top form is unique up to scale)**.** *Let $\mathbb{V}$ be a real vector space of dimension N with basis $\{b_1, \ldots, b_N\}$, and let $\Omega : \mathbb{V}^N \longrightarrow \mathbb{R}$ be N-linear (linear in each argument with the others held fixed) and* alternating*, meaning that it changes sign whenever two of its arguments are exchanged. Then, with $v_j = \sum_i v^i{}_j b_i$,*

$$\Omega\left(v_1, \ldots, v_N\right) = \Omega\left(b_1, \ldots, b_N\right) \det\left[v^i{}_j\right], \tag{5.175}$$

and consequently, for every linear $M : \mathbb{V} \longrightarrow \mathbb{V}$,

$$\Omega\left(Mv_1, \ldots, Mv_N\right) = \det M\; \Omega\left(v_1, \ldots, v_N\right)\,. \tag{5.176}$$

Rests on Equation (5.19) and Definitions 5.14 and 5.106.

Proof. *Derives Lemma 5.132.*

First, Ω vanishes whenever two of its arguments are equal: exchanging those two leaves it unchanged and, by hypothesis, reverses its sign, so $\Omega = -\Omega$ and $2\Omega = 0$ in $\mathbb{R}$.

Expanding each argument by N-linearity,

$$\Omega\left(v_1, \ldots, v_N\right) = \sum_{i_1, \ldots, i_N} v^{i_1}{}_1 \cdots v^{i_N}{}_N \, \Omega\left(b_{i_1}, \ldots, b_{i_N}\right) ,$$

and every term in which two indices coincide vanishes by the previous paragraph. The surviving tuples are exactly those of the form $i_j = \sigma(j)$ for a permutation σ of N symbols; writing σ as a product of transpositions and applying the sign change once per transposition gives $\Omega\left(b_{\sigma(1)}, \ldots, b_{\sigma(N)}\right) = \operatorname{sgn}(\sigma)\, \Omega\left(b_1, \ldots, b_N\right)$. Hence

$$\Omega\left(v_1, \ldots, v_N\right) = \Omega\left(b_1, \ldots, b_N\right) \sum_{\sigma} \operatorname{sgn}(\sigma) \prod_{j=1}^{N} v^{\sigma(j)}_{\ j} ,$$

whose sum is the Leibniz expansion Equation (5.19) of $\det \left[v^i{}_j\right]$. This is Equation (5.175).

For Equation (5.176), note that the components of Mv_j are the entries of the array $[M]\left[v^i{}_j\right]$, since a matrix acts on a column of components by Proposition 5.43. Applying Equation (5.175) twice and using the multiplicativity of the determinant,

$$\begin{aligned} \Omega\left(Mv_1, \ldots, Mv_N\right) &= \Omega\left(b_1, \ldots, b_N\right) \det\left([M]\left[v^i{}_j\right]\right) \\ &= \det M \; \Omega\left(b_1, \ldots, b_N\right) \det\left[v^i{}_j\right] \\ &= \det M \; \Omega\left(v_1, \ldots, v_N\right) . \end{aligned}$$

□

Theorem 5.133 (A symplectic transformation has determinant +1)**.** *Every* $M \in \mathrm{Sp}(2n, \mathbb{R})$ *satisfies* $\det M = 1$. *Hence* $\mathrm{Sp}(2n, \mathbb{R}) \leq \mathrm{SL}(2n, \mathbb{R})$, *and for* $n = 1$ *the two coincide.*

Rests on Definition 5.130, Lemma 5.132, and Proposition 5.115.

Proof. *Derives Theorem 5.133.*

Build from ω the $2n$-argument function

$$\Omega\left(v_1, \ldots, v_{2n}\right) = \frac{1}{2^n n!} \sum_{\sigma} \operatorname{sgn}(\sigma) \prod_{i=1}^{n} \omega\left(v_{\sigma(2i-1)}, v_{\sigma(2i)}\right) , \tag{5.177}$$

the sum running over all permutations σ of $2n$ symbols.

Ω *is* $2n$*-linear.* In each term every argument occurs in exactly one of the n factors and occurs there once, and ω is linear in each of its slots.

Ω *is alternating.* Let τ be the transposition exchanging two of the argument positions. Replacing the arguments by their τ-permutation and substituting $\sigma' = \tau\sigma$ in the sum — which merely reindexes it, $\sigma \longmapsto \tau\sigma$ being a bijection of the permutations onto themselves — gives back Equation (5.177) with $\operatorname{sgn}(\sigma) = \operatorname{sgn}(\tau)\operatorname{sgn}(\sigma') = -\operatorname{sgn}(\sigma')$, that is, with the opposite sign.

Ω *does not vanish identically.* Evaluate it on the canonical basis of Equation (5.143), taken in the interleaved order $(e_1, f_1, e_2, f_2, \ldots, e_n, f_n)$. A term survives only if each factor pairs some e_i with the corresponding f_i, that is, only if the n unordered pairs $\{\sigma(2i-1), \sigma(2i)\}$ are exactly the n pairs $\{2i-1, 2i\}$ of argument positions; there are $n!$ ways to order those pairs among the factors and 2 ways to order each pair internally, so $2^n n!$ terms survive. Each contributes $+1$: reversing one pair internally multiplies its factor $\omega(e_i, f_i) = 1$ by -1, by antisymmetry, and multiplies $\operatorname{sgn}(\sigma)$ by -1 as well, while permuting whole pairs is an

even permutation, being a product of transpositions of two-element blocks. Dividing by $2^n n!$,

$$\Omega\,(e_1, f_1, \ldots, e_n, f_n) = 1\,.$$

Conclusion. If M is symplectic then $\omega(Mu, Mv) = \omega(u, v)$, so every factor in Equation (5.177) is unchanged when each argument is replaced by its image, and $\Omega(Mv_1, \ldots, Mv_{2n}) = \Omega(v_1, \ldots, v_{2n})$. But Equation (5.176) says the left-hand side equals $\det M\,\Omega(v_1, \ldots, v_{2n})$. Evaluating both on the canonical basis, where $\Omega = 1$, gives $\det M = 1$.

For $n = 1$ a direct computation settles the converse inclusion: for any real 2×2 array M one has $(M)^{\mathsf{T}} J\, M = \det M\, J$, so Equation (5.174) reduces to $\det M = 1$ and $\mathrm{Sp}(2, \mathbb{R}) = \mathrm{SL}(2, \mathbb{R})$. □

Proposition 5.134 (Dimension of the symplectic group)**.** *The set*

$$\mathfrak{sp}(2n, \mathbb{R}) = \Big\{ X \in \mathcal{M}_{2n\times 2n}\,[\mathbb{R}] \;\Big|\; (X)^{\mathsf{T}} J + J\,X = 0 \Big\} \tag{5.178}$$

is a Lie subalgebra of the matrix algebra of Proposition 5.121, and

$$\dim \mathfrak{sp}(2n, \mathbb{R}) = n\,(2n + 1)\ , \tag{5.179}$$

which is also the dimension of $\mathrm{Sp}(2n, \mathbb{R})$ *as a Lie group.*
Rests on Definitions 5.123 and 5.130 and Proposition 5.121.

Proof. *Derives Proposition 5.134.*

It is a subspace and a subalgebra. The defining condition Equation (5.178) is linear in X, so the set is a subspace. For the bracket, let $X, Y \in \mathfrak{sp}(2n, \mathbb{R})$, so that $(X)^{\mathsf{T}} J = -JX$ and $(Y)^{\mathsf{T}} J = -JY$. Then

$$\begin{aligned} ([X, Y])^{\mathsf{T}} J &= \Big((Y)^{\mathsf{T}} (X)^{\mathsf{T}} - (X)^{\mathsf{T}} (Y)^{\mathsf{T}} \Big)\, J \\ &= (Y)^{\mathsf{T}}\,(-JX) - (X)^{\mathsf{T}}\,(-JY) \\ &= -\,(-JY)\,X + (-JX)\,Y \\ &= -J\,(XY - YX) = -J\,[X, Y]\ , \end{aligned}$$

so $[X, Y] \in \mathfrak{sp}(2n, \mathbb{R})$, and the two Lie-algebra axioms Equations (5.155) and (5.156) hold because the commutator satisfies them on the whole matrix algebra.

The dimension. Put $S = J\,X$, so that $X = J^{-1} S = -J\,S$ by Equation (5.173); the assignment $X \longmapsto S$ is a linear bijection of $\mathcal{M}_{2n\times 2n}\,[\mathbb{R}]$ onto itself. Using $(J^{-1})^{\mathsf{T}} = (-J)^{\mathsf{T}} = J$ and $J^2 = -\mathbb{1}_{2n}$,

$$(X)^{\mathsf{T}} J = (J^{-1} S)^{\mathsf{T}} J = (S)^{\mathsf{T}} (J^{-1})^{\mathsf{T}} J = (S)^{\mathsf{T}} J^2 = -(S)^{\mathsf{T}}\,,$$

so the condition $(X)^{\mathsf{T}} J + JX = 0$ becomes $-(S)^{\mathsf{T}} + S = 0$: precisely the statement that S is symmetric. The symmetric arrays of order $2n$ form a subspace of dimension $2n(2n+1)/2 = n(2n+1)$, a basis being given by the arrays with 1 in a diagonal entry and by those with 1 in a pair of mirror-image off-diagonal entries. This is Equation (5.179).

That the group has the same dimension is the general correspondence between a Lie group and its algebra, established in Chapter 14; the check $n = 1$ is reassuring, for $n(2n + 1) = 3$ agrees with the three parameters of $\mathrm{SL}(2, \mathbb{R})$ — four entries subject to one determinant condition — as Theorem 5.133 requires. □

Remark 5.135 (Where the symplectic group is used). The group is the exact linear counterpart of a structure physics meets in its first serious reformulation of mechanics. The phase space of a system with N degrees of freedom carries a non-degenerate antisymmetric form pairing

each coordinate with its conjugate momentum (Remark 5.116), so $\omega(u, v)$ has the SI unit of action, J s; the linear transformations preserving it are exactly the linear *canonical* transformations, which is why Hamilton's equations take the same shape in every canonical coordinate system (Chapter 22). The passage from the fixed form on one vector space to a form varying smoothly over a manifold, and the theorem of Darboux that says nothing is lost in the passage, belong to Chapter 24. Note also the contrast with Equation (5.161): for the orthogonal group the determinant condition $\det M = 1$ is an extra requirement, singling out SO inside O, whereas for the symplectic group Theorem 5.133 makes it automatic — there is no "special symplectic group" to define.

5.8.2 Representations

Definition 5.136 (Representation of a group)**.** Let G be a group and X a set. We define a *representation* of G on X as a group homomorphism

$$\begin{array}{rccc} \rho: & G & \longrightarrow & S_X \\ & a & \longmapsto & \rho_a : X \longrightarrow X \,. \end{array}$$

Rests on Definitions 4.20, 4.39 and 4.44.

From now on we shall consider representations in which the set X is a vector space, that is, the case

$$S_X = \mathrm{GL}(\mathbb{V}) \,,$$

so the representations we shall study are of the form

$$\begin{array}{rccccccc} U: & G & \longrightarrow & \mathrm{GL}(\mathbb{V}) & & & & \\ & a & \longmapsto & U(a): & \mathbb{V} & \longrightarrow & \mathbb{V} \\ & & & & |v\rangle & \longmapsto & U(a)\,(|v\rangle) \overset{\text{not.}}{=} U(a)\,|v\rangle \ , \end{array}$$

where $U(a)$ is a linear transformation by definition.

Definition 5.137 (Dimension of a representation)**.** We refer to the dimension of a representation $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ as the dimension of $\mathbb{V}$.

Rests on Definitions 5.15 and 5.136.

Definition 5.138 (Faithful representation)**.** We say that a representation U is *faithful* if and only if U is an isomorphism. We say that a representation is *degenerate* if it is not faithful.

Rests on Definitions 4.40 and 5.136.

Definition 5.139 (Unitary representation)**.** Let $U : G \longrightarrow \mathrm{GL}\,(\mathbb{V})$ be a representation. We say that U is *unitary* if and only if

1. the vector space $\mathbb{V}$ is equipped with an inner product;

2. the linear transformation $U(a)$ is unitary for every a.

Rests on Definitions 5.17 and 5.136 and Equation (5.171)*.*

From now on we shall consider only unitary representations, unless we specify a more general case.

Representation matrix

Consider a linear space $\mathbb{V} = \left\langle \{|\hat{e}_i\rangle\}_i^{\dim \mathbb{V}} \right\rangle$ and a representation U. We can write

$$U(a)\,|\hat{e}_i\rangle = U^j{}_i(a)\,|\hat{e}_j\rangle\ ,$$

that is, the effect of a linear transformation on an element of the basis can be written as a linear combination of the elements of the basis — for it is, indeed, a basis.

We can associate the matrix $\left[U^j{}_i(a)\right]$ with the coefficients of this linear combination. For a more compact notation we symbolize this simply as

$$\left[U^j{}_i(a)\right] \overset{\text{not.}}{=} D(a)\,,$$

which is the *matrix representation of the representation* U with respect to a; equivalently, $D(a)$ is the matrix representation of the linear transformation $U(a)$.

Let us see that the matrix representation of a representation is also a homomorphism. We have

$$\begin{aligned} U(a)U(b)\,|\hat{e}_i\rangle &= U(a)U^j{}_i(b)\,|\hat{e}_j\rangle \\ U(ab)\,|\hat{e}_i\rangle &= U^k{}_j(a)U^j{}_i(b)\,|\hat{e}_k\rangle \\ U^k{}_i(ab)\,|\hat{e}_k\rangle &= U^k{}_j(a)U^j{}_i(b)\,|\hat{e}_k\rangle\ , \end{aligned}$$

from which we conclude that

$$U^k{}_i(ab) = U^k{}_j(a)U^j{}_i(b)\,,$$

or, in matrix notation,

$$D(ab) = D(a)D(b)\,. \tag{5.180}$$

Definition 5.140 (Equivalent representations)**.** Consider the representations U and U'. We say that these representations are *equivalent* if and only if there exists an operator S such that

$$U'(a) = SU(a)S^{-1}\,,$$

which is a similarity transformation; consequently, the set of all equivalent representations of a group forms an equivalence class.

Rests on Definition 5.136.

Definition 5.141 (Character)**.** We define the *character* of a representation U as

$$\chi(a) = \operatorname{tr}\left(D(a)\right). \tag{5.181}$$

Rests on Definition 5.136.

As we know, the trace is invariant under similarity transformations, so the character of a representation is invariant under similarity transformations. In other words, an equivalence class of representations is characterized by a character. The character of a representation is thus useful because it is basis-independent.

5.8.3 Irreducible representations

Definition 5.142 (Invariant subspace)**.** Let $\mathbb{V}$ be a vector space and $\mathbb{S} \leq \mathbb{V}$ a subspace. We say that the subspace $\mathbb{S}$ is *invariant* with respect to the representation U if and only if

$$U(a)\,|v\rangle \in \mathbb{S}, \quad \forall\ |v\rangle \in \mathbb{S}\ \wedge\ \forall\, a \in G\,,$$

that is, the vectors of the subspace do not leave this set when operated on by $U(a)$.

Rests on Definitions 5.6 and 5.136.

To visualize this more easily, we may conceive an invariant subspace as a set of trapped vectors, which do not escape from $\mathbb{S}$ when operated on by the linear transformation $U(a)$.

Given a representation there are always two trivial invariant subspaces: the null space and $\mathbb{V}$ itself.

Definition 5.143 (Irreducible representation)**.** Let $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ be a representation. We say that U is *irreducible* if and only if the only invariant subspaces with respect to it are the trivial ones, namely the null space and $\mathbb{V}$.

We say that a representation is *reducible* if and only if it is not irreducible, that is, if there exists a (non-trivial) invariant subspace with respect to U.

Rests on Definition 5.142.

Definition 5.144 (Totally reducible representation)**.** Consider an invariant subspace $\mathbb{S}$ with respect to U. We say that the representation U is *totally reducible* if the orthogonal complement of $\mathbb{S}$ is also invariant with respect to U.

Rests on Definition 5.142 and Equation (5.52)*.*

Before stating the proposition, fix what "unitary" says about the operator rather than about its matrix. By Definition 5.139 and Equation (5.171), U is unitary when $\mathbb{V}$ carries an inner product and $D(a)^\dagger D(a) = \mathbb{1}$ for every a. In an orthonormal basis (Equation (5.49)) that condition is equivalent to the statement that $U(a)$ *preserves the inner product*, since

$$\begin{aligned}\langle U(a)e_i | U(a)e_j\rangle &= \sum_{k,l} \left(D^k{}_i(a)\right)^* D^l{}_j(a)\,\langle e_k|e_l\rangle \qquad \text{by Equations (5.34) and (5.36)}\\ &= \sum_{k} \left(D^k{}_i(a)\right)^* D^k{}_j(a)\\ &= \left(D(a)^\dagger D(a)\right)^i{}_j\,, \end{aligned} \tag{5.182}$$

which equals $\delta^i{}_j = \langle e_i|e_j\rangle$ for all i, j exactly when $D(a)^\dagger D(a) = \mathbb{1}$; the general case follows by expanding arbitrary u, v in the basis. We shall use the invariant form

$$\langle U(a)u | U(a)v\rangle = \langle u|v\rangle\,, \qquad \forall\, u, v \in \mathbb{V},\ \forall\, a \in G\,. \tag{5.183}$$

Lemma 5.145 (Invariance of the orthogonal complement)**.** *Let $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ be a unitary representation of a group G on a vector space $\mathbb{V}$ with an inner product, and let $\mathbb{S} \leq \mathbb{V}$ be an invariant subspace (Definition 5.142). Then the orthogonal complement $\mathbb{S}^\perp$ of Equation* (5.52) *is invariant as well.*

Rests on Definitions 5.139 and 5.142 and Equations (4.25)*,* (5.52) *and* (5.183)*.*

Proof. *Derives Lemma 5.145.*

Let $w \in \mathbb{S}^\perp$ and $a \in G$; we must show $U(a)w \in \mathbb{S}^\perp$, that is, $\langle s|U(a)w\rangle = 0$ for every $s \in \mathbb{S}$. Because U is a group homomorphism into $\mathrm{GL}(\mathbb{V})$, the operator $U(a)$ is invertible with $U(a)^{-1} = U(a^{-1})$ by Equation (4.25), so we may write $s = U(a)U(a^{-1})s$ and use Equation (5.183):

$$\begin{aligned}\langle s|U(a)w\rangle &= \Big\langle U(a)U(a^{-1})s \Big| U(a)w\Big\rangle\\ &= \Big\langle U(a^{-1})s \Big| w\Big\rangle \qquad \text{by Equation (5.183)}\\ &= 0\,, \end{aligned}$$

the last step because $a^{-1} \in G$ — a group contains the inverse of each of its elements — so $U(a^{-1})s \in \mathbb{S}$ by the invariance of $\mathbb{S}$, and w is orthogonal to every vector of $\mathbb{S}$. As s was arbitrary, $U(a)w \in \mathbb{S}^\perp$. □

Three hypotheses were used and no others: that U is unitary, that G is a group, and that U is a homomorphism. Neither the dimension of $\mathbb{V}$ nor any property of G beyond its being a group entered, so the lemma holds for infinite groups and in infinite dimension.

Proposition 5.146. *Let U be a unitary representation. If U is not totally reducible, then it is not reducible.*

Rests on Lemma 5.145 and Definitions 5.143 and 5.144.

Proof. *Derives Proposition 5.146.*

We prove the contrapositive: if U is reducible then it is totally reducible. Suppose U is reducible, so that by Definition 5.143 there exists a non-trivial invariant subspace $\mathbb{S}$. By Lemma 5.145 the orthogonal complement $\mathbb{S}^{\perp}$ is invariant too, and that is exactly the condition Definition 5.144 imposes for U to be totally reducible.

Hence no unitary representation can be reducible without being totally reducible, and the stated implication follows. □

Remark 5.147 (The proposition is the contrapositive of a stronger one). Read in the direction just proved, the statement says something the source does not spell out: for a *unitary* representation the case "reducible but not totally reducible" is empty. It is not empty for representations in general. The standard witness lives already in $\mathrm{GL}(2,\mathbb{C})$: the map

$$U(n) = \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix}, \qquad n \in \mathbb{Z},$$

is a representation of the additive group $\mathbb{Z}$, since $U(n)U(m) = U(n+m)$. The subspace spanned by $(1,0)^{\mathsf{T}}$ is invariant, so the representation is reducible; but *no* complementary subspace is invariant, because any vector with non-zero second component is moved by $U(1)$ out of every line through it other than the first axis. The representation is therefore reducible and not totally reducible — and, consistently with Proposition 5.146, it is not unitary: $U(n)$ does not preserve the standard inner product, as $\left\|U(n)(0,1)^{\mathsf{T}}\right\|^2 = 1 + n^2$ grows without bound. This is the exact point at which Proposition 5.150 does its work: for a *finite* group no such example exists, because every representation of a finite group can be made unitary.

5.9 Representations of finite groups

The two results of this section are the ones the rest of the chapter — and, through it, a good deal of the physics later in the treatise — actually stands on. The source states both and leaves their derivations in draft form; they are given here in full, with the hypotheses each of them really needs made explicit, because those hypotheses are what decides where the results may be used and where they may not.

5.9.1 Complete reducibility of a unitary representation

Proposition 5.148. *Let $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ be a unitary representation of a group G on a* finite-dimensional *vector space $\mathbb{V}$ equipped with an inner product. Then:*

1. *if U is reducible it is totally reducible — for every invariant subspace $\mathbb{S}$ the orthogonal complement $\mathbb{S}^{\perp}$ is invariant as well, and $\mathbb{V} = \mathbb{S} \oplus \mathbb{S}^{\perp}$;*
2. *consequently $\mathbb{V}$ is the orthogonal direct sum of finitely many invariant subspaces on each of which U acts irreducibly,*

$$\mathbb{V} = \bigoplus_{\mu} \mathbb{V}^{\mu}, \qquad U(a) = \bigoplus_{\mu} U^{\mu}(a), \tag{5.184}$$

with $U^{\mu}(a) = U(a)|_{\mathbb{V}^{\mu}}$ a unitary irreducible representation of G on $\mathbb{V}^{\mu}$.

Rests on Lemma 5.145, Corollary 5.27, and Definitions 5.143 and 5.144.

Proof. *Derives Proposition 5.148.*

Part 1. That $\mathbb{S}^{\perp}$ is invariant is Lemma 5.145, which used no finiteness at all. That the two subspaces exhaust $\mathbb{V}$,

$$\mathbb{V} = \mathbb{S} \oplus \mathbb{S}^{\perp},$$

is Corollary 5.27, and *this* is where the finite dimension enters: it is what guarantees the orthonormal basis of $\mathbb{S}$ from which the projection was built. Every vector of $\mathbb{V}$ therefore splits uniquely as $v = s + w$ with $s \in \mathbb{S}$ and $w \in \mathbb{S}^{\perp}$, and since $U(a)s \in \mathbb{S}$ and $U(a)w \in \mathbb{S}^{\perp}$, the operator $U(a)$ acts on the two summands separately:

$$U(a)v = U(a)|_{\mathbb{S}}\, s + U(a)|_{\mathbb{S}^{\perp}}\, w\,.$$

In a basis adapted to the splitting the matrix $D(a)$ is block diagonal for every a simultaneously, which is what *totally reducible* means operationally.

Each restriction is itself a representation: it is linear; it is invertible on its subspace, because $U(a^{-1})$ maps that subspace into itself and $U(a)U(a^{-1}) = U(e) = \mathrm{id}$; and it inherits $U(ab) = U(a)U(b)$ from U. It is unitary, because Equation (5.183) holds in particular for vectors of the subspace.

Part 2. Induction on $n = \dim \mathbb{V}$. If $n = 1$ the only subspaces are the trivial ones, so U is irreducible by Definition 5.143 and the decomposition has one summand. Let $n > 1$ and suppose the claim proved for all dimensions smaller than n. If U is irreducible we are again done. If not, there is a non-trivial invariant subspace $\mathbb{S}$, and by Part 1

$$\mathbb{V} = \mathbb{S} \oplus \mathbb{S}^{\perp}, \qquad 1 \le \dim \mathbb{S} < n\,, \quad 1 \le \dim \mathbb{S}^{\perp} < n\,,$$

the strict inequalities holding because $\mathbb{S}$ is neither the null space nor the whole of $\mathbb{V}$. The restrictions of U to $\mathbb{S}$ and to $\mathbb{S}^{\perp}$ are unitary representations on spaces of strictly smaller dimension, so the induction hypothesis applies to each and decomposes it into irreducible summands; collecting the two lists gives Equation (5.184). The recursion terminates after at most n steps because the dimension drops by at least one each time, and the summands are mutually orthogonal by construction. □

Remark 5.149 (What each hypothesis is for). Three are in play and they are used in three different places.

- *An inner product* is needed to have an orthogonal complement at all. Without one, "totally reducible" in the sense of Definition 5.144 is not even a statement; the basis-free version of the result is that every invariant subspace has *some* invariant complement, and the inner product is what supplies it canonically.

- *Unitarity* is what makes that complement invariant (Lemma 5.145). Drop it and the conclusion is false: the representation of $\mathbb{Z}$ in Remark 5.147 is reducible with no invariant complement whatsoever.

- *Finite dimension* is used twice, for the splitting Equation (5.53) and for the termination of the induction. In infinite dimension the first survives for closed subspaces of a Hilbert space (Definition 12.2) — by the projection theorem reserved for Section 12.2.1 — but the second does not, and a unitary representation there need not be a direct sum of irreducibles at all — the representation of the translation group $(\mathbb{R}, +)$ on $L^2(\mathbb{R})$ by $(U(a)f)(x) = f(x - a)$ has no irreducible subrepresentation whatever, and its decomposition is a direct *integral* over the characters $\mathrm{e}^{\mathrm{i}kx}$, which is the Fourier transform of Chapter 17 in disguise.

5.9.2 Every representation of a finite group is unitary

The preceding proposition is worth little on its own, since it presumes what is usually not given: that the representation one happens to be handed is unitary. The following result removes the presumption for finite groups, and it does so constructively — it exhibits the inner product that makes the representation unitary. The device is the averaging or "unitarian" trick, which replaces a quantity by its average over the group and thereby makes it group-invariant by construction; it is the discrete ancestor of every projection onto a symmetric configuration used later in the treatise.

Proposition 5.150 (Averaging trick)**.** *Let $G = \{g_i\}_{i=1}^{n_G}$ be a* finite *group of order n_G and let $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ be a representation on a finite-dimensional vector space $\mathbb{V}$ over $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, equipped with an inner product $\langle\ |\ \rangle$. Define*

$$\langle u, v\rangle_G = \frac{1}{n_G}\sum_{i=1}^{n_G} \langle U(g_i)u | U(g_i)v\rangle \ . \tag{5.185}$$

Then $\langle\ ,\ \rangle_G$ is an inner product on $\mathbb{V}$; it is G-invariant,

$$\langle U(a)u, U(a)v\rangle_G = \langle u, v\rangle_G \ , \qquad \forall\, a \in G\,, \tag{5.186}$$

so that U is unitary with respect to it; and there exists $S \in \mathrm{GL}(\mathbb{V})$ such that

$$U'(a) = SU(a)S^{-1} \tag{5.187}$$

is unitary with respect to the original inner product. Hence U is equivalent, in the sense of Definition 5.140, to a unitary representation.

Rests on Definitions 5.17, 5.139 and 5.140, Proposition 5.26, and Equation (5.183).

Proof. *Derives Proposition 5.150.*

Step 1: Equation (5.185) is an inner product. Each summand is the original inner product evaluated on the images of u and v, so the five axioms transfer term by term.

- *Linearity in the second argument* Equations (5.34) and (5.35): $U(g_i)$ is linear, so $U(g_i)(av + bw) = aU(g_i)v + bU(g_i)w$, and Equations (5.34) and (5.35) applied inside each summand give the same for the average. The conjugate rules Equations (5.36) and (5.37) follow in the same way.

- *Hermiticity* Equation (5.33): each summand satisfies

  $$\langle U(g_i)u | U(g_i)v\rangle^* = \langle U(g_i)v | U(g_i)u\rangle \ ,$$

  and $1/n_G$ is real, so the sum inherits the property.

- *Positive definiteness* Equation (5.32): let $u \neq 0_{\mathbb{V}}$. Since $U(g_i) \in \mathrm{GL}(\mathbb{V})$ is invertible, $U(g_i)u \neq 0_{\mathbb{V}}$, so every summand $\langle U(g_i)u | U(g_i)u\rangle$ is strictly positive by Equation (5.32); a sum of n_G strictly positive reals divided by n_G is strictly positive. Equation (5.31) follows, the direction ($\Leftarrow$) from Equation (5.38).

Note where the finiteness of G has been used: the sum has finitely many terms, and n_G is invertible in $\mathbb{K}$.

Step 2: invariance, Equation (5.186). Using the homomorphism property $U(g_i)U(a) = U(g_i a)$,

$$\begin{aligned}\langle U(a)u, U(a)v\rangle_G &= \frac{1}{n_G}\sum_{i=1}^{n_G}\langle U(g_i)U(a)u|U(g_i)U(a)v\rangle \\ &= \frac{1}{n_G}\sum_{i=1}^{n_G}\langle U(g_i a)u|U(g_i a)v\rangle \\ &= \frac{1}{n_G}\sum_{j=1}^{n_G}\langle U(g_j)u|U(g_j)v\rangle \\ &= \langle u, v\rangle_G \ ,\end{aligned}$$

the third line because right multiplication by a is a bijection of G onto itself: it is injective, since $g_i a = g_j a$ implies $g_i = g_j$ on multiplying by a^{-1}, and therefore surjective on a finite set, so $\{g_i a\}$ is a relabelling of $\{g_j\}$ and the summands are the same numbers in another order. *This is the whole of the trick*: an average over the group cannot tell which element of the group it is looking at. With Equation (5.186) in hand, U satisfies Equation (5.183) for the product $\langle\ ,\ \rangle_G$, that is, it is a unitary representation on the inner-product space $(\mathbb{V}, \langle\ ,\ \rangle_G)$.

Step 3: the equivalence Equation (5.187). What remains is bookkeeping: to say "unitary" with respect to the original product rather than the new one. By Proposition 5.26 applied twice, choose a basis $\{e_i\}_{i=1}^n$ orthonormal for $\langle\ |\ \rangle$ and a basis $\{\tilde{e}_i\}_{i=1}^n$ orthonormal for $\langle\ ,\ \rangle_G$, and let S be the linear map determined by $S\tilde{e}_i = e_i$, which is invertible because it carries a basis to a basis. For $u = \sum_i u^i \tilde{e}_i$ and $v = \sum_i v^i \tilde{e}_i$, orthonormality of each basis for its own product gives

$$\langle Su|Sv\rangle = \sum_{i=1}^{n}\left(u^i\right)^* v^i = \langle u, v\rangle_G \ ,$$

that is, S carries the averaged product to the original one. Therefore, for all $x, y \in \mathbb{V}$,

$$\begin{aligned}\langle U'(a)x|U'(a)y\rangle &= \left\langle SU(a)S^{-1}x\middle|SU(a)S^{-1}y\right\rangle \\ &= \left\langle U(a)S^{-1}x, U(a)S^{-1}y\right\rangle_G \\ &= \left\langle S^{-1}x, S^{-1}y\right\rangle_G \qquad \text{by Equation (5.186)} \\ &= \langle x|y\rangle \ ,\end{aligned}$$

so U' satisfies Equation (5.183) for $\langle\ |\ \rangle$ and is a unitary representation, equivalent to U by construction. □

Remark 5.151 (Where the finiteness is really needed, and what replaces it). Finiteness of G entered in exactly two places, both in Step 1–2: the sum Equation (5.185) must converge, and n_G must be invertible. Neither is a statement about $\mathbb{V}$, and that is what makes the trick portable.

- *Compact continuous groups.* Replace the normalized sum $n_G^{-1}\sum_i$ by the integral $\int_G \mathrm{d}\mu(g)$ against the normalized bi-invariant *Haar measure* of the group, which exists and is unique on a compact group. Step 2 goes through verbatim, since invariance of the measure under right translation is precisely what replaced the rearrangement of the finite sum; positivity in Step 1 survives because the integrand is continuous and strictly positive. Every *continuous* finite-dimensional representation of a compact group — and $\mathrm{SO}(3,\mathbb{R})$, $\mathrm{SU}(2)$ and $\mathrm{U}(1)$, the groups on which most of the physics in this treatise turns, are compact — is therefore equivalent to a unitary one and, by Proposition 5.148, completely reducible. The continuity hypothesis is not decoration and cannot be

dropped: the whole argument consists of integrating $g \longmapsto \langle U(g)u | U(g)v \rangle$ against $\mathrm{d}\mu$, and a representation that is not at least measurable has nothing there to integrate. Continuity is the hypothesis every physical example satisfies and the one under which the statement is normally quoted; measurability suffices, and for these groups the two coincide in practice. This treatise takes the existence and uniqueness of the normalized bi-invariant measure on a compact group as an imported theorem of topological group theory, due to Haar [721]; it is not constructed anywhere in this book, and the natural home for it would be the Lie-group material of Chapter 14, which at the time of writing does not carry it either.

- *Non-compact groups.* There the argument fails, and not for want of ingenuity: a non-compact group carries no finite invariant measure, so there is nothing to average with. The failure is physical as well as technical. The Lorentz group is non-compact — its boosts form a non-compact one-parameter family — and its *non-trivial* finite-dimensional representations, the ones that classify fields in Chapter 39, are *not* unitary; its non-trivial unitary representations, the ones that classify particle states, are all infinite-dimensional [849]. The qualifier is needed on both halves and for the same reason: the trivial representation, which sends every group element to the identity operator on a one-dimensional space, is finite-dimensional and unitary at once, and would falsify either statement read without it. The exception is trivial in the literal sense — it is the one representation that records nothing whatever about the group — but a statement a counterexample falsifies is a false statement, so the qualifier stands. Complete reducibility must then be argued case by case, and the sharp division between the two kinds of representation of the Poincaré group is a direct consequence of this one missing average.

- *The arithmetic caveat.* Dividing by n_G presupposes that $n_G \neq 0$ in the field. Over $\mathbb{R}$ or $\mathbb{C}$ — the only fields this chapter admits — that is automatic, but over a field whose characteristic divides the order of the group the trick collapses, and with it complete reducibility. This is the hypothesis of Maschke's theorem, and it is not idle: the modular representation theory that results is a genuinely different subject.

Remark 5.152 (Why these two propositions are cited from the Standard Model). Taken together, Proposition 5.150 and Proposition 5.148 say that a symmetry acting on a finite-dimensional space may always be taken to act by inner-product-preserving operators, and that the space then splits cleanly into irreducible pieces. The flavour sector of the Standard Model is where a physicist meets the consequence in its bluntest form.

The three known generations of quarks span a three-dimensional complex space — an *internal* space, indexed by generation, with no relation to the three spatial dimensions of Chapter 39 — and there are two natural bases for it: the states of definite mass and the states that couple to the charged weak current. The matrix V relating the two bases is the Cabibbo–Kobayashi–Maskawa matrix [1248, 1505]; the corresponding matrix in the lepton sector, relating neutrino mass states to flavour states, is the Pontecorvo–Maki–Nakagawa–Sakata matrix [1159, 1237]. Both are dimensionless, as any change of basis must be: their entries are pure numbers, and no SI unit attaches to them.

Both bases are orthonormal for the same inner product — which is available precisely because the symmetry can be realized unitarily — so the matrix carrying one to the other is unitary. Unitarity of a matrix is two families of relations, not one — its rows are orthonormal and so are its columns — and they say different physical things, so which is which has to be kept straight. That single word carries the whole experimental programme:

- unitarity of the quark matrix gives, with i, j labelling the up-type rows and k, l the

down-type columns, the row relations

$$\sum_{k} V_{ik} V_{jk}^{*} = \delta_{ij}$$

and the column relations $\sum_i V_{ik}^{*} V_{il} = \delta_{kl}$. In either family the off-diagonal case is a sum of three complex numbers equal to zero, so the three must close into a triangle in the complex plane — six triangles in all, one for each pair of rows and one for each pair of columns. The one that is actually measured, and that the phrase *the unitarity triangle* refers to, comes from the down and the bottom column. It is customarily written in the conjugated form

$$V_{ud} V_{ub}^{*} + V_{cd} V_{cb}^{*} + V_{td} V_{tb}^{*} = 0\,,$$

the complex conjugate of the column relation just displayed with $k = d$ and $l = b$, and zero exactly when that one is. Its three sides are of comparable length, which is what makes its angles measurable in CP-violation experiments (Chapter 111); a failure to close would be evidence for a fourth generation or for physics outside the model, and is reported as such;

- unitarity of the leptonic matrix likewise gives two relations, and they are not interchangeable. The *row* relation

$$\sum_{i} |U_{\alpha i}|^{2} = 1$$

holds the flavour index α fixed and sums over the mass states i: it says that the state produced together with a charged lepton of flavour α is a superposition of the three mass states whose probabilities sum to one. The *column* relation $\sum_{\alpha} |U_{\alpha i}|^{2} = 1$ holds the mass index i fixed instead, and says the different thing that the mass state i has unit total flavour content. The statement that a neutrino produced in one flavour is detected in some flavour with total probability one is $\sum_{\beta} P(\nu_\alpha \to \nu_\beta) = 1$, and it consumes both: the column relation collapses the interference between mass states when the sum over the detected flavour β is done, and the row relation is what makes the surviving $\sum_i |U_{\alpha i}|^{2}$ equal to one (Chapter 114). Without unitarity the oscillation formula would not conserve probability.

The physics of both matrices belongs to Chapter 103, which at the time of writing carries its headings, its citations and its editorial specification but not yet the derivations. What this chapter contributes is only the licence to write the word “unitary” — but the two propositions above are where that licence comes from, and neither is free: each fails outside its hypotheses, as Remark 5.151 and Remark 5.149 record.

5.9.3 The regular representation

Recall from Equation (4.28) that upon multiplying the i-th element of a group by an element a of the group, it takes the place a_i; that is, a permutation occurs. We can write

$$\begin{aligned} a g_i &= g_{a_i} \\ &= g_j \, (\Delta_a)^{j}{}_{i}\,, \end{aligned}$$

where

$$(\Delta_a)^{j}{}_{i} = \begin{cases} 1, & j = a_i \\ 0, & j \neq a_i \end{cases} \tag{5.188}$$

from which we see that

$$(\Delta_a)^{j}{}_{i} = \delta^{j}{}_{a_i}\,. \tag{5.189}$$

Consider then elements $a, b, c \in G$ such that $c = ab$. In this permutation notation we can write

$$\begin{aligned} abg_i &= ag_{b_i} \\ &= ag_j \left(\Delta_b\right)^j{}_i \\ &= g_{a_j} \left(\Delta_b\right)^j{}_i \\ &= g_k \left(\Delta_a\right)^k{}_j \left(\Delta_b\right)^j{}_i \,, \end{aligned}$$

and, in addition,

$$\begin{aligned} cg_i &= g_{c_i} \\ &= g_k \left(\Delta_c\right)^k{}_i \,, \end{aligned}$$

and since $ab = c$ we have

$$\left(\Delta_a\right)^k{}_j \left(\Delta_b\right)^j{}_i = \left(\Delta_c\right)^k{}_i \,,$$

or, in operator notation,

$$\Delta_a \Delta_b = \Delta_c \,.$$

We have therefore found a homomorphism $a \overset{U}{\longmapsto} U(a) = \Delta_a$, since

$$\begin{aligned} U(a)U(b) &= U(c) \\ &= U(ab) \,. \end{aligned}$$

This homomorphism is called the *regular representation* of G.

The coefficients of Δ_a are determined by the following cases.

1. If $a = e$, we have

$$\begin{aligned} eg_i &= g_{e_i} \\ g_i &= g_{e_i} \,. \end{aligned}$$

Since the neutral element does not permute the others, $i = e_i$, so that

$$\left(\Delta_e\right)^j{}_i = \delta^j{}_i \,, \tag{5.190}$$

and we can compute the character by setting $j = i$, obtaining

$$\chi^R_e = n_G \,, \tag{5.191}$$

where n_G is the order of the group.

2. If $a \neq e$, we have the usual case, Equation (5.189). But upon setting $j = i$, since a_i is a permutation of i, the two indices are always distinct (for $a \neq e$); hence $\delta^i{}_{a_i} = 0$, and thus

$$\chi^R_a = 0 \,. \tag{5.192}$$

For example, for the group C_2 we have

$$\Delta_e = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

and

$$\begin{aligned} \Delta_a &= \begin{pmatrix} \delta^1{}_{a_1} & \delta^1{}_{a_2} \\ \delta^2{}_{a_1} & \delta^2{}_{a_2} \end{pmatrix} \\ &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} . \end{aligned}$$

5.9.4 Direct-sum and direct-product representations

Direct-sum representation

Consider the irreducible representations $U^\mu : G \longrightarrow \mathrm{GL}(\mathbb{V}^\mu)$, $\mu \in \mathbb{N}$. Their invariant subspaces are the $\mathbb{V}^\mu$ themselves, since they are irreducible. Let $\mathbb{V}$ be the direct sum of these spaces, that is,

$$\mathbb{V} = \bigoplus_\mu \mathbb{V}^\mu ,$$

and consider further a reducible representation U for which $\mathbb{V}$ is an invariant subspace, and which coincides with $U^\mu(a)$ on $\mathbb{V}^\mu$.

We have seen that the representation of a finite group is equivalent to a unitary representation (Proposition 5.150), and that if a representation is unitary and reducible then it is completely reducible (Proposition 5.148).

In this context we can decompose the representation U into the irreducible representations U^μ. In this procedure, equivalent representations may appear a_μ times each. That is,

$$U(a) = \underbrace{U^1(a) + \ldots + U^1(a)}_{a_1 \text{ times}} + \ldots + \underbrace{U^\mu(a) + \ldots + U^\mu(a)}_{a_\mu \text{ times}} + \ldots$$

or, in compact form,

$$U(a) = \sum_\mu a_\mu U^\mu(a) . \tag{5.193}$$

$U(a)$ is called the *direct-sum representation* of the irreducible representations $U^\mu(a)$.

Direct-product representation

Consider the representations defined by $U^\mu : G \longrightarrow \mathrm{GL}(\mathbb{V}^\mu)$, $\mu \in \mathbb{N}$. We define the *direct-product representation* as

$$\left[U^{\mu\times\nu}(a)\right] = \left[U^\mu(a)\right] \otimes \left[U^\nu(a)\right] . \tag{5.194}$$

Let us compute the character of the direct-product representation. We have

$$\begin{aligned} \chi^{\mu\times\nu}(a) &= \mathrm{tr}\left[U^{\mu\times\nu}(a)\right] \\ &= \left[U^{\mu\times\nu}(a)\right]^k{}_k \\ &= \left[U^\mu(a)\right]^i{}_i \left[U^\nu(a)\right]^j{}_j \qquad \text{by Equation (5.133)} \\ &= \chi^\mu(a)\,\chi^\nu(a) . \end{aligned}$$

Thus

$$\chi^{\mu\times\nu} = \chi^\mu \chi^\nu . \tag{5.195}$$

5.10 Properties of irreducible representations

5.10.1 Fundamental theorems of representations

Theorem 5.153 (Schur's first lemma)**.** *Let $\mathbb{V}$ be a vector space over $\mathbb{C}$ with $0 < \dim \mathbb{V} < \infty$, let $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ be an irreducible representation (Definition 5.143), and let $A : \mathbb{V} \longrightarrow \mathbb{V}$ be a linear operator commuting with every operator of the representation, $[U(a), A] = 0$ for every $a \in G$. Then A is proportional to the identity operator:*

$$A = \lambda \mathbb{1} , \qquad \lambda \in \mathbb{C} . \tag{5.196}$$

Rests on Definitions 5.35, 5.142 and 5.143.

Proof. *Derives Theorem 5.153.*

Both hypotheses on $\mathbb{V}$ are used at once, and only once: because $\dim \mathbb{V}$ is finite and non-zero, A has, in any basis, a characteristic polynomial $\det([A] - \lambda \mathbb{1})$ of degree $\dim \mathbb{V} \geq 1$, and because $\mathbb{C}$ is algebraically closed that polynomial has a root λ. For that λ the operator $A - \lambda\mathbb{1}$ is not invertible, so its kernel

$$\mathbb{E} = \ker(A - \lambda\mathbb{1}) = \{v \in \mathbb{V} \mid Av = \lambda v\}$$

is a subspace different from the null space: an eigenvector exists, which is precisely what a real or an infinite-dimensional space would not guarantee.

$\mathbb{E}$ is invariant under the representation. Indeed, for $v \in \mathbb{E}$ and any $a \in G$,

$$\begin{aligned} (A - \lambda\mathbb{1})\, U(a)v &= U(a)\,(A - \lambda\mathbb{1})\, v && \text{by } [U(a), A] = 0 \\ &= U(a)\, 0_{\mathbb{V}} \\ &= 0_{\mathbb{V}}\,, \end{aligned}$$

so $U(a)v \in \mathbb{E}$.

Irreducibility (Definition 5.143) leaves an invariant subspace only the two trivial possibilities, and $\mathbb{E}$ is not the null space; hence $\mathbb{E} = \mathbb{V}$. That is $Av = \lambda v$ for every $v \in \mathbb{V}$, which is Equation (5.196). Note that nothing was assumed about A beyond linearity — in particular it was not assumed diagonalizable, and no eigenbasis was used, only one eigenvalue. □

Remark 5.154 (The hypotheses are not decoration). Drop the algebraic closure of the field and the conclusion is false, not merely unproved. Take $G = \mathrm{SO}(2)$ acting on $\mathbb{V} = \mathbb{R}^2$ by rotations. That representation is irreducible over $\mathbb{R}$, since a rotation by an angle that is not a multiple of π leaves no line fixed; yet the group is abelian, so every $U(\theta_0)$ commutes with every $U(\theta)$ and is an intertwining operator, and no rotation other than $U(0) = \mathbb{1}$ and $U(\pi) = -\mathbb{1}$ is a multiple of the identity. The same failure in its algebra form, with the same matrix, is recorded in Remark 5.160. The moral is worth stating plainly because it is easy to violate at a distance: a chapter that invokes this lemma about a *real* representation — and the representations that physics writes down are frequently real — is invoking a statement that does not hold. The finite dimension is equally load-bearing: on an infinite-dimensional space an operator need have no eigenvalue at all, which is why the unitary representation theory of non-compact groups (Remark 5.151) is a different subject rather than a longer version of this one.

Theorem 5.155 (Schur's second lemma)**.** *Consider the irreducible representations $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ and $U' : G \longrightarrow \mathrm{GL}(\mathbb{V}')$, and an operator $A : \mathbb{V}' \longrightarrow \mathbb{V}$ such that $AU'(a) = U(a)A$ for all a, with $A \neq 0$. Then $\mathbb{V}$ and $\mathbb{V}'$ are isomorphic and, moreover, U and U' are equivalent.*
Rests on Definitions 5.51, 5.140, 5.142 and 5.143.

Proof. *Derives Theorem 5.155.*

We proceed in two steps.

- First note that the image and the kernel of the operator A are the subspaces

$$\begin{aligned} \mathrm{im}(A) &= \{|v\rangle \in \mathbb{V} \mid |v\rangle = A\,|v'\rangle\} \leq \mathbb{V}\,, \\ \ker(A) &= \{|v'\rangle \in \mathbb{V}' \mid A\,|v'\rangle = |0\rangle\,,\ 0 \in \mathbb{V}\} \leq \mathbb{V}'\,. \end{aligned}$$

  The image of A is an invariant subspace with respect to U, since

$$\begin{aligned} U(a)\,|v\rangle &= U(a)A\,|v'\rangle \\ &= AU'(a)\,|v'\rangle\,, \end{aligned}$$

and since $U'(a)\,|v'\rangle \in \mathbb{V}'$, we have $AU'(a)\,|v'\rangle \in \mathrm{im}(A)$, and hence $U(a)\,|v\rangle \in \mathrm{im}(A)$. As U is irreducible, $\mathrm{im}(A)$ is a trivial invariant subspace: the image of A would be the null space if and only if $A = 0$; otherwise one may have $\mathrm{im}(A) = \mathbb{V}$.

On the other hand, the kernel of A is an invariant subspace with respect to U'. This is because

$$\begin{aligned} AU'(a)\,|v'\rangle &= U(a)A\,|v'\rangle \\ &= 0 \in \mathbb{V}\,, \end{aligned}$$

so $U'(a)\,|v'\rangle \in \ker(A)$. Since we are assuming that U' is irreducible, the kernel of A is a trivial invariant subspace: again, the kernel of A would be the whole space $\mathbb{V}'$ if and only if $A = 0$; otherwise the kernel of A is the null space.

From these observations we may summarize: either $A = 0$, or the kernel of A is the null space and the image of A is the whole codomain, which tells us that A is a bijection establishing an isomorphism between the vector spaces $\mathbb{V}'$ and $\mathbb{V}$.

- Moreover, since A is bijective its inverse exists. Therefore, operating on the right with A^{-1},

$$\begin{aligned} AU'(a) &= U(a)A \\ AU'(a)A^{-1} &= U(a)\,, \end{aligned}$$

so $U(a)$ and $U'(a)$ are equivalent.

□

Proposition 5.156 (Irreducible representations of an abelian group)**.** *The irreducible representations of an abelian group on a finite-dimensional complex vector space are one-dimensional. The hypotheses are inherited from Theorem 5.153 and cannot be dropped: over* $\mathbb{R}$ *the rotations* $\mathrm{SO}(2)$ *form an abelian group with a two-dimensional irreducible representation, as Remark 5.154 records.*

Rests on Theorem 5.153 and Definition 5.143.

Proof. *Derives Proposition 5.156.*

Consider an irreducible representation $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ of an abelian group G, with $\mathbb{V}$ complex and $0 < \dim \mathbb{V} < \infty$. Let $a, b \in G$. Applying U to $ab = ba$,

$$\begin{aligned} U(ab) &= U(ba) \\ U(a)U(b) &= U(b)U(a)\,. \end{aligned}$$

By Schur's first lemma (Theorem 5.153), applied to the operator $U(a)$, which commutes with every $U(b)$,

$$U(a) = \lambda_a \mathbb{1}\,,$$

so that

$$U(a)\,|v\rangle = \lambda_a \mathbb{1}\,|v\rangle$$

and thus

$$U(a)\,|v\rangle = \lambda_a\,|v\rangle\,, \quad \forall\ |v\rangle \in \mathbb{V}\,.$$

This does not mean that all the vectors of $\mathbb{V}$ are eigenvectors, but rather that the irreducible representations of an abelian group are one-dimensional. □

5.10.2 Orthonormality relations

Orthonormality of irreducible inequivalent representations

Consider an irreducible representation $U : G \longrightarrow \mathrm{GL}(\mathbb{V})$ of a finite group $G = \{g_i\}_{i=1}^{n_G}$ and an arbitrary operator X. Define

$$A(X) = \sum_{i=1}^{n_G} U(g_i) X U(g_i^{-1}) \,.$$

Let us compute the following:

$$\begin{aligned}
U(a)A &= \sum_{i=1}^{n_G} U(a)U(g_i)XU(g_i^{-1}) \\
&= \sum_{i=1}^{n_G} U(a)U(g_i)XU(g_i^{-1}) \Big(U(a^{-1})U(a)\Big) \\
&= \sum_{i=1}^{n_G} U(ag_i)XU(g_i^{-1}a^{-1})U(a) \\
&= \sum_{i=1}^{n_G} U(ag_i)XU((ag_i)^{-1})U(a) \\
&= \sum_{i=1}^{n_G} U(g_{a_i})XU(g_{a_i}^{-1})U(a) \qquad \text{by Equation (4.28)} \,.
\end{aligned}$$

Since it makes no difference whether we sum over i or over a_i — it is a permutation — we may relabel the indices, so that

$$U(a)A = \underbrace{\sum_{i=1}^{n_G} U(g_i)XU(g_i^{-1})}_{A}\, U(a) \,,$$

whence $[U(a), A] = 0$.

On this basis we may use Schur's first lemma (as we are assuming U irreducible), which tells us that

$$A(X) = \lambda(X)\, \mathbb{1} \,. \tag{5.197}$$

Since X is arbitrary, we may choose it as follows:

$$X = \begin{pmatrix}
 & & l & & & \\
0 & \dots & 0 & \dots & 0 & \\
\vdots & \ddots & \vdots & & & \\
0 & \dots & 1 & \dots & 0 & m \\
\vdots & & \vdots & \ddots & & \\
0 & & 0 & & 0 &
\end{pmatrix} ,$$

that is, such that only $X^l{}_m = 1$, all other entries being zero. Identify the coefficients $\lambda(X)$ as $\lambda(X) = \lambda^m_l$. With this, writing the definition of A in index notation and using the result Equation (5.197),

$$\begin{aligned}
\lambda^m_l \delta^j_k &= \sum_{i=1}^{n_G} (D(g_i))^j{}_l \, X^l{}_m \left(D(g_i^{-1})\right)^m{}_k \\
&= \sum_{i=1}^{n_G} (D(g_i))^j{}_l \left(D(g_i^{-1})\right)^m{}_k \,.
\end{aligned} \tag{5.198}$$

Evaluating at $k = j$ and summing,

$$\begin{aligned}\lambda^m{}_l\,\delta^j{}_j &= \sum_{i=1}^{n_G} (D(g_i))^j{}_l \left(D(g_i^{-1})\right)^m{}_j \\ \lambda^m{}_l\,n_U &= \sum_{i=1}^{n_G} \left(D(g_i^{-1})D(g_i)\right)^m{}_l \\ &= \sum_{i=1}^{n_G} (D(e))^m{}_l\ ,\end{aligned}$$

where n_U is the dimension of the representation U (equal, by its definition, to the order of the operator A). Since D is a homomorphism, from Equation (4.24) we see that $U(e) = \mathrm{id}_{\mathrm{GL}(\mathbb{V})}$, that is, $D(e) = \mathbb{1}$. Thus

$$\begin{aligned}\lambda^m{}_l\,n_U &= \sum_{i=1}^{n_G} \delta^m{}_l \\ &= n_G\,\delta^m{}_l\,,\end{aligned}$$

so the coefficients $\lambda^m{}_l$ are given by

$$\lambda^m{}_l = \frac{n_G}{n_U}\,\delta^m{}_l\,. \tag{5.199}$$

Substituting Equation (5.199) into Equation (5.198) we obtain

$$\sum_{i=1}^{n_G} (D(g_i))^j{}_l \left(D(g_i^{-1})\right)^m{}_k = \frac{n_G}{n_U}\,\delta^m{}_l\,\delta^j{}_k\,. \tag{5.200}$$

From Equations (5.198) and (5.199) (substitute the coefficients fixed by the trace back into the intertwining identity).

Now, had we constructed A distinguishing the irreducible representations,

$$A(X) = \sum_{i=1}^{n_G} U^\mu(g_i) X U_\nu(g_i^{-1})\,,$$

then, by a procedure analogous to the preceding one, we would arrive at

$$U^\mu(a)A = AU_\nu(a)\,,$$

and we must therefore place ourselves in the following cases:

1. if $\mu = \nu$ we recover the preceding case;
2. if $\mu \neq \nu$ we may use Schur's second lemma (Theorem 5.155): then either the representations $U^\mu(a)$ and $U_\nu(a)$ are equivalent, or $A = 0$ and the representations are inequivalent.

Consider, then, inequivalent representations (irreducible by hypothesis). We can synthesize the above in Equation (5.200) as

$$\frac{n_\mu}{n_G} \sum_{i=1}^{n_G} (D^\mu(g_i))^j{}_l \left(D_\nu(g_i^{-1})\right)^m{}_k = \delta^m{}_l\,\delta^j{}_k\,\delta^\mu{}_\nu\,, \tag{5.201}$$

where $\delta^\mu{}_\nu$ appears in order to annihilate A in the case $\mu \neq \nu$ (the representations being taken inequivalent), and where in the case $\mu = \nu$ one has $n_{U^\mu} = n_{U^\nu}$, so we make the replacement $n_U \longrightarrow n_\mu$.

We must note that the indices μ and ν only label the Kronecker delta, so $\mu = \nu$ does not indicate summation.

Equation (5.201) expresses the *orthonormality of the irreducible, inequivalent representations* a group may have.

Orthonormality of characters of irreducible unitary representations

As we have seen, the character of a representation actually identifies a whole class of equivalent representations, so in this context we need not insist on inequivalent representations.

Characters describe the intrinsic structure of a representation better, because they are basis-independent; not so the representations themselves, since the components of $D(a)$ depend on the chosen basis.

Consider then the irreducible representations U^μ. Since the matrix representation of a representation is also a homomorphism, from Equation (4.25) and Equation (5.201) we have

$$\frac{n_\mu}{n_G}\sum_{i=1}^{n_G}(D^\mu(g_i))^j{}_l\left((D_\nu(g_i))^{-1}\right)^m{}_k=\delta^m_{\ l}\,\delta^j{}_k\,\delta^\mu{}_\nu\,.$$

If we further take the representations to be unitary,

$$\frac{n_\mu}{n_G}\sum_{i=1}^{n_G}(D^\mu(g_i))^j{}_l\left((D_\nu(g_i))^{\dagger}\right)^m{}_k=\delta^m_{\ l}\,\delta^j{}_k\,\delta^\mu{}_\nu\,.$$

Evaluating at $l=j$ and $m=k$ and summing over both,

$$\frac{n_\mu}{n_G}\sum_{i=1}^{n_G}(D^\mu(g_i))^j{}_j\left((D_\nu(g_i))^{\dagger}\right)^k{}_k=\delta^k{}_j\,\delta^j{}_k\,\delta^\mu{}_\nu$$

$$\frac{n_\mu}{n_G}\sum_{i=1}^{n_G}\chi^\mu(g_i)\chi^*_\nu(g_i)=n_\mu\,\delta^\mu{}_\nu\,,$$

and the factor n_μ cancels on both sides ($\delta^k{}_j\delta^j{}_k=\delta^j{}_j=n_\mu$), leaving

$$\frac{1}{n_G}\sum_{i=1}^{n_G}\chi^\mu(g_i)\chi^*_\nu(g_i)=\delta^\mu{}_\nu\,.$$

Grouping into n_C conjugacy classes and denoting by n_s the number of elements of the s-th class, we convert the sum over each element of the group into a sum over each class. Thus

$$\frac{1}{n_G}\sum_{s=1}^{n_C}n_s\,\chi^\mu_s\chi^*_{s\nu}=\delta^\mu{}_\nu\,,\tag{5.202}$$

where χ^μ_s denotes the character of the μ-th irreducible representation on the s-th class.

5.10.3 Decomposition into irreducible representations

Coefficients of the direct-sum representation

By means of the orthonormality relations we can compute the coefficients of the direct-sum representation appearing in Equation (5.193).

Evaluating the trace on the s-th class of the group,

$$\chi_s=\sum_\mu a_\mu\chi^\mu_s\,.\tag{5.203}$$

Multiplying the equation by $n_s\chi^*_{s\nu}$ and summing over s for all the classes,

$$\begin{aligned}\sum_{s=1}^{n_C}n_s\,\chi_s\chi^*_{s\nu}&=\sum_\mu a_\mu\sum_{s=1}^{n_C}n_s\,\chi^\mu_s\chi^*_{s\nu}\\&=\sum_\mu a_\mu\,n_G\,\delta^\mu{}_\nu&&\text{by Equation (5.202)}\\&=n_G\,a_\nu\,,\end{aligned}$$

so that

$$a_\mu = \frac{1}{n_G} \sum_{s=1}^{n_C} n_s \, \chi_s \chi^*_{s\mu} \, . \tag{5.204}$$

From Equations (5.202) and (5.203) (weight the class decomposition of the character by $n_s \chi^*_{s\nu}$ and sum over the classes).

Completeness relation

We can compute the number of times an irreducible representation appears in the regular representation. From Equation (5.204),

$$a^R_\mu = \frac{1}{n_G} \sum_{s=1}^{n_C} n_s \, \chi^R_s \chi^*_{s\mu} \, ,$$

but from Equation (5.191) and Equation (5.192) we see that the only contribution comes from the class of the neutral element. That is,

$$\begin{aligned} a^R_\mu &= \frac{1}{n_G} \, n_e \, \chi^R_e \, \chi^*_{e\mu} \\ &= n_e \, \chi^*_{e\mu} \qquad\qquad \text{by Equation (5.191)} \, , \end{aligned}$$

and we know, moreover, that the class of the neutral element contains only the neutral element, that is, $n_e = 1$. On the other hand,

$$\chi^*_{e\mu} = \operatorname{tr} \left((D^\mu(e))^\dagger \right) \, ,$$

but since the matrix representation of a representation is also a homomorphism, $D^\mu(e) = \mathbb{1}$, so

$$\chi_{e\mu} = n_\mu, \quad \chi^*_{e\mu} = n_\mu \, , \tag{5.205}$$

and there results

$$a^R_\mu = n_\mu \, . \tag{5.206}$$

From Equations (5.191), (5.192), (5.204) and (5.205) (only the class of the neutral element contributes to the multiplicity).

Now, writing the regular representation as a direct sum of irreducible representations, we have — in particular for the neutral element of G —

$$\begin{aligned} \Delta_e &= \sum_\mu a^R_\mu U^\mu(e) \\ \implies \chi^R_e &= \sum_\mu a^R_\mu \chi_{e\mu} \\ &= \sum_\mu n^2_\mu \qquad\qquad \text{by Equations (5.205) and (5.206)} \, . \end{aligned}$$

Hence, from Equation (5.191) we arrive at

$$n_G = \sum_\mu n^2_\mu \, . \tag{5.207}$$

From Equations (5.191), (5.205) and (5.206) (evaluate the direct-sum decomposition of the regular representation at the neutral element).

Equation (5.207) is a completeness relation for the irreducible representations.

Irreducibility criterion

To evaluate whether a given representation is irreducible, we can find a condition that the character of a representation must satisfy with respect to the equivalence classes of the group.

From Equation (5.203) we have, taking the complex conjugate,

$$\chi_s = \sum_\mu a_\mu \chi_s^\mu \,,$$
$$\chi_s^* = \sum_\nu a_\nu \chi_{s\nu}^* \,.$$

Multiplying the two equations member by member, weighting by n_s, and summing over s for all the equivalence classes,

$$\begin{aligned}
\sum_{s=1}^{n_C} n_s \, \chi_s \chi_s^* &= \sum_\mu a_\mu \sum_\nu a_\nu \sum_{s=1}^{n_C} n_s \, \chi_s^\mu \chi_{s\nu}^* \\
\sum_{s=1}^{n_C} n_s \, |\chi_s|^2 &= \sum_\mu a_\mu \sum_\nu a_\nu \, n_G \, \delta^\mu{}_\nu \qquad \text{by Equation (5.202)} \\
&= n_G \sum_\mu a_\mu^2 \,,
\end{aligned}$$

so that

$$\sum_{s=1}^{n_C} n_s \, |\chi_s|^2 = n_G \sum_\mu a_\mu^2 \,. \tag{5.208}$$

From Equations (5.202) and (5.203) (multiply the class decomposition by its conjugate and sum over the classes).

Now, if we take $U(a)$ to be an irreducible representation, then its direct-sum decomposition (see Equation (5.193)) holds with $a_\mu = 1$ for a single μ, the others being 0. Thus

$$\sum_{s=1}^{n_C} n_s \, |\chi_s|^2 = n_G \tag{5.209}$$

is the condition that an irreducible representation must verify.

Clebsch–Gordan coefficients

The direct-product representation Equation (5.194) is in general reducible even when both factors are irreducible: the product of two characters is not a character of an irreducible representation. The apparatus of this section decomposes it. From Equation (5.195) the character of $U^{\mu\times\nu}$ on the s-th class is $\chi_s^\mu \chi_s^\nu$, so Equation (5.204) gives the multiplicity with which the irreducible representation U^λ occurs in it:

$$a_{\mu\nu}^\lambda = \frac{1}{n_G} \sum_{s=1}^{n_C} n_s \, \chi_s^\mu \chi_s^\nu \chi_{s\lambda}^* \,. \tag{5.210}$$

From Equations (5.195) and (5.204) (the character of the product representation is the product of the characters, read into the multiplicity formula).

These non-negative integers are the *Clebsch–Gordan series* of the group; they answer the question "which irreducible representations appear, and how often". Equation (5.184) then reads, for the product space,

$$\mathbb{V}^\mu \otimes \mathbb{V}^\nu = \bigoplus_\lambda \bigoplus_{\alpha=1}^{a_{\mu\nu}^\lambda} \mathbb{V}^{\lambda,\alpha} \,, \tag{5.211}$$

the second index α distinguishing the $a^{\lambda}_{\mu\nu}$ copies of one and the same $\mathbb{V}^{\lambda}$.

What Equation (5.211) does *not* give is the vectors. There are now two natural bases of the same space:

- the *product*, or uncoupled, basis $\{|\mu i\rangle \otimes |\nu j\rangle\}$, built from bases of the two factors, in which the group acts by Equation (5.194) — the natural basis if one thinks of two independent systems;
- the *coupled* basis $\{|\lambda\alpha; k\rangle\}$ adapted to Equation (5.211), in which the matrix of every $U^{\mu\times\nu}(a)$ is block diagonal with irreducible blocks — the natural basis if one thinks of the composite system as carrying a symmetry of its own.

The *Clebsch–Gordan coefficients* are the entries of the change of basis between them:

$$|\lambda\alpha; k\rangle = \sum_{i,j} \langle \mu i; \nu j | \lambda\alpha k\rangle \; |\mu i\rangle \otimes |\nu j\rangle \; . \tag{5.212}$$

They are pure numbers, carrying no SI unit whatever — a change of basis cannot — however they are used in physics.

Two properties follow from the general theory and require no further computation. First, if the representations are unitary (Proposition 5.150 makes this no restriction for a finite group) and both bases are orthonormal, then the matrix of coefficients is *unitary*, being the matrix of an operator carrying one orthonormal basis to another — the argument used in Step 3 of Proposition 5.150. Its unitarity is precisely the pair of relations

$$\sum_{i,j} \langle \mu i; \nu j | \lambda\alpha k\rangle^{*} \langle \mu i; \nu j | \lambda'\alpha' k'\rangle = \delta^{\lambda}{}_{\lambda'} \delta_{\alpha\alpha'} \delta_{kk'} \; , \tag{5.213}$$

$$\sum_{\lambda,\alpha,k} \langle \mu i; \nu j | \lambda\alpha k\rangle \langle \mu i'; \nu j' | \lambda\alpha k\rangle^{*} = \delta_{ii'} \delta_{jj'} \; , \tag{5.214}$$

orthonormality of the coupled basis and completeness of the product one. Second, the coefficients are *not* determined by the group alone. Equation (5.211) fixes the subspaces only up to an arbitrary unitary mixing within each multiplicity label α and an overall phase on each irreducible block — the freedom left by Schur's first lemma (Theorem 5.153), which pins an intertwining operator down only to a multiple of the identity. Tables of Clebsch–Gordan coefficients therefore always come attached to a phase convention; the one universally used in physics is that of Condon and Shortley [751].

For the groups this treatise actually computes with, the coefficients are tabulated and closed forms exist in the literature: for SU(2), whose Clebsch–Gordan series is the rule for adding angular momenta, Racah's closed expression [867] and the recoupling coefficients that follow it [873]. Where that development sits in this book has to be stated carefully, because the two halves of it are in different states. Which irreducible representations occur, and with what multiplicity, is proved for SU(2) in Theorem 14.47, where the group is continuous and its irreducible representations have been classified. The coefficients *themselves*, and with them the physics — the addition of angular momenta and the Wigner–Eckart theorem — belong to Section 79.4.2, which at the time of writing carries its heading and its editorial specification but not the construction; that chapter reserves it explicitly, and nothing in the present chapter depends on it. What is established here is only what holds for any finite group: the multiplicities Equation (5.210) are computable from characters alone, and the coefficients Equation (5.212) exist and form a unitary matrix. The systematic use of both in physics goes back to Wigner [687].

5.11 Representations of algebras

Everything so far has represented a *group*: a set closed under a product, with inverses. An algebra is a different object — a vector space with a bracket — and representing it means something correspondingly different. The distinction is not pedantry: it is the reason angular momenta add while rotations multiply, and getting it backwards produces expressions that are not representations of anything.

5.11.1 Basic properties of the representations

Definition 5.157 (Representation of an algebra)**.** Let A be an algebra over $\mathbb{K}$ with bracket $[\,,\,]$ (Definition 5.117) and let $\mathbb{V}$ be a vector space over $\mathbb{K}$. A *representation* of A on $\mathbb{V}$ is a *linear* map

$$\rho : A \longrightarrow \mathcal{L}(\mathbb{V})$$

that carries the bracket of A into the corresponding bracket of $\mathcal{L}(\mathbb{V})$:

$$\rho\left([X,Y]\right) = [\rho(X),\rho(Y)] = \rho(X)\rho(Y) - \rho(Y)\rho(X)\,, \qquad \forall\, X, Y \in A\,, \tag{5.215}$$

the commutator being the bracket $\mathcal{L}(\mathbb{V})$ carries by Proposition 5.121. (For an *associative* algebra, whose product is written as a juxtaposition rather than a bracket, the requirement is instead $\rho(XY) = \rho(X)\rho(Y)$; the Lie case Equation (5.215) is the one this treatise uses, and the two agree once an associative algebra is given its commutator bracket.) The *dimension* of ρ is $\dim \mathbb{V}$.

Rests on Definition 5.117 and Proposition 5.121.

How this differs from a group representation

The two definitions look similar and behave differently, in ways worth listing because each has a physical consequence.

1. *A representation of an algebra is linear in its argument; a representation of a group is multiplicative.* It makes sense to write $\rho(\alpha X + \beta Y) = \alpha\rho(X) + \beta\rho(Y)$, and it makes no sense at all to add two group elements. This is the formal expression of the fact that an algebra element is an infinitesimal generator and a group element a finite transformation.

2. *The image lies in $\mathcal{L}(\mathbb{V})$, not in* $\mathrm{GL}(\mathbb{V})$. Linearity forces $\rho(0_A) = \Theta$, the null operator of Equation (5.75), which is not invertible. More generally $\rho(X)$ may be singular for $X \neq 0_A$. A group representation, by contrast, takes values in the invertible operators only, since $U(a)U(a^{-1}) = U(e) = \mathrm{id}$.

3. *The bracket, not the product, is preserved.* A group representation preserves a product, Equation (5.180); an algebra representation preserves a commutator, Equation (5.215). This is what makes the structure constants the invariant content of an algebra representation, as Proposition 5.121 already showed for the defining one.

Everything the two notions *do* share is the vocabulary built on the underlying vector space, and it transfers unchanged.

Definition 5.158 (Faithful, equivalent, invariant)**.** A representation ρ of A on $\mathbb{V}$ is *faithful* if ρ is injective. Two representations ρ, ρ' on the same space are *equivalent* if there is $S \in \mathrm{GL}(\mathbb{V})$ with $\rho'(X) = S\rho(X)S^{-1}$ for every $X \in A$. A subspace $\mathbb{S} \leq \mathbb{V}$ is *invariant* if $\rho(X)\mathbb{S} \subset \mathbb{S}$ for every $X \in A$, and ρ is *irreducible* if the only invariant subspaces are the trivial ones.

Rests on Definitions 5.6 and 5.157.

Proposition 5.159 (The kernel is an ideal)**.** *Let ρ be a representation of the algebra A. Then*

$$\ker\rho = \{X \in A \mid \rho(X) = \Theta\}$$

is an ideal of A in the sense of Definition 5.120. Consequently, if A is simple *— its only ideals being $\{0_A\}$ and A — then every representation of A is either faithful or identically zero.*

Rests on Definitions 5.120, 5.157 and 5.158 and Equation (5.215).

Proof. *Derives Proposition 5.159.*

$\ker\rho$ is a subspace because ρ is linear. Let $X \in \ker\rho$ and $Y \in A$. Then, by Equation (5.215),

$$\begin{aligned}\rho([X,Y]) &= [\rho(X),\rho(Y)]\\ &= [\Theta,\rho(Y)]\\ &= \Theta\rho(Y) - \rho(Y)\Theta\\ &= \Theta\,,\end{aligned}$$

so $[X,Y] \in \ker\rho$; taking linear combinations, $[\ker\rho, A] \subset \ker\rho$, which is Definition 5.120. If A is simple the ideal $\ker\rho$ is either $\{0_A\}$, and ρ is injective, that is, faithful, or the whole of A, and ρ sends everything to Θ. □

This is the algebra counterpart of Definition 5.138 and it is sharper: for a group, the analogous statement is that the kernel of a representation is a normal subgroup, and a simple group likewise admits only faithful or trivial representations. Both are the reason the simple Lie algebras are classified before their representations are: the classification of the algebras is what makes the representation theory finite work.

The induced module structure

A representation is the same thing as an action, and writing it that way makes several statements shorter. Given ρ, define

$$X \cdot v = \rho(X)v\,, \qquad X \in A,\ v \in \mathbb{V}\,. \tag{5.216}$$

Then $\mathbb{V}$ becomes an *A-module*: the action is bilinear — linear in v because $\rho(X)$ is an LT, linear in X because ρ is linear — and it is compatible with the bracket in the sense that

$$[X,Y]\cdot v = X\cdot(Y\cdot v) - Y\cdot(X\cdot v)\ ,$$

which is Equation (5.215) read on a vector. In this language an invariant subspace is a *submodule*, an irreducible representation is a *simple module*, and the equivalence of Definition 5.158 is an isomorphism of modules. Nothing is added by the change of words except economy; it is used here only to say that the two Schur lemmas transfer.

Remark 5.160 (Schur's lemmas hold verbatim). The proofs of Theorems 5.153 and 5.155 use exactly three things: that the operators of the representation are linear, that the intertwining operator commutes with all of them, and that the invariant subspaces of an irreducible representation are trivial. None of the three mentions the group product, so both proofs apply word for word to a representation of an algebra — with one caveat that must be stated, since it is the only place the group was doing work: the proof of Theorem 5.155 concluded that A is a bijection from $\mathrm{im}(A) = \mathbb{V}$ and $\ker(A) = \{0\}$, which remains valid, whereas Theorem 5.153 carries the hypotheses $\mathbb{K} = \mathbb{C}$ and $0 < \dim\mathbb{V} < \infty$ — needed for

the eigenvalue its proof starts from to exist at all — and they must be carried over with it. Over $\mathbb{R}$ the conclusion genuinely fails: the algebra $\mathfrak{so}(2)$ acting on $\mathbb{R}^2$ by

$$\rho(X) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

is irreducible — a rotation generator leaves no real line fixed — yet $\rho(X)$ commutes with itself and is not a multiple of the identity.

Direct sums and tensor products

Let ρ_1 and ρ_2 be representations of the same algebra A on $\mathbb{V}_1$ and $\mathbb{V}_2$.

Direct sum. On $\mathbb{V}_1 \oplus \mathbb{V}_2$ define

$$(\rho_1 \oplus \rho_2)(X) = \begin{pmatrix} \rho_1(X) & 0 \\ 0 & \rho_2(X) \end{pmatrix} . \tag{5.217}$$

It is a representation: linearity in X is block by block, and the commutator of two block-diagonal matrices is block-diagonal with the blockwise commutators, so Equation (5.215) holds in each block. Traces add, $\operatorname{tr}(\rho_1 \oplus \rho_2)(X) = \operatorname{tr}\rho_1(X) + \operatorname{tr}\rho_2(X)$, exactly as characters did in Equation (5.193). This much is identical to the group case.

Tensor product. Here the two theories part company, and the difference is the single most consequential fact in this section. For groups the product representation is the product of the matrices, Equation (5.194). For algebras that rule is *wrong*: the map $X \mapsto \rho_1(X) \otimes \rho_2(X)$ is not even linear in X. The correct construction is

$$(\rho_1 \otimes \rho_2)(X) = \rho_1(X) \otimes \mathbb{1} + \mathbb{1} \otimes \rho_2(X) . \tag{5.218}$$

Derivation. *Derives Equation (5.218).*

Linearity in X is manifest, both terms being linear. For Equation (5.215), write $\sigma(X)$ for the right-hand side of Equation (5.218) and use that operators acting on different factors commute, $[P \otimes \mathbb{1}, \mathbb{1} \otimes Q] = 0$, together with $(P \otimes \mathbb{1})(P' \otimes \mathbb{1}) = PP' \otimes \mathbb{1}$:

$$\begin{aligned} [\sigma(X), \sigma(Y)] &= [\rho_1(X) \otimes \mathbb{1}, \rho_1(Y) \otimes \mathbb{1}] + [\mathbb{1} \otimes \rho_2(X), \mathbb{1} \otimes \rho_2(Y)] \\ &= [\rho_1(X), \rho_1(Y)] \otimes \mathbb{1} + \mathbb{1} \otimes [\rho_2(X), \rho_2(Y)] \\ &= \rho_1([X,Y]) \otimes \mathbb{1} + \mathbb{1} \otimes \rho_2([X,Y]) \qquad \text{by Equation (5.215)} \\ &= \sigma([X,Y]) , \end{aligned}$$

the two cross terms of the first line having cancelled in pairs. □

Remark 5.161 (Why generators add and group elements multiply). Equation (5.218) is not an arbitrary convention: it is forced by Equation (5.194) for the corresponding group. If a one-parameter family of group elements is written $U(t) = \exp(t\rho(X))$, then the product representation satisfies

$$U_1(t) \otimes U_2(t) = \left(\mathrm{e}^{t\rho_1(X)}\right) \otimes \left(\mathrm{e}^{t\rho_2(X)}\right) = \exp\left[t\left(\rho_1(X) \otimes \mathbb{1} + \mathbb{1} \otimes \rho_2(X)\right)\right],$$

the last step being legitimate because the two exponents commute. Differentiating at $t = 0$ recovers Equation (5.218): the multiplicative law of the group becomes an *additive* law for the generators. This is the algebraic content of the statement that angular momenta, and every other additive quantum number, add when systems are combined — the total generator of a composite system is the sum of the generators of its parts, each acting on its own factor. The exponential map that makes the step precise belongs to Chapter 14.

The adjoint representation

Every algebra represents itself, on its own underlying vector space, and the matrices of that representation are its structure constants. This is the content of the source's marginal note at this heading.

Proposition 5.162 (Adjoint representation)**.** *Let L be a Lie algebra (Definition 5.123) and define, for each $X \in L$, the map*

$$\begin{array}{rccc} \mathrm{ad}_X : & L & \longrightarrow & L \\ & Y & \longmapsto & \mathrm{ad}_X Y = [X, Y] \,. \end{array} \tag{5.219}$$

Then $X \longmapsto \mathrm{ad}_X$ is a representation of L on L itself, of dimension $\dim L$, and in a basis $\{e_i\}$ its matrices are

$$(\mathrm{ad}_{e_i})^k{}_j = C^k{}_{ij} \,. \tag{5.220}$$

Its kernel is the centre *of L, the set of elements commuting with everything.*

Rests on Definitions 5.123 and 5.157, Equation (5.150), and Proposition 5.43.

Proof. *Derives Proposition 5.162.*

Each ad_X is a linear transformation of L by right distributivity Equation (5.146) and the scalar rule Equation (5.147), so $\mathrm{ad}_X \in \mathcal{L}(L)$; and $X \longmapsto \mathrm{ad}_X$ is itself linear by left distributivity Equation (5.145). What must be verified is Equation (5.215), namely $\mathrm{ad}_{[X,Y]} = [\mathrm{ad}_X, \mathrm{ad}_Y]$. Applying both sides to an arbitrary Z,

$$\begin{aligned} [\mathrm{ad}_X, \mathrm{ad}_Y]\, Z &= \mathrm{ad}_X \,\mathrm{ad}_Y\, Z - \mathrm{ad}_Y \,\mathrm{ad}_X\, Z \\ &= [X, [Y, Z]] - [Y, [X, Z]] \\ &= [X, [Y, Z]] + [Y, [Z, X]] && \text{by Equation (5.155)} \\ &= -\,[Z, [X, Y]] && \text{by Equation (5.156)} \\ &= [[X, Y]\,, Z] && \text{by Equation (5.155)} \\ &= \mathrm{ad}_{[X,Y]}\, Z \,, \end{aligned}$$

so the adjoint map is a representation — and note what the derivation shows: *the Jacobi identity is exactly the statement that* ad *is a representation*, neither more nor less.

For the matrices, apply Equation (5.219) to a basis vector and compare with Equation (5.74) and the definition Equation (5.150) of the structure constants:

$$\mathrm{ad}_{e_i}\, e_j = [e_i, e_j] = C^k{}_{ij} e_k \,,$$

whose coefficients are, by Proposition 5.43, the matrix entries claimed in Equation (5.220).

Finally $\mathrm{ad}_X = \Theta$ means $[X, Y] = 0_L$ for every Y, which is the definition of the centre; by Proposition 5.159 the centre is an ideal, as it must be. □

Corollary 5.163. *The adjoint representation of a Lie algebra with trivial centre — in particular of a simple Lie algebra, which is by definition non-abelian and has no proper non-zero ideal — is faithful. Every such algebra is therefore isomorphic to an algebra of $\dim L \times \dim L$ matrices under the commutator.*

Rests on Propositions 5.121, 5.159 and 5.162 and Definition 5.158.

Proof. *Derives Corollary 5.163.*

Immediate from Proposition 5.162: the kernel is the centre, and a representation is faithful exactly when its kernel is trivial. For a simple L the centre is an ideal, hence $\{0_L\}$ or L; the second would make L abelian and is excluded. The matrices are those of Equation (5.220), and Proposition 5.121 guarantees they satisfy the same algebra. □

Back to unitary group representations

The two theories are joined by the exponential map, and the join is where the SI units of the treatise re-enter what has so far been pure algebra. Let G be a Lie group with algebra L, and let U be a representation of G that is unitary in the sense of Equation (5.183). Writing a one-parameter subgroup as $U(t) = \exp(t\rho(X))$, unitarity for every t requires

$$\rho(X)^\dagger = -\rho(X)\,, \tag{5.221}$$

that is, the algebra is represented by *anti-hermitian* operators: differentiate $U(t)^\dagger U(t) = \mathbb{1}$ at $t = 0$. Physics prefers hermitian operators, because those are the ones with real spectra and hence the observable ones, so one writes $\rho(X) = -\mathrm{i}\Lambda/\hbar$ with $\Lambda^\dagger = \Lambda$ — and this is where the units are fixed.

Remark 5.164 (The generator of time translations, in SI). Take G to be the group of time translations of the $3+1$ spacetime of Chapter 39, acting on the state space of a quantum system. Its unitary representation is

$$U(t) = \exp\left(-\frac{\mathrm{i}}{\hbar}\mathcal{H}t\right),$$

with $\mathcal{H}$ the Hamiltonian, of SI unit the joule, t in seconds, and $\hbar = h/2\pi = 1.054\,571\,817 \times 10^{-34}\,\mathrm{J\,s}$ the reduced Planck constant — h being exact by the SI definition of the kilogram, so that $\hbar$ is exact as a multiple of $1/2\pi$ and the decimal shown is rounded (Chapter 77 and the constants appendix). The exponent $\mathcal{H}t/\hbar$ is then a pure number, as the argument of an exponential must be, and the algebra element is represented by $\rho(X) = -\mathrm{i}\mathcal{H}/\hbar$, whose SI unit is $1/\mathrm{s}$ — an inverse time, which is what a generator of time translations has to be. The same bookkeeping applies to every generator in this treatise: an angular-momentum operator is $\rho(X) = -\mathrm{i}J/\hbar$ with J in $\mathrm{J\,s}$, so that $\rho(X)$ is dimensionless, rotation angles being dimensionless too. The habit of setting $\hbar = 1$, universal in the representation-theory literature, is what hides this; the treatise does not adopt it (editorial rule 3).

Chapter 6

Topological and Metric Spaces

Topology isolates the minimal structure a set must carry for the notions of nearness, continuity, and limit to make sense at all, before any notion of distance is introduced. Metric spaces then recover distance as an additional layer of structure, and the topology of $\mathbb{R}^N$ is the concrete arena in which the analysis of the neighbouring chapters takes place.

6.1 Topological spaces

6.1.1 Basic definitions

Definition 6.1 (Topological space)**.** Consider a set X, and consider further a family $T = \{U_i\}_{i\in I}$ of subsets $U_i \subset X$. We say that (X, T) is a *topological space* with *topology* T if and only if it satisfies the following axioms:

1. $\varnothing \in T$ and $X \in T$;
2. the union of any collection of sets in T belongs to T;
3. the intersection of any finite collection of sets in T belongs to T.

Rests on Definitions 3.30, 3.31 and 3.35 and Equation (3.51)*.*

Definition 6.2 (Open set)**.** A set that belongs, as an element, to the topology of a space is called an *open set*.
Rests on Definition 6.1.

Definition 6.3 (Closed set)**.** A set is *closed* in a topological space if and only if its complement in that space is an open set.
Rests on Definitions 3.35 and 6.2.

Definition 6.4 (Neighbourhood)**.** A *neighbourhood* of a point $x \in X$ is any open set containing x.
Rests on Definition 6.2.

Definition 6.5 (Open cover)**.** A family $\{U_i\}_{i\in I}$ of open sets in X is an *open cover* of X if and only if the union of all of them is the whole space, that is,

$$\bigcup_{i\in I} U_i = X\,. \tag{6.1}$$

An open cover of a subset $K \subseteq X$ is a family of open sets whose union contains K; a *subcover* is a subfamily that still covers.
Rests on Definition 6.2 and Equation (3.51)*.*

6.1.2 Continuity

Continuity is the property that topology is built to express: a map between topological spaces is continuous when it respects the open-set structure of the two spaces, as the following definition makes precise.

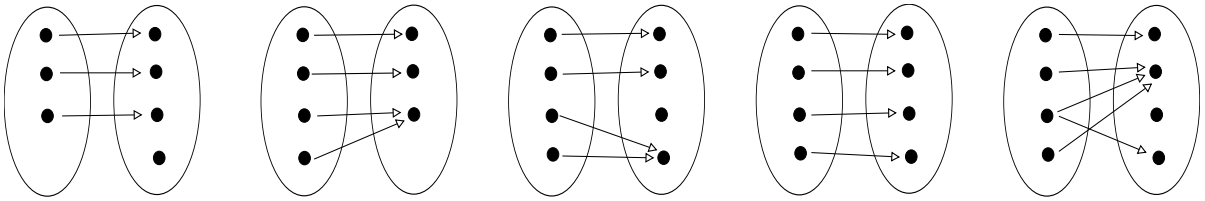

Figure 6.1: Schematic representation of maps between sets: a map assigns to each element of its domain exactly one element of its codomain. Continuity constrains how such maps interact with the topologies of the two spaces.

Definition 6.6 (Continuous map)**.** Consider two topological spaces X_1 and X_2 with topologies T_1 and T_2, and consider further a map $f : X_1 \longrightarrow X_2$. We say that f is *continuous* if and only if the inverse image of every open set in X_2 is an open set in X_1; that is,

$$\forall\, U \in T_2, \quad f^{-1}(U) \in T_1\,. \tag{6.2}$$

Rests on Definitions 3.53, 6.1 and 6.2.

Definition 6.7 (Homeomorphism)**.** A *homeomorphism* is a bijective continuous map $f : X_1 \longrightarrow X_2$ whose inverse f^{-1} is also continuous. Two spaces related by a homeomorphism are *homeomorphic*: they carry identical topological structure, and every property expressed purely in terms of open sets (compactness, connectedness, ...) transfers between them. Topology is the study of what homeomorphisms preserve.

Rests on Definitions 3.47, 3.51 and 6.6.

Remark 6.8. Bijectivity plus continuity does *not* suffice: the map $t \longmapsto (\cos t, \sin t)$ from $[0, 2\pi)$ onto the circle is continuous and bijective, but its inverse is discontinuous at the seam — the interval and the circle are not homeomorphic (removing a point disconnects one but not the other; see Section 6.1.4).

6.1.3 Compactness

Definition 6.9 (Compact set)**.** A subset K of a topological space is *compact* if and only if every open cover of K admits a finite subcover.

Rests on Definition 6.5.

Proposition 6.10 (Continuous images of compact sets)**.** *If $f : X_1 \longrightarrow X_2$ is continuous and $K \subseteq X_1$ is compact, then $f(K)$ is compact.*

Rests on Definitions 6.6 and 6.9.

Proof. *Derives Proposition 6.10.*

Let $\{U_i\}$ be an open cover of $f(K)$. The sets $f^{-1}(U_i)$ are open (Definition 6.6) and cover K, so finitely many $f^{-1}(U_{i_1}), \dots, f^{-1}(U_{i_n})$ cover K; then $U_{i_1}, \dots, U_{i_n}$ cover $f(K)$. □

The archetypal compact sets are the closed bounded intervals of the real line:

Theorem 6.11 (Heine–Borel on $\mathbb{R}$)**.** *The interval $[a, b] \subset \mathbb{R}$ is compact (in the topology of Section 6.3).*

Rests on Definition 6.9 and Axiom 7.1.

Proof. *Derives Theorem 6.11.*

Let $\{U_i\}$ be an open cover of $[a, b]$ and define

$$S = \{x \in [a, b] \mid [a, x] \text{ is covered by finitely many } U_i\} .$$

S is nonempty (a lies in some U_i) and bounded above by b, so $c = \sup S$ exists by the completeness of $\mathbb{R}$ (Axiom 7.1, proven in Appendix A.7). Some U_{i_0} contains c, and with it an interval $(c - \varepsilon, c + \varepsilon)$. Since $c - \varepsilon$ is not an upper bound of S, some $x \in S$ exceeds it; the finite subcover of $[a, x]$ together with U_{i_0} covers $[a, \min(c + \varepsilon/2, b)]$. If $c < b$ this puts points beyond c into S, contradicting $c = \sup S$; hence $c = b$, and the same finite family covers $[a, b]$. □

In $\mathbb{R}^N$ the theorem extends to the characterization that gives compactness its concrete meaning in analysis. Throughout, $B_r(\boldsymbol{x})$ denotes the Euclidean ball of Definition 6.26 for the metric Equation (6.12).

Theorem 6.12 (Heine–Borel in $\mathbb{R}^N$)**.** *A subset $K \subseteq \mathbb{R}^N$ is compact, in the topology of Section 6.3, if and only if it is closed and bounded.*

Rests on Definitions 6.3 and 6.9 and Axiom 7.1.

Proof. *Derives Theorem 6.12.*

Necessity. Let K be compact. The balls $B_n(\mathbf{0})$, $n \in \mathbb{N}$, form an open cover of K; a finite subcover is contained in the largest of its members, so K is bounded. For closedness, take $\boldsymbol{y} \notin K$ and set $r_{\boldsymbol{x}} = |\boldsymbol{x} - \boldsymbol{y}|/2 > 0$ for each $\boldsymbol{x} \in K$. The balls $B_{r_{\boldsymbol{x}}}(\boldsymbol{x})$ cover K, so finitely many of them, centred at $\boldsymbol{x}_1, \dots, \boldsymbol{x}_p$, already do; abbreviate $r_j = r_{\boldsymbol{x}_j}$ and put $\rho = \min_{j \le p} r_j > 0$. No point $\boldsymbol{z}$ can lie in both $B_\rho(\boldsymbol{y})$ and $B_{r_j}(\boldsymbol{x}_j)$, since that would give

$$2r_j = |\boldsymbol{x}_j - \boldsymbol{y}| \le |\boldsymbol{x}_j - \boldsymbol{z}| + |\boldsymbol{z} - \boldsymbol{y}| < r_j + \rho \le 2r_j .$$

Hence $B_\rho(\boldsymbol{y})$ misses K, and the complement of K is open.

Sufficiency. Consider first the closed box $Q_0 = [-R, R]^N$, and suppose some open cover $\{U_i\}$ of it admitted no finite subcover. Halving every edge splits Q_0 into 2^N closed boxes whose union is Q_0; were each of them covered by finitely many U_i, so would Q_0 be, so at least one of them — call it Q_1 — is not. Iterating produces nested closed boxes $Q_0 \supseteq Q_1 \supseteq \cdots$, none of them finitely covered, the k-th of edge $2R/2^k$ and hence of diameter $\sqrt{N}\, 2R/2^k$. In each coordinate the left endpoints of the Q_k form a nondecreasing bounded sequence and the right endpoints a nonincreasing one, the two differing by $2R/2^k$; by completeness (Axiom 7.1) each converges, and to the same number, which therefore lies in every one of the nested coordinate intervals. The point $\boldsymbol{x}$ with those N coordinates thus belongs to every Q_k. Some U_{i_0} contains $\boldsymbol{x}$, and with it a ball $B_\varepsilon(\boldsymbol{x})$; choosing k with $\sqrt{N}\, 2R/2^k < \varepsilon$ gives $Q_k \subseteq B_\varepsilon(\boldsymbol{x}) \subseteq U_{i_0}$, a subcover of Q_k by a single set — contradicting the choice of Q_k. So Q_0 is compact.

Let now K be closed and bounded, so that $K \subseteq Q_0$ for some R, and let $\{U_i\}$ be an open cover of K. Since K is closed, $\mathbb{R}^N \setminus K$ is open (Definition 6.3), so $\{U_i\}$ together with $\mathbb{R}^N \setminus K$ is an open cover of Q_0. Extract a finite subcover and discard $\mathbb{R}^N \setminus K$ from it: what remains is a finite subfamily of $\{U_i\}$, and it still covers K, because the discarded set contains no point of K. □

6.1.4 Connectedness

Definition 6.13 (Connected space)**.** We say that a topological space is *connected* if and only if it cannot be expressed as a union of disjoint nonempty open sets.

Rests on Definitions 3.36 and 6.2.

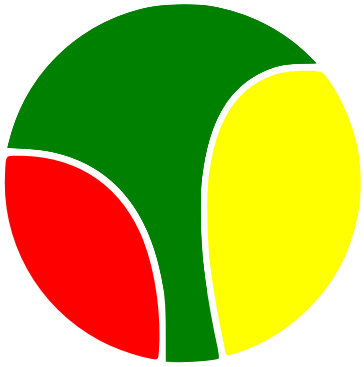

Figure 6.2: A set decomposed into pairwise disjoint subsets whose union is the whole set. A topological space that admits such a decomposition into disjoint nonempty open sets is disconnected.

Theorem 6.14 (Intervals are connected)**.** *Every interval of* $\mathbb{R}$ *is connected.*
Rests on Definition 6.13 and Axiom 7.1.

Proof. *Derives Theorem 6.14.*
Suppose $I = U \cup V$ with U, V open in I, disjoint and nonempty; pick $u \in U$, $v \in V$, say $u < v$. Let $c = \sup\{x \in U \mid x < v\}$, which exists by completeness and satisfies $u \le c \le v$, so $c \in I$. If $c \in U$, openness of U puts an interval around c inside U; since $c < v$ (as $v \in V$), points of U above c would contradict the definition of c. If $c \in V$, openness of V puts $(c - \varepsilon, c] \subseteq V$, making $c - \varepsilon$ an upper bound of the set defining c — again a contradiction. So c lies in neither, contradicting $I = U \cup V$. □

Definition 6.15 (Path-connected space)**.** X is *path-connected* iff any two points $x, y \in X$ are joined by a continuous map $\gamma : [0,1] \longrightarrow X$ with $\gamma(0) = x$, $\gamma(1) = y$.
Rests on Definition 6.6.

Proposition 6.16. *A path-connected space is connected.*
Rests on Definitions 6.13 and 6.15 and Theorem 6.14.

Proof. *Derives Proposition 6.16.*
If $X = U \cup V$ were a disconnection, join $x \in U$ to $y \in V$ by a path γ. Then $\gamma^{-1}(U)$ and $\gamma^{-1}(V)$ disconnect $[0,1]$: both are open by continuity, disjoint, nonempty (0 and 1), and cover. This contradicts Theorem 6.14. □

Definition 6.17 (Simply connected space)**.** A path-connected space X is *simply connected* iff every loop is contractible: for every continuous $\gamma : [0,1] \longrightarrow X$ with $\gamma(0) = \gamma(1) = x_0$ there is a continuous homotopy $H : [0,1] \times [0,1] \longrightarrow X$ with $H(s,0) = \gamma(s)$, $H(s,1) = x_0$, and $H(0,t) = H(1,t) = x_0$ for all s, t.
Rests on Definitions 6.6 and 6.15.

Example 6.18. $\mathbb{R}^N$, and any convex subset of it, is simply connected: the straight-line homotopy $H(s,t) = (1-t)\,\gamma(s) + t\,x_0$ stays inside a convex set and contracts any loop. The punctured plane $\mathbb{R}^2 \setminus \{0\}$ is not: a loop encircling the origin cannot be contracted without crossing it, as Proposition 6.23 proves — the fact underlying the residue theorem of Chapter 8 and property (3) of conservative fields in Chapter 7.
Rests on Definition 6.17.

6.1.5 The winding number

That a loop around a puncture cannot be contracted is a theorem, not a picture, and what proves it is an integer attached to every loop: the number of turns the loop makes about the puncture. Identify $\mathbb{R}^2$ with $\mathbb{C}$ (Chapter 8), so that a loop avoiding the origin is a continuous

map into $\mathbb{C} \setminus \{0\}$. The integer is built from a continuous choice of angle along the loop, and the whole argument rests on the fact that such a choice exists and is unique up to one additive constant.

Lemma 6.19 (Continuous argument along a path)**.** *Let $\gamma : [0,1] \longrightarrow \mathbb{C} \setminus \{0\}$ be continuous. There exists a continuous $\theta : [0,1] \longrightarrow \mathbb{R}$ with*

$$\gamma(t) = |\gamma(t)|\, \mathrm{e}^{\mathrm{i}\theta(t)}\,, \qquad t \in [0,1]\,, \tag{6.3}$$

and any two such functions differ by a constant lying in $2\pi\mathbb{Z}$.

Rests on Theorems 7.23 to 7.25.

Proof. *Derives Lemma 6.19.*

Existence. The function $t \longmapsto |\gamma(t)|$ is continuous and strictly positive on $[0,1]$, so it attains a minimum $m > 0$ (Theorem 7.24); and γ is uniformly continuous, because its real and imaginary parts are (Theorem 7.25). Uniform continuity supplies a $\delta > 0$ with $|\gamma(t) - \gamma(s)| < m$ whenever $|t - s| < \delta$; choose any partition $0 = t_0 < t_1 < \cdots < t_M = 1$ of mesh smaller than δ, so that $|\gamma(t) - \gamma(t_{j-1})| < m$ for every $t \in [t_{j-1}, t_j]$ and every j. On such an interval the quotient $w(t) = \gamma(t)/\gamma(t_{j-1})$ satisfies

$$|w(t) - 1| = \frac{|\gamma(t) - \gamma(t_{j-1})|}{|\gamma(t_{j-1})|} < \frac{m}{|\gamma(t_{j-1})|} \leq 1\,,$$

so $w(t)$ lies in the open disc of radius 1 centred at 1, hence in the half-plane $\Re w > 0$. On that half-plane the function

$$A(w) = \arctan \frac{\Im w}{\Re w} \tag{6.4}$$

is continuous, takes values in $(-\pi/2, \pi/2)$, vanishes at $w = 1$, and satisfies $w = |w|\, \mathrm{e}^{\mathrm{i}A(w)}$. Fix $\theta(0)$ with $\gamma(0) = |\gamma(0)|\, \mathrm{e}^{\mathrm{i}\theta(0)}$ and define recursively

$$\theta(t) = \theta(t_{j-1}) + A\left(\frac{\gamma(t)}{\gamma(t_{j-1})}\right), \qquad t \in [t_{j-1}, t_j]\,.$$

Each piece is continuous and, since $A(1) = 0$, the pieces agree at the nodes, so θ is continuous on $[0,1]$. Multiplying $\gamma(t_{j-1}) = |\gamma(t_{j-1})|\, \mathrm{e}^{\mathrm{i}\theta(t_{j-1})}$ by the polar form of the quotient gives Equation (6.3), one interval at a time.

Uniqueness up to $2\pi\mathbb{Z}$. If θ_1 and θ_2 both satisfy Equation (6.3), then $\mathrm{e}^{\mathrm{i}(\theta_1 - \theta_2)} = 1$, so $\varphi = (\theta_1 - \theta_2)/2\pi$ is continuous with values in $\mathbb{Z}$. Were it to take two distinct values, the intermediate value theorem (Theorem 7.23) would make it take some value strictly between two consecutive integers as well, which is not in $\mathbb{Z}$; hence φ is constant. □

Definition 6.20 (Winding number)**.** Let $\gamma : [0,1] \longrightarrow \mathbb{C} \setminus \{0\}$ be a continuous *loop*, $\gamma(1) = \gamma(0)$, and let θ be a continuous argument for it (Lemma 6.19). Since $\mathrm{e}^{\mathrm{i}\theta(1)} = \mathrm{e}^{\mathrm{i}\theta(0)}$, the number

$$n(\gamma) = \frac{\theta(1) - \theta(0)}{2\pi} \tag{6.5}$$

is an integer; by the uniqueness clause of Lemma 6.19 it does not depend on which continuous argument was chosen. It is the *winding number* of γ about the origin.

Rests on Lemma 6.19.

Example 6.21. The unit circle traversed once counterclockwise, $\gamma(s) = \mathrm{e}^{2\pi\mathrm{i}s}$, admits the continuous argument $\theta(s) = 2\pi s$, so $n(\gamma) = 1$. A constant loop admits a constant argument, so its winding number is 0.

Rests on Definition 6.20.

Lemma 6.22 (Nearby loops wind alike)**.** *Let $\gamma, \sigma : [0,1] \longrightarrow \mathbb{C} \setminus \{0\}$ be loops with*

$$|\sigma(s) - \gamma(s)| < |\gamma(s)| \,, \qquad s \in [0,1] \,. \tag{6.6}$$

Then $n(\sigma) = n(\gamma)$.
Rests on Definition 6.20 and Lemma 6.19.

Proof. *Derives Lemma 6.22.*
The quotient $w = \sigma/\gamma$ is a continuous loop, and Equation (6.6) says $|w(s) - 1| < 1$; in particular w never vanishes and takes its values in the half-plane $\Re w > 0$, where the function A of Equation (6.4) provides the continuous argument $s \longmapsto A(w(s))$. Hence $n(w) = \big(A(w(1)) - A(w(0))\big)/2\pi = 0$, because $w(1) = w(0)$. If θ is a continuous argument for γ, then $\theta + A(w)$ is one for $\sigma = w\,\gamma$, so $n(\sigma) = n(\gamma) + n(w) = n(\gamma)$. □

Proposition 6.23 (The punctured plane is not simply connected)**.** *The loop $\gamma(s) = \mathrm{e}^{2\pi \mathrm{i} s}$ in $\mathbb{R}^2 \setminus \{0\} = \mathbb{C} \setminus \{0\}$ admits no contraction in the sense of Definition 6.17. The punctured plane is therefore path-connected but not simply connected.*
Rests on Definition 6.17, Lemma 6.22, and Theorem 6.11.

Proof. *Derives Proposition 6.23.*
Path-connectedness is immediate: any two points of the punctured plane are joined by a circular arc followed by a radial segment, and neither meets the origin. Suppose then that $H : [0,1] \times [0,1] \longrightarrow \mathbb{C} \setminus \{0\}$ were a contraction of γ, that is, a continuous map with $H(s,0) = \gamma(s)$, $H(s,1) = 1$ and $H(0,t) = H(1,t) = 1$. For each fixed t the map $\gamma_t(s) = H(s,t)$ is then a loop in $\mathbb{C} \setminus \{0\}$, and we may set $n(t) = n(\gamma_t)$.

The function n is locally constant. Fix t_0 and let $m = \min_s |H(s,t_0)| > 0$, the minimum being attained by Theorem 7.24. For each $s_0 \in [0,1]$, continuity of H at (s_0,t_0) supplies a $\delta(s_0) > 0$ such that $|H(s,t) - H(s_0,t_0)| < m/2$ whenever $|s - s_0| < \delta(s_0)$ and $|t - t_0| < \delta(s_0)$. The open intervals $(s_0 - \delta(s_0)/2,\ s_0 + \delta(s_0)/2)$ cover $[0,1]$, which is compact (Theorem 6.11), so finitely many of them suffice, say those centred at $s_1, \ldots, s_k$; put $\delta = \min_j \delta(s_j)/2 > 0$. Let $|t - t_0| < \delta$ and let $s \in [0,1]$. Then $|s - s_j| < \delta(s_j)/2$ for some j, and $|t - t_0| < \delta \le \delta(s_j)$; the defining property of $\delta(s_j)$ applies both at t and at t_0, so $H(s,t)$ and $H(s,t_0)$ both lie within $m/2$ of $H(s_j,t_0)$ and

$$|H(s,t) - H(s,t_0)| \le |H(s,t) - H(s_j,t_0)| + |H(s_j,t_0) - H(s,t_0)| < m \le |H(s,t_0)| \,.$$

Lemma 6.22 then gives $n(t) = n(t_0)$ for every t with $|t - t_0| < \delta$.

Conclusion. A locally constant function is continuous, so $n : [0,1] \longrightarrow \mathbb{Z}$ is continuous and integer-valued, and the intermediate value theorem (Theorem 7.23) forces it to be constant, exactly as in Lemma 6.19. But $n(0) = 1$, since $\gamma_0 = \gamma$, and $n(1) = 0$, since γ_1 is the constant loop (Example 6.21). No such H can exist. □

The circle's winding number of 1 has an analytic counterpart in Chapter 8: the integral $\oint_C \mathrm{d}z/(z-a) = 2\pi\mathrm{i}$ of Lemma 8.11 measures the same single turn of the exponential by integration rather than by lifting.

6.2 Metric spaces

6.2.1 The metric

Definition 6.24 (Metric)**.** Let X be a set and let $d : X \times X \longrightarrow \mathbb{R}$ be a map. We say that d defines a *metric* on X if and only if it satisfies the following axioms:

1. positivity and identity of indiscernibles,

$$\forall\, x, y \in X, \quad d(x,y) \ge 0 \,, \qquad d(x,y) = 0 \iff x = y \,, \tag{6.7}$$

2. symmetry,
$$\forall\, x, y \in X, \quad d(x,y) = d(y,x)\,, \tag{6.8}$$

3. the triangle inequality,
$$\forall\, x, y, z \in X, \quad d(x,y) \le d(x,z) + d(z,y)\,. \tag{6.9}$$

Rests on Definitions 3.38 and 3.43.

Remark 6.25. These axioms bear a notable resemblance to the axioms of an equivalence relation: reflexivity, symmetry, and a triangle-shaped substitute for transitivity.

Definition 6.26 (Open ball; metric topology)**.** The *open ball* of centre $x_0 \in X$ and radius $r > 0$ is
$$B_r(x_0) = \{x \in X \mid d(x, x_0) < r\}\,. \tag{6.10}$$
The *metric topology* of (X, d) declares $U \subseteq X$ open iff every point of U has a ball around it inside U. The axioms of Definition 6.1 are verified directly: arbitrary unions inherit the property pointwise, and for a finite intersection the smallest of the finitely many radii works. Every metric space is thus a topological space.

Rests on Definitions 6.1, 6.2 and 6.24.

6.2.2 Convergence and completeness

Definition 6.27 (Convergence; Cauchy sequence; completeness)**.** A sequence (x_n) in (X, d) *converges* to x iff $d(x_n, x) \longrightarrow 0$; it is *Cauchy* iff $\forall\, \varepsilon > 0\ \exists\, N \mid m, n \ge N \implies d(x_m, x_n) < \varepsilon$. The space is *complete* iff every Cauchy sequence converges in it.

Rests on Definition 6.24.

Every convergent sequence is Cauchy (triangle inequality through the limit); the converse is exactly what completeness demands. The real line is complete (Corollary A.47, Appendix A.7); $\mathbb{Q}$ with the same metric is not, which is the entire reason $\mathbb{R}$ was constructed. Completeness of the function spaces built on this notion is what makes Hilbert spaces possible (Chapter 12).

6.2.3 Continuity in metric terms

Proposition 6.28 (ε–δ characterization)**.** *For metric spaces (X_1, d_1), (X_2, d_2), a map $f : X_1 \longrightarrow X_2$ is continuous at every point in the sense of Definition 6.6 if and only if*
$$\forall\, x_0,\ \forall\, \varepsilon > 0,\ \exists\, \delta > 0 \mid d_1(x, x_0) < \delta \implies d_2(f(x), f(x_0)) < \varepsilon\,. \tag{6.11}$$

Rests on Definitions 6.6 and 6.26.

Proof. *Derives Proposition 6.28.*

($\Rightarrow$) $B_\varepsilon(f(x_0))$ is open, so $f^{-1}(B_\varepsilon(f(x_0)))$ is open and contains x_0, hence contains a ball $B_\delta(x_0)$ — which is Equation (6.11). ($\Leftarrow$) Let U be open in X_2 and $x_0 \in f^{-1}(U)$. Some $B_\varepsilon(f(x_0)) \subseteq U$; the δ provided by Equation (6.11) gives $B_\delta(x_0) \subseteq f^{-1}(U)$, so $f^{-1}(U)$ is open. □

This recovers, for $X_1 = X_2 = \mathbb{R}$ with $d(x,y) = |x - y|$, the definition of continuity used throughout Chapter 7 — the two chapters describe one notion at two levels of generality.

6.2.4 Compactness in metric spaces

In a metric space — and there only — compactness admits a second, sequential description, which is the form in which analysis normally uses it.

Definition 6.29 (Sequential compactness)**.** A metric space (X, d) is *sequentially compact* if and only if every sequence in X has a subsequence converging to a point of X. A subset is sequentially compact if and only if it is so as a metric space in its own right, with the restricted distance.

Rests on Definitions 6.24 and 6.27.

Lemma 6.30 (Lebesgue number)**.** *Let (X, d) be sequentially compact and let $\{U_i\}_{i\in I}$ be an open cover of X. There is a $\delta > 0$ — a* Lebesgue number *of the cover — such that every ball $B_\delta(x)$, $x \in X$, is contained in a single member of the cover.*

Rests on Definitions 6.5, 6.26 and 6.29.

Proof. *Derives Lemma 6.30.*

If no such δ existed, then for every $n \in \mathbb{N}$ there would be a point $x_n \in X$ with $B_{1/n}(x_n)$ contained in no member of the cover. By sequential compactness some subsequence $x_{n_k} \longrightarrow x \in X$, and x lies in some U_{i_0}, which contains a ball $B_\varepsilon(x)$. Choose k so large that $d(x_{n_k}, x) < \varepsilon/2$ and $1/n_k < \varepsilon/2$. Every $y \in B_{1/n_k}(x_{n_k})$ then satisfies

$$d(y, x) \le d(y, x_{n_k}) + d(x_{n_k}, x) < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon\,,$$

so $B_{1/n_k}(x_{n_k}) \subseteq B_\varepsilon(x) \subseteq U_{i_0}$ — contradicting the choice of x_{n_k}. □

Theorem 6.31 (Compactness and sequential compactness)**.** *A metric space (X, d) is compact if and only if it is sequentially compact.*

Rests on Definitions 6.9 and 6.29 and Lemma 6.30.

Proof. *Derives Theorem 6.31.*

Compact $\Longrightarrow$ sequentially compact. Let (x_n) be a sequence with no convergent subsequence. Then no point $x \in X$ is the limit of a subsequence, and consequently each x admits a radius $r_x > 0$ such that $B_{r_x}(x)$ contains x_n for only finitely many indices n: otherwise every ball $B_{1/k}(x)$ would contain terms of arbitrarily large index, and picking $n_1 < n_2 < \cdots$ with $x_{n_k} \in B_{1/k}(x)$ would produce a subsequence converging to x. The balls $B_{r_x}(x)$ form an open cover of X, so finitely many of them cover X; their union then contains x_n for only finitely many indices, although it is all of X and so contains every term of the sequence. Since the index set is infinite, this is absurd.

Sequentially compact $\Longrightarrow$ compact. Let $\{U_i\}$ be an open cover of X and let $\delta > 0$ be a Lebesgue number for it (Lemma 6.30). We claim first that finitely many balls of radius δ cover X. If not, choose $x_1 \in X$ and, having chosen $x_1, \dots, x_n$, a point x_{n+1} outside $B_\delta(x_1) \cup \cdots \cup B_\delta(x_n)$; the resulting sequence satisfies $d(x_m, x_n) \ge \delta$ for all $m \ne n$, so none of its subsequences is Cauchy and none converges — contradicting sequential compactness. So $X = B_\delta(y_1) \cup \cdots \cup B_\delta(y_p)$ for suitable points $y_1, \dots, y_p$, and by the defining property of δ each $B_\delta(y_q)$ lies inside some U_{i_q}. The finitely many sets $U_{i_1}, \dots, U_{i_p}$ cover X. □

Remark 6.32. On a closed bounded subset of $\mathbb{R}$ the sequential form is exactly the Bolzano–Weierstrass theorem (Theorem 7.7), which Theorem 6.31 converts into the covering statement of Theorem 6.11. Applying Bolzano–Weierstrass in each coordinate in turn gives the sequential compactness of a closed bounded subset of $\mathbb{R}^N$, and the same conversion then reproduces Theorem 6.12 — whose direct proof above is independent of this equivalence, and so may be read as a second, covering-side derivation of it. The restriction to metric spaces is essential rather than technical: for general topological spaces neither implication holds.

6.3 The topology of $\mathbb{R}^N$

The real numbers admit no general symbolic rule that generates them all, but graphically they can be represented by a straight line built out of them: the real line, on which every $x \in \mathbb{R}$ has its place.

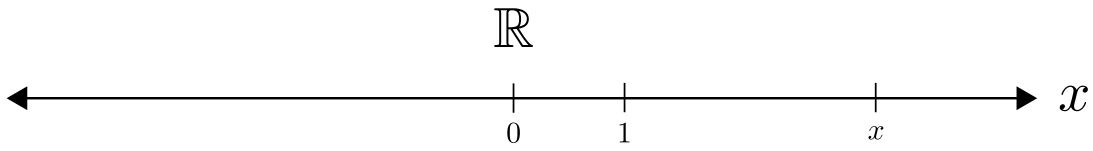

Figure 6.3: The real line: the set $\mathbb{R}$ represented as a straight line, with the integers 0 and 1 fixing origin and unit and an arbitrary real number x marked.

6.3.1 Vectors in $\mathbb{R}^N$

The set $\mathbb{R}^N$ of ordered N-tuples $\boldsymbol{x} = (x_1, \ldots, x_N)$ carries three compatible structures at once: the vector-space structure of Chapter 5 (componentwise addition and scaling), the *Euclidean metric*

$$d(\boldsymbol{x}, \boldsymbol{y}) = |\boldsymbol{x} - \boldsymbol{y}| = \left(\sum_{i=1}^{N} (x_i - y_i)^2 \right)^{1/2}, \tag{6.12}$$

whose metric axioms follow from the Cauchy–Schwarz inequality (Chapter 5), and the metric topology this induces (Definition 6.26). The identification of the N-tuple with the geometric vector is precisely the statement that these structures cohabit: the topology sees nearness, the vector space sees displacement, and the metric ties them together. Physics happens on this triple structure — configuration spaces in Part III, and, once the metric is allowed to vary from point to point and take general signature (p, q), the manifolds of Chapter 13.

Convergence in $\mathbb{R}^N$ is componentwise (each coordinate is squeezed by the Euclidean distance), so the completeness of $\mathbb{R}$ (Appendix A.7) lifts coordinatewise: $\mathbb{R}^N$ is a complete metric space.

Chapter 7

Real Analysis

Real analysis makes precise the two operations on which the whole of physics rests: the limit, from which continuity and the derivative follow, and the integral, which undoes the derivative and sums continuous distributions. Everything in this chapter descends from a single property of the real numbers — completeness — which is therefore stated first, as an axiom here and as a theorem in Appendix A.7, where the real numbers are constructed and the property is proven. It is, by design, the deepest proof of Parts I and II.

7.1 The real numbers

The rational numbers $\mathbb{Q}$ form an ordered field (Chapter 4), but a gapped one: no rational squares to 2. Analysis begins by filling the gaps.

Axiom 7.1 (Completeness of $\mathbb{R}$)**.** $\mathbb{R}$ is an ordered field containing $\mathbb{Q}$, in which every nonempty subset S that is bounded above has a least upper bound $\sup S \in \mathbb{R}$.

Full derivation: Appendix A.7 (p. 2791) constructs $\mathbb{R}$ from $\mathbb{Q}$ by Dedekind cuts and proves Axiom 7.1 as a theorem, together with three consequences used constantly below: the *Archimedean property* (Corollary A.45: for $x > 0$ and any y some $nx > y$), the *density of* $\mathbb{Q}$ (between any two reals lies a rational), and *monotone convergence* (Corollary A.46: a bounded nondecreasing sequence converges to its supremum). By symmetry, bounded nonempty sets have infima and bounded nonincreasing sequences converge to them.

Definition 7.2 (Absolute value)**.** For $x \in \mathbb{R}$, $|x| = x$ if $x \geq 0$ and $|x| = -x$ otherwise.

Proposition 7.3 (Triangle inequality)**.** $|x + y| \leq |x| + |y|$ *for all* $x, y \in \mathbb{R}$.
Rests on Definition 7.2.

Proof. *Derives Proposition 7.3.*
From $-|x| \leq x \leq |x|$ and the same for y, adding gives $-(|x| + |y|) \leq x + y \leq |x| + |y|$, which is the claim. □

7.2 Sequences

Definition 7.4 (Convergence)**.** A sequence $(a_n)_{n \in \mathbb{N}}$ in $\mathbb{R}$ *converges* to $L \in \mathbb{R}$, written $a_n \longrightarrow L$ or $\lim_{n \to \infty} a_n = L$, iff

$$\forall\, \varepsilon > 0,\ \exists\, N \in \mathbb{N} \mid n \geq N \implies |a_n - L| < \varepsilon\,. \tag{7.1}$$

Rests on Definition 7.2.

Proposition 7.5 (Uniqueness of the limit)**.** *A sequence has at most one limit.*
Rests on Definition 7.4 and Proposition 7.3.

Proof. *Derives Proposition 7.5.*

If $a_n \to L$ and $a_n \to L'$ with $L \neq L'$, take $\varepsilon = |L - L'|/2 > 0$. For n beyond both thresholds, $|L - L'| \leq |L - a_n| + |a_n - L'| < 2\varepsilon = |L - L'|$, a contradiction. □

Proposition 7.6 (Algebra of limits)**.** *If $a_n \to A$ and $b_n \to B$, then $a_n + b_n \to A + B$, $a_n b_n \to AB$, and, if $B \neq 0$, $a_n / b_n \to A/B$.*

Rests on Definition 7.4 and Proposition 7.3.

Proof. *Derives Proposition 7.6.*

Sum: given ε, beyond the larger of the two thresholds for $\varepsilon/2$, $|(a_n + b_n) - (A + B)| \leq |a_n - A| + |b_n - B| < \varepsilon$. *Product:* convergent sequences are bounded (beyond N_1 for $\varepsilon = 1$ all terms lie within 1 of the limit, and finitely many remain), say $|a_n| \leq M$; then

$$|a_n b_n - AB| = |a_n(b_n - B) + B(a_n - A)| \leq M\,|b_n - B| + |B|\,|a_n - A|\,,$$

and each term is made smaller than $\varepsilon/2$ beyond a suitable threshold. *Quotient:* it suffices to prove $1/b_n \to 1/B$. Beyond some N_0, $|b_n| > |B|/2$ (take $\varepsilon = |B|/2$); then $|1/b_n - 1/B| = |B - b_n|/(|b_n|\,|B|) \leq 2\,|b_n - B|\,/\,|B|^2$, which is controlled as before. □

Theorem 7.7 (Bolzano–Weierstrass)**.** *Every bounded sequence in $\mathbb{R}$ has a convergent subsequence.*

Rests on Corollaries A.45 and A.46.

Proof. *Derives Theorem 7.7.*

Let $a_n \in [A_0, B_0]$ for all n. Bisect the interval: at least one half contains a_n for infinitely many indices n; call it $[A_1, B_1]$ and pick n_1 with $a_{n_1} \in [A_1, B_1]$. Iterating, we obtain nested intervals $[A_k, B_k]$ of length $(B_0 - A_0)/2^k$, each containing infinitely many terms, and indices $n_1 < n_2 < \cdots$ with $a_{n_k} \in [A_k, B_k]$. The sequence (A_k) is nondecreasing and bounded above by B_0, so by monotone convergence (Corollary A.46) $A_k \to L$; since $0 \leq B_k - A_k = (B_0 - A_0)/2^k \to 0$ (Archimedean property), $B_k \to L$ as well, and $A_k \leq a_{n_k} \leq B_k$ squeezes $a_{n_k} \to L$. □

Theorem 7.8 (Cauchy criterion)**.** *A sequence in $\mathbb{R}$ converges if and only if it is a Cauchy sequence: $\forall\, \varepsilon > 0\ \exists N \mid m, n \geq N \implies |a_m - a_n| < \varepsilon$.*

Rests on Definition 7.4 and Corollary A.47.

Proof. *Derives Theorem 7.8.*

Necessity: if $a_n \to L$, then beyond the threshold for $\varepsilon/2$, $|a_m - a_n| \leq |a_m - L| + |L - a_n| < \varepsilon$. Sufficiency is Corollary A.47, proven in Appendix A.7 from monotone convergence. □

The Cauchy criterion is the working form of completeness: it certifies convergence without knowing the limit, which is how every series and every integral below will be shown to exist.

7.3 Real functions

Definition 7.9 (Real function)**.** A *real function* is a map $f : A \subseteq \mathbb{R} \longrightarrow \mathbb{R}$ (Chapter 3); A is its *domain* and $f(A) = \{f(x) \mid x \in A\}$ its *image*.

Rests on Definition 3.43.

Definition 7.10 (Constant function)**.** Consider a real number $C \in \mathbb{R}$. We define the *constant function* as

$$\begin{aligned} f : A \subseteq \mathbb{R} &\longrightarrow B \subseteq \mathbb{R} \\ x &\longmapsto f(x) = C\,. \end{aligned}$$

Rests on Definition 7.9.

Definition 7.11 (Sum of functions)**.** Consider two real functions f and g. We define the *sum of functions* as the function

$$\begin{aligned} f+g : A \subseteq \mathbb{R} &\longrightarrow B \subseteq \mathbb{R} \\ x &\longmapsto (f+g)(x) = f(x) + g(x)\,. \end{aligned}$$

Rests on Definition 7.9.

Definition 7.12 (Product of functions)**.** Consider two real functions f and g. We define the *product of functions* as the function

$$\begin{aligned} fg : A \subseteq \mathbb{R} &\longrightarrow B \subseteq \mathbb{R} \\ x &\longmapsto (fg)(x) = f(x)g(x)\,. \end{aligned}$$

Rests on Definition 7.9.

Definition 7.13 (Composite function)**.** Consider two real functions f and g. We define the *composition of f with g* as the function

$$\begin{aligned} f \circ g : A \subseteq \mathbb{R} &\longrightarrow B \subseteq \mathbb{R} \\ x &\longmapsto (f \circ g)(x) = f(g(x))\,. \end{aligned}$$

Rests on Definition 7.9.

Definition 7.14 (Inverse function)**.** Consider a bijective real function $f : A \longrightarrow B$, $x \longmapsto f(x) = y$. The *inverse function* $f^{-1} : B \longrightarrow A$ assigns to each $y \in B$ the unique $x \in A$ with $f(x) = y$, so that $f^{-1} \circ f = \mathrm{id}_A$ and $f \circ f^{-1} = \mathrm{id}_B$. A strictly monotonic function is injective, and is therefore invertible onto its image.
Rests on Definitions 3.47 and 7.13.

Definition 7.15 (Absolute-value function)**.** $|\cdot| : \mathbb{R} \longrightarrow \mathbb{R}$, $x \longmapsto |x|$, with $|x|$ as in Definition 7.2.
Rests on Definitions 7.2 and 7.9.

7.4 Limits

Definition 7.16 (Limit)**.** Consider a real function $f : x \longmapsto f(x)$. We say that the *limit* of f, as x tends to x_0, exists and equals L if and only if

$$\forall\, \varepsilon > 0,\ \exists\, \delta(\varepsilon) \in \mathbb{R}^+ \mid 0 < |x - x_0| < \delta \implies |f(x) - L| < \varepsilon\,. \tag{7.2}$$

If it exists, we denote this limit by

$$\lim_{x \longrightarrow x_0} f(x) = L\,. \tag{7.3}$$

Rests on Definitions 7.2 and 7.9.

Remark 7.17. Note that the definition requires

$$|x - x_0| > 0 \quad \implies \quad x \neq x_0\,, \tag{7.4}$$

that is, the point x_0 itself is excluded: the limit probes the values of f near x_0, never at x_0.
Rests on Definition 7.16.

The algebra of limits of sequences (Proposition 7.6) transfers verbatim to limits of functions, by the same ε–δ estimates; we use it freely.

7.4.1 One-sided limits

Consider a real function $f : (a, b) \longrightarrow B \subseteq \mathbb{R}$. From the definition of the limit we have the condition

$$0 < |x - x_0| < \delta \,.$$

- If we choose $x_0 = a$, then, since the interval is open,

$$x > a \quad \Longrightarrow \quad 0 < x - a < \delta \,.$$

We say that the *limit of f from the right, as x tends to a, is L* if and only if

$$\lim_{x \longrightarrow a} f(x) = L, \quad x > a \,, \tag{7.5}$$

which we denote by

$$\lim_{x \longrightarrow a^+} f(x) = L \,. \tag{7.6}$$

- If we choose $x_0 = b$, then, since the interval is open,

$$\begin{aligned} x < b \implies & 0 < -(x - b) < \delta \\ \iff & 0 > x - b > -\delta \\ \iff & -\delta < x - b < 0 \,. \end{aligned}$$

We say that the *limit of f from the left, as x tends to b, is L* if and only if

$$\lim_{x \longrightarrow b} f(x) = L, \quad x < b \,, \tag{7.7}$$

which we denote by

$$\lim_{x \longrightarrow b^-} f(x) = L \,. \tag{7.8}$$

Proposition 7.18 (Two-sided limit from one-sided limits)**.** *Let x_0 be interior to the domain of f. Then $\lim_{x \to x_0} f(x) = L$ if and only if both one-sided limits exist and*

$$\lim_{x \longrightarrow x_0^-} f(x) = \lim_{x \longrightarrow x_0^+} f(x) = L \,. \tag{7.9}$$

Rests on Definition 7.16 and Equations (7.5) and (7.7).

Proof. *Derives Proposition 7.18.*

($\Rightarrow$) The two-sided δ works for each side separately. ($\Leftarrow$) Given ε, let δ_- and δ_+ be the one-sided thresholds and $\delta = \min(\delta_-, \delta_+)$. Any x with $0 < |x - x_0| < \delta$ lies on one of the two sides and satisfies the corresponding estimate, so $|f(x) - L| < \varepsilon$. □

7.4.2 Infinite limits and limits at infinity

Definition 7.19 (Infinite limits)**.** $\lim_{x \to a} f(x) = \infty$ iff for every $M \in \mathbb{R}$ there is $\delta > 0$ with $0 < |x - a| < \delta \implies f(x) > M$; and $L = \lim_{x \to \infty} f(x)$ iff for every $\varepsilon > 0$ there is $R \in \mathbb{R}$ with $x > R \implies |f(x) - L| < \varepsilon$. The variants with $-\infty$ are defined by the obvious sign changes.

Rests on Definitions 7.2 and 7.16.

An *asymptote* of f is a line approached by its graph in one of these senses: vertical at a when $\lim_{x \to a^{\pm}} f(x) = \pm\infty$, horizontal at height L when $\lim_{x \to \pm\infty} f(x) = L$, and oblique $y = mx + c$ when $\lim_{x \to \pm\infty} [f(x) - mx - c] = 0$.

7.5 Continuity

Definition 7.20 (Continuity at a point)**.** Consider a function $f : A \subseteq \mathbb{R} \longrightarrow B \subseteq \mathbb{R}$ and a point $x_0 \in A$. We say that f is *continuous* at x_0 if and only if

$$\exists \lim_{x \longrightarrow x_0} f(x) = f(x_0)\,. \tag{7.10}$$

f is *continuous on* A iff it is continuous at every point of A; the set of such functions is denoted $C^0(A)$. It is *piecewise continuous* on $[a, b]$ iff it is continuous there except at finitely many points, at each of which both one-sided limits exist.

Rests on Definition 7.16 and Equations (7.5) and (7.7).

Remark 7.21. Two ways of failing this condition are distinguished:

- if the limit exists but differs from $f(x_0)$, we say that f has a *removable discontinuity* at x_0;
- if the limit does not exist, we say that f has an *essential discontinuity* at x_0.

Rests on Definitions 7.16 and 7.20.

Proposition 7.22 (Sequential characterization)**.** *f is continuous at x_0 if and only if for every sequence $x_n \longrightarrow x_0$ in its domain, $f(x_n) \longrightarrow f(x_0)$.*

Rests on Definitions 7.4 and 7.20.

Proof. *Derives Proposition 7.22.*

($\Rightarrow$) Given ε, choose δ from continuity, then N so that $n \geq N \implies |x_n - x_0| < \delta$; then $|f(x_n) - f(x_0)| < \varepsilon$. ($\Leftarrow$) If f is not continuous at x_0, some ε_0 admits no δ: for each n there is x_n with $|x_n - x_0| < 1/n$ but $|f(x_n) - f(x_0)| \geq \varepsilon_0$. Then $x_n \to x_0$ while $f(x_n) \not\to f(x_0)$. □

Sums, products, quotients (where defined) and compositions of continuous functions are continuous, by Proposition 7.22 and Proposition 7.6.

Theorem 7.23 (Intermediate value theorem)**.** *Let $f \in C^0([a, b])$ with $f(a) < 0 < f(b)$. Then there is $c \in (a, b)$ with $f(c) = 0$.*

Rests on Axiom 7.1 and Definition 7.20.

Proof. *Derives Theorem 7.23.*

Let $S = \{x \in [a, b] \mid f(x) < 0\}$; S is nonempty ($a \in S$) and bounded above by b, so $c = \sup S$ exists (Axiom 7.1). We claim $f(c) = 0$. If $f(c) < 0$, then $c < b$, and continuity provides $\delta > 0$ with $f < 0$ on $(c - \delta, c + \delta) \cap [a, b]$ (take $\varepsilon = -f(c)$); points just above c would then lie in S, contradicting that c bounds S. If $f(c) > 0$, continuity gives $f > 0$ on $(c - \delta, c]$ for some $\delta > 0$; then $c - \delta$ is already an upper bound of S, contradicting leastness. Hence $f(c) = 0$, and $c \neq a, b$ because $f(a) < 0 < f(b)$. □

Theorem 7.24 (Extreme value theorem)**.** *A continuous function on a closed bounded interval $[a, b]$ is bounded and attains its supremum and infimum.*

Rests on Axiom 7.1, Theorem 7.7, and Proposition 7.22.

Proof. *Derives Theorem 7.24.*

Bounded: if not, pick $x_n \in [a, b]$ with $|f(x_n)| > n$. By Bolzano–Weierstrass (Theorem 7.7) a subsequence $x_{n_k} \to c \in [a, b]$; continuity forces $f(x_{n_k}) \to f(c)$, but $|f(x_{n_k})| > n_k \to \infty$ — contradiction. *Attained:* let $M = \sup f([a, b])$, which now exists; pick x_n with $f(x_n) > M - 1/n$. A convergent subsequence $x_{n_k} \to c$ gives $f(c) = \lim f(x_{n_k}) = M$. The infimum is the supremum of $-f$. □

Theorem 7.25 (Heine–Cantor: uniform continuity)**.** *A continuous function on $[a,b]$ is uniformly continuous: for every $\varepsilon > 0$ there is a single $\delta > 0$ such that $|x-y| < \delta \implies |f(x) - f(y)| < \varepsilon$ for* all *$x, y \in [a,b]$.*

Rests on Theorem 7.7 and Proposition 7.22.

Proof. *Derives Theorem 7.25.*

If not, some ε_0 admits points x_n, y_n with $|x_n - y_n| < 1/n$ but $|f(x_n) - f(y_n)| \geq \varepsilon_0$. Extract $x_{n_k} \to c$ (Theorem 7.7); then $y_{n_k} \to c$ too, and continuity gives $f(x_{n_k}) - f(y_{n_k}) \to f(c) - f(c) = 0$, contradicting $|f(x_{n_k}) - f(y_{n_k})| \geq \varepsilon_0$. □

7.6 The derivative

Definition 7.26 (Derivative of a function at a point)**.** Consider a real function

$$\begin{array}{rccc} f: & (a,b) & \longrightarrow & \mathbb{R} \\ & x & \longmapsto & f(x) \end{array}$$

and a point $x_0 \in (a,b)$. We define the *derivative of f at x_0* as the real number given by

$$f'(x_0) = \lim_{x \longrightarrow x_0} \frac{f(x) - f(x_0)}{x - x_0}\,. \tag{7.11}$$

Rests on Definitions 7.9 and 7.16.

We may introduce

$$h = x - x_0\,, \tag{7.12}$$

in terms of which the derivative reads

$$f'(x_0) = \lim_{h \longrightarrow 0} \frac{f(x_0 + h) - f(x_0)}{h}\,. \tag{7.13}$$

Proposition 7.27 (Differentiable implies continuous)**.** *If $f'(x_0)$ exists, f is continuous at x_0.*

Rests on Definitions 7.20 and 7.26 and Proposition 7.6.

Proof. *Derives Proposition 7.27.*

$f(x) - f(x_0) = \dfrac{f(x) - f(x_0)}{x - x_0}\,(x - x_0) \longrightarrow f'(x_0) \cdot 0 = 0$ as $x \to x_0$, by the algebra of limits. □

7.6.1 Geometric interpretation of the derivative

The construction underlying Equation (7.11) is geometric: the difference quotient is the slope of the secant line through the points $(x_0, f(x_0))$ and $(x, f(x))$ of the graph, and the derivative is the slope of the tangent line obtained in the limit $x \longrightarrow x_0$, as the sequence of figures Figures 7.1 to 7.4 illustrates. It is for this reason that we must take only open intervals: the limit must be able to approach the point from within the domain.

7.6.2 The derivative function

From the definition in Equation (7.11) we may take $x_0 = u$ to be an arbitrary point of the interval (a,b) at which the derivative is evaluated, and thereby obtain a general expression for the derivative at any point of (a,b). We define the *derivative function* of f as the real function that assigns to each point of the domain of f the derivative of f at that point, which we denote by f'. Making the change of variable $h = x - u$,

$$f'(x) = \lim_{h \longrightarrow 0} \frac{f(x + h) - f(x)}{h}\,. \tag{7.14}$$

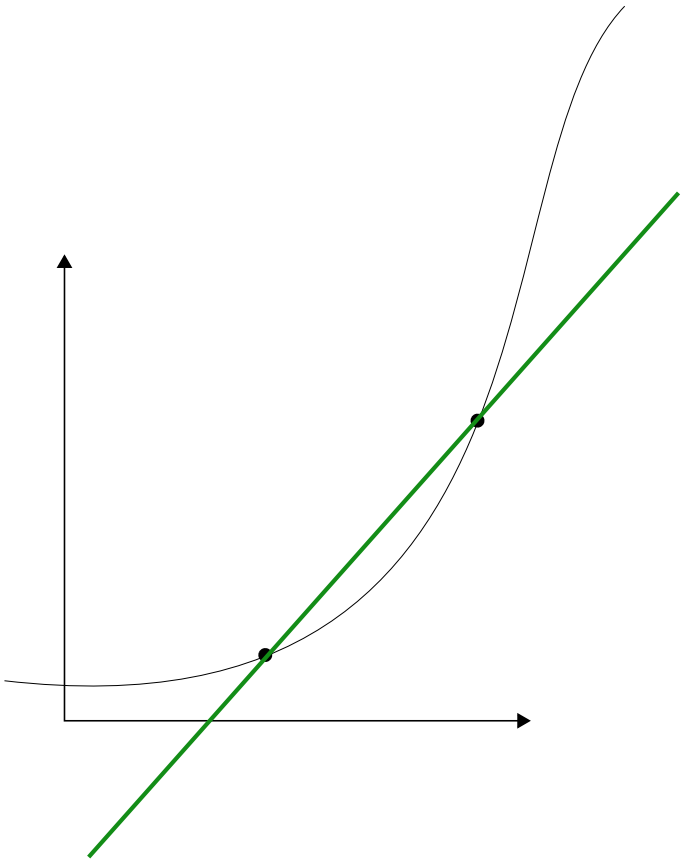

Figure 7.1: The secant-to-tangent construction of the derivative (panel 1 of 4).

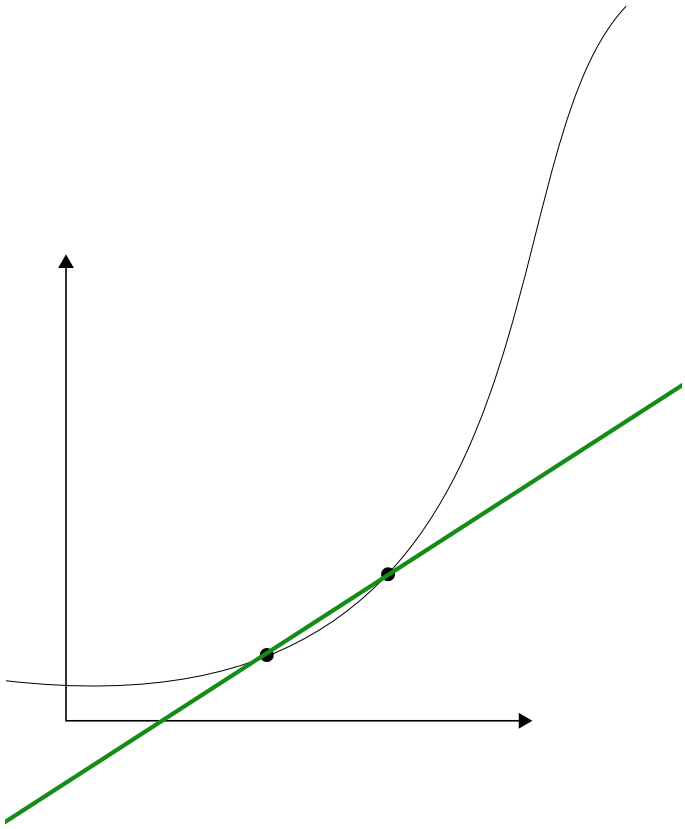

Figure 7.2: The secant-to-tangent construction of the derivative (panel 2 of 4).

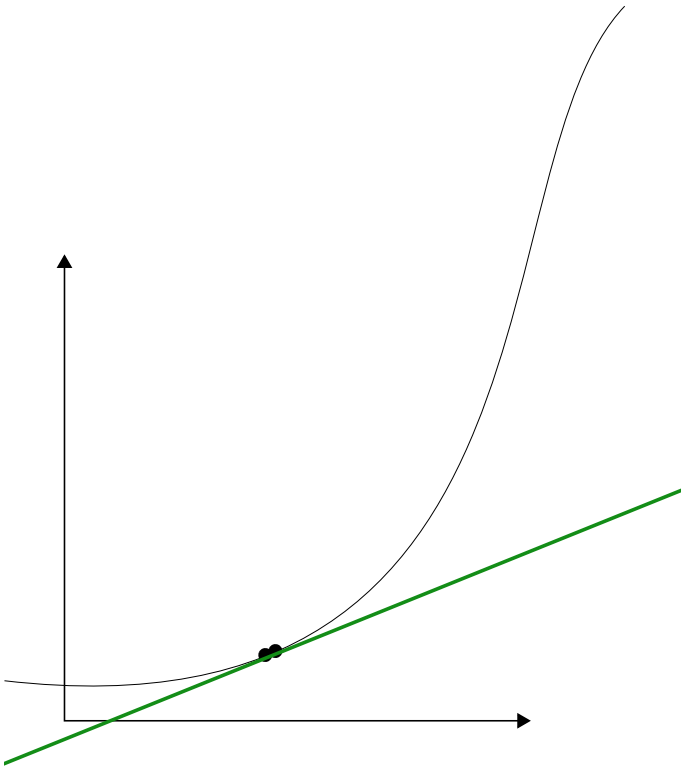

Figure 7.3: The secant-to-tangent construction of the derivative (panel 3 of 4).

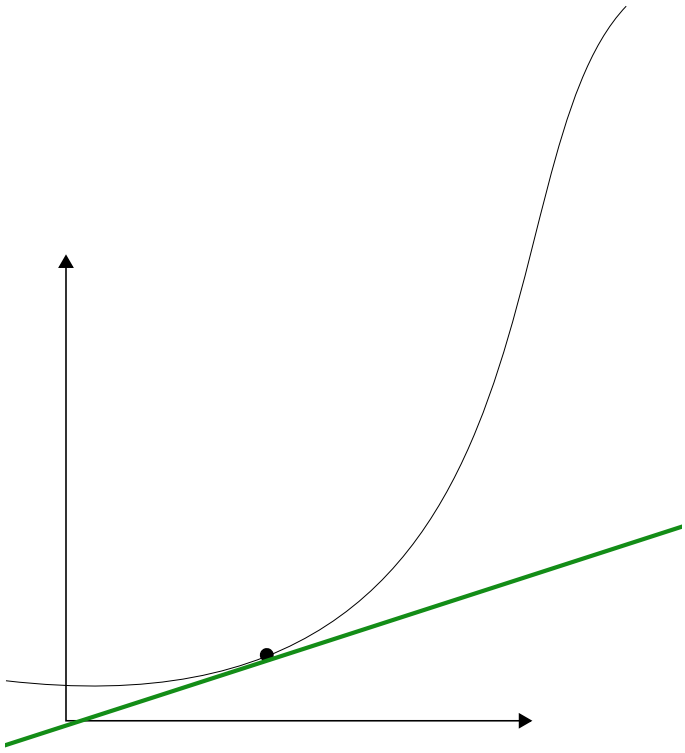

Figure 7.4: The secant-to-tangent construction of the derivative (panel 4 of 4).

7.6.3 Rules of differentiation

Proposition 7.28 (Derivative of a constant function)**.** *Let $f : x \longmapsto C$ be a constant real function. Then*

$$f = C \quad \Longrightarrow \quad f' = 0\,. \tag{7.15}$$

Rests on Definition 7.10 and Equation (7.14).

Derivation. Derives Proposition 7.28.

From Equation (7.14) we have

$$\begin{aligned} f'(x) &= \lim_{h \longrightarrow 0} \frac{f(x+h) - f(x)}{h} \\ &= \lim_{h \longrightarrow 0} \frac{C - C}{h} = 0\,. \end{aligned}$$

□

Proposition 7.29 (Linearity)**.** $(\lambda f)' = \lambda f'$ *and* $(f+g)' = f' + g'$ *for* $\lambda \in \mathbb{R}$.
Rests on Definition 7.11, Equation (7.14), and Proposition 7.6.

Proof. Derives Proposition 7.29.

Both difference quotients split termwise, and the algebra of limits (Proposition 7.6) distributes the limit over the pieces. □

Proposition 7.30 (Leibniz rule)**.** *Let f and g be real functions. Then*

$$(fg)' = f'g + fg'\,. \tag{7.16}$$

Rests on Definition 7.12, Equation (7.14), and Propositions 7.6 and 7.27.

Derivation. Derives Proposition 7.30.

We have

$$\begin{aligned} (fg)'(x) &= \lim_{h \longrightarrow 0} \frac{(fg)(x+h) - (fg)(x)}{h} \\ &= \lim_{h \longrightarrow 0} \frac{f(x+h)g(x+h) - f(x)g(x)}{h} \\ &= \lim_{h \longrightarrow 0} \frac{f(x+h)g(x+h) - f(x)g(x) + f(x)g(x+h) - f(x)g(x+h)}{h} \\ &= \lim_{h \longrightarrow 0} \frac{f(x)\,[g(x+h) - g(x)] + g(x+h)\,[f(x+h) - f(x)]}{h} \\ &= f(x) \lim_{h \longrightarrow 0} \frac{g(x+h) - g(x)}{h} + \lim_{h \longrightarrow 0} g(x+h) \lim_{h \longrightarrow 0} \frac{f(x+h) - f(x)}{h} \\ &= f(x)g'(x) + f'(x)g(x)\,, \end{aligned}$$

where the last step uses Equation (7.14) and the continuity of g (Proposition 7.27). □

Proposition 7.31 (Chain rule)**.** *Let f be differentiable at x and g differentiable at $f(x)$. Then*

$$(g \circ f)'(x) = g'(f(x))\, f'(x)\,. \tag{7.17}$$

Rests on Definition 7.13 and Propositions 7.6 and 7.27.

Derivation. Derives Proposition 7.31.

Define, for y in the domain of g and $u_0 = f(x)$,

$$\varphi(y) = \begin{cases} \dfrac{g(y) - g(u_0)}{y - u_0}\,, & y \neq u_0\,, \\[2ex] g'(u_0)\,, & y = u_0\,. \end{cases}$$

Differentiability of g at u_0 says precisely that φ is continuous at u_0, and by construction $g(y) - g(u_0) = \varphi(y)\,(y - u_0)$ for *all* y — including $y = u_0$, which is the case the naive quotient argument cannot handle. Substituting $y = f(x+h)$,

$$\frac{g(f(x+h)) - g(f(x))}{h} = \varphi(f(x+h))\,\frac{f(x+h) - f(x)}{h}\,.$$

As $h \to 0$: $f(x+h) \to f(x)$ by Proposition 7.27, so $\varphi(f(x+h)) \to \varphi(f(x)) = g'(f(x))$ by continuity of φ, while the second factor tends to $f'(x)$. The algebra of limits gives Equation (7.17). □

Proposition 7.32 (Derivative of the inverse function)**.** *Let f be strictly monotonic and continuous on an interval, and differentiable at x_0 with $f'(x_0) \neq 0$. Then f^{-1} is differentiable at $y_0 = f(x_0)$ and*

$$(f^{-1})'(y_0) = \frac{1}{f'(x_0)}\,. \tag{7.18}$$

Rests on Definition 7.14, Theorem 7.23, and Proposition 7.6.

Proof. *Derives Proposition 7.32.*

For $y \neq y_0$ write $x = f^{-1}(y)$; continuity and strict monotonicity make f^{-1} continuous (its one-sided limits exist by monotonicity and cannot jump without leaving a gap in the image, forbidden by Theorem 7.23), so $y \to y_0$ forces $x \to x_0$. Then

$$\frac{f^{-1}(y) - f^{-1}(y_0)}{y - y_0} = \frac{x - x_0}{f(x) - f(x_0)} \longrightarrow \frac{1}{f'(x_0)}\,.$$

□

7.6.4 The mean value theorems

Lemma 7.33 (Fermat: interior extremum)**.** *If f attains a local maximum or minimum at an interior point c and $f'(c)$ exists, then $f'(c) = 0$.*

Rests on Definition 7.26 and Proposition 7.18.

Proof. *Derives Lemma 7.33.*

Say the extremum is a maximum. For $h > 0$ small, $[f(c+h) - f(c)]\,/h \leq 0$, so the right limit gives $f'(c) \leq 0$; for $h < 0$, the quotient is ≥ 0, so $f'(c) \geq 0$. Hence $f'(c) = 0$. □

Theorem 7.34 (Rolle)**.** *If $f \in C^0([a,b])$ is differentiable on (a,b) and $f(a) = f(b)$, then $f'(c) = 0$ for some $c \in (a,b)$.*

Rests on Theorem 7.24 and Lemma 7.33.

Proof. *Derives Theorem 7.34.*

By the extreme value theorem (Theorem 7.24) f attains a maximum and a minimum on $[a,b]$. If both are attained at the endpoints, f is constant (max = min) and any interior c works. Otherwise one extremum is interior, and Lemma 7.33 finishes. □

Theorem 7.35 (Mean value theorem)**.** *If $f \in C^0([a,b])$ is differentiable on (a,b), there is $c \in (a,b)$ with*

$$f(b) - f(a) = f'(c)\,(b - a)\,. \tag{7.19}$$

Rests on Theorem 7.34 and Proposition 7.29.

Proof. *Derives Theorem 7.35.*

Apply Rolle to $\phi(x) = f(x) - f(a) - \dfrac{f(b) - f(a)}{b - a}\,(x - a)$, which is continuous on $[a,b]$, differentiable inside, and vanishes at both endpoints; $\phi'(c) = 0$ is Equation (7.19). □

Corollary 7.36. *Let f be continuous on an interval and differentiable at its interior points. If $f' = 0$ there, f is constant; if $f' > 0$ there, f is strictly increasing — on the whole interval, endpoints included.*

Rests on Theorem 7.35.

Proof. *Derives Corollary 7.36.*

For $x < y$ in the interval, Theorem 7.35 on $[x, y]$ gives $f(y) - f(x) = f'(c)(y - x)$ with $c \in (x, y)$ — an interior point — and the right side vanishes in the first case and is positive in the second. □

Theorem 7.37 (Cauchy mean value theorem and l'Hôpital's rule)**.** *Let $f, g \in C^0([a, b])$ be differentiable on (a, b) with $g' \neq 0$ there. Then there is $c \in (a, b)$ with $[f(b) - f(a)]\, g'(c) = [g(b) - g(a)]\, f'(c)$. Consequently, if $f(x_0) = g(x_0) = 0$ and $\lim_{x \to x_0} f'(x)/g'(x) = L$ exists, then*

$$\lim_{x \longrightarrow x_0} \frac{f(x)}{g(x)} = L\,. \tag{7.20}$$

Rests on Theorem 7.34 and Definition 7.16.

Proof. *Derives Theorem 7.37.*

Rolle applied to $\psi(x) = [f(b) - f(a)]\, g(x) - [g(b) - g(a)]\, f(x)$ (which takes the value $f(b)g(a) - g(b)f(a)$ at both ends) gives the first claim. For the second, take $x \neq x_0$ and apply it on the interval with endpoints x_0, x: since $f(x_0) = g(x_0) = 0$,

$$\frac{f(x)}{g(x)} = \frac{f'(c_x)}{g'(c_x)} \quad \text{for some } c_x \text{ between } x_0 \text{ and } x\,.$$

As $x \to x_0$, also $c_x \to x_0$, and the right-hand side tends to L. □

Theorem 7.38 (Taylor's theorem with Lagrange remainder)**.** *Let f be $n+1$ times differentiable on an interval containing x_0 and x. Then*

$$f(x) = \sum_{k=0}^{n} \frac{f^{(k)}(x_0)}{k!}\,(x - x_0)^k + \frac{f^{(n+1)}(\xi)}{(n+1)!}\,(x - x_0)^{n+1} \tag{7.21}$$

for some ξ between x_0 and x.

Rests on Theorem 7.34 and Proposition 7.30.

Proof. *Derives Theorem 7.38.*

Fix x and let M be defined by $f(x) = \sum_{k=0}^{n} \frac{f^{(k)}(x_0)}{k!}(x - x_0)^k + M\,(x - x_0)^{n+1}$. Consider

$$g(t) = f(x) - \sum_{k=0}^{n} \frac{f^{(k)}(t)}{k!}\,(x - t)^k - M\,(x - t)^{n+1}\,.$$

Then $g(x) = 0$ and $g(x_0) = 0$ by the choice of M, so Rolle gives ξ between x_0 and x with $g'(\xi) = 0$. Differentiating the sum in t telescopes: all terms cancel pairwise except the last, leaving

$$g'(t) = -\frac{f^{(n+1)}(t)}{n!}\,(x - t)^n + (n+1)M\,(x - t)^n\,.$$

Setting $t = \xi$ and dividing by $(x - \xi)^n \neq 0$ yields $M = f^{(n+1)}(\xi)/(n+1)!$, which is Equation (7.21). □

7.7 The Riemann integral

Definition 7.39 (Darboux sums and the definite integral)**.** Let $f : [a,b] \longrightarrow \mathbb{R}$ be bounded and $P : a = x_0 < x_1 < \cdots < x_n = b$ a partition. With $m_i = \inf_{[x_{i-1},x_i]} f$ and $M_i = \sup_{[x_{i-1},x_i]} f$, the *lower* and *upper sums* are

$$L(f,P) = \sum_{i=1}^{n} m_i \,(x_i - x_{i-1})\,, \qquad U(f,P) = \sum_{i=1}^{n} M_i \,(x_i - x_{i-1})\,. \tag{7.22}$$

f is *Riemann integrable* iff $\sup_P L(f,P) = \inf_P U(f,P)$, and the common value is the *definite integral* $\int_a^b f(x)\,\mathrm{d}x$. (Both extrema exist by Axiom 7.1: every lower sum is $\le$ every upper sum, since refining a partition raises L and lowers U.)

Rests on Axiom 7.1.

Theorem 7.40 (Continuous functions are integrable)**.** *$f \in C^0([a,b])$ is Riemann integrable.*

Rests on Definition 7.39 and Theorems 7.24 and 7.25.

Proof. *Derives Theorem 7.40.*

Given $\varepsilon > 0$, Heine–Cantor (Theorem 7.25) provides δ with $|f(x) - f(y)| < \varepsilon/(b-a)$ whenever $|x - y| < \delta$. For any partition with all steps $x_i - x_{i-1} < \delta$, the extreme value theorem gives points where m_i, M_i are attained, at distance $< \delta$, so $M_i - m_i < \varepsilon/(b-a)$ and

$$U(f,P) - L(f,P) = \sum_i (M_i - m_i)(x_i - x_{i-1}) < \frac{\varepsilon}{b-a}\,(b-a) = \varepsilon\,.$$

Upper and lower extrema squeezed within every ε coincide. □

The integral is linear and monotone in f, and additive over subintervals, $\int_a^b = \int_a^c + \int_c^b$ — each property follows directly from the corresponding property of the Darboux sums.

Definition 7.41 (Antiderivative)**.** We define the *antiderivative* of a function f as the function F such that

$$F' = f\,, \tag{7.23}$$

and we denote it by

$$F = \int f\,. \tag{7.24}$$

By Corollary 7.36, two antiderivatives of the same f on an interval differ by a constant.

Rests on Definition 7.26 and Corollary 7.36.

7.8 The fundamental theorem of calculus

Theorem 7.42 (Fundamental theorem of calculus, I)**.** *Let $f \in C^0([a,b])$ and define $F(x) = \int_a^x f(t)\,\mathrm{d}t$. Then F is differentiable on (a,b) and*

$$F'(x) = f(x)\,. \tag{7.25}$$

Rests on Theorems 7.24 and 7.40 and Definition 7.26.

Proof. *Derives Theorem 7.42.*

For $h > 0$ (the case $h < 0$ is symmetric), additivity gives

$$\frac{F(x+h) - F(x)}{h} = \frac{1}{h}\int_x^{x+h} f(t)\,\mathrm{d}t\,.$$

On $[x, x+h]$ let m_h, M_h be the (attained) minimum and maximum of f; monotonicity of the integral squeezes $m_h \le \frac{1}{h}\int_x^{x+h} f \le M_h$. As $h \to 0$, continuity of f at x drives $m_h, M_h \to f(x)$, and the difference quotient converges to $f(x)$. □

Theorem 7.43 (Fundamental theorem of calculus, II)**.** *If $f \in C^0([a,b])$ and G is any antiderivative of f, then*

$$\int_a^b f(x)\,\mathrm{d}x = G(b) - G(a)\,. \tag{7.26}$$

Rests on Theorem 7.42 and Definition 7.41.

Proof. *Derives Theorem 7.43.*

$F(x) = \int_a^x f$ is an antiderivative by Theorem 7.42, so $G = F + C$ for a constant C (Definition 7.41). Then $G(b) - G(a) = F(b) - F(a) = \int_a^b f - 0$. □

Corollary 7.44 (Substitution and integration by parts)**.** *For C^1 functions on the relevant intervals,*

$$\int_a^b f(g(t))\,g'(t)\,\mathrm{d}t = \int_{g(a)}^{g(b)} f(x)\,\mathrm{d}x\,, \tag{7.27}$$

$$\int_a^b f'(x)\,g(x)\,\mathrm{d}x = [f(x)g(x)]_a^b - \int_a^b f(x)\,g'(x)\,\mathrm{d}x\,. \tag{7.28}$$

Rests on Theorem 7.43 and Propositions 7.30 and 7.31.

Proof. *Derives Corollary 7.44.*

Both sides of Equation (7.27) equal $F(g(b)) - F(g(a))$ for an antiderivative F of f, by Theorem 7.43 and the chain rule $(F \circ g)' = f(g)\,g'$ (Proposition 7.31). Equation Equation (7.28) is Theorem 7.43 applied to the Leibniz rule $(fg)' = f'g + fg'$ (Proposition 7.30). □

7.9 Series

Definition 7.45 (Series)**.** Given a sequence (a_n), the *series* $\sum_{n=0}^{\infty} a_n$ is the limit of its partial sums $s_N = \sum_{n=0}^{N} a_n$, when it exists. It *converges absolutely* iff $\sum |a_n|$ converges.

Rests on Definitions 7.2 and 7.4.

Proposition 7.46 (Geometric series)**.** *For $|q| < 1$,* $\displaystyle\sum_{n=0}^{\infty} q^n = \frac{1}{1-q}$.

Rests on Definition 7.45 and Corollary A.46.

Proof. *Derives Proposition 7.46.*

$(1-q)\,s_N = 1 - q^{N+1}$, so $s_N = (1-q^{N+1})/(1-q)$. Since $|q| < 1$, $q^{N+1} \to 0$ (its absolute value is decreasing and bounded below, so it converges by monotone convergence, and the limit ℓ satisfies $\ell = |q|\,\ell$, forcing $\ell = 0$). □

Proposition 7.47 (Comparison; absolute convergence)**.** *If $0 \le a_n \le b_n$ and $\sum b_n$ converges, then $\sum a_n$ converges. Moreover an absolutely convergent series converges.*

Rests on Definition 7.45, Corollary A.46, and Theorem 7.8.

Proof. *Derives Proposition 7.47.*

The partial sums of $\sum a_n$ are nondecreasing and bounded above by $\sum b_n$; monotone convergence (Corollary A.46) concludes. For the second claim, apply the Cauchy criterion (Theorem 7.8): for $M > N$, $|s_M - s_N| = \left|\sum_{N+1}^{M} a_n\right| \le \sum_{N+1}^{M} |a_n|$, and the right side is the Cauchy difference of the convergent series $\sum |a_n|$. □

Proposition 7.48 (Ratio test)**.** *If $\limsup_n |a_{n+1}/a_n| = r < 1$, then $\sum a_n$ converges absolutely; if $|a_{n+1}/a_n| \ge 1$ eventually, it diverges.*

Rests on Propositions 7.46 and 7.47 and Theorem 7.8.

Proof. *Derives Proposition 7.48.*

Pick q with $r < q < 1$: beyond some N, $|a_{n+1}| \le q\,|a_n|$, so $|a_{N+k}| \le q^k\,|a_N|$ and comparison with the geometric series (Propositions 7.46 and 7.47) gives absolute convergence. In the divergent case $|a_n|$ is eventually nondecreasing and nonzero, so $a_n \not\to 0$, while convergence of a series forces its terms to 0 (Cauchy criterion with $M = N+1$). □

Proposition 7.49 (Cauchy product)**.** *Let $\sum_{n=0}^{\infty} a_n = A$ and $\sum_{n=0}^{\infty} b_n = B$ converge absolutely. Then their* Cauchy product

$$\sum_{n=0}^{\infty} c_n\,, \qquad c_n = \sum_{k=0}^{n} a_k\, b_{n-k}\,, \tag{7.29}$$

converges absolutely, with sum AB.

Rests on Definition 7.45, Corollary A.46, and Proposition 7.6.

Proof. *Derives Proposition 7.49.*

Write $A^* = \sum_n |a_n|$ and $B^* = \sum_n |b_n|$. For any N,

$$\sum_{n=0}^{N} |c_n| \le \sum_{n=0}^{N}\sum_{k=0}^{n} |a_k|\;|b_{n-k}| \le \left(\sum_{k=0}^{N} |a_k|\right)\left(\sum_{j=0}^{N} |b_j|\right) \le A^*B^*\,,$$

since every product $|a_k|\,|b_j|$ with $k+j \le N$ appears exactly once in the middle double sum and all products are nonnegative. The partial sums of $\sum |c_n|$ are nondecreasing and bounded, hence convergent (Corollary A.46): the Cauchy product converges absolutely. For its value, compare $C_N = \sum_{n=0}^{N} c_n$ with the product of partial sums $A_N B_N$: expanding both, $A_N B_N - C_N$ consists exactly of the products $a_j b_k$ with $j,k \le N$ but $j+k > N$. Every such pair has $j > N/2$ or $k > N/2$ (double counting only enlarges the bound), so

$$|A_N B_N - C_N| \le B^* \sum_{j>N/2} |a_j| + A^* \sum_{k>N/2} |b_k| \longrightarrow 0\,,$$

because each tail is the difference between A^* (respectively B^*) and one of its own partial sums, and those partial sums converge to it. Since $A_N B_N \to AB$ by the algebra of limits (Proposition 7.6), also $C_N \to AB$. □

Theorem 7.50 (Power series; radius of convergence)**.** *For a power series $\sum_n c_n (x-x_0)^n$ there is $R \in [0,\infty]$ such that the series converges absolutely for $|x-x_0| < R$ and diverges for $|x-x_0| > R$.*

Rests on Axiom 7.1 and Propositions 7.46 and 7.47.

Proof. *Derives Theorem 7.50.*

Let $S = \{\rho \ge 0 \mid (|c_n|\,\rho^n) \text{ is bounded}\}$ and $R = \sup S$ (allowing ∞). If $|x-x_0| < R$, pick $\rho \in S$ with $|x-x_0| < \rho$ and a bound $|c_n|\,\rho^n \le M$; then $|c_n (x-x_0)^n| \le M\,(|x-x_0|/\rho)^n$, a convergent geometric majorant, so comparison gives absolute convergence. If $|x-x_0| > R$, the terms $c_n(x-x_0)^n$ are unbounded (else $|x-x_0| \in S$), so they cannot tend to 0 and the series diverges. □

Theorem 7.51 (Termwise differentiation)**.** *Let $f(x) = \sum_{n=0}^{\infty} c_n (x-x_0)^n$ have radius of convergence $R > 0$. Then the derived series $\sum_{n\ge 1} n\,c_n\,(x-x_0)^{n-1}$ has the same radius R, and on $|x-x_0| < R$ the function f is differentiable with*

$$f'(x) = \sum_{n=1}^{\infty} n\,c_n\,(x-x_0)^{n-1}\,. \tag{7.30}$$

Iterating, f has derivatives of every order inside its radius; in particular it is continuous there.

Rests on Theorem 7.50 and Propositions 7.6, 7.27, 7.47 and 7.48.

Proof. *Derives Theorem 7.51.*

Translate so that $x_0 = 0$. *Same radius.* Let $|x| < R$. As in the proof of Theorem 7.50, pick ρ in the set S of that proof with $|x| < \rho$ (possible because $R = \sup S > |x|$) and a bound $|c_n|\,\rho^n \le M$; then

$$n\,|c_n|\,|x|^{n-1} \le \frac{M}{\rho}\,n\left(\frac{|x|}{\rho}\right)^{n-1},$$

and $\sum_n n\,t^{n-1}$ converges for $0 < t < 1$ by the ratio test (Proposition 7.48: the ratio of consecutive terms is $\frac{n+1}{n}\,t \to t < 1$), and trivially at $t = 0$, where only the $n = 1$ term survives. Comparison (Proposition 7.47) gives absolute convergence of the derived series whenever $|x| < R$. Conversely $|c_n x^n| \le |x| \cdot n\,|c_n|\,|x|^{n-1}$ for $n \ge 1$, so wherever the derived series converges absolutely the original does too: the two radii coincide. Applying the statement to the derived series itself, $\sum_{n\ge2} n(n-1)\,c_n\,x^{n-2}$ also has radius R.

The difference quotient. Fix $|x| < R$, choose r with $|x| < r < R$, and let $y \ne x$ with $|y| \le r$. Subtracting the two absolutely convergent series term by term and dividing by $y - x$ (Proposition 7.6 on partial sums),

$$\frac{f(y) - f(x)}{y - x} - \sum_{n=1}^{\infty} n\,c_n\,x^{n-1} = \sum_{n=1}^{\infty} c_n\left[\frac{y^n - x^n}{y - x} - n\,x^{n-1}\right].$$

The factorization $y^n - x^n = (y - x)\sum_{k=0}^{n-1} y^k x^{n-1-k}$ turns the bracket into $\sum_{k=0}^{n-1}\left(y^k - x^k\right)x^{n-1-k}$, and the same factorization once more bounds $\left|y^k - x^k\right| \le k\,r^{k-1}\,|y - x|$, so

$$\left|\frac{y^n - x^n}{y - x} - n\,x^{n-1}\right| \le |y - x|\sum_{k=0}^{n-1} k\,r^{k-1}\,r^{n-1-k} = |y - x|\,\frac{n(n-1)}{2}\,r^{n-2}.$$

Multiplying by $|c_n|$ and summing,

$$\left|\frac{f(y) - f(x)}{y - x} - \sum_{n=1}^{\infty} n\,c_n\,x^{n-1}\right| \le \frac{|y - x|}{2}\sum_{n=2}^{\infty} n(n-1)\,|c_n|\,r^{n-2} = \frac{K}{2}\,|y - x|,$$

with $K < \infty$ because $r < R$ (the twice-derived series above). Letting $y \to x$, the difference quotient converges to $\sum_n n\,c_n\,x^{n-1}$, which is Equation (7.30). Differentiability implies continuity (Proposition 7.27), and iterating on the derived series — again a power series of radius R — yields derivatives of every order. □

Termwise *integration* is the mirror statement: the antiderivative series $\sum_n c_n(x - x_0)^{n+1}/(n+1)$ has the same radius (the same comparison, run backwards) and differentiates termwise back to f by Theorem 7.51. Both are used freely in Chapter 8, where power series become the *definition* of analyticity.

7.9.1 The numbers e and π

Two real numbers recur in every branch of this treatise, from the oscillator of Chapter 28 to the phase factors of Part IX. Both are defined here, rigorously, from the machinery just built — not quoted as decimal approximations.

Proposition 7.52 (Alternating series test)**.** *Let $(b_n)_{n\ge0}$ be a nonincreasing sequence of nonnegative reals with $b_n \to 0$. Then $\sum_{n=0}^{\infty}(-1)^n b_n$ converges, and its sum S satisfies $S_1 \le S \le S_0 = b_0$, where S_N denotes the N-th partial sum.*

Rests on Definition 7.45 and Corollary A.46.

Proof. *Derives Proposition 7.52.*

The even partial sums are nonincreasing, $S_{2k+2} - S_{2k} = -b_{2k+1} + b_{2k+2} \leq 0$, and bounded below by S_1 (since $S_{2k+1} \leq S_{2k+2} \leq S_{2k}$, shown by the same computation applied once more); the odd partial sums are nondecreasing and bounded above by S_0 by the mirror argument. Both are monotone and bounded, hence convergent (Corollary A.46), to limits S_{e} and S_{o} respectively; since $S_{2k} - S_{2k+1} = b_{2k+1} \to 0$, $S_{\mathrm{e}} = S_{\mathrm{o}} =: S$. Monotonicity of each subsequence gives $S_1 \leq S \leq S_0$. □

Figure 7.5 shows the mechanism at work: each pair of consecutive partial sums traps the limit in an interval of width $b_{N+1} \to 0$, which is what makes the test also an *error bound* — the property Lemma 7.60 will exploit.

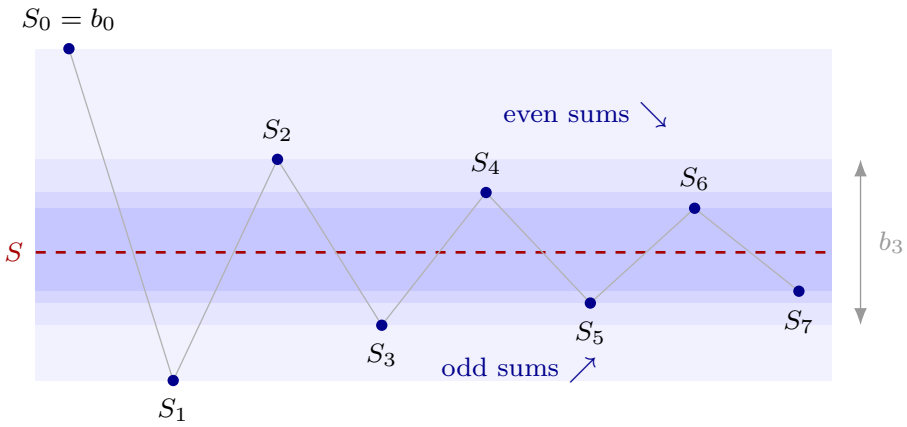

Figure 7.5: The alternating series test (Proposition 7.52) on $\sum_n (-1)^n b_n$ with $b_n = 1/(n+1)$. Even partial sums descend, odd partial sums ascend, and every consecutive pair brackets the sum S in a nested interval of width b_{N+1}.

Euler's number

Definition 7.53 (e)**.**

$$\mathrm{e} = \sum_{n=0}^{\infty} \frac{1}{n!}\,. \tag{7.31}$$

Rests on Definition 7.45 and Proposition 7.48.

The series converges absolutely by the ratio test (Proposition 7.48: the ratio of consecutive terms is $1/(n+1) \to 0$).

Convergence by itself yields no digit. What turns Equation (7.31) into a *computational* definition is that its truncation error admits a closed bound, and one sharp enough that a dozen terms already settle nine decimals.

Lemma 7.54 (Truncation error)**.** *Let $s_n = \sum_{k=0}^{n} 1/k!$ denote the n-th partial sum of Equation (7.31). Then for every integer $n \geq 1$,*

$$\frac{1}{(n+1)!} \;\leq\; \mathrm{e} - s_n \;<\; \frac{1}{n \cdot n!}\,. \tag{7.32}$$

Rests on Equation (7.31) and Proposition 7.46.

Proof. *Derives Lemma 7.54.*

The tail $\mathrm{e} - s_n = \sum_{k=n+1}^{\infty} 1/k!$ has positive terms, so it is at least its first term $1/(n+1)!$; that is the left inequality. For the right one, put $k = n+1+j$ with $j \geq 0$ and factor out $1/(n+1)!$:

$$\mathrm{e} - s_n = \frac{1}{(n+1)!} \sum_{j=0}^{\infty} \prod_{i=2}^{j+1} \frac{1}{n+i}\,, \tag{7.33}$$

the empty product at $j = 0$ being 1. Each of the j factors obeys $n+i \geq n+2 > n+1$, so the product is at most $(n+1)^{-j}$, strictly so once $j \geq 1$. The comparison series is geometric with ratio $1/(n+1) \in (0,1)$, hence summable (Proposition 7.46), and

$$\mathrm{e} - s_n < \frac{1}{(n+1)!} \sum_{j=0}^{\infty} \frac{1}{(n+1)^j} = \frac{1}{(n+1)!} \cdot \frac{n+1}{n} = \frac{1}{n \cdot n!}\,.$$

□

The two bounds trap e between two *rationals* computable in finitely many integer operations, and the width of the trap collapses faster than any geometric rate. This is what produces digits.

Corollary 7.55 (The decimal expansion)**.**

$$\mathrm{e} = 2.718\,281\,828\ldots\,. \tag{7.34}$$

Rests on Lemma 7.54.

Derivation. *Derives Corollary 7.55.*

Take $n = 12$ in Lemma 7.54. Over the common denominator $12! = 479\,001\,600$ the partial sum is a ratio of integers obtained by finitely many additions, with no limit process anywhere:

$$s_{12} = \frac{1}{12!} \sum_{k=0}^{12} \frac{12!}{k!} = \frac{1\,302\,061\,345}{479\,001\,600} = \frac{260\,412\,269}{95\,800\,320}\,. \tag{7.35}$$

The error bound is $1/(12 \cdot 12!) = 1/5\,748\,019\,200$, itself smaller than 1.74×10^{-10}. Carrying out the two divisions to sixteen decimals — rounding the lower endpoint down and the upper endpoint up, so that the enclosure is certain — Equation (7.32) gives

$$2.718\,281\,828\,286\,168\,5 \;<\; \mathrm{e} \;<\; 2.718\,281\,828\,460\,141\,6\,. \tag{7.36}$$

The endpoints agree in their first nine decimals, so every real number between them — e among them — begins 2.718281828. □

Nothing about $n = 12$ is special: raising n narrows Equation (7.36) at will, $n = 15$ already fixing eleven decimals. What the argument does *not* do is terminate. No finite decimal is ever reached, and the next result explains why not.

Proposition 7.56 (Irrationality)**.** $\mathrm{e} \notin \mathbb{Q}$. *Consequently its decimal expansion neither terminates nor becomes periodic, and no finite decimal equals* e*: Equation* (7.34) *records the opening digits of an expansion that never ends.*

Rests on Definition 7.53 and Lemma 7.54.

Proof. *Derives Proposition 7.56.*

Suppose $\mathrm{e} = p/q$ with p, q positive integers, and set $n = \max\{q, 2\}$. Consider

$$x = n!\,(\mathrm{e} - s_n) = n!\,\mathrm{e} - \sum_{k=0}^{n} \frac{n!}{k!}\,.$$

Every $n!/k!$ with $k \le n$ is an integer, so the sum is an integer; and $n!\,\mathrm{e} = n!\,p/q$ is an integer because $q \le n$ makes q a divisor of $n!$. Hence $x \in \mathbb{Z}$. Multiplying Equation (7.32) by $n! > 0$, however,

$$0 < \frac{1}{n+1} \le x < \frac{1}{n} \le \frac{1}{2}\,,$$

so x is an integer lying strictly between 0 and 1. No such integer exists, and the assumption fails. □

Proposition 7.57 (The limit definition)**.**

$$\mathrm{e} = \lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^n . \tag{7.37}$$

Rests on Definition 7.53, Equation (5.3), and Proposition 7.6.

Proof. *Derives Proposition 7.57.*

By the binomial theorem (Equation (5.3)),

$$\left(1 + \frac{1}{n}\right)^n = \sum_{k=0}^{n} \binom{n}{k} \frac{1}{n^k} = \sum_{k=0}^{n} \frac{1}{k!} \prod_{j=0}^{k-1} \left(1 - \frac{j}{n}\right) , \tag{7.38}$$

using $\binom{n}{k}/n^k = \frac{1}{k!}\prod_{j=0}^{k-1}(n-j)/n = \frac{1}{k!}\prod_{j=0}^{k-1}(1-j/n)$. Each factor $1 - j/n \in (0,1]$, so every term of Equation (7.38) is at most $1/k!$; summing,

$$\left(1 + \frac{1}{n}\right)^n \le \sum_{k=0}^{n} \frac{1}{k!} \le \mathrm{e}\,,$$

the last step because a partial sum of a convergent series of positive terms is bounded by the full sum. This gives $\limsup_n (1+1/n)^n \le \mathrm{e}$. Conversely, fix N; for $n \ge N$, truncating Equation (7.38) at $k = N$ (dropping the remaining nonnegative terms) gives

$$\left(1 + \frac{1}{n}\right)^n \ge \sum_{k=0}^{N} \frac{1}{k!} \prod_{j=0}^{k-1} \left(1 - \frac{j}{n}\right) .$$

For each fixed $k \le N$, the product $\to 1$ as $n \to \infty$ (a finite product of terms each $\to 1$, by Proposition 7.6), so the right side $\to \sum_{k=0}^{N} 1/k!$ as $n \to \infty$. Hence $\liminf_n (1+1/n)^n \ge \sum_{k=0}^{N} 1/k!$ for every N, and letting $N \to \infty$, $\liminf_n (1+1/n)^n \ge \mathrm{e}$. The limsup and liminf bounds coincide, so the limit exists and equals e. □

Remark 7.58 (An identity, not a recipe). Proposition 7.57 is often taken as the definition of e, but it is useless for computing one. Taking logarithms and expanding, $n\ln(1+1/n) = 1 - \frac{1}{2n} + O(n^{-2})$, so

$$\left(1 + \frac{1}{n}\right)^n = \mathrm{e}\left(1 - \frac{1}{2n} + O(n^{-2})\right) , \qquad \mathrm{e} - \left(1 + \frac{1}{n}\right)^n \sim \frac{\mathrm{e}}{2n}\,. \tag{7.39}$$

The error falls off like $1/n$: one further decimal per tenfold increase in n. Matching the nine decimals that Equation (7.35) obtains from twelve terms would take $n > 2.7 \times 10^9$, and the eleven decimals available at $n = 15$ would take $n > 2.7 \times 10^{11}$. The factorial series converges faster than any geometric rate and the limit slower than one; that asymmetry, not tradition, is why Equation (7.31) is the definition here and Equation (7.37) a theorem about it.

Rests on Proposition 7.57 and Lemma 7.54.

The real exponential $\exp(x) = \sum_{n=0}^{\infty} x^n/n!$ (Theorem 7.50: radius ∞, ratio test) satisfies $\exp(1) = \mathrm{e}$ and extends to the complex exponential e^z of Definition 8.3 without changing a single coefficient.

The number π

The trigonometric functions are defined, on $\mathbb{R}$, by the same series used in Definition 8.3 restricted to real argument:

$$\cos x = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!}\,, \qquad \sin x = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{(2n+1)!}\,, \tag{7.40}$$

both with infinite radius of convergence (ratio test, as for e^x).

Lemma 7.59 (Derivatives; the Pythagorean identity)**.** *For every $x \in \mathbb{R}$,*

$$\sin' x = \cos x\,, \qquad \cos' x = -\sin x\,, \qquad \sin^2 x + \cos^2 x = 1\,. \tag{7.41}$$

Rests on Equations (5.3) and (7.40), Theorem 7.51, and Proposition 7.49.

Proof. *Derives Lemma 7.59.*

Derivatives. Termwise differentiation (Theorem 7.51) of Equation (7.40) gives

$$\sin' x = \sum_{n=0}^{\infty} \frac{(-1)^n (2n+1)\, x^{2n}}{(2n+1)!} = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} = \cos x\,,$$

and, re-indexing $n = m+1$ in the derived series of cos,

$$\cos' x = \sum_{n=1}^{\infty} \frac{(-1)^n (2n)\, x^{2n-1}}{(2n)!} = \sum_{m=0}^{\infty} \frac{(-1)^{m+1} x^{2m+1}}{(2m+1)!} = -\sin x\,.$$

Pythagorean identity. Both series converge absolutely at every x, so each square is a Cauchy product (Proposition 7.49). Squaring the cosine series, the terms $a_j = (-1)^j x^{2j}/(2j)!$ collect at fixed $j+k=n$ into

$$\cos^2 x = \sum_{n=0}^{\infty} (-1)^n x^{2n} \sum_{j=0}^{n} \frac{1}{(2j)!\,(2n-2j)!} = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} \sum_{j=0}^{n} \binom{2n}{2j}\,,$$

multiplying and dividing by $(2n)!$ in the last step. The same computation squares the sine series (terms $(-1)^j x^{2j+1}/(2j+1)!$, product powers x^{2n+2}, then re-indexed so the power reads x^{2n}):

$$\sin^2 x = \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^{2n}}{(2n)!} \sum_{j=0}^{n-1} \binom{2n}{2j+1}\,.$$

Adding the two, the constant term is 1 and the coefficient of x^{2n} for $n \geq 1$ is

$$\frac{(-1)^n}{(2n)!}\left[\sum_{j=0}^{n} \binom{2n}{2j} - \sum_{j=0}^{n-1} \binom{2n}{2j+1}\right] = \frac{(-1)^n}{(2n)!}\,(1-1)^{2n} = 0\,,$$

by the binomial theorem (Equation (5.3)): the two brackets are the even and the odd halves of $\sum_{i=0}^{2n} (-1)^i \binom{2n}{i}$. Hence $\sin^2 x + \cos^2 x = 1$. (Once the derivatives are known the identity also follows in one line — $(\sin^2 + \cos^2)' = 2\sin\cos - 2\cos\sin = 0$, so the function is constant (Corollary 7.36) with value 1 at $x=0$; the Cauchy-product computation above is that statement read coefficient by coefficient.) □

Lemma 7.60 ($\cos 2 < 0$)**.** *Rests on Equation (7.40) and Proposition 7.52.*

Proof. *Derives Lemma 7.60.*

At $x = 2$ the terms of Equation (7.40) have magnitude $t_n = 2^{2n}/(2n)!$; for $n \geq 1$,

$$\frac{t_{n+1}}{t_n} = \frac{4}{(2n+1)(2n+2)} \leq \frac{4}{3 \cdot 4} = \frac{1}{3},$$

so $(t_n)_{n\geq 1}$ is nonincreasing (and $t_n \to 0$). By Proposition 7.52 applied to the tail starting at $n = 2$, the sum $S = \sum_{n=2}^{\infty}(-1)^n t_n = t_2 - t_3 + t_4 - \cdots$ satisfies $0 \leq S \leq t_2 = 16/24 = 2/3$. Since $\cos 2 = t_0 - t_1 + S = 1 - 2 + S = -1 + S$,

$$\cos 2 \in \left[-1, -\tfrac{1}{3}\right],$$

in particular $\cos 2 < 0$. □

Definition 7.61 (π)**.** By Lemma 7.60, $\cos 0 = 1 > 0$, and cos is continuous (Theorem 7.51: a power series is differentiable, hence continuous, inside its radius — here infinite). The intermediate value theorem (Theorem 7.23) applied to cos on $[0, 2]$ gives at least one zero (Figure 7.6); let

$$z = \inf\{x > 0 \mid \cos x = 0\},$$

a nonempty set bounded below by 0 and above by 2, so z exists by completeness (Axiom 7.1) and $\cos z = 0$ by continuity (a limit of a sequence of zeros approaching the infimum, or directly: cos > 0 on $[0, z)$ by minimality of z, and $\cos z \leq 0$ by continuity from the right, forcing $\cos z = 0$). We define

$$\pi = 2z. \tag{7.42}$$

Rests on Lemma 7.60, Theorems 7.23 and 7.51, and Axiom 7.1.

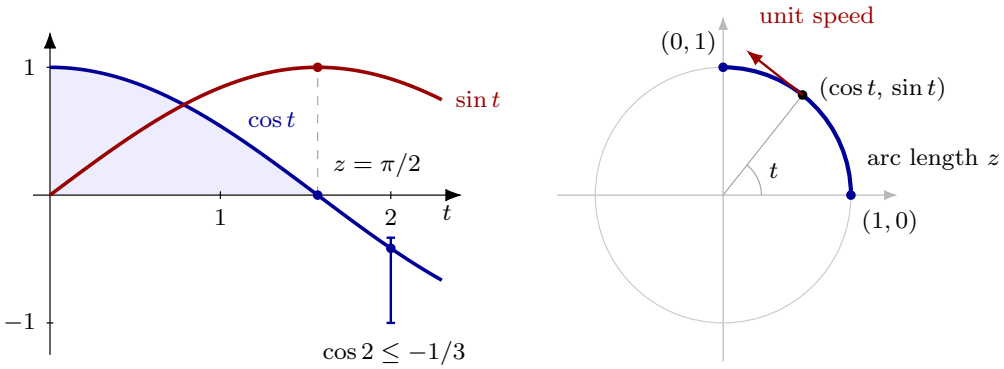

Figure 7.6: Left: the series Equation (7.40) pin $\cos 0 = 1$ and $\cos 2 \leq -\frac{1}{3}$ (Lemma 7.60), so the first positive zero $z = \pi/2$ of cos exists by the intermediate value theorem (Definition 7.61). Right: on $[0, z]$ the path $t \mapsto (\cos t, \sin t)$ traverses a quarter of the unit circle once, at unit speed, so the arc has length exactly z (Proposition 7.62).

The *arc length* of a continuously differentiable path $\gamma : [a, b] \longrightarrow \mathbb{R}^2$ is $\int_a^b |\gamma'(t)|\, \mathrm{d}t$, the integral of its speed — the notion taken up systematically in Definition 13.11. Only two of its immediate properties are needed here: reflections preserve it, since they leave the speed $|\gamma'|$ unchanged, and the circumference of a circle is the sum of the lengths of arcs covering it with only endpoints in common.

Proposition 7.62 (π as the circle constant)**.** *The arc length of the unit circle is* 2π*.*

Rests on Definitions 7.61 and 13.11, Lemma 7.59, Corollary 7.36, and Theorem 7.23.

Proof. *Derives Proposition 7.62.*

On $[0, z)$, $\cos > 0$ by minimality of z in Definition 7.61, and $\sin' = \cos$ (Lemma 7.59), so sin is strictly increasing on $[0, z]$ (Corollary 7.36); from $\sin 0 = 0$ it is positive on $(0, z]$, and $\sin^2 z = 1 - \cos^2 z = 1$ (Lemma 7.59 again, with $\cos z = 0$) forces $\sin z = 1$. The path $t \mapsto (\cos t, \sin t)$, $t \in [0, z]$, therefore lies on the unit circle by the Pythagorean identity, starts at $(1, 0)$, ends at $(0, 1)$, and traverses the first-quadrant arc exactly once: sin is a continuous strictly increasing bijection of $[0, z]$ onto $[0, 1]$ (Theorem 7.23), and on that arc the height $\sin t$ determines the point, since $\cos t \geq 0$. The speed of the path is

$$\sqrt{\cos'^2 t + \sin'^2 t} = \sqrt{\sin^2 t + \cos^2 t} = 1$$

(both parts of Lemma 7.59), so its arc length is $\int_0^z 1 \, \mathrm{d}t = z$. The reflections $(x, y) \mapsto (-x, y)$ and $(x, y) \mapsto (x, -y)$ map the unit circle to itself and preserve arc length, so the four quadrantal arcs have the same length z, and the full circumference is $4z = 2\pi$. □

Scaling by $r > 0$ multiplies every arc length by r (the scaled path $r\gamma$ has speed $r\,|\gamma'|$, pulling the factor r out of the integral), so a circle of radius r has circumference $2\pi r$: *the circumference of any circle is π times its diameter* (Figure 7.7).

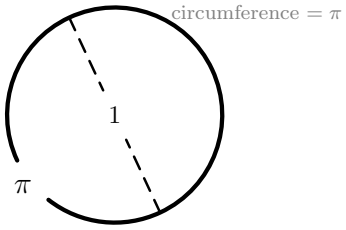

Figure 7.7: The circle constant, reduced to its emblem: a circle of diameter 1 has circumference π (Proposition 7.62). The number so drawn — twice the first positive zero of cos (Definition 7.61) — is the same π in every formula of this treatise.

Remark 7.63 (π elsewhere in this treatise). The connection between Definition 7.61 (an analytic definition, the first positive zero of cos) and Euler's identity $\mathrm{e}^{\mathrm{i}\pi} = -1$ is made in Proposition 8.4: π is exactly half the period of $\theta \mapsto \mathrm{e}^{\mathrm{i}\theta}$ (Lemma 8.11), the same constant defined here through cos alone. Every subsequent appearance of π in this treatise — the $2\pi\mathrm{i}$ of the residue theorem, the phase-space volumes of statistical mechanics, the angles of Part III — is this one number.

7.10 Multivariable calculus

7.10.1 Planes in $\mathbb{R}^3$

Definition 7.64 (Plane)**.** Let $\boldsymbol{n} = (a, b, c) \neq \boldsymbol{0}$, $\boldsymbol{p}_0 = (x_0, y_0, z_0)$, and $\boldsymbol{p} = (x, y, z)$. A *plane* is the set of points $\boldsymbol{p}$ satisfying

$$\boldsymbol{n} \cdot \boldsymbol{p} = \boldsymbol{n} \cdot \boldsymbol{p}_0 \,, \tag{7.43}$$

where $\boldsymbol{n} \cdot \boldsymbol{p}_0$ is a real constant.

Rests on Definition 5.17.

7.10.2 Differentiable functions

Let $\boldsymbol{F} : A \subseteq \mathbb{R}^m \longrightarrow \mathbb{R}^n$ be a function, with $\boldsymbol{x} = (x_1, \ldots, x_m)$, $\boldsymbol{F} = (F_1(\boldsymbol{x}), \ldots, F_n(\boldsymbol{x}))$, and A an open set.

Definition 7.65 (Partial derivative; gradient)**.** The *k-th partial derivative* of a scalar function $f : A \subseteq \mathbb{R}^m \longrightarrow \mathbb{R}$ at $\boldsymbol{a} \in A$ is the ordinary derivative of the one-variable function obtained by freezing every coordinate but the k-th,

$$\frac{\partial f}{\partial x_k}(\boldsymbol{a}) = \partial_k f(\boldsymbol{a}) = \lim_{t \longrightarrow 0} \frac{f(\boldsymbol{a} + t\,\boldsymbol{e}_k) - f(\boldsymbol{a})}{t}\,, \tag{7.44}$$

where $\boldsymbol{e}_k$ is the k-th vector of the canonical basis of $\mathbb{R}^m$. The *gradient* $\nabla f(\boldsymbol{a}) = (\partial_1 f(\boldsymbol{a}), \ldots, \partial_m f(\boldsymbol{a}))$ collects the m of them.

Rests on Definitions 5.14 and 7.26.

Definition 7.66 (Functions of class C^1)**.** We say that $\boldsymbol{F}$ is C^1 on A if and only if the m first-order partial derivatives of each of its n components have domain A and are continuous on A.

Rests on Definitions 7.20 and 7.65.

Definition 7.67 (Differentiability at a point)**.** $\boldsymbol{F}$ is *differentiable* at $\boldsymbol{a} \in A$ if and only if there is a linear map $L : \mathbb{R}^m \longrightarrow \mathbb{R}^n$ such that

$$\lim_{\boldsymbol{h} \longrightarrow \boldsymbol{0}} \frac{|\boldsymbol{F}(\boldsymbol{a} + \boldsymbol{h}) - \boldsymbol{F}(\boldsymbol{a}) - L(\boldsymbol{h})|}{|\boldsymbol{h}|} = 0\,, \tag{7.45}$$

the bars denoting Euclidean length (Equation (6.12)). Such an L is unique: if L and L' both satisfy Equation (7.45), subtracting gives $|(L - L')(\boldsymbol{h})| \,/\, |\boldsymbol{h}| \longrightarrow 0$, and taking $\boldsymbol{h} = t\,\boldsymbol{u}$ with $|\boldsymbol{u}| = 1$ and $t \longrightarrow 0$ leaves $(L - L')(\boldsymbol{u}) = \boldsymbol{0}$ for every unit vector, so $L = L'$. The same substitution also identifies L: taking $\boldsymbol{h} = t\,\boldsymbol{e}_k$ in Equation (7.45) and letting $t \longrightarrow 0$ gives $(\boldsymbol{F}(\boldsymbol{a} + t\,\boldsymbol{e}_k) - \boldsymbol{F}(\boldsymbol{a}))\,/t \longrightarrow L(\boldsymbol{e}_k)$, so each partial derivative $\partial_k F_j(\boldsymbol{a})$ exists (Definition 7.65) and $L(\boldsymbol{e}_k)$ is the vector of the n of them. The matrix of L in the canonical bases is therefore $(\partial_k F_j(\boldsymbol{a}))$, whose j-th row is the gradient $\nabla F_j(\boldsymbol{a})$. Note what this does and does not say: differentiability at a single point already forces the partial derivatives to exist and to assemble into the differential, with nothing assumed about their continuity — but the converse fails, as Remark 7.69 shows.

Rests on Definitions 5.35 and 7.16 and Equation (6.12).

Theorem 7.68 (C^1 implies differentiable)**.** *Let $A \subseteq \mathbb{R}^m$ be open and let $\boldsymbol{F} : A \longrightarrow \mathbb{R}^n$ be of class C^1. Then $\boldsymbol{F}$ is differentiable at every $\boldsymbol{a} \in A$, and its differential is the linear map*

$$L(\boldsymbol{h}) = (\nabla F_1(\boldsymbol{a}) \cdot \boldsymbol{h}, \ldots, \nabla F_n(\boldsymbol{a}) \cdot \boldsymbol{h})\,, \tag{7.46}$$

that is, the differential of Definition 7.70 below.

Rests on Definitions 7.66 and 7.67 and Theorem 7.35.

Proof. *Derives Theorem 7.68.*

Reduction to one component. With L as in Equation (7.46), the j-th component of $\boldsymbol{F}(\boldsymbol{a} + \boldsymbol{h}) - \boldsymbol{F}(\boldsymbol{a}) - L(\boldsymbol{h})$ is $R_j(\boldsymbol{h}) = F_j(\boldsymbol{a} + \boldsymbol{h}) - F_j(\boldsymbol{a}) - \nabla F_j(\boldsymbol{a}) \cdot \boldsymbol{h}$, and the Euclidean length of a vector is at most the sum of the absolute values of its components. It therefore suffices to prove that $|R_j(\boldsymbol{h})| \,/\, |\boldsymbol{h}| \longrightarrow 0$ for a single scalar C^1 function $f = F_j$.

A staircase of coordinate steps. Since A is open, fix $r > 0$ with $B_r(\boldsymbol{a}) \subseteq A$ (Definition 6.26) and let $|\boldsymbol{h}| < r$. Put $\boldsymbol{p}_0 = \boldsymbol{a}$ and

$$\boldsymbol{p}_k = \boldsymbol{a} + \sum_{i=1}^{k} h_i\,\boldsymbol{e}_i\,, \qquad k = 1, \ldots, m\,,$$

so that $\boldsymbol{p}_m = \boldsymbol{a} + \boldsymbol{h}$. Every point of the segment joining $\boldsymbol{p}_{k-1}$ to $\boldsymbol{p}_k$ has the form $\boldsymbol{a} + \sum_{i<k} h_i \boldsymbol{e}_i + t\,h_k \boldsymbol{e}_k$ with $t \in [0, 1]$, and its distance to $\boldsymbol{a}$ is at most $|\boldsymbol{h}| < r$: the whole staircase lies inside $B_r(\boldsymbol{a})$. Telescoping,

$$f(\boldsymbol{a} + \boldsymbol{h}) - f(\boldsymbol{a}) = \sum_{k=1}^{m} [f(\boldsymbol{p}_k) - f(\boldsymbol{p}_{k-1})]\,. \tag{7.47}$$

The mean value theorem on each step. The k-th bracket moves only the k-th coordinate, so it is the increment over $[0,1]$ of the one-variable function $g_k(t) = f(\boldsymbol{p}_{k-1} + t\,h_k \boldsymbol{e}_k)$. Assume $h_k \neq 0$. The difference quotient of g_k at t with increment s becomes, on substituting $u = s\,h_k$, exactly h_k times the quotient appearing in Equation (7.44), so $g_k'(t) = h_k\,\partial_k f(\boldsymbol{p}_{k-1} + t\,h_k \boldsymbol{e}_k)$ wherever the partial derivative $\partial_k f$ exists — that is, throughout $B_r(\boldsymbol{a})$. Both endpoints of the segment lie at distance $|\boldsymbol{h}| < r$ from $\boldsymbol{a}$, hence in the interior of the ball, so g_k is defined and differentiable on an open interval containing $[0,1]$ and is in particular continuous there (Proposition 7.27). By Theorem 7.35 there is $\theta_k \in (0,1)$ with

$$f(\boldsymbol{p}_k) - f(\boldsymbol{p}_{k-1}) = h_k\,\partial_k f(\boldsymbol{\xi}_k)\,, \qquad \boldsymbol{\xi}_k = \boldsymbol{p}_{k-1} + \theta_k h_k \boldsymbol{e}_k\,, \tag{7.48}$$

and $|\boldsymbol{\xi}_k - \boldsymbol{a}| \leq |\boldsymbol{h}|$. If $h_k = 0$ both sides of Equation (7.48) vanish and $\boldsymbol{\xi}_k = \boldsymbol{p}_{k-1}$ serves.

The estimate. Subtracting $\nabla f(\boldsymbol{a}) \cdot \boldsymbol{h} = \sum_k h_k\,\partial_k f(\boldsymbol{a})$ from Equation (7.47) and inserting Equation (7.48),

$$f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a}) - \nabla f(\boldsymbol{a}) \cdot \boldsymbol{h} = \sum_{k=1}^{m} h_k \left[\partial_k f(\boldsymbol{\xi}_k) - \partial_k f(\boldsymbol{a})\right]\,,$$

so that, since $|h_k| \leq |\boldsymbol{h}|$ for every k,

$$\frac{|f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a}) - \nabla f(\boldsymbol{a}) \cdot \boldsymbol{h}|}{|\boldsymbol{h}|} \leq \sum_{k=1}^{m} |\partial_k f(\boldsymbol{\xi}_k) - \partial_k f(\boldsymbol{a})|\,. \tag{7.49}$$

Given $\varepsilon > 0$, continuity of the m partial derivatives at $\boldsymbol{a}$ (Definition 7.66) provides $\delta \in (0, r)$ such that $|\boldsymbol{y} - \boldsymbol{a}| < \delta$ implies $|\partial_k f(\boldsymbol{y}) - \partial_k f(\boldsymbol{a})| < \varepsilon/m$ for every k. For $|\boldsymbol{h}| < \delta$ each $\boldsymbol{\xi}_k$ obeys $|\boldsymbol{\xi}_k - \boldsymbol{a}| \leq |\boldsymbol{h}| < \delta$, so the right-hand side of Equation (7.49) is smaller than ε. This is Equation (7.45). □

Remark 7.69 (Partial derivatives alone do not suffice). Continuity of the partial derivatives is doing real work in Theorem 7.68: their bare existence does not even force continuity of the function, let alone differentiability. The standard witness on $\mathbb{R}^2$ is

$$f(x,y) = \frac{xy}{x^2+y^2} \quad \text{for } (x,y) \neq (0,0)\,, \qquad f(0,0) = 0\,. \tag{7.50}$$

Both partial derivatives exist at the origin and vanish there, because f vanishes identically on each axis; yet $f(x,x) = 1/2$ for every $x \neq 0$, so f has no limit at the origin and is discontinuous there. The partial derivatives of this f are accordingly not continuous at the origin, and the hypothesis of Theorem 7.68 fails.

Rests on Theorem 7.68 and Definition 7.20.

Definition 7.70 (Differential of a function)**.** We say that the linear map

$$\begin{aligned} \mathrm{d}\boldsymbol{F}(\boldsymbol{a}) : \mathbb{R}^m &\longrightarrow \mathbb{R}^n \\ \boldsymbol{x} &\longmapsto \mathrm{d}\boldsymbol{F}(\boldsymbol{a})(\boldsymbol{x}) = (\nabla F_1(\boldsymbol{a}) \cdot \boldsymbol{x}, \ldots, \nabla F_n(\boldsymbol{a}) \cdot \boldsymbol{x}) \end{aligned}$$

is the *differential* of $\boldsymbol{F}$ at $\boldsymbol{a} \in A$ if and only if $\boldsymbol{F}$ is differentiable at $\boldsymbol{a}$. The two prescriptions agree whenever they apply at all: if $\boldsymbol{F}$ is differentiable at $\boldsymbol{a}$ then the unique linear map of Definition 7.67 has exactly the matrix written here, as identified there — differentiability alone, with no continuity assumed of the partial derivatives. Theorem 7.68 adds that such a map exists whenever $\boldsymbol{F}$ is C^1.

Rests on Definitions 7.65 and 7.67.

Remark 7.71. If $n = 1$, one has

$$\mathrm{d}F_1(\boldsymbol{a}) = \nabla F_1(\boldsymbol{a}) \cdot \boldsymbol{x}\,. \tag{7.51}$$

Rests on Definition 7.70.

Proposition 7.72 (Chain rule in several variables)**.** *Let $A \subseteq \mathbb{R}^m$ and $B \subseteq \mathbb{R}^p$ be open, let $\boldsymbol{G} : A \longrightarrow B$ be differentiable at $\boldsymbol{a} \in A$, and let $\boldsymbol{F} : B \longrightarrow \mathbb{R}^n$ be differentiable at $\boldsymbol{b} = \boldsymbol{G}(\boldsymbol{a})$. Then $\boldsymbol{F} \circ \boldsymbol{G}$ is differentiable at $\boldsymbol{a}$, with differential the composite $\mathrm{d}\boldsymbol{F}(\boldsymbol{b}) \circ \mathrm{d}\boldsymbol{G}(\boldsymbol{a})$; in components,*

$$\partial_j \left(F_i \circ \boldsymbol{G}\right)(\boldsymbol{a}) = \sum_{l=1}^{p} \partial_l F_i(\boldsymbol{b})\, \partial_j G_l(\boldsymbol{a})\,. \tag{7.52}$$

Rests on Definitions 7.13, 7.67 and 7.70.

Proof. *Derives Proposition 7.72.*

Write $L = \mathrm{d}\boldsymbol{G}(\boldsymbol{a})$ and $M = \mathrm{d}\boldsymbol{F}(\boldsymbol{b})$. A linear map between Euclidean spaces is bounded: expanding in the canonical bases and applying the Cauchy–Schwarz inequality (Chapter 5) row by row produces constants C_L, C_M with $|L\boldsymbol{v}| \le C_L\,|\boldsymbol{v}|$ and $|M\boldsymbol{w}| \le C_M\,|\boldsymbol{w}|$. By Definition 7.67,

$$\begin{aligned} \boldsymbol{G}(\boldsymbol{a}+\boldsymbol{h}) &= \boldsymbol{b} + L\boldsymbol{h} + \boldsymbol{\rho}(\boldsymbol{h})\,, \\ \boldsymbol{F}(\boldsymbol{b}+\boldsymbol{k}) &= \boldsymbol{F}(\boldsymbol{b}) + M\boldsymbol{k} + \boldsymbol{\sigma}(\boldsymbol{k})\,, \end{aligned}$$

where $|\boldsymbol{\rho}(\boldsymbol{h})| \,/\, |\boldsymbol{h}| \longrightarrow 0$, and where $|\boldsymbol{\sigma}(\boldsymbol{k})| = \varepsilon(\boldsymbol{k})\ |\boldsymbol{k}|$ with $\varepsilon(\boldsymbol{k}) \longrightarrow 0$ as $\boldsymbol{k} \longrightarrow \boldsymbol{0}$; setting $\varepsilon(\boldsymbol{0}) = 0$ is consistent, since $\boldsymbol{\sigma}(\boldsymbol{0}) = \boldsymbol{0}$. Put $\boldsymbol{k}(\boldsymbol{h}) = L\boldsymbol{h} + \boldsymbol{\rho}(\boldsymbol{h})$, so that

$$\boldsymbol{F}(\boldsymbol{G}(\boldsymbol{a}+\boldsymbol{h})) = \boldsymbol{F}(\boldsymbol{b}) + ML\,\boldsymbol{h} + M\boldsymbol{\rho}(\boldsymbol{h}) + \boldsymbol{\sigma}(\boldsymbol{k}(\boldsymbol{h}))\,.$$

The first remainder obeys $|M\boldsymbol{\rho}(\boldsymbol{h})| \le C_M\,|\boldsymbol{\rho}(\boldsymbol{h})|$ and is therefore $o(|\boldsymbol{h}|)$. For the second, taking $|\boldsymbol{h}|$ small enough that $|\boldsymbol{\rho}(\boldsymbol{h})| \le |\boldsymbol{h}|$ gives $|\boldsymbol{k}(\boldsymbol{h})| \le (C_L + 1)\,|\boldsymbol{h}|$, whence

$$|\boldsymbol{\sigma}(\boldsymbol{k}(\boldsymbol{h}))| = \varepsilon(\boldsymbol{k}(\boldsymbol{h}))\ |\boldsymbol{k}(\boldsymbol{h})| \le (C_L+1)\,\varepsilon(\boldsymbol{k}(\boldsymbol{h}))\ |\boldsymbol{h}|\,,$$

and $\boldsymbol{k}(\boldsymbol{h}) \longrightarrow \boldsymbol{0}$ with $\boldsymbol{h}$, so this remainder is $o(|\boldsymbol{h}|)$ as well. Hence ML satisfies Equation (7.45) for $\boldsymbol{F} \circ \boldsymbol{G}$ and is its differential, by the uniqueness established in Definition 7.67. Reading off the matrix of ML in the canonical bases, the rows of L and of M being the gradients of the components — which mere differentiability already secures, by the identification in Definition 7.67 — is Equation (7.52). □

Proposition 7.73 (Clairaut–Schwarz)**.** *If $f : A \subseteq \mathbb{R}^2 \longrightarrow \mathbb{R}$ has continuous second partial derivatives, then $\partial_x \partial_y f = \partial_y \partial_x f$.*

Rests on Theorem 7.35 and Definition 7.20.

Proof. *Derives Proposition 7.73.*

Fix (x, y) and consider the second difference $\Delta(h,k) = f(x+h, y+k) - f(x+h, y) - f(x, y+k) + f(x, y)$. Applying the mean value theorem (Theorem 7.35) in x to $u(t) = f(t, y+k) - f(t, y)$ gives $\Delta = [\partial_x f(\xi, y+k) - \partial_x f(\xi, y)]\,h$ for some ξ, and a second application in y gives $\Delta = \partial_y \partial_x f(\xi, \eta)\,hk$. Symmetrically, $\Delta = \partial_x \partial_y f(\xi', \eta')\,hk$. Dividing by hk and letting $(h,k) \to 0$, continuity of the second partials forces $\partial_y \partial_x f(x,y) = \partial_x \partial_y f(x,y)$. □

7.10.3 Taylor expansion in several variables

Theorem 7.74 (Taylor's theorem in several variables)**.** *Let $A \subseteq \mathbb{R}^m$ be open, let $f : A \longrightarrow \mathbb{R}$ have continuous second partial derivatives on A, let $\boldsymbol{a} \in A$, and let $\boldsymbol{h} \in \mathbb{R}^m$ be small enough that the whole segment $\{\boldsymbol{a} + t\boldsymbol{h} \mid t \in [0,1]\}$ lies in A. Write*

$$H_{ij}(\boldsymbol{x}) = \partial_i \partial_j f(\boldsymbol{x}) \tag{7.53}$$

for the Hessian *of f, a symmetric matrix by Proposition 7.73. Then there is $\theta \in (0,1)$ with*

$$f(\boldsymbol{a}+\boldsymbol{h}) = f(\boldsymbol{a}) + \nabla f(\boldsymbol{a}) \cdot \boldsymbol{h} + \frac{1}{2} \sum_{i,j=1}^{m} H_{ij}(\boldsymbol{a} + \theta\boldsymbol{h})\, h_i h_j\,, \tag{7.54}$$

and consequently, as $\boldsymbol{h} \longrightarrow \mathbf{0}$*,*

$$f(\boldsymbol{a}+\boldsymbol{h}) = f(\boldsymbol{a}) + \nabla f(\boldsymbol{a}) \cdot \boldsymbol{h} + \frac{1}{2}\, \boldsymbol{h}^{\mathsf{T}} H(\boldsymbol{a})\, \boldsymbol{h} + o\Big(|\boldsymbol{h}|^2\Big)\,. \tag{7.55}$$

Rests on Theorem 7.38 and Propositions 7.72 and 7.73.

Proof. *Derives Theorem 7.74.*

Since A is open and the segment is compact, there is $\varepsilon > 0$ with $\boldsymbol{a} + t\boldsymbol{h} \in A$ for every $t \in (-\varepsilon, 1+\varepsilon)$; put $g(t) = f(\boldsymbol{a} + t\boldsymbol{h})$ there. The map $t \longmapsto \boldsymbol{a} + t\boldsymbol{h}$ is differentiable with differential $\boldsymbol{h}$, so the chain rule Equation (7.52) gives

$$g'(t) = \sum_{i=1}^{m} \partial_i f(\boldsymbol{a} + t\boldsymbol{h})\, h_i\,, \qquad g''(t) = \sum_{i,j=1}^{m} \partial_j \partial_i f(\boldsymbol{a} + t\boldsymbol{h})\, h_i h_j\,, \tag{7.56}$$

the second by applying the same rule to each $\partial_i f$, which is C^1 by hypothesis. Hence g is twice differentiable on an interval containing $[0,1]$, and Theorem 7.38 at order $n = 1$ supplies $\theta \in (0,1)$ with $g(1) = g(0) + g'(0) + \frac{1}{2} g''(\theta)$, which is Equation (7.54).

For Equation (7.55), subtract the two quadratic terms: the difference is

$$\frac{1}{2} \sum_{i,j=1}^{m} \big[H_{ij}(\boldsymbol{a} + \theta\boldsymbol{h}) - H_{ij}(\boldsymbol{a})\big]\, h_i h_j\,,$$

whose modulus is at most $\frac{1}{2}\,|\boldsymbol{h}|^2 \sum_{i,j} |H_{ij}(\boldsymbol{a} + \theta\boldsymbol{h}) - H_{ij}(\boldsymbol{a})|$, since $|h_i| \le |\boldsymbol{h}|$ for every i. As $\boldsymbol{h} \longrightarrow \mathbf{0}$ the point $\boldsymbol{a} + \theta\boldsymbol{h}$ tends to $\boldsymbol{a}$ whatever value $\theta \in (0,1)$ takes, so continuity of the second partial derivatives sends that sum to zero. The difference is therefore $o(|\boldsymbol{h}|^2)$. □

Remark 7.75 (What the Hessian is for). Equation (7.55) is the statement behind every expansion of a potential about an equilibrium: at a stationary point $\nabla f(\boldsymbol{a}) = \mathbf{0}$ the leading behaviour is the quadratic form $\boldsymbol{h}^{\mathsf{T}} H(\boldsymbol{a}) \boldsymbol{h}$, whose signature (Theorem 5.112) decides whether the point is a minimum, a maximum or a saddle, and whose symmetry — Proposition 7.73, not a modelling assumption — is what allows it to be diagonalized by an orthogonal change of axes.

Rests on Theorems 5.112 and 7.74.

Proposition 7.76 (Euler's theorem on homogeneous functions)**.** *Let* $U \subseteq \mathbb{R}^n$ *be open and a* cone*, meaning that* $\mu\boldsymbol{u} \in U$ *whenever* $\boldsymbol{u} \in U$ *and* $\mu > 0$*, and let* $f : U \longrightarrow \mathbb{R}$ *be differentiable. Then* f *is* homogeneous of degree k*,*

$$f(\mu\boldsymbol{u}) = \mu^k f(\boldsymbol{u})\,, \qquad \mu > 0\,, \quad \boldsymbol{u} \in U\,, \tag{7.57}$$

if and only if

$$\sum_{i=1}^{n} u^i\, \frac{\partial f}{\partial u^i}(\boldsymbol{u}) = \boldsymbol{u} \cdot \nabla f(\boldsymbol{u}) = k\, f(\boldsymbol{u}) \tag{7.58}$$

at every $\boldsymbol{u} \in U$*.*

Rests on Propositions 7.30 and 7.72 and Corollary 7.36.

Proof. *Derives Proposition 7.76.*

Fix $\boldsymbol{u} \in U$. Because U is a cone, $\mu \longmapsto f(\mu\boldsymbol{u})$ is defined for every $\mu > 0$, and the chain rule Equation (7.52) makes it differentiable with

$$\frac{\mathrm{d}}{\mathrm{d}\mu} f(\mu\boldsymbol{u}) = \sum_{i=1}^{n} u^i\, \partial_i f(\mu\boldsymbol{u}) = \frac{1}{\mu}\, (\mu\boldsymbol{u}) \cdot \nabla f(\mu\boldsymbol{u})\,. \tag{7.59}$$

If Equation (7.57) holds, differentiate it in μ: the left-hand side is Equation (7.59) and the right-hand side is $k\mu^{k-1} f(\boldsymbol{u})$. Setting $\mu = 1$ leaves Equation (7.58).

Conversely, assume Equation (7.58) throughout U and put $\psi(\mu) = \mu^{-k} f(\mu \boldsymbol{u})$ for $\mu > 0$. By the product rule (Proposition 7.30) and Equation (7.59),

$$\psi'(\mu) = \mu^{-k-1} \left[(\mu \boldsymbol{u}) \cdot \nabla f(\mu \boldsymbol{u}) - k\, f(\mu \boldsymbol{u}) \right] = 0 \,,$$

the bracket vanishing because Equation (7.58) holds at the point $\mu \boldsymbol{u} \in U$. A function with vanishing derivative on an interval is constant (Corollary 7.36), so $\psi(\mu) = \psi(1) = f(\boldsymbol{u})$ for every $\mu > 0$, which is Equation (7.57). □

7.10.4 Differentiation under the integral sign

An integral over a fixed region, of an integrand carrying a parameter, is a function of that parameter, and the question when it may be differentiated by differentiating the integrand is answered by the mean value theorem and uniform continuity alone. The statement is placed here, beside the chain rule, because that is what it is used with; the multiple integral it is written for is Definition 7.93 below, and the one-dimensional case is contained in it as $N = 1$.

Theorem 7.77 (Leibniz integral rule)**.** *Let $D \subset \mathbb{R}^N$ be a compact region that decomposes into finitely many simple regions (Definition 7.95), of volume $V = \int_D 1$; let $I \subseteq \mathbb{R}$ be an open interval; and let $f : D \times I \longrightarrow \mathbb{R}$ be continuous with continuous partial derivative $\partial f / \partial t$ on $D \times I$. Then $F(t) = \int_D f(\boldsymbol{x}, t)\, \mathrm{d}V$ is differentiable on I and*

$$\frac{\mathrm{d}F}{\mathrm{d}t}(t) = \int_D \frac{\partial f}{\partial t}(\boldsymbol{x}, t)\, \mathrm{d}V \,, \qquad t \in I \,, \tag{7.60}$$

the right-hand side being itself continuous in t.

Rests on Definition 7.93 and Theorems 7.25 and 7.35.

Proof. *Derives Theorem 7.77.*

Fix $t \in I$ and choose $\eta > 0$ with $J = [t - \eta, t + \eta] \subset I$. The set $D \times J$ is closed and bounded in $\mathbb{R}^{N+1}$, hence compact (Theorem 6.12), so $\partial f / \partial t$ is uniformly continuous on it (Theorem 7.25). Both $f(\cdot, s)$ and $\partial_t f(\cdot, s)$ are continuous on D, hence integrable there (Remark 7.96); write $G(t) = \int_D \partial_t f(\boldsymbol{x}, t)\, \mathrm{d}V$.

Let $0 < |h| \leq \eta$. For each fixed $\boldsymbol{x} \in D$ the one-variable function $s \longmapsto f(\boldsymbol{x}, s)$ is differentiable on J, so the mean value theorem (Theorem 7.35) supplies $\theta = \theta(\boldsymbol{x}, h) \in (0, 1)$ with

$$\frac{f(\boldsymbol{x}, t + h) - f(\boldsymbol{x}, t)}{h} = \partial_t f\left(\boldsymbol{x}, t + \theta h\right) . \tag{7.61}$$

Subtracting $\partial_t f(\boldsymbol{x}, t)$, integrating over D and bounding the integral of a function by the volume times its supremum,

$$\left| \frac{F(t + h) - F(t)}{h} - G(t) \right| \leq V \sup_{\boldsymbol{x} \in D} \left| \partial_t f\left(\boldsymbol{x}, t + \theta h\right) - \partial_t f(\boldsymbol{x}, t) \right| . \tag{7.62}$$

Given $\varepsilon > 0$, uniform continuity provides $\delta \in (0, \eta]$ such that $|s - s'| < \delta$ implies $|\partial_t f(\boldsymbol{x}, s) - \partial_t f(\boldsymbol{x}, s')| < \varepsilon / (V + 1)$ for every $\boldsymbol{x} \in D$. Since $|(t + \theta h) - t| \leq |h|$, taking $|h| < \delta$ makes the right-hand side of Equation (7.62) smaller than ε; this is Equation (7.60). The same bound with $t + \theta h$ replaced by an arbitrary $t' \in J$ gives $|G(t) - G(t')| \leq V \sup_D |\partial_t f(\cdot, t) - \partial_t f(\cdot, t')|$, so G is continuous. □

Corollary 7.78 (Variable limits of integration)**.** *Let f and $\partial f / \partial t$ be continuous on $[c, d] \times I$ and let $\alpha, \beta : I \longrightarrow [c, d]$ be of class C^1. Then*

$$\frac{\mathrm{d}}{\mathrm{d}t} \int_{\alpha(t)}^{\beta(t)} f(x, t)\, \mathrm{d}x = f\left(\beta(t), t\right) \beta'(t) - f\left(\alpha(t), t\right) \alpha'(t) + \int_{\alpha(t)}^{\beta(t)} \frac{\partial f}{\partial t}(x, t)\, \mathrm{d}x \,. \tag{7.63}$$

Rests on Theorems 7.42 and 7.77 and Proposition 7.72.

Proof. *Derives Corollary 7.78.*

Put $\Phi(u,v,t) = \int_u^v f(x,t)\,\mathrm{d}x$ on $[c,d]\times[c,d]\times I$. The fundamental theorem of calculus (Theorem 7.42), together with the sign rule for exchanging the limits of integration, gives $\partial_v\Phi = f(v,t)$ and $\partial_u\Phi = -f(u,t)$; Theorem 7.77 applied on the interval with endpoints u and v gives $\partial_t\Phi = \int_u^v \partial_t f(x,t)\,\mathrm{d}x$. All three are continuous in (u,v,t): the first two because f is, the third by the last clause of Theorem 7.77 together with the estimate $\left|\int_u^v g - \int_{u'}^{v'} g\right| \le (|u-u'|+|v-v'|)\sup|g|$ applied to $g = \partial_t f$. Hence Φ is C^1 and therefore differentiable (Theorem 7.68), and the chain rule Equation (7.52) applied to $t \longmapsto \Phi\left(\alpha(t),\beta(t),t\right)$ is Equation (7.63). □

The derivative of a determinant has already appeared, in Proposition 5.1 of Chapter 5, differentiated a column at a time — the form wanted when the columns are the objects that move. The same derivative resolved into the n^2 individual entries is the form wanted when the entries are, and it is what the change-of-variables and Liouville arguments below use. The two are the same identity: expand each differentiated column of the column form along that column and its cofactors, which contain no entry of it, and the column sum becomes the entry sum term for term.

Proposition 7.79 (Jacobi's formula, cofactor form)**.** *Let $I \subseteq \mathbb{R}$ be an open interval and let $A : I \longrightarrow \mathbb{R}^{n\times n}$ be a differentiable matrix-valued function, with entries $A^i{}_j(t)$. Then $t \longmapsto \det A(t)$ is differentiable and*

$$\frac{\mathrm{d}}{\mathrm{d}t}\det A = \sum_{i,j=1}^{n} C^i{}_j\,\frac{\mathrm{d}A^i{}_j}{\mathrm{d}t}\,, \qquad C^i{}_j = \frac{\partial \det A}{\partial A^i{}_j}\,, \tag{7.64}$$

$C^i{}_j$ being the cofactor *of the entry $A^i{}_j$. Wherever $A(t)$ is invertible this reads*

$$\frac{\mathrm{d}}{\mathrm{d}t}\det A(t) = \det A(t)\ \mathrm{tr}\Big(A(t)^{-1}\frac{\mathrm{d}A}{\mathrm{d}t}(t)\Big)\,, \tag{7.65}$$

and where moreover $\det A > 0$, $\mathrm{d}\left(\ln\det A\right)/\mathrm{d}t = \mathrm{tr}\left(A^{-1}\mathrm{d}A/\mathrm{d}t\right)$.

Rests on Propositions 5.1, 7.30 and 7.31 and Equation (5.19).

Proof. *Derives Proposition 7.79.*

The cofactor form. By Equation (5.19) the determinant is a polynomial in the n^2 entries, and each of its terms carries exactly one entry from each column. Differentiating that sum of products by the product rule (Proposition 7.30),

$$\frac{\mathrm{d}}{\mathrm{d}t}\det A = \sum_{\sigma}\mathrm{sgn}(\sigma)\sum_{k=1}^{n}\frac{\mathrm{d}A^{\sigma(k)}{}_k}{\mathrm{d}t}\prod_{j\neq k}A^{\sigma(j)}{}_j\,.$$

Collecting the terms that multiply one fixed $\mathrm{d}A^i{}_j/\mathrm{d}t$ leaves precisely the coefficient of $A^i{}_j$ in Equation (5.19), that is $\partial\det A/\partial A^i{}_j = C^i{}_j$, which is Equation (7.64). Note that $C^i{}_j$ contains no entry of the j-th column at all.

The trace form. Since det is linear in the j-th column and $C^i{}_j$ is free of that column, expanding along it gives $\sum_i A^i{}_j C^i{}_j = \det A$ for each j; and for $k \neq j$ the sum $\sum_i A^i{}_k C^i{}_j$ is that same expansion for the matrix whose j-th column has been replaced by its k-th, a matrix with two equal columns, whose determinant therefore vanishes. These are the two properties of Equation (5.19) on which Equation (5.16) also rests, and together they say

$$\sum_{i=1}^{n} A^i{}_k\, C^i{}_j = \delta_{jk}\det A\,. \tag{7.66}$$

If $\det A \neq 0$, Equation (7.66) states that the matrix with entries $C^i{}_j/\det A$, read with its indices exchanged, is a left inverse of A and hence its inverse: $(A^{-1})^j{}_i = C^i{}_j/\det A$. Substituting in Equation (7.64),

$$\frac{\mathrm{d}}{\mathrm{d}t}\det A = \det A \sum_{i,j} \left(A^{-1}\right)^j{}_i \frac{\mathrm{d}A^i{}_j}{\mathrm{d}t} = \det A \ \mathrm{tr}\left(A^{-1}\frac{\mathrm{d}A}{\mathrm{d}t}\right) ,$$

because the j-th diagonal entry of $A^{-1}\mathrm{d}A/\mathrm{d}t$ is $\sum_i (A^{-1})^j{}_i \mathrm{d}A^i{}_j/\mathrm{d}t$. This is Equation (7.65), and the logarithmic form follows from it by the chain rule (Proposition 7.31). □

7.10.5 The implicit function theorem

Theorem 7.80 (Implicit function theorem)**.** *Let $A \subseteq \mathbb{R}^m \times \mathbb{R}^n$ be open, let $\boldsymbol{F} : A \longrightarrow \mathbb{R}^n$ be of class C^k with $k \geq 1$, write the points of A as $(\boldsymbol{x}, \boldsymbol{y})$ with $\boldsymbol{x} \in \mathbb{R}^m$ and $\boldsymbol{y} \in \mathbb{R}^n$, and abbreviate $(D_{\boldsymbol{y}}\boldsymbol{F})_{ij} = \partial F_i/\partial y_j$ and $(D_{\boldsymbol{x}}\boldsymbol{F})_{ij} = \partial F_i/\partial x_j$. Let $(\boldsymbol{a}, \boldsymbol{b}) \in A$ satisfy*

$$\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b}) = \boldsymbol{0} , \qquad \det\left[D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b})\right] \neq 0 . \tag{7.67}$$

Then there are open sets $W \ni \boldsymbol{a}$ in $\mathbb{R}^m$ and $V \ni \boldsymbol{b}$ in $\mathbb{R}^n$ with $W \times V \subseteq A$, and a unique map $\boldsymbol{h} : W \longrightarrow V$ whose graph is the zero set,

$$\{(\boldsymbol{x}, \boldsymbol{y}) \in W \times V \mid \boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{0}\} = \{(\boldsymbol{x}, \boldsymbol{h}(\boldsymbol{x})) \mid \boldsymbol{x} \in W\} , \tag{7.68}$$

with $\boldsymbol{h}(\boldsymbol{a}) = \boldsymbol{b}$. That map is of class C^k, and

$$D\boldsymbol{h}(\boldsymbol{x}) = -\left[D_{\boldsymbol{y}}\boldsymbol{F}\right]^{-1} D_{\boldsymbol{x}}\boldsymbol{F} , \tag{7.69}$$

both blocks being evaluated at $(\boldsymbol{x}, \boldsymbol{h}(\boldsymbol{x}))$.

Rests on Theorem 7.68, Proposition 7.72, and Definition 7.67.

Full derivation: Appendix A.28 (p. 2914).

Derives Theorem 7.80.

Corollary 7.81 (Inverse function theorem)**.** *Let $U \subseteq \mathbb{R}^n$ be open, let $\boldsymbol{f} : U \longrightarrow \mathbb{R}^n$ be of class C^k with $k \geq 1$, and let $\boldsymbol{\alpha} \in U$ satisfy $\det\left[D\boldsymbol{f}(\boldsymbol{\alpha})\right] \neq 0$. Then $\boldsymbol{f}$ maps some open $U_0 \ni \boldsymbol{\alpha}$ bijectively onto an open $V_0 \ni \boldsymbol{f}(\boldsymbol{\alpha})$; the inverse $\boldsymbol{g} : V_0 \longrightarrow U_0$ is of class C^k; and*

$$D\boldsymbol{g}(\boldsymbol{v}) = \left[D\boldsymbol{f}\left(\boldsymbol{g}(\boldsymbol{v})\right)\right]^{-1} . \tag{7.70}$$

A C^k map whose derivative is everywhere invertible is therefore a local C^k diffeomorphism*: a bijection between open sets with C^k inverse.*

Rests on Theorem 7.80, Definition 7.66, and Proposition 7.72.

Full derivation: Appendix A.28 (p. 2914).

Derives Corollary 7.81.

Remark 7.82 (Where the proof is, and why). Both statements are proved in Appendix A.28, as Theorem A.286 and Corollary A.292, from exactly the material of Section 7.10.2 and nothing else: no fixed-point theorem is imported, the Newton iteration being run explicitly and its convergence read off the Cauchy criterion (Theorem 7.8). The proof runs to several pages and would unbalance this chapter, which is why it sits in the appendix. The *statements* belong here, because this is where several-variable differentiability is developed and because what uses them — the constant-rank theorem and the multiplier rule below, the regular value theorem of Chapter 13, the inversion of a Legendre transformation in Chapter 16 — reaches for them as calculus, not as geometry.

Rests on Theorem 7.80 and Corollary 7.81.

Theorem 7.83 (Constant rank)**.** *Let $U \subseteq \mathbb{R}^N$ be open, let $\boldsymbol{F} : U \longrightarrow \mathbb{R}^{N'}$ be of class C^k with $k \geq 1$, and suppose the derivative $D\boldsymbol{F}$ has one and the same rank r at every point of U. Then about each $\boldsymbol{p} \in U$ and about its image there are C^k diffeomorphisms (Corollary 7.81) φ, of a neighbourhood of $\boldsymbol{p}$ onto a neighbourhood of the origin of $\mathbb{R}^N$, and χ, of a neighbourhood of $\boldsymbol{F}(\boldsymbol{p})$ onto a neighbourhood of the origin of $\mathbb{R}^{N'}$, in which $\boldsymbol{F}$ reads*

$$\chi \circ \boldsymbol{F} \circ \varphi^{-1}\left(v^1, \dots, v^N\right) = \left(v^1, \dots, v^r, 0, \dots, 0\right) . \tag{7.71}$$

In particular the image of a small enough neighbourhood of $\boldsymbol{p}$ is, in the coordinates χ, the intersection of an r-dimensional coordinate plane with an open set, cut out by the vanishing of $N' - r$ coordinate functions with independent differentials.

Rests on Corollaries 7.36 and 7.81 and Proposition 7.72.

Proof. *Derives Theorem 7.83.*

Replacing $\boldsymbol{F}$ by $\boldsymbol{F} - \boldsymbol{F}(\boldsymbol{p})$ — a translation of the target, which changes neither $D\boldsymbol{F}$ nor its rank — we may assume $\boldsymbol{F}(\boldsymbol{p}) = \boldsymbol{0}$.

Straightening the source. Since $D\boldsymbol{F}(\boldsymbol{p})$ has rank r, some $r \times r$ minor of it is non-zero; relabelling the coordinates of $\mathbb{R}^N$ and of $\mathbb{R}^{N'}$, which are linear changes and hence C^∞, we may take it to be the minor built from the first r rows and the first r columns. Define

$$\varphi(\boldsymbol{u}) = \left(F^1(\boldsymbol{u}), \dots, F^r(\boldsymbol{u}), u^{r+1} - p^{r+1}, \dots, u^N - p^N\right) . \tag{7.72}$$

Its derivative at $\boldsymbol{p}$ is block triangular, carrying that invertible $r \times r$ minor in the upper left and the identity in the lower right, so $\det D\varphi(\boldsymbol{p}) \neq 0$ and Corollary 7.81 makes φ a C^k diffeomorphism of a neighbourhood of $\boldsymbol{p}$ onto a neighbourhood of $\varphi(\boldsymbol{p}) = \boldsymbol{0}$. Shrink the latter to an open box $B = B' \times B''$ with $B' \subseteq \mathbb{R}^r$ and $B'' \subseteq \mathbb{R}^{N-r}$, and shrink the former to its preimage.

The tail depends only on the head. Put $\boldsymbol{G} = \boldsymbol{F} \circ \varphi^{-1}$ on B, of class C^k. By construction the first r components of $\boldsymbol{G}$ are the first r coordinates, so

$$\boldsymbol{G}\left(\boldsymbol{v}', \boldsymbol{v}''\right) = \left(\boldsymbol{v}', \, \boldsymbol{g}\left(\boldsymbol{v}', \boldsymbol{v}''\right)\right) , \qquad \boldsymbol{g} : B \longrightarrow \mathbb{R}^{N'-r} , \tag{7.73}$$

and the derivative has the block form

$$D\boldsymbol{G} = \begin{pmatrix} \mathbb{1}_r & 0 \\ D_{\boldsymbol{v}'}\boldsymbol{g} & D_{\boldsymbol{v}''}\boldsymbol{g} \end{pmatrix} . \tag{7.74}$$

The chain rule Equation (7.52) gives $D\boldsymbol{G} = D\boldsymbol{F} \cdot D\varphi^{-1}$ with $D\varphi^{-1}$ invertible, so $D\boldsymbol{G}$ has rank r at every point of B. Its first r columns are already independent by Equation (7.74), so every column of $D_{\boldsymbol{v}''}\boldsymbol{g}$ must be a combination of them; but those columns vanish in the first r rows, so each is a combination with zero coefficients, that is $D_{\boldsymbol{v}''}\boldsymbol{g} \equiv 0$ on B. Because B'' is a box, any two of its points are joined inside B by a chain of coordinate steps, along each of which $\boldsymbol{g}$ is constant (Corollary 7.36); hence $\boldsymbol{g}$ does not depend on $\boldsymbol{v}''$, and we write $\boldsymbol{g} = \boldsymbol{g}(\boldsymbol{v}')$.

Straightening the target. On $B' \times \mathbb{R}^{N'-r}$ define

$$\chi\left(\boldsymbol{w}', \boldsymbol{w}''\right) = \left(\boldsymbol{w}', \;\; \boldsymbol{w}'' - \boldsymbol{g}(\boldsymbol{w}')\right) . \tag{7.75}$$

It is C^k, and it is a bijection of $B' \times \mathbb{R}^{N'-r}$ onto itself with the C^k inverse $(\boldsymbol{w}', \boldsymbol{w}'') \longmapsto (\boldsymbol{w}', \boldsymbol{w}'' + \boldsymbol{g}(\boldsymbol{w}'))$, hence a C^k diffeomorphism. Composing with Equation (7.73),

$$\chi\left(\boldsymbol{G}\left(\boldsymbol{v}', \boldsymbol{v}''\right)\right) = \left(\boldsymbol{v}', \, \boldsymbol{g}(\boldsymbol{v}') - \boldsymbol{g}(\boldsymbol{v}')\right) = \left(\boldsymbol{v}', \boldsymbol{0}\right) ,$$

which is Equation (7.71). The final clause is that statement read backwards: in the coordinates χ the image is where the last $N' - r$ coordinates vanish. □

Lemma 7.84 (Functions vanishing on a regular zero set)**.** *Let $A \subseteq \mathbb{R}^n$ be open, let $\phi_1, \dots, \phi_J : A \longrightarrow \mathbb{R}$ be smooth with linearly independent gradients at every point of their common zero set*

$$\Sigma = \{\boldsymbol{x} \in A \mid \phi_1(\boldsymbol{x}) = \cdots = \phi_J(\boldsymbol{x}) = 0\} \,, \tag{7.76}$$

and let f be smooth on A and vanish identically on Σ. Then every point of Σ has a neighbourhood on which

$$f = \sum_{j=1}^{J} c^j \, \phi_j \tag{7.77}$$

for smooth functions $c^1, \dots, c^J$.

Rests on Corollary 7.81 and Theorems 7.43 and 7.77.

Proof. *Derives Lemma 7.84.*

Adapted coordinates. Fix $\boldsymbol{p} \in \Sigma$. The $J \times n$ matrix of the gradients $\nabla\phi_j(\boldsymbol{p})$ has rank J, so J of its columns are independent; relabelling the coordinates, take them to be the first J. Let $i_1 < \cdots < i_{n-J}$ be the remaining indices and put

$$\boldsymbol{\Psi}(\boldsymbol{x}) = \Big(\phi_1(\boldsymbol{x}), \dots, \phi_J(\boldsymbol{x}),\, x^{i_1} - p^{i_1}, \dots, x^{i_{n-J}} - p^{i_{n-J}}\Big) \,. \tag{7.78}$$

Expanding $\det D\boldsymbol{\Psi}(\boldsymbol{p})$ along its last $n-J$ rows, each of which is a vector of the canonical basis, leaves — up to sign — exactly the non-zero $J \times J$ minor just chosen, so $\boldsymbol{\Psi}$ is a smooth diffeomorphism of a neighbourhood of $\boldsymbol{p}$ onto a neighbourhood of $\boldsymbol{\Psi}(\boldsymbol{p}) = \boldsymbol{0}$ (Corollary 7.81), which we shrink to an open box $B = B' \times B''$, $B' \subseteq \mathbb{R}^J$, $B'' \subseteq \mathbb{R}^{n-J}$. Write $\boldsymbol{y} = (\boldsymbol{y}', \boldsymbol{y}'') = \boldsymbol{\Psi}(\boldsymbol{x})$ and $\tilde{f} = f \circ \boldsymbol{\Psi}^{-1}$, smooth on B. By construction $\boldsymbol{y}' = (\phi_1, \dots, \phi_J)$, so Σ meets the chart in $\{\boldsymbol{y}' = \boldsymbol{0}\}$ and $\tilde{f}$ vanishes there.

Integrating along the segment. For $\boldsymbol{y} \in B$ the segment from $(\boldsymbol{0}, \boldsymbol{y}'')$ to $(\boldsymbol{y}', \boldsymbol{y}'')$ lies in the box B, so the fundamental theorem of calculus (Theorem 7.43) and the chain rule Equation (7.52) give

$$\tilde{f}\,(\boldsymbol{y}', \boldsymbol{y}'') = \int_0^1 \frac{\mathrm{d}}{\mathrm{d}s} \tilde{f}\,(s\boldsymbol{y}', \boldsymbol{y}'')\,\mathrm{d}s = \sum_{j=1}^{J} y'^{\,j}\, \tilde{c}_j(\boldsymbol{y}) \,, \quad \tilde{c}_j(\boldsymbol{y}) = \int_0^1 \frac{\partial \tilde{f}}{\partial y'^{\,j}}\,(s\boldsymbol{y}', \boldsymbol{y}'')\,\mathrm{d}s \,, \tag{7.79}$$

where the integral computes $\tilde{f}(\boldsymbol{y}', \boldsymbol{y}'') - \tilde{f}(\boldsymbol{0}, \boldsymbol{y}'')$ and the subtracted term is zero because $\tilde{f}$ vanishes on $\{\boldsymbol{y}' = \boldsymbol{0}\}$. Each $\tilde{c}_j$ is smooth: its integrand and every partial derivative of the integrand are continuous on $B \times [0,1]$, so Theorem 7.77 may be applied to it as often as one pleases. Setting $c^j = \tilde{c}_j \circ \boldsymbol{\Psi}$ and recalling $y'^{\,j} = \phi_j(\boldsymbol{x})$ turns Equation (7.79) into Equation (7.77). □

Proposition 7.85 (Lagrange multipliers in finitely many variables)**.** *Let $A \subseteq \mathbb{R}^n$ be open, let f and $g_1, \dots, g_J$ be of class C^1 on A with $J < n$, and let $\boldsymbol{x}_\star \in A$ satisfy $g_\alpha(\boldsymbol{x}_\star) = 0$ for every α and have linearly independent gradients $\nabla g_\alpha(\boldsymbol{x}_\star)$. If the restriction of f to the constraint set $\{\boldsymbol{x} \in A \mid g_1(\boldsymbol{x}) = \cdots = g_J(\boldsymbol{x}) = 0\}$ has a local extremum at $\boldsymbol{x}_\star$, then there are unique numbers $\lambda^1, \dots, \lambda^J$ with*

$$\nabla f(\boldsymbol{x}_\star) = \sum_{\alpha=1}^{J} \lambda^\alpha \, \nabla g_\alpha(\boldsymbol{x}_\star) \,. \tag{7.80}$$

Rests on Theorem 7.80, Lemma 7.33, and Proposition 7.72.

Proof. *Derives Proposition 7.85.*

Write $\boldsymbol{G} = (g_1, \dots, g_J)$. Its derivative at $\boldsymbol{x}_\star$ has rank J, so J of its columns are independent; relabelling the coordinates, split $\boldsymbol{x} = (\boldsymbol{x}', \boldsymbol{y})$ with $\boldsymbol{y} \in \mathbb{R}^J$ carrying those columns, so that $\det\,[D_{\boldsymbol{y}}\boldsymbol{G}(\boldsymbol{x}_\star)] \neq 0$. By Theorem 7.80 there are neighbourhoods $W \ni \boldsymbol{x}'_\star$

and $V \ni \boldsymbol{y}_\star$ and a C^1 map $\boldsymbol{h} : W \longrightarrow V$ whose graph is the constraint set inside $W \times V$, with the derivative Equation (7.69).

The function $\Xi(\boldsymbol{x}') = f\,(\boldsymbol{x}', \boldsymbol{h}(\boldsymbol{x}'))$ therefore has an ordinary, unconstrained local extremum at $\boldsymbol{x}'_\star$; applying Lemma 7.33 to each one-variable function $t \longmapsto \Xi(\boldsymbol{x}'_\star + t\boldsymbol{e}_i)$ gives $\nabla\Xi(\boldsymbol{x}'_\star) = \boldsymbol{0}$, and the chain rule Equation (7.52) turns that into

$$D_{\boldsymbol{x}'} f + D_{\boldsymbol{y}} f \cdot D\boldsymbol{h} = 0\,, \qquad D\boldsymbol{h} = -\,[D_{\boldsymbol{y}}\boldsymbol{G}]^{-1}\, D_{\boldsymbol{x}'}\boldsymbol{G}\,, \tag{7.81}$$

everything evaluated at $\boldsymbol{x}_\star$, the second equality being Equation (7.69). Now *define* the row vector $\lambda = D_{\boldsymbol{y}} f\,[D_{\boldsymbol{y}}\boldsymbol{G}]^{-1}$, which exists and is unique because $D_{\boldsymbol{y}}\boldsymbol{G}$ is invertible; unwinding, λ is the unique solution of $\partial f/\partial y_j = \sum_\alpha \lambda^\alpha \partial g_\alpha/\partial y_j$, which is Equation (7.80) in the $\boldsymbol{y}$ block. Substituting it into Equation (7.81),

$$D_{\boldsymbol{x}'} f = -D_{\boldsymbol{y}} f \cdot D\boldsymbol{h} = \lambda\, D_{\boldsymbol{x}'}\boldsymbol{G}\,,$$

which is Equation (7.80) in the $\boldsymbol{x}'$ block. Uniqueness over all n components follows from the linear independence of the $\nabla g_\alpha(\boldsymbol{x}_\star)$: two solutions would differ by a vanishing combination of them. □

Remark 7.86 (The multiplier rule and its functional counterpart). Proposition 7.85 is the finite-dimensional statement from which the functional multiplier rule of Chapter 16 takes its name and its shape: the gradient of the objective lies in the span of the gradients of the constraints, so that the constrained problem is the unconstrained problem for $f - \lambda^\alpha g_\alpha$. What the variational version must supply for itself is the infinite-dimensional replacement of the implicit function theorem used here; the algebra of the multipliers is the same.

Rests on Proposition 7.85.

Definition 7.87 (Envelope of a family)**.** Let $\Omega \subseteq \mathbb{R}^n$ be open, let $I \subseteq \mathbb{R}$ be an open interval and let $f : \Omega \times I \longrightarrow \mathbb{R}$ be of class C^2. The member of the family labelled by $a \in I$ is the level set $S_a = \{\boldsymbol{x} \in \Omega \mid f(\boldsymbol{x}, a) = 0\}$, and the *envelope* of the family is

$$E = \left\{ \boldsymbol{x} \in \Omega \mid \exists\, a \in I :\ f(\boldsymbol{x}, a) = 0 \ \text{ and } \ \frac{\partial f}{\partial a}(\boldsymbol{x}, a) = 0 \right\}. \tag{7.82}$$

Rests on Definitions 7.65 and 7.66.

Proposition 7.88 (The envelope touches every member it meets)**.** *Let $\boldsymbol{x}_0 \in E$ with witness a_0, and suppose that $\nabla_{\boldsymbol{x}} f(\boldsymbol{x}_0, a_0) \neq \boldsymbol{0}$ and that $\partial^2 f/\partial a^2(\boldsymbol{x}_0, a_0) \neq 0$. Then on a neighbourhood of $\boldsymbol{x}_0$ the witness is a C^1 function $a(\boldsymbol{x})$, the set E is contained in the zero set of $\Psi(\boldsymbol{x}) = f\,(\boldsymbol{x}, a(\boldsymbol{x}))$, and*

$$\nabla\Psi(\boldsymbol{x}_0) = \nabla_{\boldsymbol{x}} f(\boldsymbol{x}_0, a_0) \neq \boldsymbol{0}\,. \tag{7.83}$$

Hence E and S_{a_0} have the same tangent plane at $\boldsymbol{x}_0$: the envelope is tangent to the member through each of its points.

Rests on Definition 7.87, Theorem 7.80, and Proposition 7.72.

Proof. *Derives Proposition 7.88.*

Apply Theorem 7.80 to the scalar equation $\partial f/\partial a(\boldsymbol{x}, a) = 0$ at $(\boldsymbol{x}_0, a_0)$, where the derivative with respect to a is $\partial^2 f/\partial a^2 \neq 0$: it returns a neighbourhood of $\boldsymbol{x}_0$ and a C^1 function $a(\boldsymbol{x})$ with $a(\boldsymbol{x}_0) = a_0$ and

$$\frac{\partial f}{\partial a}\,(\boldsymbol{x}, a(\boldsymbol{x})) = 0 \tag{7.84}$$

identically there, and no other root of $\partial f/\partial a$ nearby — so every point of E in that neighbourhood has $a(\boldsymbol{x})$ as its witness and satisfies $\Psi(\boldsymbol{x}) = 0$. By the chain rule Equation (7.52),

$$\nabla\Psi(\boldsymbol{x}) = \nabla_{\boldsymbol{x}} f\,(\boldsymbol{x}, a(\boldsymbol{x})) + \frac{\partial f}{\partial a}\,(\boldsymbol{x}, a(\boldsymbol{x}))\,\nabla a(\boldsymbol{x})\,,$$

whose second term vanishes identically by Equation (7.84); at $\boldsymbol{x}_0$ this is Equation (7.83). That same vector is the gradient at $\boldsymbol{x}_0$ of $\boldsymbol{x} \longmapsto f(\boldsymbol{x}, a_0)$, the defining function of S_{a_0}. Two level sets through one point whose defining functions have the same non-zero gradient there have the same tangent plane (Definition 7.64), which is the assertion. □

7.11 Vector analysis

7.11.1 The nabla operator

Let $\psi : \mathbb{R}^3 \longrightarrow \mathbb{R}$ and $\boldsymbol{A} : \mathbb{R}^3 \longrightarrow \mathbb{R}^3$.

- In Cartesian coordinates,

$$\nabla\psi = \hat{\boldsymbol{x}}\,\frac{\partial\psi}{\partial x} + \hat{\boldsymbol{y}}\,\frac{\partial\psi}{\partial y} + \hat{\boldsymbol{z}}\,\frac{\partial\psi}{\partial z}\,, \tag{7.85}$$

$$\nabla\cdot\boldsymbol{A} = \frac{\partial A_x}{\partial x} + \frac{\partial A_y}{\partial y} + \frac{\partial A_z}{\partial z}\,, \tag{7.86}$$

$$\nabla\times\boldsymbol{A} = \hat{\boldsymbol{x}}\left(\frac{\partial A_z}{\partial y} - \frac{\partial A_y}{\partial z}\right) + \hat{\boldsymbol{y}}\left(\frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x}\right) + \hat{\boldsymbol{z}}\left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y}\right), \tag{7.87}$$

$$\nabla^2\psi = \nabla\cdot\nabla\psi = \frac{\partial^2\psi}{\partial x^2} + \frac{\partial^2\psi}{\partial y^2} + \frac{\partial^2\psi}{\partial z^2}\,. \tag{7.88}$$

- In cylindrical coordinates (ρ, φ, z),

$$\nabla\psi = \hat{\boldsymbol{\rho}}\,\frac{\partial\psi}{\partial\rho} + \hat{\boldsymbol{\varphi}}\,\frac{1}{\rho}\frac{\partial\psi}{\partial\varphi} + \hat{\boldsymbol{z}}\,\frac{\partial\psi}{\partial z}\,, \tag{7.89}$$

$$\nabla\cdot\boldsymbol{A} = \frac{1}{\rho}\frac{\partial(\rho A_\rho)}{\partial\rho} + \frac{1}{\rho}\frac{\partial A_\varphi}{\partial\varphi} + \frac{\partial A_z}{\partial z}\,, \tag{7.90}$$

$$\nabla^2\psi = \frac{1}{\rho}\,\partial_\rho(\rho\,\partial_\rho\psi) + \frac{1}{\rho^2}\,\partial_\varphi^2\psi + \partial_z^2\psi\,. \tag{7.91}$$

- In spherical coordinates (r, θ, φ) (Figure 7.8),

$$\nabla\psi = \hat{\boldsymbol{r}}\,\frac{\partial\psi}{\partial r} + \hat{\boldsymbol{\theta}}\,\frac{1}{r}\frac{\partial\psi}{\partial\theta} + \hat{\boldsymbol{\varphi}}\,\frac{1}{r\sin\theta}\frac{\partial\psi}{\partial\varphi}\,, \tag{7.92}$$

$$\nabla\cdot\boldsymbol{A} = \frac{1}{r^2}\frac{\partial(r^2 A_r)}{\partial r} + \frac{1}{r\sin\theta}\frac{\partial(\sin\theta\, A_\theta)}{\partial\theta} + \frac{1}{r\sin\theta}\frac{\partial A_\varphi}{\partial\varphi}\,, \tag{7.93}$$

$$\nabla^2\psi = \frac{1}{r^2}\,\partial_r\Big(r^2\,\partial_r\psi\Big) + \frac{1}{r^2\sin\theta}\,\partial_\theta(\sin\theta\,\partial_\theta\psi) + \frac{1}{r^2\sin^2\theta}\,\partial_\varphi^2\psi\,. \tag{7.94}$$

  The curl expressions in curvilinear coordinates follow from the general covariant machinery of Chapter 13.

7.11.2 Identities of the nabla calculus

Every identity below is an equality of Cartesian components, and each is proved by writing both sides in index notation. Indices i, j, k, l, m run over $1, 2, 3$; a repeated index is summed; $\partial_i = \partial/\partial x^i$; δ_{ij} is the Kronecker delta, equal to 1 when $i = j$ and 0 otherwise; and ϵ_{ijk} is the *Levi-Civita symbol*, the totally antisymmetric array with $\epsilon_{123} = +1$. In this notation Equation (7.87) and the cross product of two vectors of $\mathbb{R}^3$ read

$$(\nabla\times\boldsymbol{A})_i = \epsilon_{ijk}\,\partial_j A_k\,, \qquad (\boldsymbol{A}\times\boldsymbol{B})_i = \epsilon_{ijk} A_j B_k\,. \tag{7.95}$$

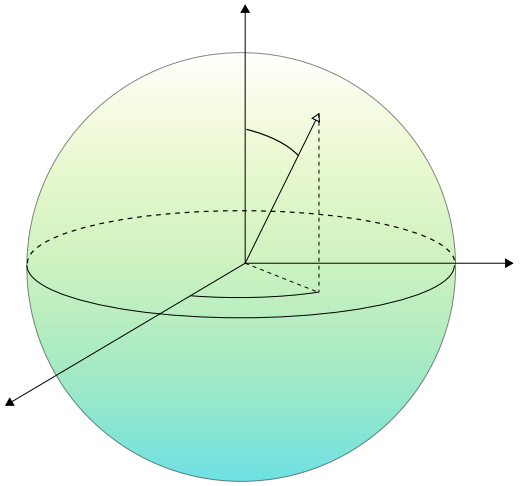

Figure 7.8: Spherical coordinates of a point in $\mathbb{R}^3$.

Lemma 7.89 (Contraction of two Levi-Civita symbols)**.** *For all $j,k,l,m \in \{1,2,3\}$,*

$$\epsilon_{ijk}\,\epsilon_{ilm} = \delta_{jl}\delta_{km} - \delta_{jm}\delta_{kl}\,, \tag{7.96}$$

the repeated index i being summed over $1,2,3$.
Rests on Equation (7.95).

Proof. *Derives Lemma 7.89.*

Both sides change sign under $j \leftrightarrow k$ and under $l \leftrightarrow m$, and both vanish when $j = k$ or $l = m$; so only the cases with $j \neq k$ and $l \neq m$ need checking. On the left the sum over i has at most one surviving term, the one whose i differs from both j and k, and it survives only if i also differs from l and m — that is, only if $\{l,m\}$ is the same pair as $\{j,k\}$. If $(l,m) = (j,k)$ that term is $(\epsilon_{ijk})^2 = 1$ and the right-hand side is $1\cdot 1 - 0 = 1$; if $(l,m) = (k,j)$ the term is $\epsilon_{ijk}\epsilon_{ikj} = -1$ and the right-hand side is $0 - 1\cdot 1 = -1$; and if $\{l,m\} \neq \{j,k\}$ the left-hand side vanishes, while on the right $\delta_{jl}\delta_{km} = 1$ would force $(l,m) = (j,k)$ and $\delta_{jm}\delta_{kl} = 1$ would force $(l,m) = (k,j)$, so both products vanish too. This exhausts the cases. □

Proposition 7.90 (Product identities of the nabla calculus)**.** *Let ψ be a C^1 scalar field and let $\boldsymbol{A}, \boldsymbol{B}$ be C^1 vector fields on an open subset of $\mathbb{R}^3$. Then*

$$\nabla\cdot(\psi\boldsymbol{A}) = \psi\,\nabla\cdot\boldsymbol{A} + \boldsymbol{A}\cdot\nabla\psi\,, \tag{7.97}$$

$$\nabla\times(\psi\boldsymbol{A}) = \psi\,\nabla\times\boldsymbol{A} + \nabla\psi\times\boldsymbol{A}\,, \tag{7.98}$$

$$\nabla\cdot(\boldsymbol{A}\times\boldsymbol{B}) = \boldsymbol{B}\cdot(\nabla\times\boldsymbol{A}) - \boldsymbol{A}\cdot(\nabla\times\boldsymbol{B})\,, \tag{7.99}$$

$$\nabla\times(\boldsymbol{A}\times\boldsymbol{B}) = (\boldsymbol{B}\cdot\nabla)\,\boldsymbol{A} - (\boldsymbol{A}\cdot\nabla)\,\boldsymbol{B} + \boldsymbol{A}\,(\nabla\cdot\boldsymbol{B}) - \boldsymbol{B}\,(\nabla\cdot\boldsymbol{A})\,, \tag{7.100}$$

$$\nabla\,(\boldsymbol{A}\cdot\boldsymbol{B}) = (\boldsymbol{A}\cdot\nabla)\,\boldsymbol{B} + (\boldsymbol{B}\cdot\nabla)\,\boldsymbol{A} + \boldsymbol{A}\times(\nabla\times\boldsymbol{B}) + \boldsymbol{B}\times(\nabla\times\boldsymbol{A})\,, \tag{7.101}$$

where $(\boldsymbol{A}\cdot\nabla)\,\boldsymbol{B}$ denotes the vector with components $A_j\,\partial_j B_i$. Setting $\boldsymbol{B} = \boldsymbol{A}$ in Equation (7.101) gives the identity

$$(\boldsymbol{A}\cdot\nabla)\,\boldsymbol{A} = \nabla\left(\frac{|\boldsymbol{A}|^2}{2}\right) - \boldsymbol{A}\times(\nabla\times\boldsymbol{A})\,, \tag{7.102}$$

which splits an advective derivative into a gradient and a term orthogonal to $\boldsymbol{A}$.
Rests on Lemma 7.89, Equation (7.95), and Proposition 7.30.

Proof. *Derives Proposition 7.90.*

Throughout, the product rule Proposition 7.30 is applied to each Cartesian component and Equation (7.96) is used to contract the two symbols that appear whenever two cross products meet.

Equations (7.97) *and* (7.98). Directly, $\partial_i(\psi A_i) = \psi\,\partial_i A_i + A_i\,\partial_i\psi$, which is the first; and $\epsilon_{ijk}\partial_j(\psi A_k) = \psi\,\epsilon_{ijk}\partial_j A_k + \epsilon_{ijk}(\partial_j\psi)A_k$, whose second term is $(\nabla\psi\times\boldsymbol{A})_i$ by Equation (7.95).

Equation (7.99). $\partial_i\left(\epsilon_{ijk}A_jB_k\right) = \epsilon_{ijk}\left(\partial_i A_j\right)B_k + \epsilon_{ijk}A_j\left(\partial_i B_k\right)$. In the first term relabel $\epsilon_{ijk} = \epsilon_{kij}$, so that it is $B_k\left(\nabla\times\boldsymbol{A}\right)_k$; in the second, $\epsilon_{ijk} = -\epsilon_{jik}$, so that it is $-A_j\left(\nabla\times\boldsymbol{B}\right)_j$.

Equation (7.100). Using Equation (7.95) twice and then Equation (7.96) with the summed index moved to the front of both symbols,

$$\begin{aligned}\left[\nabla\times(\boldsymbol{A}\times\boldsymbol{B})\right]_i &= \epsilon_{ijk}\,\partial_j\left(\epsilon_{klm}A_lB_m\right) = \epsilon_{kij}\epsilon_{klm}\,\partial_j\left(A_lB_m\right)\\ &= \left(\delta_{il}\delta_{jm}-\delta_{im}\delta_{jl}\right)\partial_j\left(A_lB_m\right) = \partial_m\left(A_iB_m\right) - \partial_l\left(A_lB_i\right)\,,\end{aligned}$$

and expanding the two derivatives by the product rule gives $A_i\,\partial_m B_m + B_m\,\partial_m A_i - B_i\,\partial_l A_l - A_l\,\partial_l B_i$, which is Equation (7.100) component by component.

Equation (7.101). By the same two steps,

$$\left[\boldsymbol{A}\times(\nabla\times\boldsymbol{B})\right]_i = \epsilon_{ijk}A_j\,\epsilon_{klm}\,\partial_l B_m = A_j\,\partial_i B_j - A_j\,\partial_j B_i\,,$$

and interchanging $\boldsymbol{A}$ and $\boldsymbol{B}$, $\left[\boldsymbol{B}\times(\nabla\times\boldsymbol{A})\right]_i = B_j\,\partial_i A_j - B_j\,\partial_j A_i$. Adding the two and using $\partial_i\left(A_jB_j\right) = A_j\,\partial_i B_j + B_j\,\partial_i A_j$ rearranges to Equation (7.101). Equation (7.102) is the case $\boldsymbol{B} = \boldsymbol{A}$, in which the two advective terms coincide and $\partial_i(A_jA_j) = \partial_i\left|\boldsymbol{A}\right|^2$, so that the whole identity may be divided by two. □

Proposition 7.91 (Second-order identities of the nabla calculus)**.** *Let ψ be a C^2 scalar field and let $\boldsymbol{A}$ be a C^2 vector field on an open subset of $\mathbb{R}^3$. Then*

$$\nabla\times\nabla\psi = \boldsymbol{0}\,, \tag{7.103}$$

$$\nabla\cdot(\nabla\times\boldsymbol{A}) = 0\,, \tag{7.104}$$

$$\nabla\times(\nabla\times\boldsymbol{A}) = \nabla\left(\nabla\cdot\boldsymbol{A}\right) - \nabla^2\boldsymbol{A}\,, \tag{7.105}$$

where $\nabla^2\boldsymbol{A}$ is the vector whose Cartesian components are the Laplacians Equation (7.88) of the Cartesian components of $\boldsymbol{A}$. The first of the three is Equation (7.128) of Proposition 7.104 below, recorded here so that the three second-order identities stand together.

Rests on Lemma 7.89, Proposition 7.73, and Equation (7.88).

Proof. *Derives Proposition 7.91.*

The first two are the contraction of an object antisymmetric in two indices with one symmetric in them. By Proposition 7.73 the second partial derivatives of a C^2 field commute, so $\partial_j\partial_k\psi$ is symmetric in (j,k) while ϵ_{ijk} is antisymmetric, and $(\nabla\times\nabla\psi)_i = \epsilon_{ijk}\partial_j\partial_k\psi$ vanishes: interchanging the summation labels j and k turns the sum into minus itself. The same argument on $\nabla\cdot(\nabla\times\boldsymbol{A}) = \epsilon_{ijk}\,\partial_i\partial_j A_k$ gives Equation (7.104). For the third, by Equation (7.95) and then Equation (7.96),

$$\begin{aligned}\left[\nabla\times(\nabla\times\boldsymbol{A})\right]_i &= \epsilon_{ijk}\,\partial_j\left(\epsilon_{klm}\,\partial_l A_m\right) = \left(\delta_{il}\delta_{jm}-\delta_{im}\delta_{jl}\right)\partial_j\partial_l A_m\\ &= \partial_j\partial_i A_j - \partial_j\partial_j A_i = \partial_i\left(\nabla\cdot\boldsymbol{A}\right) - \nabla^2 A_i\,,\end{aligned}$$

the last step again by Proposition 7.73, and this is Equation (7.105). □

Remark 7.92 (The Laplacian of a vector field is a Cartesian notion). Equation (7.105) is the *definition* of ∇^2 on a vector field in any coordinate system other than the Cartesian one: the componentwise Laplacian of Equation (7.91) or Equation (7.94) applied to A_ρ, A_θ and the rest is *not* $\nabla^2\boldsymbol{A}$, because those basis vectors themselves vary from point to point. The combination $\nabla(\nabla\cdot\boldsymbol{A}) - \nabla\times(\nabla\times\boldsymbol{A})$ is built from operations that are defined without reference to a basis and is therefore the right object to carry over; the covariant reading of the same statement is in Chapter 13.

Rests on Proposition 7.91 and Equation (7.94).

7.11.3 The integral theorems

The three classical integral theorems trade a derivative integrated over a region for the field itself integrated over the boundary of that region. They are the multivariable descendants of the fundamental theorem of calculus (Theorem 7.43), and each derivation below reduces to it. We first fix the integrals that appear in them.

Definition 7.93 (Multiple integral)**.** Let $R = [a_1, b_1] \times \cdots \times [a_N, b_N] \subset \mathbb{R}^N$ be a closed box and $f : R \longrightarrow \mathbb{R}$ bounded. Partition each edge; the lower and upper sums of Equation (7.22) are then formed with the infimum and the supremum of f on each sub-box weighted by the volume of that sub-box, and f is *integrable* on R, with integral $\int_R f$, when the supremum of the lower sums and the infimum of the upper sums coincide. For a bounded $D \subseteq R$, $\int_D f$ means $\int_R \tilde{f}$, where $\tilde{f}$ agrees with f on D and vanishes off it. We write $\iint_D$ and $\iiint_V$ for $N = 2$ and $N = 3$, and $\mathrm{d}V = \mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z$.

Rests on Definition 7.39 and Axiom 7.1.

Definition 7.94 (Line and surface integrals)**.** Let γ be a piecewise-C^1 path $\boldsymbol{r} : [\alpha, \beta] \longrightarrow \mathbb{R}^3$ and let $\boldsymbol{A}$ be continuous on its image. The *line integral* of $\boldsymbol{A}$ along γ is

$$\int_\gamma \boldsymbol{A} \cdot \mathrm{d}\boldsymbol{l} = \int_\alpha^\beta \boldsymbol{A}(\boldsymbol{r}(t)) \cdot \boldsymbol{r}'(t)\,\mathrm{d}t\,, \tag{7.106}$$

and in the plane, with $\boldsymbol{r}(t) = (x(t), y(t))$,

$$\int_\gamma (P\,\mathrm{d}x + Q\,\mathrm{d}y) = \int_\alpha^\beta \left[P(\boldsymbol{r}(t))\,x'(t) + Q(\boldsymbol{r}(t))\,y'(t)\right]\mathrm{d}t\,. \tag{7.107}$$

Let S be a surface carried by a C^1 parametrization $\boldsymbol{r} : D \subseteq \mathbb{R}^2 \longrightarrow \mathbb{R}^3$, injective on the interior of D and with $\partial_u \boldsymbol{r} \times \partial_v \boldsymbol{r} \neq \boldsymbol{0}$ there. Its *oriented surface element*, and the *flux* of $\boldsymbol{A}$ through S, are

$$\mathrm{d}\boldsymbol{S} = (\partial_u \boldsymbol{r} \times \partial_v \boldsymbol{r})\,\mathrm{d}u\,\mathrm{d}v\,, \tag{7.108}$$

$$\iint_S \boldsymbol{A} \cdot \mathrm{d}\boldsymbol{S} = \iint_D \boldsymbol{A}(\boldsymbol{r}(u,v)) \cdot (\partial_u \boldsymbol{r} \times \partial_v \boldsymbol{r})\,\mathrm{d}u\,\mathrm{d}v\,. \tag{7.109}$$

Reversing the orientation of γ or of S reverses the sign.

Rests on Definitions 7.66 and 7.93.

Definition 7.95 (Simple regions)**.** A compact set $D \subset \mathbb{R}^2$ is *vertically simple* if

$$D = \left\{(x, y) \in \mathbb{R}^2 \mid a \le x \le b,\ \varphi_1(x) \le y \le \varphi_2(x)\right\} \tag{7.110}$$

for piecewise-C^1 functions $\varphi_1 \le \varphi_2$ on $[a, b]$, and *horizontally simple* if it admits the same description with the two coordinates exchanged, between $\psi_1 \le \psi_2$ on $[c, d]$. It is *simple* if it is both. A compact $V \subset \mathbb{R}^3$ is *simple* if, for each of the three coordinate directions, it is the region between the graphs of two piecewise-C^1 functions over a simple plane region — for the z direction,

$$V = \left\{(x, y, z) \in \mathbb{R}^3 \mid (x, y) \in D_z,\ \chi_1(x, y) \le z \le \chi_2(x, y)\right\}. \tag{7.111}$$

Rests on Definitions 6.9 and 7.66.

Remark 7.96 (What the derivations below take as given)*.* Three properties of the multiple integral are used repeatedly. A function continuous on a simple region is integrable there; the integral is additive over a decomposition of the region into finitely many pieces meeting

only along their boundaries; and on a vertically simple region the integral of a continuous f reduces to the iterated integral

$$\iint_D f \,\mathrm{d}x\,\mathrm{d}y = \int_a^b \left[\int_{\varphi_1(x)}^{\varphi_2(x)} f(x,y)\,\mathrm{d}y \right] \mathrm{d}x\,, \tag{7.112}$$

with the analogous statements on a horizontally simple region and in $\mathbb{R}^3$. All three follow from the Darboux construction by the argument of Theorem 7.40 once one knows that the graph of a continuous φ carries no area: given $\varepsilon > 0$, uniform continuity (Theorem 7.25) splits $[a,b]$ into n subintervals on each of which φ varies by less than ε, and the n rectangles so obtained cover the graph with total area at most $(b-a)\varepsilon$. Hence the boundary of a simple region contributes nothing to any upper–lower gap. These statements are inputs to what follows, not consequences of it.

Rests on Definition 7.93 and Theorems 7.25 and 7.40.

The one further property of the multiple integral that the physical parts use constantly is the several-variable substitution rule. In one variable it is Corollary 7.44; in N variables the derivative of the substitution is a matrix, and what replaces it is the modulus of the determinant.

Theorem 7.97 (Change of variables in a multiple integral)**.** *Let $U, V \subseteq \mathbb{R}^N$ be open and bounded and let $\boldsymbol{\Phi} : U \longrightarrow V$ be a bijection of class C^1 with $\det D\boldsymbol{\Phi}(\boldsymbol{u}) \neq 0$ at every $\boldsymbol{u} \in U$ — equivalently, by Corollary 7.81, a C^1 bijection whose inverse is C^1. Let f be continuous and bounded on V. Then both integrals below exist in the sense of Definition 7.93 and are equal:*

$$\int_V f(\boldsymbol{x})\,\mathrm{d}^N x = \int_U f\left(\boldsymbol{\Phi}(\boldsymbol{u})\right) \left|\det D\boldsymbol{\Phi}(\boldsymbol{u})\right| \,\mathrm{d}^N u\,. \tag{7.113}$$

The same identity holds when $\boldsymbol{\Phi}$ fails to be injective, or its determinant fails to be nonzero, on a set contained in finitely many graphs of continuous functions, since such a set contributes nothing to a Darboux sum (Remark 7.96).

Rests on Definition 7.93, Corollary 7.81, and Remark 7.96.

Full derivation: Appendix A.44 (p. 3018).

Derives Theorem 7.97.

Example 7.98 (The two Jacobians this treatise uses)**.** In the plane, the polar map $\boldsymbol{\Phi}(\rho,\varphi) = (\rho\cos\varphi, \rho\sin\varphi)$ has

$$D\boldsymbol{\Phi} = \begin{pmatrix} \cos\varphi & -\rho\sin\varphi \\ \sin\varphi & \rho\cos\varphi \end{pmatrix}, \qquad \det D\boldsymbol{\Phi} = \rho\,, \tag{7.114}$$

so $\mathrm{d}x\,\mathrm{d}y = \rho\,\mathrm{d}\rho\,\mathrm{d}\varphi$; in space, the spherical map of Figure 7.8, $(r,\theta,\varphi) \longmapsto (r\sin\theta\cos\varphi, r\sin\theta\sin\varphi, r\cos\theta)$, has $\det D\boldsymbol{\Phi} = r^2\sin\theta$ on expanding the 3×3 determinant along its last row, so $\mathrm{d}V = r^2\sin\theta\,\mathrm{d}r\,\mathrm{d}\theta\,\mathrm{d}\varphi$. Each map is a diffeomorphism away from its coordinate degeneracies — $\rho = 0$ in the plane, $r = 0$ or $\sin\theta = 0$ in space — and those lie in finitely many graphs of continuous functions, so the last clause of Theorem 7.97 covers them. These are the volume elements used for the Gaussian integral of Chapter 11 and for every radial integration in the physical parts.

Rests on Theorem 7.97 and Equation (7.92).

Theorem 7.99 (Green)**.** *Let $D \subset \mathbb{R}^2$ be a region bounded by a piecewise-C^1 simple closed curve ∂D, traversed counterclockwise, and let P, Q be C^1 on $D \cup \partial D$. Then*

$$\oint_{\partial D} (P\,\mathrm{d}x + Q\,\mathrm{d}y) = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \mathrm{d}x\,\mathrm{d}y\,. \tag{7.115}$$

Rests on Theorem 7.43, Definition 7.95, and Remark 7.96.

Proof. *Derives Theorem 7.99.*

We derive the identity for a simple region (Definition 7.95) and then for any region that can be cut into finitely many of them; what that leaves uncovered is stated in Remark 7.102.

Step 1: the P term on a vertically simple region. Let D be as in Equation (7.110). Since $\partial_y P$ is continuous, Equation (7.112) and the fundamental theorem of calculus (Theorem 7.43), applied in y at fixed x, give

$$\iint_D \frac{\partial P}{\partial y}\,\mathrm{d}x\,\mathrm{d}y = \int_a^b \left[P(x,\varphi_2(x)) - P(x,\varphi_1(x))\right]\mathrm{d}x\,. \tag{7.116}$$

Traversed counterclockwise, ∂D consists of the lower graph $x \longmapsto (x,\varphi_1(x))$ run from $x=a$ to $x=b$, the vertical segment at $x=b$, the upper graph $x \longmapsto (x,\varphi_2(x))$ run back from $x=b$ to $x=a$, and the vertical segment at $x=a$. On the two vertical pieces x is constant, so $x'(t)=0$ and they contribute nothing to Equation (7.107). Hence, using Equation (7.116) in the last step,

$$\oint_{\partial D} P\,\mathrm{d}x = \int_a^b P(x,\varphi_1(x))\,\mathrm{d}x + \int_b^a P(x,\varphi_2(x))\,\mathrm{d}x = -\iint_D \frac{\partial P}{\partial y}\,\mathrm{d}x\,\mathrm{d}y\,. \tag{7.117}$$

Step 2: the Q term on a horizontally simple region. With $D = \{(x,y) \mid c \le y \le d,\ \psi_1(y) \le x \le \psi_2(y)\}$ the same two moves give

$$\iint_D \frac{\partial Q}{\partial x}\,\mathrm{d}x\,\mathrm{d}y = \int_c^d \left[Q(\psi_2(y),y) - Q(\psi_1(y),y)\right]\mathrm{d}y\,.$$

The counterclockwise boundary now runs up the right graph $y \longmapsto (\psi_2(y),y)$ from $y=c$ to $y=d$, which is the sense that keeps the interior on the left, and down the left graph $y \longmapsto (\psi_1(y),y)$ from $y=d$ to $y=c$; the two horizontal pieces have $y'(t)=0$ and contribute nothing to $\oint Q\,\mathrm{d}y$. Therefore

$$\oint_{\partial D} Q\,\mathrm{d}y = \iint_D \frac{\partial Q}{\partial x}\,\mathrm{d}x\,\mathrm{d}y\,. \tag{7.118}$$

Step 3: simple regions. On a region that is both vertically and horizontally simple, both steps apply, and adding Equation (7.117) to Equation (7.118) is exactly Equation (7.115).

Step 4: decomposition. Let $D = \bigcup_{k=1}^{N} D_k$ with every D_k simple and any two of them meeting at most along parts of their boundaries. Summing Equation (7.115) over k, the area integrals add to $\iint_D (\partial_x Q - \partial_y P)$ by additivity (Remark 7.96). On the boundary side, an arc interior to D belongs to exactly two of the ∂D_k, whose regions lie on opposite sides of it, so it is traversed once in each direction; the two line integrals then cancel, since reversing the parametrization reverses the sign of Equation (7.107). What survives is the integral over the arcs making up ∂D, traversed counterclockwise. □

Theorem 7.100 (Stokes)**.** *For an oriented piecewise-smooth surface S with boundary curve ∂S (oriented compatibly) and $\boldsymbol{A} \in C^1$,*

$$\oint_{\partial S} \boldsymbol{A}\cdot\mathrm{d}\boldsymbol{l} = \iint_S (\nabla\times\boldsymbol{A})\cdot\mathrm{d}\boldsymbol{S}\,. \tag{7.119}$$

Rests on Theorem 7.99 and Propositions 7.72 and 7.73.

Proof. *Derives Theorem 7.100.*

It suffices to treat a surface that is a graph over a plane region to which Theorem 7.99 applies: a piecewise-smooth oriented surface can be cut into finitely many such pieces — after a permutation of the coordinate axes for each — and the line integrals along the interior cuts cancel in pairs exactly as in Step 4 of the derivation of Theorem 7.99.

So let $S = \{(x, y, g(x, y)) \in \mathbb{R}^3 \mid (x, y) \in D\}$ with g of class C^2 on a neighbourhood of D, oriented by the upward normal. The parametrization $\boldsymbol{r}(x, y) = (x, y, g(x, y))$ has

$$\partial_x \boldsymbol{r} \times \partial_y \boldsymbol{r} = \left(-\frac{\partial g}{\partial x},\ -\frac{\partial g}{\partial y},\ 1 \right), \tag{7.120}$$

whose third component is positive, so Equation (7.108) with this parametrization is the chosen orientation; and ∂S is the lift of ∂D, traversed so that ∂D runs counterclockwise.

The line integral. Parametrize ∂D by $t \longmapsto (x(t), y(t))$. Its lift has $z(t) = g(x(t), y(t))$, so the chain rule (Proposition 7.72) gives $z' = \partial_x g\, x' + \partial_y g\, y'$. Writing $\tilde{A}_i(x, y) = A_i(x, y, g(x, y))$ and collecting the coefficients of x' and y' in Equation (7.106),

$$\oint_{\partial S} \boldsymbol{A} \cdot \mathrm{d}\boldsymbol{l} = \oint_{\partial D} (P\,\mathrm{d}x + Q\,\mathrm{d}y), \qquad P = \tilde{A}_x + \tilde{A}_z \frac{\partial g}{\partial x}, \quad Q = \tilde{A}_y + \tilde{A}_z \frac{\partial g}{\partial y}. \tag{7.121}$$

Both P and Q are C^1 on D, because $\boldsymbol{A}$ is C^1 and g is C^2.

Green's theorem. Apply Theorem 7.99 to Equation (7.121). The chain rule (Equation (7.52), applied to the composition of $(x, y) \longmapsto (x, y, g(x, y))$ with A_i) gives $\partial_x \tilde{A}_i = \partial_x A_i + \partial_z A_i\, \partial_x g$ and $\partial_y \tilde{A}_i = \partial_y A_i + \partial_z A_i\, \partial_y g$, every partial derivative of A_i being evaluated on S, so that

$$\begin{aligned}
\frac{\partial Q}{\partial x} &= \partial_x A_y + \partial_z A_y \frac{\partial g}{\partial x} + \left(\partial_x A_z + \partial_z A_z \frac{\partial g}{\partial x} \right) \frac{\partial g}{\partial y} + \tilde{A}_z \frac{\partial^2 g}{\partial x\, \partial y}, \\
\frac{\partial P}{\partial y} &= \partial_y A_x + \partial_z A_x \frac{\partial g}{\partial y} + \left(\partial_y A_z + \partial_z A_z \frac{\partial g}{\partial y} \right) \frac{\partial g}{\partial x} + \tilde{A}_z \frac{\partial^2 g}{\partial y\, \partial x}.
\end{aligned}$$

On subtraction the two second-derivative terms cancel by Clairaut–Schwarz (Proposition 7.73), which is the one place where g is required to be C^2, and so do the two terms carrying $\partial_z A_z\, \partial_x g\, \partial_y g$. What is left is

$$\begin{aligned}
\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} &= (\partial_x A_y - \partial_y A_x) + \frac{\partial g}{\partial x} (\partial_z A_y - \partial_y A_z) + \frac{\partial g}{\partial y} (\partial_x A_z - \partial_z A_x) \\
&= (\nabla \times \boldsymbol{A}) \cdot \left(-\frac{\partial g}{\partial x},\ -\frac{\partial g}{\partial y},\ 1 \right),
\end{aligned} \tag{7.122}$$

the second line being just Equation (7.87) read component by component. Integrating Equation (7.122) over D and comparing with Equation (7.109) and Equation (7.120),

$$\oint_{\partial S} \boldsymbol{A} \cdot \mathrm{d}\boldsymbol{l} = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \mathrm{d}x\, \mathrm{d}y = \iint_S (\nabla \times \boldsymbol{A}) \cdot \mathrm{d}\boldsymbol{S},$$

which is Equation (7.119). □

Theorem 7.101 (Gauss)**.** *For a bounded region $V \subset \mathbb{R}^3$ with piecewise-smooth boundary ∂V, outward oriented, and $\boldsymbol{A} \in C^1$,*

$$\oint_{\partial V} \boldsymbol{A} \cdot \mathrm{d}\boldsymbol{S} = \iiint_V \nabla \cdot \boldsymbol{A}\, \mathrm{d}V. \tag{7.123}$$

Rests on Theorem 7.43, Definition 7.95, and Remark 7.96.

Proof. *Derives Theorem 7.101.*

Again we derive the identity for a simple region (Definition 7.95) and extend it by decomposition.

The z component. Let V be as in Equation (7.111). Because $\partial_z A_z$ is continuous, the three-dimensional form of Equation (7.112) and the fundamental theorem of calculus (Theorem 7.43), applied in z at fixed (x, y), give

$$\iiint_V \frac{\partial A_z}{\partial z}\, \mathrm{d}V = \iint_{D_z} [A_z(x, y, \chi_2(x, y)) - A_z(x, y, \chi_1(x, y))]\, \mathrm{d}x\, \mathrm{d}y. \tag{7.124}$$

The boundary ∂V splits into the upper cap $z = \chi_2$, the lower cap $z = \chi_1$, and a lateral part on which the outward normal is horizontal — possibly empty, as for a ball, whose two caps meet along the equator. On the upper cap the parametrization $\boldsymbol{r}(x, y) = (x, y, \chi_2(x, y))$ has $\partial_x \boldsymbol{r} \times \partial_y \boldsymbol{r} = (-\partial_x \chi_2, -\partial_y \chi_2, 1)$, whose third component is positive; this is therefore the outward orientation, and Equation (7.109) gives $\iint A_z\, \hat{\boldsymbol{z}} \cdot \mathrm{d}\boldsymbol{S} = \iint_{D_z} A_z(x, y, \chi_2)\, \mathrm{d}x\, \mathrm{d}y$. On the lower cap the outward normal points downwards, so $\mathrm{d}\boldsymbol{S} = (\partial_x \chi_1, \partial_y \chi_1, -1)\, \mathrm{d}x\, \mathrm{d}y$ and the same computation returns $-\iint_{D_z} A_z(x, y, \chi_1)\, \mathrm{d}x\, \mathrm{d}y$. On the lateral part $\hat{\boldsymbol{z}} \cdot \mathrm{d}\boldsymbol{S} = 0$. Adding the three contributions and comparing with Equation (7.124),

$$\oint_{\partial V} A_z\, \hat{\boldsymbol{z}} \cdot \mathrm{d}\boldsymbol{S} = \iiint_V \frac{\partial A_z}{\partial z}\, \mathrm{d}V\,. \tag{7.125}$$

The other two components. Because V is simple in all three coordinate directions, the identical argument with the axes permuted gives the analogues of Equation (7.125) for $A_x \hat{\boldsymbol{x}}$ and $A_y \hat{\boldsymbol{y}}$. Adding the three identities, and using $\boldsymbol{A} = A_x \hat{\boldsymbol{x}} + A_y \hat{\boldsymbol{y}} + A_z \hat{\boldsymbol{z}}$ together with Equation (7.86), yields Equation (7.123).

Decomposition. If $V = \bigcup_k V_k$ with every V_k simple and any two meeting at most along parts of their boundaries, summing the identity over k adds the volume integrals. On the surface side an interior face belongs to exactly two of the ∂V_k, which assign it opposite outward normals, so those two fluxes cancel; the flux through ∂V is what remains. □

Remark 7.102 (Scope of these three derivations). Three limitations should be stated exactly. First, the derivations cover every region and every surface that decomposes into finitely many simple pieces (Definition 7.95) — which is every region and surface this treatise integrates over — but not an arbitrary region bounded by a piecewise-C^1 curve; the passage to that generality is an exhaustion argument, not carried out here. Second, the derivation of Theorem 7.100 asks the surface to be C^2, one degree smoother than the statement, because it applies Clairaut–Schwarz to the height function; the C^1 case follows by approximating the surface, again not done here. Third, the flux Equation (7.109) was defined through a parametrization, and its independence of that choice rests on the change-of-variables formula Theorem 7.97: two parametrizations of one surface differ by a C^1 diffeomorphism of their parameter domains, and Equation (7.113) converts one integral into the other, the Jacobian factor cancelling the corresponding factor in $\partial_u \boldsymbol{r} \times \partial_v \boldsymbol{r}$.

The three theorems are instances of a single statement, the general Stokes theorem $\int_M \mathrm{d}\omega = \int_{\partial M} \omega$ for a differential form ω on an oriented manifold with boundary: Theorem 7.99 is the case of a 1-form on a plane region, Theorem 7.100 that of a 1-form on a surface in $\mathbb{R}^3$, and Theorem 7.101 that of a 2-form on a solid. The language for that formulation is built in Chapter 13, where the antisymmetric-tensor form Equation (13.231) is stated — but its derivation is still owed there, which is why the classical theorems are proved directly above rather than deduced from it.

7.11.4 Conservative fields

Definition 7.103 (Conservative field)**.** For a function $\boldsymbol{F} : A \subseteq \mathbb{R}^3 \longrightarrow \mathbb{R}^3$, with A an open connected set, we say that $\boldsymbol{F}$ is *conservative* on A if and only if

$$\exists\, f : A \subseteq \mathbb{R}^3 \longrightarrow \mathbb{R} \mid \boldsymbol{F} = \nabla f\,. \tag{7.126}$$

Rests on Equation (7.85).

Proposition 7.104 (Properties of conservative fields)**.** *Let A be open and connected.*

1. *If $\boldsymbol{F} = \nabla f$ on A and $L \subseteq A$ is a closed piecewise-C^1 loop, then*

$$\oint_L \boldsymbol{F} \cdot \mathrm{d}\boldsymbol{l} = 0\,. \tag{7.127}$$

2. *If $\boldsymbol{F} \in C^1(A)$ is conservative, then*

$$\nabla \times \boldsymbol{F} = \boldsymbol{0}\,. \tag{7.128}$$

3. *If $\boldsymbol{F} \in C^1(A)$, A is moreover simply connected (Chapter 6), and $\nabla \times \boldsymbol{F} = \boldsymbol{0}$, then $\boldsymbol{F}$ is conservative.*

Rests on Definition 7.103, Proposition 7.72, and Theorem 7.100.

Proof. *Derives Proposition 7.104.*

(1) Parametrize the loop by $\boldsymbol{r}(t)$, $t \in [0,1]$, with $\boldsymbol{r}(0) = \boldsymbol{r}(1)$. By the chain rule (Proposition 7.72), $\frac{\mathrm{d}}{\mathrm{d}t} f(\boldsymbol{r}(t)) = \nabla f(\boldsymbol{r}(t)) \cdot \boldsymbol{r}'(t)$, so

$$\oint_L \boldsymbol{F} \cdot \mathrm{d}\boldsymbol{l} = \int_0^1 \frac{\mathrm{d}}{\mathrm{d}t} f(\boldsymbol{r}(t))\,\mathrm{d}t = f(\boldsymbol{r}(1)) - f(\boldsymbol{r}(0)) = 0$$

by the fundamental theorem of calculus (Theorem 7.43). (2) Componentwise, e.g. $(\nabla \times \nabla f)_z = \partial_x \partial_y f - \partial_y \partial_x f = 0$ by Clairaut–Schwarz (Proposition 7.73); the hypothesis $\boldsymbol{F} \in C^1$ makes f twice continuously differentiable. (3) Fix $\boldsymbol{a} \in A$ and define $f(\boldsymbol{p}) = \int_\gamma \boldsymbol{F} \cdot \mathrm{d}\boldsymbol{l}$ along any path $\gamma \subset A$ from $\boldsymbol{a}$ to $\boldsymbol{p}$. Well-definedness is the point: two paths bound (by simple connectedness) a surface swept by a homotopy inside A, and Stokes' theorem (Theorem 7.100) with $\nabla \times \boldsymbol{F} = \boldsymbol{0}$ makes the two line integrals equal. Differentiating along a coordinate step then gives $\partial_i f = F_i$, i.e. $\nabla f = \boldsymbol{F}$. □

7.11.5 The Helmholtz decomposition

Proposition 7.104 says when a field is a gradient; the companion statement says that an arbitrary field is a gradient plus a curl. It is the capstone of this section, and it is what licenses the routine physical move of splitting a vector field into an irrotational and a solenoidal part and treating the two separately.

Theorem 7.105 (Helmholtz decomposition)**.** *Let $\boldsymbol{u} : \mathbb{R}^3 \longrightarrow \mathbb{R}^3$ be smooth with compact support. Then there are a smooth scalar field ϕ and a smooth vector field $\boldsymbol{\Psi}$ on $\mathbb{R}^3$ with*

$$\boldsymbol{u} = \nabla\phi + \nabla \times \boldsymbol{\Psi}\,, \qquad \nabla \cdot \boldsymbol{\Psi} = 0\,, \tag{7.129}$$

namely

$$\boldsymbol{w}(\boldsymbol{x}) = -\frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{\boldsymbol{u}(\boldsymbol{y})}{|\boldsymbol{x} - \boldsymbol{y}|}\,\mathrm{d}^3 y\,, \qquad \phi = \nabla \cdot \boldsymbol{w}\,, \qquad \boldsymbol{\Psi} = -\nabla \times \boldsymbol{w}\,. \tag{7.130}$$

The first summand is curl-free and the second divergence-free (Proposition 7.91), and the two are unique: if $\nabla\phi_1 + \nabla \times \boldsymbol{\Psi}_1 = \nabla\phi_2 + \nabla \times \boldsymbol{\Psi}_2$ with all four fields tending to zero at infinity, then $\nabla\phi_1 = \nabla\phi_2$ and $\nabla \times \boldsymbol{\Psi}_1 = \nabla \times \boldsymbol{\Psi}_2$.

Rests on Propositions 7.91 and 10.67 and Theorem 7.77.

Full derivation: Appendix A.45 (p. 3026).

Derives Theorem 7.105.

The mechanism is worth stating even though the estimates are not. Each Cartesian component of $\boldsymbol{w}$ is the Newtonian potential of the corresponding component of $\boldsymbol{u}$, so $\nabla^2 \boldsymbol{w} = \boldsymbol{u}$ by Proposition 10.67; and Equation (7.105), read backwards, turns that Laplacian into $\nabla(\nabla \cdot \boldsymbol{w}) - \nabla \times (\nabla \times \boldsymbol{w})$, which is Equation (7.129) with the potentials Equation (7.130). That $\nabla \cdot \boldsymbol{\Psi} = 0$ is Equation (7.104). Uniqueness is the observation that the difference of two decompositions is a field that is at once a gradient and a curl, hence by Equations (7.103) and (7.104) both curl-free and divergence-free, hence harmonic in each component by Equation (7.105); a harmonic function on $\mathbb{R}^3$ that tends to zero at infinity vanishes, by

the maximum principle Theorem 10.75 applied on balls of growing radius. What the appendix supplies is the analytic work the display above skips: that the singular integral Equation (7.130) may be differentiated under the integral sign as often as one likes — Theorem 7.77 after the singularity has been excised, with the excised part estimated uniformly — and that the result decays.

7.12 Sets of measure zero and Hausdorff dimension

The Darboux construction already asks which sets are small enough to be ignored: the graph of a continuous function carries no area (Remark 7.96), which is why the boundary of a simple region contributes nothing to an integral. This section makes "small" precise in the two senses the physical parts use — a set of measure zero, and the dimension of a set that is small in no whole number of dimensions. Neither needs the Lebesgue integral, and this treatise does not construct it; what is defined here is the covering notion alone, and every statement below is proved from it.

Definition 7.106 (Set of measure zero)**.** A set $E \subseteq \mathbb{R}^N$ is *null*, or *of measure zero*, if for every $\varepsilon > 0$ there is a countable family of boxes $R_1, R_2, \ldots$ (Definition 7.93) with

$$E \subseteq \bigcup_{k \geq 1} R_k \,, \qquad \sum_{k \geq 1} \operatorname{vol} R_k < \varepsilon \,, \tag{7.131}$$

where $\operatorname{vol} R$ is the product of the edge lengths of R.

Rests on Definitions 3.65 and 7.93.

Lemma 7.107 (A countable union of null sets is null)**.** *If $E_1, E_2, \ldots$ are null subsets of $\mathbb{R}^N$ then so is $\bigcup_{j \geq 1} E_j$. In particular every countable subset of $\mathbb{R}^N$ is null, and the rational points $\mathbb{Q}^N$ are a null set.*

Rests on Definition 7.106 and Propositions 3.67 and 7.46.

Proof. *Derives Lemma 7.107.*

Let $\varepsilon > 0$. For each j choose, by Definition 7.106, a countable family of boxes covering E_j of total volume less than $\varepsilon 2^{-j}$. The union of these families is a countable family — a countable union of countable families is countable, by Proposition 3.67 — it covers $\bigcup_j E_j$, and its total volume is at most $\sum_{j \geq 1} \varepsilon 2^{-j} = \varepsilon$ by the geometric series (Proposition 7.46). A single point is null, being contained in a cube of arbitrarily small volume, so a countable set is a countable union of null sets and the first part applies; and $\mathbb{Q}^N$ is countable by Corollary 3.68 and Proposition 3.67. □

Definition 7.108 (Hausdorff measure)**.** The *diameter* of a non-empty $U \subseteq \mathbb{R}^N$ is $\operatorname{diam} U = \sup \{ |\boldsymbol{p} - \boldsymbol{q}| \mid \boldsymbol{p}, \boldsymbol{q} \in U \}$. For $E \subseteq \mathbb{R}^N$, $s \geq 0$ and $\delta > 0$ let

$$\mathcal{H}^s_\delta(E) = \inf \sum_{k \geq 1} (\operatorname{diam} U_k)^s \,, \tag{7.132}$$

the infimum taken over all countable families $\{U_k\}$ that cover E and satisfy $\operatorname{diam} U_k \leq \delta$, with the convention that an empty set of competitors gives $+\infty$. Fewer families compete as δ decreases, so $\mathcal{H}^s_\delta(E)$ does not decrease, and the *s-dimensional Hausdorff measure*

$$\mathcal{H}^s(E) = \lim_{\delta \longrightarrow 0^+} \mathcal{H}^s_\delta(E) = \sup_{\delta > 0} \mathcal{H}^s_\delta(E) \in [0, +\infty] \tag{7.133}$$

exists. The normalising constants that make $\mathcal{H}^N$ agree with the ordinary volume on $\mathbb{R}^N$ are omitted; nothing below needs them.

Rests on Definitions 6.24 and 7.106 and Axiom 7.1.

Proposition 7.109 (The critical exponent, and the Hausdorff dimension)**.** *For every $E \subseteq \mathbb{R}^N$ there is exactly one $d = \dim_{\mathrm{H}} E \in [0, N]$, called the* Hausdorff dimension *of E, with*

$$\mathcal{H}^s(E) = \begin{cases} +\infty\,, & 0 \le s < d\,, \\ 0\,, & s > d\,. \end{cases} \tag{7.134}$$

Moreover $\mathcal{H}^N(E) = 0$ implies that E is null in the sense of Definition 7.106; in particular every set of Hausdorff dimension smaller than N is null.

Rests on Definitions 7.106 and 7.108 and Lemma 7.107.

Proof. *Derives Proposition 7.109.*

One threshold. Let $0 \le s < t$ and suppose $\mathcal{H}^s(E) < \infty$. For any family covering E with diameters at most δ,

$$\sum_k (\operatorname{diam} U_k)^t \le \delta^{\,t-s} \sum_k (\operatorname{diam} U_k)^s\,, \tag{7.135}$$

so $\mathcal{H}^t_\delta(E) \le \delta^{\,t-s}\mathcal{H}^s_\delta(E) \le \delta^{\,t-s}\mathcal{H}^s(E)$, which tends to 0 as $\delta \longrightarrow 0^+$: hence $\mathcal{H}^t(E) = 0$ for every $t > s$. Consequently the set $Z = \{s \ge 0 \mid \mathcal{H}^s(E) = 0\}$ contains, with any of its points, every larger one, and contains every s at which $\mathcal{H}^s(E)$ is merely finite together with everything above it. Put $d = \inf Z$, which exists by Axiom 7.1 once Z is known to be non-empty — the next paragraph shows $(N, \infty) \subseteq Z$. If $s > d$ there is $t \in Z$ with $t < s$, so $\mathcal{H}^s(E) = 0$. If $s < d$ then $\mathcal{H}^s(E)$ cannot be finite: were it finite, every $t > s$ would lie in Z and $\inf Z$ would be at most $s < d$. So $\mathcal{H}^s(E) = +\infty$, which is Equation (7.134); and those two clauses determine d as $\inf Z$, so it is unique.

The bound $d \le N$. It is enough to show $\mathcal{H}^s(E) = 0$ for every $s > N$. First, $\mathcal{H}^s_\delta$ is countably subadditive — covers of the pieces concatenate into a cover of the union — so $\mathcal{H}^s_\delta\left(\bigcup_j E_j\right) \le \sum_j \mathcal{H}^s_\delta(E_j) \le \sum_j \mathcal{H}^s(E_j)$, and letting $\delta \longrightarrow 0^+$ shows $\mathcal{H}^s$ is countably subadditive too. Since $\mathbb{R}^N$ is the union of countably many unit lattice cubes, it is enough to treat E inside one such cube Q. Split Q into n^N closed subcubes of edge $1/n$, hence of diameter $\sqrt{N}/n$: they cover E, and

$$n^N \left(\frac{\sqrt{N}}{n}\right)^s = N^{s/2}\, n^{\,N-s} \longrightarrow 0 \qquad (n \longrightarrow \infty)$$

whenever $s > N$, while their diameters tend to 0. Hence $\mathcal{H}^s_\delta(E) = 0$ for every $\delta > 0$, so $\mathcal{H}^s(E) = 0$.

Null sets. Suppose $\mathcal{H}^N(E) = 0$ and let $\varepsilon > 0$. Choose a family $\{U_k\}$ covering E with $\sum_k (\operatorname{diam} U_k)^N < \varepsilon$. A set of diameter t has each of its N coordinate projections contained in an interval of length t, hence lies in a closed cube of edge t and volume t^N. Replacing each U_k by such a cube covers E by countably many boxes of total volume less than ε, which is Equation (7.131). If $\dim_{\mathrm{H}} E < N$ then $\mathcal{H}^N(E) = 0$ by Equation (7.134), so E is null. □

Definition 7.110 (Box-counting dimension)**.** For a bounded non-empty $E \subseteq \mathbb{R}^N$ let $N_\delta(E)$ be the least number of sets of diameter at most δ needed to cover E, a finite number because E is bounded. The *upper* and *lower box-counting dimensions* of E are

$$\overline{\dim}_{\mathrm{B}} E = \limsup_{\delta \longrightarrow 0^+} \frac{\ln N_\delta(E)}{\ln(1/\delta)}\,, \qquad \underline{\dim}_{\mathrm{B}} E = \liminf_{\delta \longrightarrow 0^+} \frac{\ln N_\delta(E)}{\ln(1/\delta)}\,, \tag{7.136}$$

and where the two agree their common value is the *box-counting dimension* $\dim_{\mathrm{B}} E$. It is this quantity, not the Hausdorff dimension, that a numerical box-count measures.

Rests on Definitions 6.9 and 7.108.

Proposition 7.111 (The Hausdorff dimension never exceeds the box dimension)**.** *For every bounded non-empty $E \subseteq \mathbb{R}^N$,*

$$\dim_{\mathrm{H}} E \le \underline{\dim}_{\mathrm{B}} E \le \overline{\dim}_{\mathrm{B}} E \,, \tag{7.137}$$

and the first inequality can be strict: the rationals of $[0,1]$ have Hausdorff dimension 0 and box-counting dimension 1.

Rests on Definition 7.110, Proposition 7.109, and Lemma 7.107.

Proof. *Derives Proposition 7.111.*

The second inequality is the definition of a lower and an upper limit. For the first, let $s > \underline{\dim}_{\mathrm{B}} E$ and pick s' with $\underline{\dim}_{\mathrm{B}} E < s' < s$. By Equation (7.136) there is a sequence $\delta_1 > \delta_2 > \cdots \longrightarrow 0$ along which $\ln N_{\delta_j}(E)/\ln(1/\delta_j) < s'$, that is $N_{\delta_j}(E) < \delta_j^{-s'}$. Covering E by that many sets of diameter at most δ_j,

$$\mathcal{H}^s_{\delta_j}(E) \le N_{\delta_j}(E)\, \delta_j^{\,s} < \delta_j^{\,s-s'} \longrightarrow 0 \,,$$

and since $\mathcal{H}^s(E)$ is the limit of $\mathcal{H}^s_\delta(E)$ along any sequence $\delta \longrightarrow 0^+$ (Equation (7.133)), it follows that $\mathcal{H}^s(E) = 0$ and hence $\dim_{\mathrm{H}} E \le s$ by Equation (7.134). Letting s decrease to $\underline{\dim}_{\mathrm{B}} E$ gives Equation (7.137).

For the example, let $E = \mathbb{Q} \cap [0,1]$. It is countable, so for $s > 0$ and $\varepsilon \in (0, \delta)$ covering its k-th point by an interval of length $\varepsilon 2^{-k}$ gives $\mathcal{H}^s_\delta(E) \le \varepsilon^s \sum_{k \ge 1} 2^{-ks} = \varepsilon^s/(2^s - 1)$, which tends to 0 with ε; hence $\mathcal{H}^s(E) = 0$ for every $s > 0$ and $\dim_{\mathrm{H}} E = 0$ (consistently with Lemma 7.107, which already makes E null). But any cover of E by sets of diameter at most δ may be replaced by the cover by their closures, of the same diameters, which then covers the closure $[0,1]$ of E; so $N_\delta(E) \ge 1/\delta$, and Equation (7.136) gives $\underline{\dim}_{\mathrm{B}} E \ge 1$, while $E \subseteq [0,1]$ forces $\overline{\dim}_{\mathrm{B}} E \le 1$. □

Remark 7.112 (What is developed here, and what is not). Exactly three notions are constructed above — the null set, the Hausdorff measures $\mathcal{H}^s$, and the two counting dimensions — and nothing else is assumed. The Lebesgue integral, the σ-algebra of measurable sets and the countable additivity of a measure defined on it are not built in this treatise, and no statement in it rests on them: where an argument needs "almost every point" it needs Definition 7.106 and Lemma 7.107, and where it needs a fractal dimension it needs Definition 7.108 or Definition 7.110. The integral used throughout remains the Darboux–Riemann integral of Definition 7.39 and Definition 7.93.

Rests on Definitions 7.106, 7.108 and 7.110.

7.13 Functional calculus

A *functional* assigns a number to a whole function, the archetype being the action integral $S[q] = \int_{t_1}^{t_2} \mathcal{L}(q(t), \dot q(t), t)\, \mathrm{d}t$ of Chapter 21. The *functional derivative* $\delta S/\delta q(t)$ is defined by the first-order response

$$S[q + \varepsilon\eta] - S[q] = \varepsilon \int \frac{\delta S}{\delta q(t)}\, \eta(t)\, \mathrm{d}t + O(\varepsilon^2) \tag{7.138}$$

for arbitrary smooth variations η vanishing at the endpoints. Its calculus — the Euler–Lagrange equation, constrained variations, second variations — is developed where it is first needed, in Chapter 21, with the general field-theoretic case in Chapter 64.

7.14 The Dirac delta

No function $\delta : \mathbb{R} \to \mathbb{R}$ satisfies $\int f(x)\,\delta(x)\,\mathrm{d}x = f(0)$ for all continuous f; the Dirac delta is instead a *distribution*: the linear functional $\delta : f \longmapsto f(0)$ on smooth test functions of compact support. The integral notation

$$\int_{-\infty}^{\infty} f(x)\,\delta(x - x_0)\,\mathrm{d}x = f(x_0) \tag{7.139}$$

is shorthand for its action, the *sifting property*, which is the definition rather than a theorem.

Proposition 7.113 (Delta as a limit; elementary properties)**.** *Let* $\delta_\sigma(x) = \dfrac{1}{\sigma\sqrt{2\pi}}\,\mathrm{e}^{-x^2/2\sigma^2}$. *Then for every bounded continuous* f*,*

$$\lim_{\sigma \to 0^+} \int_{-\infty}^{\infty} f(x)\,\delta_\sigma(x - x_0)\,\mathrm{d}x = f(x_0)\,, \tag{7.140}$$

and, as distributions, $\delta(ax) = \delta(x)/\,|a|$ *for* $a \neq 0$*, and* $x\,\delta(x) = 0$*.*
Rests on Equation (7.139)*, Corollary 7.44, and Definition 7.20.*

Proof. *Derives Proposition 7.113.*

Each δ_σ is positive with unit integral (the Gaussian integral; computed in Chapter 11), so

$$\left| \int f\,\delta_\sigma(x - x_0)\,\mathrm{d}x - f(x_0) \right| \leq \int |f(x) - f(x_0)|\;\delta_\sigma(x - x_0)\,\mathrm{d}x\,.$$

Split the domain at $|x - x_0| = \eta$: on the inner part continuity makes $|f - f(x_0)| < \varepsilon$ and the weight integrates to at most 1; on the outer part $|f - f(x_0)| \leq 2\sup|f|$ while the Gaussian tail mass tends to 0 as $\sigma \to 0$ for fixed η. Both contributions are eventually below ε. The scaling rule follows by substituting $u = ax$ in $\int f(x)\,\delta(ax)\,\mathrm{d}x$ (Corollary 7.44), which gives $f(0)/\,|a|$ (the sign of a flips the orientation, whence the absolute value); and $\int f(x)\,x\,\delta(x)\,\mathrm{d}x = 0 \cdot f(0) = 0$ for every test function, which is the meaning of $x\,\delta(x) = 0$. □

The three-dimensional delta $\delta^3(\boldsymbol{r}) = \delta(x)\delta(y)\delta(z)$ represents point sources; its central identity for field theory,

$$\nabla^2 \frac{1}{|\boldsymbol{r}|} = -4\pi\,\delta^3(\boldsymbol{r})\,, \tag{7.141}$$

is derived where it is used, in electrostatics (Chapter 58).

Chapter 8

Complex Analysis

Complex analysis is the calculus of functions differentiable in the complex sense — a condition so much stronger than real differentiability that it forces infinite smoothness, rigidity, and the exact integral formulas carrying the factor $2\pi\mathrm{i}$ on which physics relies: contour representations of Green functions (Chapter 10), dispersion relations, and the spectral calculus of operators (Chapter 12). Everything rests on the real analysis of Chapter 7, hence ultimately on the completeness of $\mathbb{R}$ (Appendix A.7).

8.1 The complex field

Definition 8.1 (Complex numbers)**.** $\mathbb{C}$ is the set $\mathbb{R}^2$ equipped with componentwise addition and the multiplication

$$(x_1, y_1)\,(x_2, y_2) = (x_1x_2 - y_1y_2,\; x_1y_2 + y_1x_2)\,. \tag{8.1}$$

Writing $z = x + \mathrm{i}y$ with $\mathrm{i} = (0,1)$, so that $\mathrm{i}^2 = -1$, the maps $z \mapsto \Re z = x$ and $z \mapsto \Im z = y$ extract the real and imaginary parts, $\bar z = x - \mathrm{i}y$ is the *conjugate*, and $|z| = \sqrt{x^2+y^2} = \sqrt{z\bar z}$ the *modulus*.

Proposition 8.2 ($\mathbb{C}$ is a field)**.** *$(\mathbb{C}, +, \cdot)$ is a field, with $z^{-1} = \bar z / |z|^2$ for $z \neq 0$; the modulus is multiplicative, $|zw| = |z|\,|w|$, and satisfies the triangle inequality $|z+w| \le |z| + |w|$.*
Rests on Equations (6.12) and (8.1).

Proof. *Derives Proposition 8.2.*
The field axioms are direct computations with Equation (8.1); associativity and distributivity reduce to real arithmetic, and $z\,\bar z/|z|^2 = |z|^2/|z|^2 = 1$ exhibits the inverse. Multiplicativity: $|zw|^2 = zw\,\overline{zw} = z\bar z\, w\bar w = |z|^2\,|w|^2$, using $\overline{zw} = \bar z\,\bar w$ (a computation). Triangle inequality: with the Euclidean identification this is the triangle inequality of $\mathbb{R}^2$ (Equation (6.12)); algebraically, $|z+w|^2 = |z|^2 + |w|^2 + 2\Re(z\bar w) \le |z|^2 + |w|^2 + 2\,|z|\,|w|$ since $\Re u \le |u|$. □

$\mathbb{C}$ inherits the metric $d(z,w) = |z-w|$ of the Euclidean plane, hence its topology (Chapter 6) and its completeness ($\mathbb{R}^2$ is complete, Section 6.3). Unlike $\mathbb{R}$, the field $\mathbb{C}$ carries no compatible order — $\mathrm{i}^2 = -1$ would violate the sign rules of an ordered field — and in exchange it will turn out to be algebraically closed (Theorem 8.19).

Definition 8.3 (Exponential, sine, cosine)**.** For $z \in \mathbb{C}$,

$$\exp z = \mathrm{e}^z = \sum_{n=0}^{\infty} \frac{z^n}{n!}\,, \qquad \cos z = \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n}}{(2n)!}\,, \qquad \sin z = \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{(2n+1)!}\,. \tag{8.2}$$

All three converge absolutely for every z by the ratio test (Proposition 7.48), so their radius of convergence is infinite (Theorem 7.50).
Rests on Proposition 7.48 and Theorem 7.50.

Proposition 8.4 (Euler's formula)**.** *For $\theta \in \mathbb{R}$,*

$$\mathrm{e}^{\mathrm{i}\theta} = \cos\theta + \mathrm{i}\sin\theta\,, \tag{8.3}$$

and every $z \neq 0$ has the polar form $z = |z|\,\mathrm{e}^{\mathrm{i}\arg z}$, with $\arg z$ defined modulo 2π.

Rests on Equation (8.2) and Proposition 7.47.

Proof. *Derives Proposition 8.4.*

Insert $z = \mathrm{i}\theta$ into Equation (8.2) and split even and odd powers, using $\mathrm{i}^{2n} = (-1)^n$ and $\mathrm{i}^{2n+1} = (-1)^n\mathrm{i}$: absolute convergence permits the rearrangement (Proposition 7.47), and the two sub-series are exactly $\cos\theta$ and $\mathrm{i}\sin\theta$. The polar form is plane trigonometry: $(x, y) = |z|\,(\cos\theta, \sin\theta)$ for the angle θ of the point. □

The number 2π enters complex analysis here, as the period of $\theta \mapsto \mathrm{e}^{\mathrm{i}\theta}$; every $2\pi\mathrm{i}$ in the theorems below descends from one full turn of this exponential.

8.2 Holomorphic functions

Definition 8.5 (Complex derivative)**.** Let $\Omega \subseteq \mathbb{C}$ be open and $f : \Omega \longrightarrow \mathbb{C}$. f is *complex differentiable* at z_0 iff

$$f'(z_0) = \lim_{h \longrightarrow 0} \frac{f(z_0 + h) - f(z_0)}{h} \tag{8.4}$$

exists, with $h \in \mathbb{C}$ approaching 0 from *every* direction of the plane. f is *holomorphic on* Ω iff it is complex differentiable at every point of Ω.

The rules of differentiation — linearity, Leibniz, chain, quotient — hold with the proofs of Section 7.6.3 verbatim, since those proofs used only field arithmetic and limits. Polynomials are holomorphic; so is e^z term by term inside its radius (Section 7.9), with $(\mathrm{e}^z)' = \mathrm{e}^z$.

Theorem 8.6 (Cauchy–Riemann equations)**.** *Write $f(x + \mathrm{i}y) = u(x, y) + \mathrm{i}v(x, y)$. If f is complex differentiable at $z_0 = x_0 + \mathrm{i}y_0$, then the partial derivatives exist there and satisfy*

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}\,, \qquad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}\,. \tag{8.5}$$

Conversely, if u, v are C^1 near z_0 and satisfy Equation (8.5) at z_0, then f is complex differentiable at z_0, with $f' = \partial_x u + \mathrm{i}\,\partial_x v$.

Rests on Equation (8.4) and Definition 7.66.

Proof. *Derives Theorem 8.6.*

Necessity. Take the limit Equation (8.4) first along real $h = t$: $f'(z_0) = \partial_x u + \mathrm{i}\,\partial_x v$. Then along imaginary $h = \mathrm{i}t$:

$$f'(z_0) = \lim_{t \to 0} \frac{f(z_0 + \mathrm{i}t) - f(z_0)}{\mathrm{i}t} = \frac{1}{\mathrm{i}}\left(\frac{\partial u}{\partial y} + \mathrm{i}\,\frac{\partial v}{\partial y}\right) = \frac{\partial v}{\partial y} - \mathrm{i}\,\frac{\partial u}{\partial y}\,.$$

Equating real and imaginary parts of the two expressions gives Equation (8.5).

Sufficiency. C^1 regularity makes (u, v) differentiable as a map $\mathbb{R}^2 \to \mathbb{R}^2$ (Definition 7.66), so

$$f(z_0 + h) - f(z_0) = (\partial_x u + \mathrm{i}\,\partial_x v)\,\eta + (\partial_y u + \mathrm{i}\,\partial_y v)\,\xi + o(|h|)\,,$$

with $h = \eta + \mathrm{i}\xi$. Substituting Equation (8.5) turns the second coefficient into $\mathrm{i}\,(\partial_x u + \mathrm{i}\,\partial_x v)$, so the two terms combine into $(\partial_x u + \mathrm{i}\,\partial_x v)\,(\eta + \mathrm{i}\xi) = (\partial_x u + \mathrm{i}\,\partial_x v)\,h$; dividing by h and letting $h \to 0$ kills the $o(|h|)/h$ remainder. □

Example 8.7. $f(z) = \bar{z}$ has $u = x$, $v = -y$, so $\partial_x u = 1 \neq -1 = \partial_y v$: nowhere complex differentiable, despite being real-smooth. Complex differentiability is a genuine constraint, not a notational variant — it demands that the Jacobian of (u, v) be a rotation-scaling, i.e. that f preserve angles where $f' \neq 0$.

Rests on Theorem 8.6.

8.3 Contour integrals

Definition 8.8 (Contour integral)**.** A *contour* γ is a piecewise-C^1 path $z : [a,b] \longrightarrow \mathbb{C}$. For continuous f,

$$\int_\gamma f(z)\,\mathrm{d}z = \int_a^b f(z(t))\,z'(t)\,\mathrm{d}t\,, \tag{8.6}$$

the right side being a pair of real integrals (Section 7.7). The integral is independent of the parametrization (substitution rule, Corollary 7.44) and changes sign under orientation reversal. A contour is *closed* iff $z(b) = z(a)$, written $\oint_\gamma$.

Rests on Corollary 7.44.

Lemma 8.9 (ML estimate)**.** *If $|f| \le M$ on γ and $L = \int_a^b |z'(t)|\,\mathrm{d}t$ is the length of γ, then $\left|\int_\gamma f\,\mathrm{d}z\right| \le ML$.*

Rests on Equation (8.6).

Proof. *Derives Lemma 8.9.*

Write $\int_\gamma f\,\mathrm{d}z = R\,\mathrm{e}^{\mathrm{i}\varphi}$ with $R \ge 0$. Then $R = \Re \int_a^b \mathrm{e}^{-\mathrm{i}\varphi} f(z(t))\,z'(t)\,\mathrm{d}t \le \int_a^b |f(z(t))|\,|z'(t)|\,\mathrm{d}t \le ML$, using $\Re u \le |u|$ and monotonicity of the real integral. □

Proposition 8.10 (Fundamental theorem for contours)**.** *If $f = F'$ for a holomorphic F on Ω and $\gamma \subset \Omega$ runs from z_1 to z_2, then $\int_\gamma f\,\mathrm{d}z = F(z_2) - F(z_1)$; in particular the integral of f over every closed contour vanishes.*

Rests on Equation (8.6) and Theorem 7.43.

Proof. *Derives Proposition 8.10.*

$\frac{\mathrm{d}}{\mathrm{d}t}F(z(t)) = F'(z(t))\,z'(t)$ by the chain rule, so Equation (8.6) is $\int_a^b \frac{\mathrm{d}}{\mathrm{d}t}F(z(t))\,\mathrm{d}t = F(z(b)) - F(z(a))$ by the fundamental theorem of calculus (Theorem 7.43), applied to real and imaginary parts. □

Lemma 8.11 (The fundamental $2\pi\mathrm{i}$)**.** *Let C_r be the circle $|z-a| = r$ traversed once counterclockwise. Then for $n \in \mathbb{Z}$,*

$$\oint_{C_r} (z-a)^n\,\mathrm{d}z = \begin{cases} 2\pi\mathrm{i}\,, & n = -1\,, \\ 0\,, & n \ne -1\,. \end{cases} \tag{8.7}$$

Rests on Equation (8.6) and Proposition 8.4.

Proof. *Derives Lemma 8.11.*

Parametrize $z = a + r\mathrm{e}^{\mathrm{i}\theta}$, $\theta \in [0, 2\pi]$, $\mathrm{d}z = \mathrm{i}r\mathrm{e}^{\mathrm{i}\theta}\mathrm{d}\theta$:

$$\oint_{C_r} (z-a)^n\,\mathrm{d}z = \mathrm{i}r^{\,n+1} \int_0^{2\pi} \mathrm{e}^{\mathrm{i}(n+1)\theta}\,\mathrm{d}\theta\,.$$

For $n \ne -1$ the integrand is the derivative of $\mathrm{e}^{\mathrm{i}(n+1)\theta}/(\mathrm{i}(n+1))$, periodic over $[0, 2\pi]$, so the integral vanishes; for $n = -1$ it is $\mathrm{i}\int_0^{2\pi} \mathrm{d}\theta = 2\pi\mathrm{i}$. □

Every $2\pi\mathrm{i}$ below is this lemma: one full turn of Euler's exponential, surviving only in the term $(z-a)^{-1}$ — precisely the power with no single-valued antiderivative.

8.4 Cauchy's integral theorem

Theorem 8.12 (Cauchy)**.** *Let f be holomorphic with continuous derivative on an open set containing a region D and its piecewise-C^1 boundary ∂D (counterclockwise). Then*

$$\oint_{\partial D} f(z)\,\mathrm{d}z = 0\,. \tag{8.8}$$

Rests on Theorem 7.99 and Equation (8.5).

Proof. *Derives Theorem 8.12.*

Separate real and imaginary parts with $f = u + \mathrm{i}v$ and $\mathrm{d}z = \mathrm{d}x + \mathrm{i}\,\mathrm{d}y$:

$$\oint_{\partial D} f\,\mathrm{d}z = \oint_{\partial D} (u\,\mathrm{d}x - v\,\mathrm{d}y) + \mathrm{i}\oint_{\partial D} (v\,\mathrm{d}x + u\,\mathrm{d}y)\ .$$

Green's theorem (Theorem 7.99) converts the two circulations to

$$\iint_D \left(-\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right)\mathrm{d}x\,\mathrm{d}y + \mathrm{i}\iint_D \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y}\right)\mathrm{d}x\,\mathrm{d}y\,,$$

and both integrands vanish identically by the Cauchy–Riemann equations Equation (8.5). □

Continuity of f' need not be assumed. Goursat's quadrisection argument reaches the same conclusion on a triangle from bare complex differentiability, and pays for the weaker hypothesis by giving up Green's theorem in favour of an estimate that shrinks the contour.

Theorem 8.13 (Goursat)**.** *Let $\Omega \subseteq \mathbb{C}$ be open and let f be complex differentiable at every point of Ω, with no assumption whatever on the continuity of f'. Then for every closed triangle $\Delta \subset \Omega$, with boundary $\partial\Delta$ traversed once,*

$$\oint_{\partial\Delta} f(z)\,\mathrm{d}z = 0\,. \tag{8.9}$$

Rests on Equation (8.4), Proposition 8.10, and Lemma 8.9.

Proof. *Derives Theorem 8.13.*

Write $I(\Delta) = \oint_{\partial\Delta} f\,\mathrm{d}z$ and let L and d be the perimeter and the diameter of Δ.

Quadrisection. Joining the midpoints of the three sides divides Δ into four closed triangles $\Delta^{(1)}, \dots, \Delta^{(4)}$, each similar to Δ with ratio $1/2$, hence of perimeter $L/2$ and diameter $d/2$. Traversing the four boundaries coherently, every interior edge is covered twice in opposite senses and cancels, so

$$I(\Delta) = \sum_{j=1}^{4} I(\Delta^{(j)})\,,$$

and at least one of the four obeys $\left|I(\Delta^{(j)})\right| \geq |I(\Delta)|\,/4$; call it Δ_1. Iterating the construction produces nested closed triangles $\Delta = \Delta_0 \supseteq \Delta_1 \supseteq \cdots$ with

$$|I(\Delta)| \leq 4^n\ |I(\Delta_n)|\,, \qquad L_n = 2^{-n}L\,, \qquad d_n = 2^{-n}d\,. \tag{8.10}$$

The limit point. Pick $z_n \in \Delta_n$. For $m \geq n$ both z_m and z_n lie in Δ_n, so $|z_m - z_n| \leq d_n \longrightarrow 0$ and the sequence is Cauchy; by completeness of $\mathbb{C}$ (Section 6.3) it converges to some z_0, which belongs to every Δ_n, each Δ_n being closed and containing all later terms. In particular $z_0 \in \Omega$.

The estimate. Complex differentiability at z_0 (Equation (8.4)) means that

$$f(z) = f(z_0) + f'(z_0)\,(z - z_0) + \eta(z)\,(z - z_0)\,, \tag{8.11}$$

with $\eta(z) \longrightarrow 0$ as $z \longrightarrow z_0$ and $\eta(z_0) = 0$. The affine part of Equation (8.11) is the derivative of the polynomial $f(z_0)\,z + \frac{1}{2}f'(z_0)\,(z - z_0)^2$, so its integral over the closed contour $\partial\Delta_n$ vanishes (Proposition 8.10), leaving

$$I(\Delta_n) = \oint_{\partial\Delta_n} \eta(z)\,(z - z_0)\,\mathrm{d}z\,.$$

Given $\varepsilon > 0$, choose $\rho > 0$ with $|\eta(z)| \le \varepsilon$ whenever $|z - z_0| < \rho$, and take n large enough that $d_n < \rho$. Since $z_0 \in \Delta_n$, every z on $\partial\Delta_n$ satisfies $|z - z_0| \le d_n$, so the integrand is bounded by $\varepsilon\, d_n$ and the ML estimate (Lemma 8.9) gives

$$|I(\Delta_n)| \le \varepsilon\, d_n\, L_n = \varepsilon\, d\, L\, 4^{-n}\,.$$

Combined with Equation (8.10) this yields $|I(\Delta)| \le \varepsilon\, d\, L$ for every $\varepsilon > 0$, whence $I(\Delta) = 0$. □

Remark 8.14 (Goursat). Theorem 8.13 removes the continuity hypothesis on f' from Theorem 8.12. The triangle suffices: in a convex domain the function $F(z) = \int_{z_*}^{z} f(w)\,\mathrm{d}w$, integrated along the straight segment from a fixed z_*, is well defined, and Equation (8.9) applied to the triangle $z_*, z, z+h$ gives $F(z+h) - F(z) = \int_z^{z+h} f(w)\,\mathrm{d}w$, whence $F' = f$ by continuity of f; Proposition 8.10 then returns Equation (8.8) for every closed contour in the domain, and a general region is handled by triangulation. Once the integral formula Equation (8.12) is available it shows that f' is automatically continuous — indeed infinitely differentiable (Theorem 8.17) — so the hypothesis discarded here was never a restriction, and the circle closes.

Corollary 8.15 (Deformation of contours)**.** *If f is holomorphic on a region containing two closed contours γ_1, γ_2 and the annular region between them, then $\oint_{\gamma_1} f\,\mathrm{d}z = \oint_{\gamma_2} f\,\mathrm{d}z$. In a simply connected domain (Definition 6.17), the integral of a holomorphic function over any closed contour vanishes.*

Rests on Theorem 8.12 and Definition 6.17.

Proof. *Derives Corollary 8.15.*

Join the two contours by a cut; the boundary of the cut annulus is $\gamma_1 - \gamma_2$ plus the cut traversed both ways, whose contributions cancel. Cauchy's theorem on the annulus gives $\oint_{\gamma_1} - \oint_{\gamma_2} = 0$. In a simply connected domain every closed contour bounds, and Theorem 8.12 applies directly. □

8.5 The Cauchy integral formula

Theorem 8.16 (Cauchy integral formula)**.** *Let f be holomorphic on an open set containing the disc $|z - a| \le r$ and its boundary circle C (counterclockwise). Then for every z_0 inside C,*

$$f(z_0) = \frac{1}{2\pi\mathrm{i}} \oint_C \frac{f(z)}{z - z_0}\,\mathrm{d}z\,. \tag{8.12}$$

Rests on Corollary 8.15 and Lemmas 8.9 and 8.11.

Proof. *Derives Theorem 8.16.*

The integrand is holomorphic between C and any small circle $C_\varepsilon : |z - z_0| = \varepsilon$, so by deformation (Corollary 8.15)

$$\oint_C \frac{f(z)}{z - z_0}\,\mathrm{d}z = \oint_{C_\varepsilon} \frac{f(z)}{z - z_0}\,\mathrm{d}z = f(z_0) \oint_{C_\varepsilon} \frac{\mathrm{d}z}{z - z_0} + \oint_{C_\varepsilon} \frac{f(z) - f(z_0)}{z - z_0}\,\mathrm{d}z\,.$$

The first integral is $2\pi\mathrm{i}$ by Lemma 8.11. In the second, continuity of f at z_0 bounds the integrand by $\varepsilon^{-1} \sup_{C_\varepsilon} |f - f(z_0)|$, so the ML estimate (Lemma 8.9) bounds the integral by $2\pi \sup_{C_\varepsilon} |f - f(z_0)| \longrightarrow 0$ as $\varepsilon \to 0$. Since the left side does not depend on ε, it equals $2\pi\mathrm{i} f(z_0)$. □

A holomorphic function is thus determined inside a circle by its boundary values — the first sign of the rigidity of holomorphy.

Theorem 8.17 (Derivatives of all orders; Cauchy estimates)**.** *Under the hypotheses of Theorem 8.16, f has complex derivatives of every order inside C, given by*

$$f^{(n)}(z_0) = \frac{n!}{2\pi\mathrm{i}} \oint_C \frac{f(z)}{(z-z_0)^{n+1}}\,\mathrm{d}z\,, \tag{8.13}$$

and if $|f| \le M$ on C and z_0 is its centre, $\left|f^{(n)}(z_0)\right| \le n!\,M/r^n$.

Rests on Theorem 8.16 and Lemma 8.9.

Proof. *Derives Theorem 8.17.*

For $n = 1$, form the difference quotient of Equation (8.12) at z_0 and $z_0 + h$:

$$\frac{f(z_0+h) - f(z_0)}{h} = \frac{1}{2\pi\mathrm{i}} \oint_C \frac{f(z)}{(z-z_0-h)(z-z_0)}\,\mathrm{d}z\,,$$

an algebraic identity of the two kernels. As $h \to 0$ the integrand converges uniformly on C to $f(z)/(z-z_0)^2$ (the denominators are bounded away from zero for z_0 interior and $|h|$ small), so the ML estimate carries the limit inside, giving Equation (8.13) with $n = 1$. Induction repeats the argument on each successive formula. The estimate follows from Lemma 8.9 with $|z - z_0| = r$ and $L = 2\pi r$. □

Theorem 8.18 (Liouville)**.** *A function holomorphic and bounded on all of $\mathbb{C}$ is constant.*

Rests on Theorem 8.17 and Proposition 8.10.

Proof. *Derives Theorem 8.18.*

If $|f| \le M$ everywhere, the Cauchy estimate with $n = 1$ on a circle of radius r about any z_0 gives $|f'(z_0)| \le M/r \longrightarrow 0$ as $r \to \infty$. So $f' \equiv 0$, and (integrating along any path, Proposition 8.10) f is constant. □

Theorem 8.19 (Fundamental theorem of algebra)**.** *Every non-constant polynomial p with complex coefficients has a root in $\mathbb{C}$.*

Rests on Theorem 8.18.

Proof. *Derives Theorem 8.19.*

If p had no root, $1/p$ would be holomorphic on $\mathbb{C}$ (quotient rule). For large $|z|$ the leading term dominates, $|p(z)| \ge \frac{1}{2}\,|c_n|\,|z|^n \longrightarrow \infty$, so $1/p \to 0$ at infinity and, being continuous on the (compact, Theorem 6.11) complement of the large-$|z|$ region, is bounded on $\mathbb{C}$. Liouville (Theorem 8.18) forces $1/p$ constant — contradicting non-constancy of p. Dividing out roots inductively, p factors completely: $\mathbb{C}$ is algebraically closed. □

Theorem 8.20 (Taylor expansion)**.** *A function holomorphic on the open disc $|z - a| < R$ equals its Taylor series there:*

$$f(z) = \sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!}\,(z-a)^n\,, \qquad |z-a| < R\,. \tag{8.14}$$

Rests on Equations (8.12) and (8.13), Proposition 7.46, and Lemma 8.9.

Proof. *Derives Theorem 8.20.*

Fix z with $|z - a| = \rho < r < R$ and integrate over $C : |w - a| = r$. Expand the Cauchy kernel geometrically (Proposition 7.46), uniformly on C since $|(z-a)/(w-a)| = \rho/r < 1$:

$$\frac{1}{w-z} = \frac{1}{(w-a)\left(1 - \frac{z-a}{w-a}\right)} = \sum_{n=0}^{\infty} \frac{(z-a)^n}{(w-a)^{n+1}}\,.$$

Insert into Equation (8.12) and exchange sum and integral (uniform convergence, ML estimate); the coefficient integrals are Equation (8.13) evaluated at a, giving Equation (8.14). □

Holomorphy and analyticity thus coincide on $\mathbb{C}$ — the deep justification for defining the elementary functions by their series in Definition 8.3.

8.6 Laurent series and singularities

Theorem 8.21 (Laurent expansion)**.** *Let f be holomorphic on the annulus $r < |z-a| < R$. Then, uniquely,*

$$f(z) = \sum_{n=-\infty}^{\infty} c_n (z-a)^n, \qquad c_n = \frac{1}{2\pi \mathrm{i}} \oint_C \frac{f(w)}{(w-a)^{n+1}} \, \mathrm{d}w, \tag{8.15}$$

with C any counterclockwise circle in the annulus.

Rests on Theorems 8.16 and 8.20, Corollary 8.15, and Lemma 8.11.

Proof. *Derives Theorem 8.21.*

For z in the annulus choose radii $r < r_1 < |z-a| < r_2 < R$. The cut-annulus argument of Corollary 8.15 applied to the Cauchy formula gives

$$f(z) = \frac{1}{2\pi \mathrm{i}} \oint_{|w-a|=r_2} \frac{f(w)}{w-z} \, \mathrm{d}w - \frac{1}{2\pi \mathrm{i}} \oint_{|w-a|=r_1} \frac{f(w)}{w-z} \, \mathrm{d}w .$$

On the outer circle expand the kernel as in Theorem 8.20 (powers $(z-a)^n$, $n \geq 0$); on the inner circle the roles reverse, $|(w-a)/(z-a)| < 1$, giving $-1/(w-z) = \sum_{m \geq 0} (w-a)^m/(z-a)^{m+1}$, i.e. the negative powers. Deforming both coefficient circles to the common C (Corollary 8.15) yields Equation (8.15). Uniqueness: integrating $\sum c_n (z-a)^n$ against $(z-a)^{-m-1}$ term by term over C kills every term except $n = m$ by Lemma 8.11, returning c_m. □

Definition 8.22 (Isolated singularities; residue)**.** If f is holomorphic on a punctured disc $0 < |z-a| < R$, the point a is an *isolated singularity*, classified by the Laurent series Equation (8.15) on the punctured disc:

- *removable* iff $c_n = 0$ for all $n < 0$ (then f extends holomorphically through a);
- a *pole of order m* iff $c_{-m} \neq 0$ and $c_n = 0$ for $n < -m$;
- *essential* iff infinitely many negative coefficients are nonzero.

The coefficient c_{-1} is the *residue* of f at a, written $\operatorname{Res}_{z=a} f$ — the sole survivor of termwise integration (Lemma 8.11).

Rests on Theorem 8.21 and Lemma 8.11.

Proposition 8.23 (Residue at a simple pole)**.** *If $f = g/h$ with g, h holomorphic at a, $g(a) \neq 0$, $h(a) = 0$, $h'(a) \neq 0$, then*

$$\operatorname{Res}_{z=a} \frac{g}{h} = \frac{g(a)}{h'(a)} . \tag{8.16}$$

Rests on Theorem 8.20 and Definition 8.22.

Proof. *Derives Proposition 8.23.*

$h(z) = h'(a)(z-a)\,[1 + O(z-a)]$ by its Taylor expansion (Theorem 8.20), so $f(z) = \dfrac{g(a)}{h'(a)} (z-a)^{-1} +$ (holomorphic part); the coefficient of $(z-a)^{-1}$ is read off. □

8.7 The residue theorem

Theorem 8.24 (Residue theorem)**.** *Let f be holomorphic on an open set containing a region D and its boundary ∂D (counterclockwise), except for finitely many isolated singularities $a_1, \ldots, a_k$ in the interior of D. Then*

$$\oint_{\partial D} f(z) \, \mathrm{d}z = 2\pi \mathrm{i} \sum_{j=1}^{k} \operatorname{Res}_{z=a_j} f . \tag{8.17}$$

Rests on Corollary 8.15, Theorem 8.21, Lemma 8.11, and Definition 8.22.

Proof. *Derives Theorem 8.24.*

Excise from D a small disc $|z-a_j|\le\varepsilon$ around each singularity. On the excised region f is holomorphic, so Cauchy's theorem in the cut-boundary form (Corollary 8.15) gives

$$\oint_{\partial D} f\,\mathrm{d}z=\sum_{j=1}^{k}\oint_{C_{\varepsilon,j}} f\,\mathrm{d}z\,,$$

with $C_{\varepsilon,j}$ the small circles, counterclockwise. On each, insert the Laurent series of f about a_j (Theorem 8.21), which converges uniformly on $C_{\varepsilon,j}$, and integrate term by term: by Lemma 8.11 every power dies except $(z-a_j)^{-1}$, which contributes $2\pi\mathrm{i}\,\operatorname{Res}_{z=a_j} f$. □

Example 8.25 (A real integral by residues)**.** For the archetype

$$\int_{-\infty}^{\infty}\frac{\mathrm{d}x}{1+x^2}=\pi\,,\tag{8.18}$$

close the contour with the upper semicircle S_R of radius R. The integrand $1/(1+z^2)$ has simple poles at $z=\pm\mathrm{i}$; only $z=\mathrm{i}$ lies inside, with residue $1/(2\mathrm{i})$ by Equation (8.16) (here $h'=2z$). The residue theorem gives $\oint=2\pi\mathrm{i}\cdot\frac{1}{2\mathrm{i}}=\pi$, while on S_R the ML estimate (Lemma 8.9) bounds the contribution by $\pi R/(R^2-1)\longrightarrow 0$. The real line's share is therefore π — in agreement with the elementary antiderivative arctan, but obtained by a method that survives when no elementary antiderivative exists. This closing of contours is the engine behind the Green-function and propagator computations of Chapter 10 and Part XI.

Rests on Theorem 8.24, Equation (8.16), and Lemma 8.9.

With the residue theorem the chapter's arc is complete: one full turn of Euler's exponential (Lemma 8.11) has become an exact bookkeeping device relating global contour data to local expansion coefficients. The deeper function theory — analytic continuation, the argument principle, conformal mapping — is developed where physics first demands it.

Chapter 9

Ordinary Differential Equations and Sturm–Liouville Theory

The linear boundary-value problems of physics — the vibrating string, the temperature of a bar, the electrostatic potential inside a cavity, the stationary states of a quantum particle — all reduce, once the partial differential equation is separated into ordinary ones (Chapter 10), to a single template: a linear second-order ordinary differential equation containing an eigenvalue parameter and a weight function. This is the Sturm–Liouville problem. Its power lies in what all its instances share: the solutions belonging to distinct eigenvalues are orthogonal with respect to the weight, and the full solution set is a basis in which arbitrary admissible functions can be expanded. The present chapter sets up the language of orthonormal function systems, defines the Sturm–Liouville operator, derives the semiclassical approximation that serves every potential for which no closed-form solution exists, and then works through the classical families — Helmholtz (Fourier), Bessel and its modified companion, Legendre and its associated equation with the spherical harmonics, Hermite, Laguerre and Mathieu — recording for each the identification of the Sturm–Liouville data, the solutions, and the orthogonality relations given in the source.

Around that core sit the parts of the general theory of ordinary differential equations that the physical parts of this treatise consume constantly and that no other chapter owns: existence, uniqueness and continuous dependence; the elementary first-order equations solvable by an integrating factor or by separation; linear systems with constant coefficients, the matrix exponential, and the reading of stability off the eigenvalues; Floquet's theorem for periodic coefficients, which is what makes parametric resonance a statement rather than an estimate; and the elliptic integrals and Jacobi elliptic functions, which are what a conservative system with one degree of freedom reduces to when the small-amplitude approximation is dropped.

9.1 Ordinary differential equations

An *ordinary differential equation* (ODE) relates a function of a single real variable to its derivatives; every equation treated in this chapter is an ODE that is linear and of second order. The source outline opens the subject with a section of general definitions — order, linearity, homogeneity, the structure of solution spaces — but that section contains only its heading, so the present section supplies it. None of what follows is special to the Sturm–Liouville problem. It is what entitles every closed form recorded later in this chapter to be called *the* general solution rather than merely *a* pair of solutions: a linear homogeneous equation of order n has a solution set of dimension exactly n, so two solutions of a second-order equation with non-vanishing Wronskian already exhaust it.

9.1.1 Order, linearity, homogeneity

Definition 9.1 (Ordinary differential equation)**.** Let $I \subseteq \mathbb{R}$ be an open interval. An *ordinary differential equation of order* n on I is a relation

$$F\left(x,\ y(x),\ \frac{\mathrm{d}y}{\mathrm{d}x}(x),\ \ldots,\ \frac{\mathrm{d}^n y}{\mathrm{d}x^n}(x)\right) = 0 \tag{9.1}$$

between a function y of the single variable $x \in I$ and its derivatives up to the n-th, the n-th being present. A *solution* is a function y, n times differentiable on I, satisfying Equation (9.1) at every point of I.

Definition 9.2 (Linear equation; homogeneity)**.** Equation (9.1) is *linear* when it can be written

$$L[y] = b\,, \qquad L[y](x) = \sum_{i=0}^{n} a_i(x)\,\frac{\mathrm{d}^i y}{\mathrm{d}x^i}(x)\,, \tag{9.2}$$

with the coefficients $a_0, \ldots, a_n$ and the inhomogeneity b continuous on I and a_n nowhere zero there. It is *homogeneous* when b vanishes identically. The map L is linear: $L[\alpha u + \beta v] = \alpha L[u] + \beta L[v]$ for all real constants α, β.

Rests on Definition 9.1.

Remark 9.3 (Normal form and first-order systems). Dividing Equation (9.2) by a_n — legitimate because a_n does not vanish — solves the equation for its highest derivative. Any equation so solved, linear or not, becomes a first-order system for the vector $\boldsymbol{Y} = (y, y', \ldots, y^{(n-1)})$ of the function and its first $n-1$ derivatives,

$$\frac{\mathrm{d}\boldsymbol{Y}}{\mathrm{d}x} = \boldsymbol{f}\big(x, \boldsymbol{Y}(x)\big)\,, \qquad \boldsymbol{f} = \big(Y_2,\ Y_3,\ \ldots,\ Y_n,\ f(x, Y_1, \ldots, Y_n)\big)\,, \tag{9.3}$$

where $y^{(n)} = f\big(x, y, y', \ldots, y^{(n-1)}\big)$ is the equation in normal form. Solutions of the system and of the scalar equation correspond one to one, so every statement below is made for Equation (9.3) and read back for the scalar equation.

9.1.2 Existence and uniqueness

Definition 9.4 (Lipschitz condition)**.** Let $R = \{(x, \boldsymbol{Y}) : |x - x_0| \le a\,,\ \|\boldsymbol{Y} - \boldsymbol{Y}_0\| \le b\}$. A map $\boldsymbol{f} : R \longrightarrow \mathbb{R}^n$ is *Lipschitz in its second argument*, with constant L, if

$$\|\boldsymbol{f}(x, \boldsymbol{U}) - \boldsymbol{f}(x, \boldsymbol{V})\| \le L\,\|\boldsymbol{U} - \boldsymbol{V}\| \tag{9.4}$$

for every $(x, \boldsymbol{U})$ and $(x, \boldsymbol{V})$ in R.

Remark 9.5 (Continuity is not enough). A continuously differentiable $\boldsymbol{f}$ satisfies Equation (9.4) on the compact box R, with L the maximum there of the norm of its derivative with respect to $\boldsymbol{Y}$, by the mean value theorem Theorem 7.35. Mere continuity does not suffice for uniqueness: $\mathrm{d}y/\mathrm{d}x = 3\,y^{2/3}$ with $y(0) = 0$ is solved both by $y \equiv 0$ and by $y = x^3$, and $3y^{2/3}$ is continuous everywhere but Lipschitz nowhere near $y = 0$.

Lemma 9.6 (Weierstrass M-test; uniform limits are continuous)**.** *Let $S \subseteq \mathbb{R}$ and let $\boldsymbol{u}_j : S \longrightarrow \mathbb{R}^n$, $j \ge 0$, satisfy $\|\boldsymbol{u}_j(x)\| \le M_j$ for every $x \in S$, with $\sum_{j\ge 0} M_j$ convergent. Then $\sum_{j\ge 0} \boldsymbol{u}_j(x)$ converges absolutely at every $x \in S$, and its partial sums converge to the sum $\boldsymbol{U}$* uniformly on S*: for every $\varepsilon > 0$ there is an N, depending on ε alone and not on x, such that*

$$\left\| \boldsymbol{U}(x) - \sum_{j=0}^{k} \boldsymbol{u}_j(x) \right\| < \varepsilon \qquad \text{for all } k \ge N \text{ and all } x \in S\,. \tag{9.5}$$

If in addition every $\boldsymbol{u}_j$ is continuous on S, then so is $\boldsymbol{U}$.

Rests on Proposition 7.47 and Definition 7.20.

Derivation. *Derives Lemma 9.6.*

Fix $x \in S$. Each component obeys $\left|u_j^i(x)\right| \le \|\boldsymbol{u}_j(x)\| \le M_j$, so $\sum_j \left|u_j^i(x)\right|$ converges by comparison with $\sum_j M_j$ and the component series converges, both by Proposition 7.47. Call the limit $\boldsymbol{U}(x)$.

For the uniformity, subtract the k-th partial sum: for $k \ge N$,

$$\left\| \boldsymbol{U}(x) - \sum_{j=0}^{k} \boldsymbol{u}_j(x) \right\| = \left\| \sum_{j>k} \boldsymbol{u}_j(x) \right\| \le \sum_{j>k} M_j \le \sum_{j>N} M_j \,,$$

and the right-hand side is the tail of a convergent series of numbers, hence below any prescribed ε once N is large enough. It contains no x, which is exactly Equation (9.5).

Suppose now every $\boldsymbol{u}_j$ is continuous and fix $x_0 \in S$ and $\varepsilon > 0$. Choose N with $\sum_{j>N} M_j < \varepsilon/3$ and write $\boldsymbol{S}_N = \sum_{j=0}^{N} \boldsymbol{u}_j$, a finite sum of continuous maps and therefore continuous (Definition 7.20): there is a $\delta > 0$ with $\|\boldsymbol{S}_N(x) - \boldsymbol{S}_N(x_0)\| < \varepsilon/3$ for every $x \in S$ with $|x - x_0| < \delta$. For such an x,

$$\|\boldsymbol{U}(x) - \boldsymbol{U}(x_0)\| \le \|\boldsymbol{U}(x) - \boldsymbol{S}_N(x)\| + \|\boldsymbol{S}_N(x) - \boldsymbol{S}_N(x_0)\| + \|\boldsymbol{S}_N(x_0) - \boldsymbol{U}(x_0)\| < \varepsilon \,,$$

the outer two terms being bounded by $\sum_{j>N} M_j$ by the estimate just proved. Hence $\boldsymbol{U}$ is continuous at x_0. □

Remark 9.7 (Why the numerical comparison test is not enough). Proposition 7.47 is a statement about series of *numbers*: it decides convergence at each fixed x separately and says nothing about how fast. What Lemma 9.6 adds is the single N that serves every x at once, and it is that uniformity — not the pointwise convergence — which carries continuity across to the limit and licenses the exchange of a limit with an integral. Both halves are stated and proved here because Theorem 9.8 needs them in exactly this form; the same two facts are what the Fourier arguments of Chapter 17 invoke under the name of the M-test.

Theorem 9.8 (Picard–Lindelöf)**.** *Let $\boldsymbol{f}$ be continuous on the box R of Definition 9.4, bounded there by $\|\boldsymbol{f}\| \le M$, and Lipschitz in its second argument with constant L. Then the initial value problem*

$$\frac{\mathrm{d}\boldsymbol{Y}}{\mathrm{d}x} = \boldsymbol{f}(x, \boldsymbol{Y}(x)) \,, \qquad \boldsymbol{Y}(x_0) = \boldsymbol{Y}_0 \,, \tag{9.6}$$

has exactly one solution on $|x - x_0| \le h$, where $h = \min\{a,\ b/M\}$.

Rests on Definition 9.4, Equation (9.3), and Lemma 9.6.

Derivation. *Derives Theorem 9.8.*

A continuous $\boldsymbol{Y}$ solves Equation (9.6) if and only if it solves the integral equation

$$\boldsymbol{Y}(x) = \boldsymbol{Y}_0 + \int_{x_0}^{x} \boldsymbol{f}(s, \boldsymbol{Y}(s))\, \mathrm{d}s \,, \tag{9.7}$$

by the fundamental theorem of calculus (Theorems 7.42 and 7.43): differentiating Equation (9.7) returns Equation (9.6) and evaluating it at x_0 returns the initial value, while integrating Equation (9.6) from x_0 to x returns Equation (9.7).

Define the *Picard iterates* by $\boldsymbol{Y}_0(x) = \boldsymbol{Y}_0$ and

$$\boldsymbol{Y}_{k+1}(x) = \boldsymbol{Y}_0 + \int_{x_0}^{x} \boldsymbol{f}(s, \boldsymbol{Y}_k(s))\, \mathrm{d}s \,. \tag{9.8}$$

Every iterate stays inside the box on $|x - x_0| \le h$: if $\|\boldsymbol{Y}_k(s) - \boldsymbol{Y}_0\| \le b$ there, the integrand of Equation (9.8) is defined and bounded by M, so $\|\boldsymbol{Y}_{k+1}(x) - \boldsymbol{Y}_0\| \le M\,|x - x_0| \le Mh \le b$; and the hypothesis holds trivially for $k = 0$.

The successive differences obey

$$\|\boldsymbol{Y}_{k+1}(x)-\boldsymbol{Y}_k(x)\| \le \frac{M\,L^k\,|x-x_0|^{k+1}}{(k+1)!}\,, \qquad |x-x_0|\le h\,. \tag{9.9}$$

For $k=0$ this is the bound just used. Assuming it at $k-1$ and applying Equation (9.4),

$$\begin{aligned}\|\boldsymbol{Y}_{k+1}(x)-\boldsymbol{Y}_k(x)\| &\le \left|\int_{x_0}^{x} \|\boldsymbol{f}(s,\boldsymbol{Y}_k(s))-\boldsymbol{f}(s,\boldsymbol{Y}_{k-1}(s))\|\,\mathrm{d}s\right| \\ &\le L\left|\int_{x_0}^{x} \|\boldsymbol{Y}_k(s)-\boldsymbol{Y}_{k-1}(s)\|\,\mathrm{d}s\right| \le L\left|\int_{x_0}^{x} \frac{M\,L^{k-1}\,|s-x_0|^{k}}{k!}\,\mathrm{d}s\right| \\ &= \frac{M\,L^k\,|x-x_0|^{k+1}}{(k+1)!}\,,\end{aligned}$$

which is Equation (9.9).

Write $\boldsymbol{Y}_k=\boldsymbol{Y}_0+\sum_{j=0}^{k-1}(\boldsymbol{Y}_{j+1}-\boldsymbol{Y}_j)$. By Equation (9.9) the terms of that series are bounded in supremum norm on $|x-x_0|\le h$ by $ML^jh^{j+1}/(j+1)!$, whose sum is $M(\mathrm{e}^{Lh}-1)/L$, a finite number; these are the constants M_j of Lemma 9.6, so the series converges absolutely and uniformly on $|x-x_0|\le h$. Its sum $\boldsymbol{Y}$ is therefore continuous, by the last clause of the same lemma, and obeys $\|\boldsymbol{Y}-\boldsymbol{Y}_0\|\le b$. Passing to the limit under the integral sign in Equation (9.8) is legitimate because Equation (9.4) gives $\|\boldsymbol{f}(s,\boldsymbol{Y}_k)-\boldsymbol{f}(s,\boldsymbol{Y})\|\le L\,\|\boldsymbol{Y}_k-\boldsymbol{Y}\|$, which tends to zero uniformly by Equation (9.5), while the error committed on the integral is at most h times that supremum. Hence $\boldsymbol{Y}$ solves Equation (9.7).

For uniqueness let $\boldsymbol{Y}$ and $\tilde{\boldsymbol{Y}}$ both solve Equation (9.7) on $|x-x_0|\le h$ and put $\delta=\sup\left\|\boldsymbol{Y}-\tilde{\boldsymbol{Y}}\right\|$, finite because both stay in the box. Subtracting the two integral equations and using Equation (9.4) gives $\left\|\boldsymbol{Y}(x)-\tilde{\boldsymbol{Y}}(x)\right\|\le L\,\delta\,|x-x_0|$; feeding that bound back into the same inequality gives $L^2\delta\,|x-x_0|^2/2$, and after k rounds

$$\left\|\boldsymbol{Y}(x)-\tilde{\boldsymbol{Y}}(x)\right\| \le \frac{\delta\,(Lh)^k}{k!}\,,$$

which tends to zero as $k\to\infty$ because the exponential series Equation (7.31) converges. Hence $\delta=0$. □

Corollary 9.9 (Linear equations: existence on the whole interval)**.** *Let A be a continuous matrix-valued function and $\boldsymbol{g}$ a continuous vector-valued function on a compact interval J containing x_0. Then $\mathrm{d}\boldsymbol{Y}/\mathrm{d}x=A(x)\,\boldsymbol{Y}+\boldsymbol{g}(x)$ with $\boldsymbol{Y}(x_0)=\boldsymbol{Y}_0$ has exactly one solution, and it is defined on the whole of J. In particular the scalar linear equation Equation (9.2) has exactly one solution on I for each choice of the initial data $y(x_0)$, $y'(x_0)$, …, $y^{(n-1)}(x_0)$.*

Rests on Theorem 9.8, Remark 9.3, and Definition 9.2.

Derivation. Derives Corollary 9.9.

Here $\boldsymbol{f}(x,\boldsymbol{Y})=A(x)\boldsymbol{Y}+\boldsymbol{g}(x)$ is defined for every $\boldsymbol{Y}$, so the box of Definition 9.4 may be taken to be $J\times\mathbb{R}^n$ and Equation (9.4) holds globally with $L=\max_J\|A\|$, the maximum existing because J is compact and A continuous (Theorem 7.24). The construction in the proof of Theorem 9.8 then runs on all of J without the restriction $h\le b/M$, which was needed only to keep the iterates inside a bounded box: the estimate Equation (9.9) holds on J with $M=\max_J\|\boldsymbol{f}(\cdot,\boldsymbol{Y}_0)\|$, and the comparison series is again the exponential one. Uniqueness is unchanged. The scalar statement follows through Equation (9.3), whose coefficients $-a_i/a_n$ and inhomogeneity b/a_n are continuous precisely because a_n does not vanish. □

Theorem 9.8 says that the solution through a point exists and is unique. It says nothing about how two solutions through *nearby* points separate, and that quantitative question is the one every stability argument asks. The answer is a single inequality, and it is worth isolating because it is used far more often than it is named.

Lemma 9.10 (Grönwall's inequality)**.** *Let u be continuous and non-negative on $[x_0, x_1]$ and suppose that*

$$u(x) \le \alpha + \beta \int_{x_0}^{x} u(s)\,\mathrm{d}s \qquad \text{for every } x \in [x_0, x_1]\,, \tag{9.10}$$

with constants $\alpha \ge 0$ and $\beta > 0$. Then

$$u(x) \le \alpha\, \mathrm{e}^{\beta\,(x - x_0)} \qquad \text{for every } x \in [x_0, x_1]\,. \tag{9.11}$$

Rests on Theorem 7.42 and Corollary 7.36.

Derivation. *Derives Lemma 9.10.*

Write $U(x) = \alpha + \beta \int_{x_0}^{x} u(s)\,\mathrm{d}s$. Since u is continuous, U is differentiable with $U' = \beta u$ (Theorem 7.42), and $U(x_0) = \alpha$. The hypothesis Equation (9.10) is exactly $u \le U$, so $U' = \beta u \le \beta U$ and

$$\frac{\mathrm{d}}{\mathrm{d}x}\Big[\mathrm{e}^{-\beta(x-x_0)}\,U(x)\Big] = \mathrm{e}^{-\beta(x-x_0)}\big[U'(x) - \beta\,U(x)\big] \le 0\,.$$

A function whose derivative is nowhere positive does not increase (Corollary 7.36), so $\mathrm{e}^{-\beta(x-x_0)}U(x) \le U(x_0) = \alpha$ throughout, and $u(x) \le U(x) \le \alpha\,\mathrm{e}^{\beta(x-x_0)}$. □

Proposition 9.11 (Continuous dependence on the initial data)**.** *Let $\boldsymbol{f}$ satisfy the hypotheses of Theorem 9.8, with Lipschitz constant L, and let $\boldsymbol{Y}$ and $\tilde{\boldsymbol{Y}}$ solve $\mathrm{d}\boldsymbol{Y}/\mathrm{d}x = \boldsymbol{f}(x, \boldsymbol{Y})$ on $[x_0, x_1]$ with initial values $\boldsymbol{Y}_0$ and $\tilde{\boldsymbol{Y}}_0$, both trajectories remaining in the box R. Then*

$$\big\|\boldsymbol{Y}(x) - \tilde{\boldsymbol{Y}}(x)\big\| \le \big\|\boldsymbol{Y}_0 - \tilde{\boldsymbol{Y}}_0\big\|\ \mathrm{e}^{L\,(x-x_0)}\,, \qquad x \in [x_0, x_1]\,. \tag{9.12}$$

In particular the value of the solution at x depends continuously on its initial value, and two solutions that agree at one point agree throughout.

Rests on Theorem 9.8, Lemma 9.10, and Equation (9.4).

Derivation. *Derives Proposition 9.11.*

Both solutions satisfy the integral equation Equation (9.7) with their own initial values. Subtracting and using Equation (9.4),

$$\big\|\boldsymbol{Y}(x) - \tilde{\boldsymbol{Y}}(x)\big\| \le \big\|\boldsymbol{Y}_0 - \tilde{\boldsymbol{Y}}_0\big\| + L \int_{x_0}^{x} \big\|\boldsymbol{Y}(s) - \tilde{\boldsymbol{Y}}(s)\big\|\,\mathrm{d}s\,.$$

This is Equation (9.10) for the continuous non-negative function $u = \big\|\boldsymbol{Y} - \tilde{\boldsymbol{Y}}\big\|$ with $\alpha = \big\|\boldsymbol{Y}_0 - \tilde{\boldsymbol{Y}}_0\big\|$ and $\beta = L$, so Lemma 9.10 gives Equation (9.12). Taking $\alpha = 0$ recovers the uniqueness half of Theorem 9.8. □

Remark 9.12 (What the exponential in the bound is, and is not). Equation (9.12) is an upper bound and nothing more. It licenses the statement that neighbouring solutions cannot separate faster than e^{Lx} — which is what makes a numerical trajectory meaningful over a finite time, and what turns a linearised decay estimate into a genuine statement about the nonlinear flow in Proposition 9.31. It does *not* assert that any pair of solutions actually separates at that rate. A system in which some pairs do separate exponentially, and in which the rate is a property of the flow rather than of a Lipschitz constant, is a different subject altogether; the exponents that measure it are defined in Chapter 32, and Grönwall's inequality is the tool that shows the linear estimate there survives the neglected quadratic terms.

9.1.3 The solution space and the Wronskian

Theorem 9.13 (Dimension of the solution space)**.** *The solutions on I of the homogeneous linear equation $L[y] = 0$ of Equation (9.2) form a real vector space of dimension exactly n. The solutions of the inhomogeneous equation $L[y] = b$ form the affine set $y_p + \ker L$, with y_p any one solution of it.*

Rests on Definition 9.2 and Corollary 9.9.

Derivation. *Derives Theorem 9.13.*

Linearity of L makes $\ker L$ a vector space and makes the difference of two solutions of $L[y] = b$ a solution of $L[y] = 0$, which is the second statement. Fix $x_0 \in I$ and consider the evaluation map

$$E : \ker L \longrightarrow \mathbb{R}^n , \qquad E(y) = \big(y(x_0),\, y'(x_0),\, \ldots,\, y^{(n-1)}(x_0)\big) ,$$

which is linear. It is surjective because Corollary 9.9 produces a solution for every prescribed initial vector, and injective because that solution is unique: a y in $\ker L$ with $E(y) = \mathbf{0}$ agrees with the zero solution. An isomorphism onto $\mathbb{R}^n$ forces $\dim \ker L = n$. □

Definition 9.14 (Wronskian)**.** The *Wronskian* of n functions $y_1, \ldots, y_n$, each $n-1$ times differentiable on I, is the determinant

$$W(x) = \det \begin{pmatrix} y_1 & y_2 & \cdots & y_n \\ y_1' & y_2' & \cdots & y_n' \\ \vdots & \vdots & & \vdots \\ y_1^{(n-1)} & y_2^{(n-1)} & \cdots & y_n^{(n-1)} \end{pmatrix} (x) . \tag{9.13}$$

Proposition 9.15 (Abel's identity)**.** *If $y_1, \ldots, y_n$ all solve $L[y] = 0$, their Wronskian satisfies*

$$\frac{\mathrm{d}W}{\mathrm{d}x}(x) = -\frac{a_{n-1}(x)}{a_n(x)}\, W(x) , \qquad W(x) = W(x_0)\, \exp\left[-\int_{x_0}^{x} \frac{a_{n-1}(s)}{a_n(s)}\, \mathrm{d}s \right] . \tag{9.14}$$

In particular W either vanishes identically on I or vanishes nowhere.

Rests on Definitions 9.2 and 9.14.

Derivation. *Derives Proposition 9.15.*

A determinant is multilinear in its rows, so $\mathrm{d}W/\mathrm{d}x$ is a sum of n determinants, the i-th obtained by differentiating the i-th row of Equation (9.13). For $i < n$ the differentiated row becomes equal to the row below it, so that determinant has two equal rows and vanishes. Only the last term survives, and in it the bottom row is $(y_1^{(n)}, \ldots, y_n^{(n)})$. Each solution obeys $y_j^{(n)} = -\sum_{i<n} (a_i/a_n)\, y_j^{(i)}$, so that row is a linear combination of the rows of Equation (9.13); subtracting the multiples of the rows carrying $y^{(i)}$ for $i \le n-2$, which changes no determinant, leaves $-a_{n-1}/a_n$ times the row $(y_1^{(n-1)}, \ldots, y_n^{(n-1)})$, that is $-(a_{n-1}/a_n)\, W$. The resulting first-order linear equation integrates to the stated exponential, and an exponential never vanishes, so $W(x)$ and $W(x_0)$ vanish together. □

Proposition 9.16 (Wronskian test for independence)**.** *Let $y_1, \ldots, y_n$ solve $L[y] = 0$ on I. They are linearly independent if and only if $W(x) \neq 0$ at one — equivalently at every — point of I, and in that case every solution of $L[y] = 0$ is a unique linear combination of them.*

Rests on Theorem 9.13 and Proposition 9.15.

Derivation. *Derives Proposition 9.16.*

If $\sum_j c_j y_j$ vanishes identically with the c_j not all zero, differentiating $n-1$ times shows that the columns of Equation (9.13) are linearly dependent at every x, so W vanishes

identically. Conversely, if $W(x_0) = 0$ there is a non-zero vector $\boldsymbol{c}$ annihilating the columns at x_0, and $y = \sum_j c_j y_j$ is then a solution with $E(y) = \mathbf{0}$ in the notation of the proof of Theorem 9.13; by uniqueness y vanishes identically, so the y_j are dependent. Proposition 9.15 makes "at one point" and "at every point" the same statement. Finally n independent solutions inside an n-dimensional space (Theorem 9.13) are a basis of it. □

Remark 9.17 (What this buys the rest of the chapter). Every equation treated below is linear, homogeneous and of second order, so its solution space is two-dimensional and exhibiting two solutions with non-vanishing Wronskian settles the general solution completely. That is the status of Equation (9.107), Equation (9.126), Equation (9.147) and Equation (9.158). The Sturm–Liouville equation Equation (9.55) is in normal form wherever p does not vanish; the endpoints at which p *does* vanish — $x = 0$ for Bessel, $x = \pm 1$ for Legendre and its associated equation — are exactly the singular points at which Corollary 9.9 does not apply, and they are also the points at which one of the two solutions ceases to be bounded.

9.1.4 Elementary first-order equations

Two first-order equations can be integrated outright, and between them they cover almost every first-order equation the physical parts of this treatise meet: a decay law, the charging of a capacitor, a relaxation towards equilibrium, a body falling against linear or quadratic drag. Theorem 9.8 already guarantees that each has exactly one solution; what follows produces that solution in closed form, so a later chapter can quote a formula instead of exhibiting an answer and verifying it.

Proposition 9.18 (The linear equation: integrating factor)**.** *Let p and q be continuous on an interval I and let $x_0 \in I$. Put $P(x) = \int_{x_0}^{x} p(s)\,\mathrm{d}s$. Then the solutions on I of*

$$\frac{\mathrm{d}y}{\mathrm{d}x}(x) + p(x)\,y(x) = q(x) \tag{9.15}$$

are exactly the functions

$$y(x) = \mathrm{e}^{-P(x)}\left[\,C + \int_{x_0}^{x} q(s)\,\mathrm{e}^{P(s)}\,\mathrm{d}s\right], \qquad C \in \mathbb{R}\,, \tag{9.16}$$

one for each constant $C = y(x_0)$. The factor e^{P}, which turns the left-hand side of Equation (9.15) into an exact derivative, is the integrating factor.

Rests on Corollary 9.9 and Theorems 7.42 and 7.43.

Derivation. *Derives Proposition 9.18.*

P is differentiable with $P' = p$ (Theorem 7.42), so for any differentiable y,

$$\frac{\mathrm{d}}{\mathrm{d}x}\Big[\mathrm{e}^{P(x)}y(x)\Big] = \mathrm{e}^{P(x)}\left[\frac{\mathrm{d}y}{\mathrm{d}x}(x) + p(x)\,y(x)\right], \tag{9.17}$$

and e^{P} never vanishes. Hence y solves Equation (9.15) if and only if $(\mathrm{e}^{P}y)' = q\,\mathrm{e}^{P}$, which by Theorem 7.43 holds if and only if $\mathrm{e}^{P(x)}y(x) - \mathrm{e}^{P(x_0)}y(x_0) = \int_{x_0}^{x} q\,\mathrm{e}^{P}$; since $P(x_0) = 0$ this is Equation (9.16) with $C = y(x_0)$. Every C occurs and no solution is missed, because Corollary 9.9 gives exactly one solution on I for each initial value. □

Proposition 9.19 (Separation of variables)**.** *Let g be continuous on an interval I and h continuous and nowhere zero on an interval J, let $x_0 \in I$ and let y_0 be an interior point of J. Then, near x_0, the initial-value problem*

$$\frac{\mathrm{d}y}{\mathrm{d}x}(x) = g(x)\,h(y(x))\,, \qquad y(x_0) = y_0\,, \tag{9.18}$$

has exactly one solution with values in J, and it is obtained by inverting the quadrature

$$\int_{y_0}^{y} \frac{\mathrm{d}v}{h(v)} = \int_{x_0}^{x} g(s)\,\mathrm{d}s\,. \tag{9.19}$$

For the autonomous equation $\mathrm{d}y/\mathrm{d}x = F(y)$ with F continuous and non-vanishing this reads $x - x_0 = \int_{y_0}^{y} \mathrm{d}v/F(v)$: the independent variable is recovered from the dependent one by a single integral, and inverting that integral is the whole of the solution.

Rests on Proposition 7.32, Theorem 7.42, and Corollary 7.36.

Derivation. Derives Proposition 9.19.

Set $H(y) = \int_{y_0}^{y} \mathrm{d}v/h(v)$ on J and $G(x) = \int_{x_0}^{x} g(s)\,\mathrm{d}s$ on I; both are differentiable, with $H' = 1/h$ and $G' = g$ (Theorem 7.42). Since h is continuous and nowhere zero on the interval J it has one sign there (Theorem 7.23), so H' has one sign and H is strictly monotone (Corollary 7.36); it therefore maps J bijectively onto an interval $H(J)$ containing $0 = H(y_0)$, and its inverse is differentiable with $(H^{-1})' = 1/H' \circ H^{-1} = h \circ H^{-1}$ (Proposition 7.32).

Let $I_0 \subseteq I$ be a neighbourhood of x_0 on which $G(x) \in H(J)$; such a neighbourhood exists because G is continuous and $G(x_0) = H(y_0) = 0$ is an interior point of $H(J)$, H being a strictly monotone continuous map and y_0 interior to J. On I_0 define $y = H^{-1} \circ G$. It takes the value $H^{-1}(0) = y_0$ at x_0, and by the chain rule (Proposition 7.31)

$$\frac{\mathrm{d}y}{\mathrm{d}x}(x) = \big(H^{-1}\big)'\big(G(x)\big)\,G'(x) = h\big(y(x)\big)\,g(x)\,,$$

so it solves Equation (9.18). Conversely, if y is any solution with values in J, then $\mathrm{d}\big[H(y(x)) - G(x)\big]/\mathrm{d}x = y'/h(y) - g = 0$, so $H(y(x)) - G(x)$ is constant (Corollary 7.36) and equal to its value 0 at x_0; that is Equation (9.19), and H being injective determines y uniquely. □

Remark 9.20 (Where the hypotheses bite). Both hypotheses on h are doing work. If h vanishes at y_* then $y \equiv y_*$ is a constant solution, the integral $\int \mathrm{d}v/h$ diverges there or ceases to be defined, and uniqueness may fail — Remark 9.5 is exactly this situation with $h(y) = 3y^{2/3}$. Physically the zeros of h are the equilibria, and the divergence of the quadrature at one of them is the statement that the equilibrium is reached only asymptotically: a body falling against drag approaches its terminal speed and never attains it, and the integral $\int^{v_t} \mathrm{d}v/(1 - v/v_t)$ diverging is that fact in one line.

9.2 Linear systems with constant coefficients

The theory so far is scalar. A great deal of physics is not: Euler's equations for a rotating body, a chain of coupled oscillators, a chemical or nuclear decay chain and every linearisation of a nonlinear flow are first-order systems $\mathrm{d}\boldsymbol{Y}/\mathrm{d}x = A\boldsymbol{Y}$ with A a constant matrix. Corollary 9.9 already says such a system has exactly one solution for each initial vector; this section produces that solution, describes the shape of every solution, and reads the stability of the equilibrium $\boldsymbol{Y} = \boldsymbol{0}$ off the eigenvalues of A. Nothing here is deeper than the series for the exponential and the residue theorem of Chapter 8, but the conclusions are what every stability argument in the physical parts appeals to.

9.2.1 The matrix exponential

Definition 9.21 (Matrix exponential)**.** Let A be an $n \times n$ matrix with real or complex entries and let $\|\cdot\|$ be the matrix norm induced by a norm on the underlying vector space (Definition 5.18),

$$\|A\| = \sup_{\|\boldsymbol{v}\|=1} \|A\boldsymbol{v}\|\,, \qquad \text{so that} \qquad \|A\boldsymbol{v}\| \le \|A\|\,\|\boldsymbol{v}\| \quad \text{and} \quad \|AB\| \le \|A\|\,\|B\|\,. \tag{9.20}$$

The *matrix exponential* is

$$\mathrm{e}^{A} = \sum_{k=0}^{\infty} \frac{A^k}{k!}\,, \qquad A^0 = \mathbb{1}\,. \tag{9.21}$$

Rests on Definition 5.18 and Proposition 5.121.

Proposition 9.22 (The exponential and its derivative)**.** *The series Equation (9.21) converges absolutely for every A, and uniformly in x on every bounded interval when A is replaced by xA. The map $x \mapsto \mathrm{e}^{xA}$ is differentiable with*

$$\frac{\mathrm{d}}{\mathrm{d}x}\,\mathrm{e}^{xA} = A\,\mathrm{e}^{xA} = \mathrm{e}^{xA}A\,, \qquad \mathrm{e}^{0\cdot A} = \mathbb{1}\,, \tag{9.22}$$

and $\mathrm{e}^{(x+y)A} = \mathrm{e}^{xA}\mathrm{e}^{yA}$; in particular e^{xA} is invertible, with inverse e^{-xA}. If $AB = BA$ then $\mathrm{e}^{A+B} = \mathrm{e}^{A}\mathrm{e}^{B}$.

Rests on Definition 9.21, Lemma 9.6, and Theorem 7.51.

Derivation. Derives Proposition 9.22.

Submultiplicativity gives $\left\|x^k A^k/k!\right\| \le |x|^k \,\|A\|^k/k! \le R^k \,\|A\|^k/k!$ on $|x| \le R$, and those bounds sum to $\mathrm{e}^{R\|A\|}$; by Lemma 9.6 the series converges absolutely and uniformly there, entry by entry. Each entry is a power series in x with infinite radius of convergence, so it may be differentiated term by term (Theorem 7.51), and $\sum_{k\ge1} k x^{k-1}A^k/k! = A\sum_{k\ge0} x^k A^k/k!$, the factor A coming out on either side since it commutes with its own powers. That is Equation (9.22).

For the addition law with $AB = BA$, expand the Cauchy product of the two absolutely convergent series (Proposition 7.49) and collect the terms of total degree m: $\sum_{j+k=m} A^j B^k/(j!\,k!) = (A+B)^m/m!$, the binomial theorem being available precisely because A and B commute. Taking $B = yA$, which commutes with A, gives $\mathrm{e}^{(x+y)A} = \mathrm{e}^{xA}\mathrm{e}^{yA}$, and $y = -x$ identifies the inverse. □

Theorem 9.23 (Solution of a constant-coefficient system)**.** *Let A be a constant $n \times n$ matrix. The initial-value problem*

$$\frac{\mathrm{d}\boldsymbol{Y}}{\mathrm{d}x}(x) = A\,\boldsymbol{Y}(x)\,, \qquad \boldsymbol{Y}(x_0) = \boldsymbol{Y}_0\,, \tag{9.23}$$

has exactly one solution, defined for every $x \in \mathbb{R}$, namely

$$\boldsymbol{Y}(x) = \mathrm{e}^{(x-x_0)A}\,\boldsymbol{Y}_0\,. \tag{9.24}$$

The inhomogeneous system $\boldsymbol{Y}' = A\boldsymbol{Y} + \boldsymbol{g}(x)$ with $\boldsymbol{g}$ continuous has the unique solution

$$\boldsymbol{Y}(x) = \mathrm{e}^{(x-x_0)A}\boldsymbol{Y}_0 + \int_{x_0}^{x} \mathrm{e}^{(x-s)A}\,\boldsymbol{g}(s)\,\mathrm{d}s\,. \tag{9.25}$$

Rests on Proposition 9.22 and Corollary 9.9.

Derivation. Derives Theorem 9.23.

Equation (9.22) makes Equation (9.24) a solution with the right initial value, and Corollary 9.9 says there is no other and that it lives on the whole line. For the inhomogeneous system, multiply by the integrating factor $\mathrm{e}^{-(x-x_0)A}$ — the matrix analogue of Equation (9.17), legitimate because e^{-xA} commutes with A — to get $\left(\mathrm{e}^{-(x-x_0)A}\boldsymbol{Y}\right)' = \mathrm{e}^{-(x-x_0)A}\boldsymbol{g}$, and integrate (Theorem 7.43). Multiplying back by $\mathrm{e}^{(x-x_0)A}$ and using the addition law gives Equation (9.25). □

Remark 9.24 (The same exponential, seen twice). Equation (9.22) says that $x \mapsto \mathrm{e}^{xA}$ is a one-parameter group of invertible matrices with generator A. Proposition 14.3 proves the converse — every differentiable one-parameter group of linear maps is the exponential of its generator — and is the entry point to the Lie theory of Chapter 14. The two statements are the same computation read in opposite directions, and it is worth seeing that the flow of a linear autonomous system and the exponential map of a matrix group are not two constructions but one.

9.2.2 The shape of the solutions

The exponential is a closed form but not yet an answer: one still wants to know what the solutions *look like*. They are combinations of $x^k \mathrm{e}^{\lambda x}$, and the eigenvalues of A supply the λ. The diagonalizable case is immediate; the general case is proved below without any appeal to a normal form for A, by reading the exponential off the resolvent with the residue theorem.

Corollary 9.25 (Normal modes of a diagonalizable system)**.** *Suppose A has n linearly independent eigenvectors $\boldsymbol{v}_1, \dots, \boldsymbol{v}_n$ with eigenvalues $\lambda_1, \dots, \lambda_n$. Then every solution of Equation (9.23) is*

$$\boldsymbol{Y}(x) = \sum_{r=1}^{n} c_r \, \mathrm{e}^{\lambda_r (x - x_0)} \, \boldsymbol{v}_r \,, \tag{9.26}$$

the constants c_r being the components of $\boldsymbol{Y}_0$ in the eigenbasis. If A is real and $\lambda = \alpha + \mathrm{i}\beta$ is a non-real eigenvalue with eigenvector $\boldsymbol{v} = \boldsymbol{a} + \mathrm{i}\boldsymbol{b}$, then $\bar{\lambda}$ is an eigenvalue with eigenvector $\bar{\boldsymbol{v}}$, and the two real solutions carried by the pair are

$$\mathrm{e}^{\alpha x}\big[\boldsymbol{a}\cos\beta x - \boldsymbol{b}\sin\beta x\big] \,, \qquad \mathrm{e}^{\alpha x}\big[\boldsymbol{a}\sin\beta x + \boldsymbol{b}\cos\beta x\big] \,. \tag{9.27}$$

Rests on Theorem 9.23 and Definitions 5.14 and 5.65.

Derivation. *Derives Corollary 9.25.*

For an eigenvector, $A^k \boldsymbol{v}_r = \lambda_r^k \boldsymbol{v}_r$, so term-by-term application of Equation (9.21) gives $\mathrm{e}^{xA}\boldsymbol{v}_r = \mathrm{e}^{\lambda_r x}\boldsymbol{v}_r$. Expanding $\boldsymbol{Y}_0 = \sum_r c_r \boldsymbol{v}_r$ in the eigenbasis — a basis by hypothesis — and applying Equation (9.24) gives Equation (9.26). For the real form, conjugating $A\boldsymbol{v} = \lambda\boldsymbol{v}$ with A real gives $A\bar{\boldsymbol{v}} = \bar{\lambda}\bar{\boldsymbol{v}}$; the real and imaginary parts of the complex solution $\mathrm{e}^{\lambda x}\boldsymbol{v}$ are then themselves solutions, because A is real and the equation is linear, and expanding $\mathrm{e}^{(\alpha+\mathrm{i}\beta)x}(\boldsymbol{a}+\mathrm{i}\boldsymbol{b})$ with Euler's formula (Proposition 8.4) exhibits them as Equation (9.27). □

Theorem 9.26 (Structure of the solutions)**.** *Let A be an $n \times n$ complex matrix, let $\lambda_1, \dots, \lambda_p$ be the distinct roots of its characteristic polynomial $\chi(\lambda) = \det(\lambda\mathbb{1} - A)$, and let m_j be the multiplicity of λ_j as a root. Then every entry of e^{xA} has the form*

$$\sum_{j=1}^{p} \pi_j(x)\, \mathrm{e}^{\lambda_j x} \,, \qquad \deg \pi_j \le m_j - 1 \,, \tag{9.28}$$

and the same is true of every component of every solution of Equation (9.23). Every entry of the N-th power A^N likewise has the form $\sum_j \varpi_j(N)\, \lambda_j^N$ with $\deg \varpi_j \le m_j - 1$.

Rests on Theorems 5.67, 8.24 and 9.23.

Derivation. *Derives Theorem 9.26.*

The resolvent. For $|\lambda| > \|A\|$ the series $\sum_{k\ge 0} A^k \lambda^{-k-1}$ converges absolutely and uniformly, by Lemma 9.6 with $M_k = \|A\|^k\, |\lambda|^{-k-1}$ and the geometric series Proposition 7.46; multiplying it by $\lambda\mathbb{1} - A$ telescopes to $\mathbb{1}$, so its sum is the resolvent

$$R(\lambda) = (\lambda\mathbb{1} - A)^{-1} = \sum_{k=0}^{\infty} \frac{A^k}{\lambda^{k+1}} \,, \qquad |\lambda| > \|A\| \,. \tag{9.29}$$

Solving $(\lambda \mathbb{1} - A)\boldsymbol{X} = \boldsymbol{e}_j$ by Cramer's rule Equation (5.16) expresses the (i,j) entry of $R(\lambda)$ as a quotient $D_{ij}(\lambda)/\chi(\lambda)$ in which D_{ij} is the determinant of a matrix whose entries are affine in λ, hence a polynomial of degree at most $n-1$. So each entry of R is a rational function of λ whose poles lie among the roots of χ, that of λ_j being of order at most m_j.

The contour integral. Let Γ be the positively oriented circle $|\lambda| = \rho$ with $\rho > \|A\|$, so that Equation (9.29) holds on Γ and every root of χ lies inside (an eigenvalue λ_j has $|\lambda_j| \le \|A\|$, since an eigenvector would otherwise be lengthened by A beyond the bound its norm allows). Multiplying Equation (9.29) by $\mathrm{e}^{\lambda x}$, which is bounded on Γ, preserves the uniform convergence, so the integral may be taken term by term; and $(2\pi\mathrm{i})^{-1}\oint_\Gamma \mathrm{e}^{\lambda x}\lambda^{-k-1}\mathrm{d}\lambda = x^k/k!$, the k-th Taylor coefficient of $\mathrm{e}^{\lambda x}$ at $\lambda = 0$ (Theorem 8.17). Summing,

$$\mathrm{e}^{xA} = \frac{1}{2\pi\mathrm{i}} \oint_\Gamma \mathrm{e}^{\lambda x}\, R(\lambda)\, \mathrm{d}\lambda\,. \tag{9.30}$$

The residues. By the residue theorem Theorem 8.24 the right-hand side of Equation (9.30) is the sum over j of the residues of $\mathrm{e}^{\lambda x}R(\lambda)$ at λ_j. Near λ_j the entry $(\lambda-\lambda_j)^{m_j}R_{ik}(\lambda)$ is holomorphic and has a Taylor expansion $\sum_{l\ge 0} c_l(\lambda-\lambda_j)^l$ (Theorem 8.20), while $\mathrm{e}^{\lambda x} = \mathrm{e}^{\lambda_j x}\sum_{i\ge 0} x^i(\lambda-\lambda_j)^i/i!$. The residue is the coefficient of $(\lambda-\lambda_j)^{-1}$ in the product (Theorem 8.21 and Definition 8.22), that is

$$\mathrm{e}^{\lambda_j x}\sum_{i=0}^{m_j-1} c_{m_j-1-i}\,\frac{x^i}{i!}\,,$$

a polynomial in x of degree at most m_j-1 times $\mathrm{e}^{\lambda_j x}$. Summing over j gives Equation (9.28), and Equation (9.24) carries it to every solution. Replacing $\mathrm{e}^{\lambda x}$ throughout by λ^N — also holomorphic, with $(2\pi\mathrm{i})^{-1}\oint \lambda^{N-k-1}\mathrm{d}\lambda = \delta_{kN}$ — gives A^N in place of e^{xA} and the stated form of its entries. □

Corollary 9.27 (Linear stability)**.** *Write $\sigma(A) = \max_j \Re\lambda_j$. For every $\sigma > \sigma(A)$ there is a constant C with*

$$\left\|\mathrm{e}^{xA}\right\| \le C\,\mathrm{e}^{\sigma x}\,, \qquad x \ge 0\,. \tag{9.31}$$

Consequently every solution of Equation (9.23) tends to $\mathbf{0}$ as $x \to +\infty$ if and only if every eigenvalue of A has strictly negative real part, and some solution is unbounded if some eigenvalue has strictly positive real part. If in addition A has n independent eigenvectors, every solution stays bounded on $x \ge 0$ whenever no eigenvalue has positive real part. Similarly $A^N \to 0$ as $N \to \infty$ if and only if every eigenvalue satisfies $|\lambda_j| < 1$, and the powers A^N stay bounded whenever every $|\lambda_j| \le 1$ and A has n independent eigenvectors.

Rests on Theorem 9.26 and Corollary 9.25.

Derivation. Derives Corollary 9.27.

By Equation (9.28) each entry of e^{xA} is a finite sum of terms $x^k\mathrm{e}^{\lambda_j x}$, whose modulus is $x^k\mathrm{e}^{x\Re\lambda_j}$. For $\sigma > \sigma(A)$ the quotient $x^k\mathrm{e}^{x\Re\lambda_j}/\mathrm{e}^{\sigma x} = x^k\mathrm{e}^{-(\sigma-\Re\lambda_j)x}$ tends to zero as $x \to +\infty$ and is continuous on $[0,\infty)$, hence bounded there; summing the finitely many bounds gives Equation (9.31). If every $\Re\lambda_j < 0$, choose $\sigma < 0$ and every solution decays exponentially. Conversely an eigenvector for λ furnishes the solution $\mathrm{e}^{\lambda x}\boldsymbol{v}$ of Corollary 9.25, whose norm is $\mathrm{e}^{x\Re\lambda}\,\|\boldsymbol{v}\|$: it does not tend to zero when $\Re\lambda \ge 0$ and is unbounded when $\Re\lambda > 0$. When A has an eigenbasis, Equation (9.26) writes every solution as a fixed combination of the $\mathrm{e}^{\lambda_r x}\boldsymbol{v}_r$, each of norm $\mathrm{e}^{x\Re\lambda_r}\,\|\boldsymbol{v}_r\| \le \|\boldsymbol{v}_r\|$ for $x \ge 0$ when $\Re\lambda_r \le 0$; the triangle inequality bounds the sum. The statements about A^N are the same two arguments on the second half of Theorem 9.26, with $|\lambda_j|^N$ in place of $\mathrm{e}^{x\Re\lambda_j}$ and, in the diagonalizable case, with $A^N\boldsymbol{v}_r = \lambda_r^N\boldsymbol{v}_r$. □

Proposition 9.28 (The scalar constant-coefficient equation)**.** *Let $a_0, \dots, a_n$ be constants with $a_n \neq 0$, let*

$$P(\lambda) = \sum_{i=0}^{n} a_i \lambda^i \tag{9.32}$$

be the characteristic polynomial *of $L[y] = \sum_i a_i \,\mathrm{d}^i y/\mathrm{d}x^i$, and let $\lambda_1, \dots, \lambda_p$ be its distinct roots, with multiplicities $m_1, \dots, m_p$. Then the n functions*

$$x^{\kappa}\, \mathrm{e}^{\lambda_j x}, \qquad 1 \leq j \leq p, \quad 0 \leq \kappa \leq m_j - 1, \tag{9.33}$$

are a basis of the solution space of $L[y] = 0$. In particular, for $n = 2$ the general solution is $c_1 \mathrm{e}^{\lambda_1 x} + c_2 \mathrm{e}^{\lambda_2 x}$ when the two roots differ and $(c_1 + c_2 x)\mathrm{e}^{\lambda x}$ when they coincide; and if the a_i are real and the roots are $\alpha \pm \mathrm{i}\beta$ with $\beta \neq 0$, the real solutions are spanned by $\mathrm{e}^{\alpha x}\cos \beta x$ and $\mathrm{e}^{\alpha x}\sin \beta x$.

Rests on Theorems 8.19 and 9.13 and Proposition 7.30.

Derivation. Derives Proposition 9.28.

Write D for $\mathrm{d}/\mathrm{d}x$. Polynomials in D with constant coefficients multiply exactly as polynomials in λ do, because D commutes with itself and with constants, so the factorization $P(\lambda) = a_n \prod_j (\lambda - \lambda_j)^{m_j}$ furnished by the fundamental theorem of algebra (Theorem 8.19) gives the operator identity $L = a_n \prod_j (D - \lambda_j)^{m_j}$, in which the factors may be applied in any order.

A single factor acts on the proposed solutions by

$$(D - \lambda)\big[x^{\kappa}\mathrm{e}^{\lambda x}\big] = \kappa\, x^{\kappa - 1}\mathrm{e}^{\lambda x}$$

(Proposition 7.30), so $(D - \lambda)^m$ annihilates $x^{\kappa}\mathrm{e}^{\lambda x}$ for every $\kappa \leq m - 1$. Applying the factors of L in an order that puts $(D - \lambda_j)^{m_j}$ last shows every function Equation (9.33) solves $L[y] = 0$.

They are independent. Suppose $\sum_j p_j(x)\mathrm{e}^{\lambda_j x}$ vanishes identically, with p_j polynomials; we show every p_j is zero, by induction on the number p of distinct exponents. For $p = 1$, an exponential never vanishes, so p_1 has infinitely many roots and is the zero polynomial. For $p > 1$, multiply by $\mathrm{e}^{-\lambda_p x}$ and differentiate $\deg p_p + 1$ times. The last term dies; each other term $p_j \mathrm{e}^{\mu_j x}$, with $\mu_j = \lambda_j - \lambda_p \neq 0$, becomes $q_j \mathrm{e}^{\mu_j x}$ with $\deg q_j = \deg p_j$, since each differentiation multiplies the leading coefficient by $\mu_j \neq 0$. The inductive hypothesis makes every q_j, hence every p_j with $j < p$, zero; and then p_p is zero by the case $p = 1$.

There are $\sum_j m_j = n$ of them, and the solution space has dimension n (Theorem 9.13), so they are a basis. The real form of a conjugate pair is obtained as in Corollary 9.25, by taking the real and imaginary parts of $\mathrm{e}^{(\alpha + \mathrm{i}\beta)x}$ (Proposition 8.4); they are independent because their Wronskian is $\beta\, \mathrm{e}^{2\alpha x} \neq 0$ (Proposition 9.16). □

9.2.3 Planar systems: classification of the equilibrium

Proposition 9.29 (The planar classification)**.** *Let A be a real 2×2 matrix with $\tau = \operatorname{tr} A$, $\Delta = \det A$ and discriminant $D = \tau^2 - 4\Delta$, so that the eigenvalues are*

$$\lambda_{\pm} = \tfrac{1}{2}\big(\tau \pm \sqrt{D}\big)\,. \tag{9.34}$$

The origin, the only equilibrium of $\boldsymbol{Y}' = A\boldsymbol{Y}$ when $\Delta \neq 0$, is classified by (τ, Δ) exactly as in Table 9.1. In particular it is asymptotically stable if and only if $\tau < 0$ and $\Delta > 0$, and unstable whenever $\Delta < 0$ or $\tau > 0$.

Rests on Corollaries 9.25 and 9.27.

Derivation. Derives Proposition 9.29.

The characteristic polynomial of a 2×2 matrix is $\lambda^2 - \tau\lambda + \Delta$ (Theorem 5.67), whose roots are Equation (9.34); they multiply to Δ and add to τ. If $D > 0$ the roots are real

and distinct: they have opposite signs when $\Delta < 0$ (a saddle, one growing and one decaying direction) and the common sign of τ when $\Delta > 0$ (a node). If $D < 0$ they are a conjugate pair $\tau/2 \pm \mathrm{i}\beta$ with $\beta = \sqrt{-D}/2 \neq 0$, and Equation (9.27) shows every solution to be a rotation of period $2\pi/\beta$ scaled by $\mathrm{e}^{\tau x/2}$: a focus spiralling in for $\tau < 0$ and out for $\tau > 0$, and for $\tau = 0$ a centre, every orbit of which is closed and periodic. If $D = 0$ the eigenvalue $\tau/2$ is double and Equation (9.28) permits a factor of x, present exactly when A is not a multiple of the identity: a degenerate node, or a star node when it is. The stability statements are Corollary 9.27 read through $\Re\lambda_{\pm}$, both of which are negative precisely when their sum τ is negative and their product Δ positive. □

Table 9.1: Classification of the equilibrium of a planar linear system $\boldsymbol{Y}' = A\boldsymbol{Y}$ by $\tau = \operatorname{tr} A$, $\Delta = \det A$ and $D = \tau^2 - 4\Delta$, as proved in Proposition 9.29. The parabola $D = 0$ separates the nodes from the foci and the axis $\Delta = 0$ from the saddles; the half-line $\tau = 0$, $\Delta > 0$ carries the centres.

Condition	Eigenvalues	Equilibrium
$\Delta < 0$	real, opposite signs	saddle (unstable)
$\Delta > 0$, $D > 0$, $\tau < 0$	real, both negative	stable node
$\Delta > 0$, $D > 0$, $\tau > 0$	real, both positive	unstable node
$\Delta > 0$, $D < 0$, $\tau < 0$	complex, $\Re < 0$	stable focus
$\Delta > 0$, $D < 0$, $\tau > 0$	complex, $\Re > 0$	unstable focus
$\Delta > 0$, $\tau = 0$	purely imaginary	centre
$\Delta > 0$, $D = 0$	real, equal	degenerate or star node
$\Delta = 0$	one eigenvalue zero	a line of equilibria

9.2.4 Equilibria of a nonlinear system

A nonlinear autonomous system $\mathrm{d}\boldsymbol{Y}/\mathrm{d}x = \boldsymbol{F}(\boldsymbol{Y})$ with $\boldsymbol{F}(\boldsymbol{Y}_*) = \boldsymbol{0}$ is approximated near its equilibrium by the linear system carried by the derivative matrix $A = D\boldsymbol{F}(\boldsymbol{Y}_*)$. Two questions follow, and they have different answers. Whether the *stability* of the equilibrium is decided by A is settled below, and affirmatively when no eigenvalue sits on the imaginary axis. Whether the whole *phase portrait* is decided by A is a deeper statement, and is the one theorem of this chapter that is quoted rather than proved.

Definition 9.30 (Hyperbolic equilibrium)**.** An equilibrium $\boldsymbol{Y}_*$ of $\mathrm{d}\boldsymbol{Y}/\mathrm{d}x = \boldsymbol{F}(\boldsymbol{Y})$, $\boldsymbol{F}$ of class C^1, is *hyperbolic* when no eigenvalue of $A = D\boldsymbol{F}(\boldsymbol{Y}_*)$ has zero real part.

Rests on Definitions 5.65 and 7.66.

Proposition 9.31 (Lyapunov's first method: asymptotic stability)**.** *Let $\boldsymbol{F}$ be of class C^1 near an equilibrium $\boldsymbol{Y}_*$ and suppose every eigenvalue of $A = D\boldsymbol{F}(\boldsymbol{Y}_*)$ has $\Re\lambda < 0$. Then $\boldsymbol{Y}_*$ is asymptotically stable: there are $\varepsilon > 0$, $C > 0$ and $\mu > 0$ such that every solution starting within ε of $\boldsymbol{Y}_*$ satisfies*

$$\|\boldsymbol{Y}(x) - \boldsymbol{Y}_*\| \leq C\,\mathrm{e}^{-\mu x}\,\|\boldsymbol{Y}(0) - \boldsymbol{Y}_*\|\,, \qquad x \geq 0\,. \tag{9.35}$$

Rests on Corollary 9.27, Lemma 9.10, and Theorem 9.23.

Derivation. *Derives Proposition 9.31.*

Put $\boldsymbol{Z} = \boldsymbol{Y} - \boldsymbol{Y}_*$ and $\boldsymbol{N}(\boldsymbol{Z}) = \boldsymbol{F}(\boldsymbol{Y}_* + \boldsymbol{Z}) - A\boldsymbol{Z}$, so that $\boldsymbol{Z}' = A\boldsymbol{Z} + \boldsymbol{N}(\boldsymbol{Z})$. Because $\boldsymbol{F}$ is C^1 and A is its derivative at the equilibrium, $\|\boldsymbol{N}(\boldsymbol{Z})\| / \|\boldsymbol{Z}\| \to 0$ as $\boldsymbol{Z} \to \boldsymbol{0}$ (Theorem 7.68): given any $\eta > 0$ there is a $\delta > 0$ with $\|\boldsymbol{N}(\boldsymbol{Z})\| \leq \eta\,\|\boldsymbol{Z}\|$ for $\|\boldsymbol{Z}\| \leq \delta$.

Choose σ with $\sigma(A) < \sigma < 0$ and let C be the constant of Equation (9.31). Fix $\eta = -\sigma/(2C)$ and the corresponding δ, and treat $\boldsymbol{N}$ as an inhomogeneity in Equation (9.25): as long as the solution stays within δ,

$$\|\boldsymbol{Z}(x)\| \le C\mathrm{e}^{\sigma x}\,\|\boldsymbol{Z}(0)\| + \int_0^x C\,\mathrm{e}^{\sigma(x-s)}\,\eta\,\|\boldsymbol{Z}(s)\|\,\mathrm{d}s\,.$$

Multiplying by $\mathrm{e}^{-\sigma x}$ and writing $u(x) = \mathrm{e}^{-\sigma x}\,\|\boldsymbol{Z}(x)\|$ turns this into $u(x) \le C\,\|\boldsymbol{Z}(0)\| + C\eta\int_0^x u$, so Lemma 9.10 gives $u(x) \le C\,\|\boldsymbol{Z}(0)\|\,\mathrm{e}^{C\eta x}$, that is

$$\|\boldsymbol{Z}(x)\| \le C\;\|\boldsymbol{Z}(0)\|\;\mathrm{e}^{(\sigma+C\eta)x} = C\;\|\boldsymbol{Z}(0)\|\;\mathrm{e}^{\sigma x/2}\,,$$

by the choice of η. Taking $\varepsilon = \delta/C$ makes the right-hand side at most δ for every $x \ge 0$, so the solution never leaves the ball on which the estimate was assumed and the bound holds for all $x \ge 0$. This is Equation (9.35) with $\mu = -\sigma/2 > 0$. □

Theorem 9.32 (Hartman–Grobman; quoted)**.** *Let $\boldsymbol{F}$ be of class C^1 near a hyperbolic equilibrium $\boldsymbol{Y}_*$ and let $A = D\boldsymbol{F}(\boldsymbol{Y}_*)$. Then there are neighbourhoods U of $\boldsymbol{Y}_*$ and V of $\boldsymbol{0}$ and a homeomorphism $\varphi : U \longrightarrow V$ carrying the trajectories of $\boldsymbol{Y}' = \boldsymbol{F}(\boldsymbol{Y})$ in U onto the trajectories of $\boldsymbol{Z}' = A\boldsymbol{Z}$ in V, preserving the direction and the parametrization of time [1183]. The nonlinear flow near a hyperbolic equilibrium is therefore a continuous distortion of its linearization, and in particular the equilibrium is unstable whenever some eigenvalue of A has positive real part.*

Rests on Definitions 6.7 and 9.30 and Theorem 9.23.

Remark 9.33 (What is quoted here). Theorem 9.32 is the only statement of this chapter about ordinary differential equations that carries no derivation, and the omission is a decision rather than a debt. Its proof constructs the conjugating map as the fixed point of a contraction on a space of bounded continuous maps, after splitting the linearization into its contracting and expanding parts and cutting the nonlinearity off outside a small ball; the technique is that of Theorem 9.8 applied in a function space, but the bookkeeping is a chapter's worth and it serves this one statement.

Three things about the statement are worth fixing in the reader's mind, because each is a place where more is often claimed than is true. The conjugacy is a *homeomorphism* and in general not differentiable, so it preserves the qualitative phase portrait — which trajectories go where — and not the eigenvalues or any other number computed from the linearization. Hyperbolicity is essential: Proposition 9.29 shows a centre, where $\Re\lambda = 0$, and an arbitrarily small nonlinear perturbation can turn a centre into a stable or an unstable focus, so no conjugacy can exist there. And the theorem is local; it says nothing about the flow away from the equilibrium.

What the rest of this treatise actually uses is weaker and is proved here. The decay statement is Proposition 9.31, obtained from Equation (9.31) and Grönwall's inequality with no conjugacy anywhere; only the instability half of Theorem 9.32 is genuinely borrowed.

9.2.5 Planar flows and closed orbits

Theorem 9.34 (Poincaré–Bendixson; quoted)**.** *Let $\boldsymbol{F}$ be of class C^1 on an open subset of $\mathbb{R}^2$ and let K be a compact subset of it containing no equilibrium of $\boldsymbol{Y}' = \boldsymbol{F}(\boldsymbol{Y})$. If a trajectory enters K and remains in K for all later times, then it is a closed orbit or it approaches one [220, 298]. A bounded planar trajectory that does not converge to an equilibrium therefore has periodic behaviour as its only possible fate.*

Rests on Definitions 6.9 and 9.1 and Theorem 9.8.

Remark 9.35 (What is quoted here, and why it is a statement about the plane). The proof rests on two facts about the plane and on nothing else: a simple closed curve separates

the plane into an inside and an outside (the Jordan curve theorem, which this treatise does not prove — Chapter 6 carries the winding number, Definition 6.20, which is the tool such a proof uses, but stops short of the separation theorem), and successive crossings of a short segment transverse to the flow are therefore monotone along that segment, because a trajectory arc together with the chord joining its ends bounds a region the flow cannot re-enter. It is the dimension that does the work, and the theorem is false in three dimensions: a bounded trajectory there may wander forever without approaching any closed orbit. That failure is not a technicality but the opening of a subject, and it is where Chapter 32 begins.

Proposition 9.36 (Bendixson–Dulac negative criterion)**.** *Let $\boldsymbol{F} = (F_1, F_2)$ be of class C^1 on a simply connected open $\Omega \subseteq \mathbb{R}^2$ and let φ be a positive C^1 function on Ω. If*

$$\frac{\partial}{\partial y_1}(\varphi F_1) + \frac{\partial}{\partial y_2}(\varphi F_2) \tag{9.36}$$

has one strict sign throughout Ω, then $\boldsymbol{Y}' = \boldsymbol{F}(\boldsymbol{Y})$ has no closed orbit lying in Ω.
Rests on Theorem 7.99 and Definition 6.17.

Derivation. *Derives Proposition 9.36.*

Suppose a closed orbit γ lay in Ω, and let S be the region it bounds, contained in Ω because Ω is simply connected. Green's theorem Theorem 7.99 equates the integral of Equation (9.36) over S with the circulation $\oint_\gamma \varphi\,(F_1\,\mathrm{d}y_2 - F_2\,\mathrm{d}y_1)$. On the orbit $\mathrm{d}y_1 = F_1\,\mathrm{d}x$ and $\mathrm{d}y_2 = F_2\,\mathrm{d}x$, so the integrand is $\varphi\,(F_1F_2 - F_2F_1)\,\mathrm{d}x = 0$ and the circulation vanishes. But the area integral of a function of one strict sign over a region of positive area cannot vanish — a contradiction. □

9.3 Linear systems with periodic coefficients

A linear system whose coefficients vary periodically in the independent variable is not solvable in closed form, and yet its stability is decided completely by a single matrix. That is Floquet's theorem, and it is the exact statement behind every parametric-resonance calculation: a swing pumped by shortening the rope at twice its natural frequency, a mass on a vibrating support, a charged particle in the radio-frequency field of an ion trap, the tension modulation of a plucked string. The physical parts of this treatise derive the leading resonance band by a slowly-varying-amplitude argument; what follows is the theorem that argument approximates, and it is what entitles anyone to speak of a *tongue* structure at all.

9.3.1 The monodromy matrix

Definition 9.37 (Fundamental matrix)**.** Let A be continuous on $\mathbb{R}$ with values in the $n \times n$ matrices. The *fundamental matrix* of $\boldsymbol{Y}' = A(x)\boldsymbol{Y}$ based at x_0 is the matrix-valued solution Φ of

$$\frac{\mathrm{d}\Phi}{\mathrm{d}x}(x) = A(x)\,\Phi(x)\,, \qquad \Phi(x_0) = \mathbb{1}\,, \tag{9.37}$$

that is, the matrix whose j-th column is the solution with initial value $\boldsymbol{e}_j$. Every solution is $\boldsymbol{Y}(x) = \Phi(x)\boldsymbol{Y}(x_0)$.
Rests on Corollary 9.9 and Theorem 9.13.

Proposition 9.38 (Liouville's formula)**.** *The fundamental matrix satisfies*

$$\det \Phi(x) = \exp\left[\int_{x_0}^{x} \operatorname{tr} A(s)\,\mathrm{d}s\right], \tag{9.38}$$

and is therefore invertible at every x.
Rests on Definition 9.37 and Proposition 9.15.

Derivation. *Derives Proposition 9.38.*

This is the computation of Proposition 9.15 carried out on the columns of Φ instead of on a Wronskian. A determinant is multilinear in its rows, so $\mathrm{d}(\det\Phi)/\mathrm{d}x$ is the sum over i of the determinant of Φ with its i-th row differentiated. By Equation (9.37) that row is $\sum_k A_{ik}\Phi_{k\cdot}$, a combination of the rows of Φ; subtracting the multiples of the other rows, which changes no determinant, leaves $A_{ii}\det\Phi$. Summing over i gives $\mathrm{d}(\det\Phi)/\mathrm{d}x = (\operatorname{tr}A)\det\Phi$, a scalar linear equation whose solution with $\det\Phi(x_0)=1$ is Equation (9.38) by Proposition 9.18. An exponential never vanishes. □

Theorem 9.39 (Floquet)**.** *Let A be continuous and T-periodic, $A(x+T)=A(x)$, and let Φ be the fundamental matrix based at $x_0=0$. Write $M=\Phi(T)$, the* monodromy matrix*, and let $\rho_1,\dots,\rho_n$ be its eigenvalues, the* characteristic multipliers*. Then*

1. *$\Phi(x+T)=\Phi(x)\,M$ for every x, and hence $\Phi(x+NT)=\Phi(x)M^N$ for every integer $N\geq 0$;*
2. *M is invertible, with $\det M=\prod_i\rho_i=\exp\bigl[\int_0^T\operatorname{tr}A\bigr]$, so no multiplier is zero;*
3. *to each multiplier ρ belongs a solution with $\boldsymbol{Y}(x+T)=\rho\,\boldsymbol{Y}(x)$; writing $\rho=\mathrm{e}^{\mu T}$ for a* characteristic exponent *μ, that solution is*

$$\boldsymbol{Y}(x)=\mathrm{e}^{\mu x}\,\boldsymbol{P}(x)\,,\qquad \boldsymbol{P}(x+T)=\boldsymbol{P}(x)\,, \tag{9.39}$$

   an exponential times a T-periodic vector function;
4. *every solution tends to $\mathbf{0}$ as $x\to+\infty$ if and only if $|\rho_i|<1$ for every i, and some solution is unbounded if $|\rho_i|>1$ for some i.*

Rests on Definition 9.37, Proposition 9.38, and Corollary 9.27.

Derivation. *Derives Theorem 9.39.*

(i) Put $\Psi(x)=\Phi(x+T)$. Then $\Psi'=A(x+T)\Psi=A(x)\Psi$ by periodicity, so Ψ solves Equation (9.37) column by column; and $\Phi(x)M$ solves it too, being a fixed linear combination of solutions. The two agree at $x=0$, where both equal M, so they agree everywhere by the uniqueness in Corollary 9.9. Iterating gives the statement for NT.

(ii) is Equation (9.38) at $x=T$ together with the fact that the determinant is the product of the eigenvalues (Theorem 5.67, comparing the constant terms of the characteristic polynomial).

(iii) Let $M\boldsymbol{w}=\rho\boldsymbol{w}$ with $\boldsymbol{w}\neq\mathbf{0}$ and put $\boldsymbol{Y}(x)=\Phi(x)\boldsymbol{w}$. By (i), $\boldsymbol{Y}(x+T)=\Phi(x)M\boldsymbol{w}=\rho\,\boldsymbol{Y}(x)$. Since $\rho\neq 0$ by (ii), the complex exponential takes the value ρ (Proposition 8.4: write $\rho=|\rho|\,\mathrm{e}^{\mathrm{i}\theta}$ and take $\mu T=\ln|\rho|+\mathrm{i}\theta$). Setting $\boldsymbol{P}(x)=\mathrm{e}^{-\mu x}\boldsymbol{Y}(x)$ gives $\boldsymbol{P}(x+T)=\mathrm{e}^{-\mu T}\mathrm{e}^{-\mu x}\rho\,\boldsymbol{Y}(x)=\boldsymbol{P}(x)$, which is Equation (9.39).

(iv) By (i), $\boldsymbol{Y}(x+NT)=\Phi(x)M^N\boldsymbol{Y}(0)$. The matrix Φ is continuous, hence bounded on the compact interval $[0,T]$ (Theorem 7.24), and $\Phi(x)^{-1}$ is bounded there too by Equation (9.38). So the solution tends to zero, or is bounded, exactly as the sequence $M^N\boldsymbol{Y}(0)$ does, and the statements about the powers A^N in Corollary 9.27 settle that by the moduli of the multipliers: $M^N\to 0$ when every $|\rho_i|<1$, while an eigenvector for a multiplier of modulus greater than one gives $M^N\boldsymbol{w}=\rho^N\boldsymbol{w}$, unbounded. □

Remark 9.40 (The normal form, and the one place a logarithm is needed)*.* Floquet's theorem is often stated as the single assertion $\Phi(x)=P(x)\,\mathrm{e}^{xB}$ with P a T-periodic invertible matrix function and B constant. That form follows from Theorem 9.39(iii) whenever M has n independent eigenvectors: collect them as the columns of V, put $B=V\operatorname{diag}(\mu_1,\dots,\mu_n)V^{-1}$ and $P(x)=\Phi(x)\mathrm{e}^{-xB}$, which is periodic because each column is by (iii). In general it requires a logarithm of the matrix M itself, which exists because M is invertible but whose

construction needs a normal form for M that Chapter 5 does not develop. Nothing below uses the aggregate form: every statement this treatise makes about a periodically forced linear system is a statement about the multipliers, and Theorem 9.39(iii) and (iv) supply those without any logarithm of a matrix. A further caution: B and P are generally complex even for a real system, because a negative real multiplier has no real logarithm; the standard repair is to work with period $2T$, under which the multipliers are squared and become positive.

9.3.2 Hill's equation and the tongues of instability

Corollary 9.41 (Hill's equation)**.** *Let Q be continuous and T-periodic and consider*

$$\frac{\mathrm{d}^2 y}{\mathrm{d}x^2}(x) + Q(x)\, y(x) = 0\,, \tag{9.40}$$

written as a first-order system for (y, y'). Then $\operatorname{tr} A = 0$, so $\det M = 1$ and the two multipliers satisfy

$$\rho^2 - (\operatorname{tr} M)\,\rho + 1 = 0\,, \qquad \rho_1\rho_2 = 1\,, \qquad \rho_1 + \rho_2 = \operatorname{tr} M\,. \tag{9.41}$$

Consequently, with $\Delta_{\mathrm{H}} = \operatorname{tr} M$ the discriminant *of Equation (9.40):*

1. *if $|\Delta_{\mathrm{H}}| < 2$ the multipliers are $\mathrm{e}^{\pm \mathrm{i}\theta}$ with $2\cos\theta = \Delta_{\mathrm{H}}$, distinct and of unit modulus, and every solution is bounded on $\mathbb{R}$: the equation is* stable*;*
2. *if $|\Delta_{\mathrm{H}}| > 2$ the multipliers are real, reciprocal and distinct, one of modulus greater than one, so some solution grows like $|\rho|^{x/T}$ — exponentially, at the rate $\mu = T^{-1}\ln|\rho|$: the equation is* unstable*;*
3. *if $|\Delta_{\mathrm{H}}| = 2$ the multipliers are both $+1$ or both -1, and Equation (9.40) has a solution of period T or of period $2T$ respectively.*

Rests on Theorem 9.39, Proposition 9.38, and Corollary 9.27.

Derivation. *Derives Corollary 9.41.*

In the system for $\boldsymbol{Y} = (y, y')$ the matrix is $A = \begin{pmatrix} 0 & 1 \\ -Q & 0 \end{pmatrix}$, of zero trace, so Equation (9.38) gives $\det M = 1$ and the characteristic polynomial of the 2×2 matrix M is Equation (9.41) (Proposition 9.29, the same identity read for M). Its roots are $\rho_{\pm} = \left[\Delta_{\mathrm{H}} \pm \sqrt{\Delta_{\mathrm{H}}^2 - 4}\,\right]/2$.

If $|\Delta_{\mathrm{H}}| < 2$ the discriminant is negative, the roots are complex conjugates of product 1, hence of modulus 1, and distinct; M then has two independent eigenvectors (Proposition 5.71), so the powers M^N stay bounded by the last clause of Corollary 9.27, and by the argument of Theorem 9.39(iv) every solution is bounded. If $|\Delta_{\mathrm{H}}| > 2$ the roots are real and distinct with product 1, so one has modulus greater than 1 and Theorem 9.39(iv) gives an unbounded solution; by Equation (9.39) it is $\mathrm{e}^{\mu x}$ times a periodic function, with $\mathrm{e}^{\mu T} = \rho$. If $|\Delta_{\mathrm{H}}| = 2$ the double root is $\rho = \Delta_{\mathrm{H}}/2 = \pm 1$, and the eigenvector of M belonging to it furnishes, by Theorem 9.39(iii), a solution with $y(x + T) = \pm y(x)$. □

Remark 9.42 (Why the unstable set is a family of tongues)*.* Let Q depend on two parameters — a mean value a and a modulation depth h — continuously. Then M, and with it $\Delta_{\mathrm{H}}(a, h)$, depends continuously on (a, h), because the solution of an initial-value problem does (Proposition 9.11, applied to the system with parameters carried along). Corollary 9.41 therefore partitions the parameter plane into the open stable set $|\Delta_{\mathrm{H}}| < 2$, the open unstable set $|\Delta_{\mathrm{H}}| > 2$, and the level curves $\Delta_{\mathrm{H}} = \pm 2$ that separate them. On those curves a periodic

or antiperiodic solution exists, by Corollary 9.41(iii), which is what makes them locatable in practice: one looks for solutions of period T and $2T$ rather than computing M. The unstable set is the union of the regions bounded by those curves, and at $h = 0$ it degenerates — as Proposition 9.43 shows for the Mathieu equation — to a discrete set of points on the a axis, from which the regions open out as h grows. That is the origin of the name.

9.3.3 The Mathieu equation

The canonical Hill equation, and the one that the separation of the Helmholtz operator in elliptic-cylinder coordinates produces [173], is

$$\frac{\mathrm{d}^2 y}{\mathrm{d}x^2}(x) + \left[a - 2h\cos 2x\right] y(x) = 0\,. \tag{9.42}$$

Its Sturm–Liouville data, in the convention of Definition 9.54, are

$$p(x) = 1\,, \qquad q(x) = -2h\cos 2x\,, \qquad \lambda^2 = a\,, \qquad r(x) = 1\,, \tag{9.43}$$

so the spectral parameter is a and the modulation depth h is a parameter of the operator; much of the literature writes q for what is here called h, which would collide with the Sturm–Liouville coefficient $q(x)$. The coefficient has period π in x, so Theorem 9.39 applies with $T = \pi$. The solutions that are periodic — which by Corollary 9.41(iii) exist exactly on the boundaries of the unstable regions — are the *Mathieu functions*; the remaining solutions are, by Equation (9.39), an exponential times a periodic function, and it is the sign of the exponent that the experiment sees.

Proposition 9.43 (The unmodulated line, and the feet of the tongues)**.** *On the line $h = 0$, Equation (9.42) is stable in the sense of Corollary 9.41 at every $a > 0$ with $\sqrt{a}$ not an integer, and unstable at every $a \le 0$. Consequently the closure of the unstable set meets the ray $a > 0$ exactly at the points*

$$a = n^2\,, \qquad n = 1, 2, 3, \ldots\,, \tag{9.44}$$

which are the feet from which the instability tongues open out as $|h|$ grows; the whole ray $a \le 0$ is unstable already at $h = 0$ and is the $n = 0$ region.

Rests on Corollary 9.41, Theorem 9.23, and Equation (9.42).

Derivation. *Derives Proposition 9.43.*

At $h = 0$ the equation is $y'' + ay = 0$ with constant coefficients, whose fundamental matrix over one period $T = \pi$ is computed from Theorem 9.23. For $a > 0$ the solutions are $\cos(\sqrt{a}\,x)$ and $\sin(\sqrt{a}\,x)/\sqrt{a}$, so

$$M = \begin{pmatrix} \cos(\pi\sqrt{a}) & \sin(\pi\sqrt{a})/\sqrt{a} \\ -\sqrt{a}\,\sin(\pi\sqrt{a}) & \cos(\pi\sqrt{a}) \end{pmatrix}, \qquad \Delta_{\mathrm{H}} = 2\cos(\pi\sqrt{a})\,.$$

Hence $|\Delta_{\mathrm{H}}| < 2$, the stable case of Corollary 9.41, at every $a > 0$ except where $\cos(\pi\sqrt{a}) = \pm 1$, that is where $\pi\sqrt{a} = n\pi$, that is at $a = n^2$ with $n \ge 1$; there $|\Delta_{\mathrm{H}}| = 2$ and the second solution grows linearly, so those points belong to the closure of the unstable set. For $a = 0$ the solutions are 1 and x, giving $\Delta_{\mathrm{H}} = 2$ with an unbounded solution, and for $a < 0$ they are real exponentials with $\Delta_{\mathrm{H}} = 2\cosh(\pi\sqrt{-a}) > 2$, the unstable case outright. So on the line $h = 0$ the unstable set is the ray $a \le 0$ together with the isolated points $a = n^2$, $n \ge 1$, which is the statement. □

Remark 9.44 (Reading the feet of the tongues as a resonance condition). An oscillator of natural angular frequency ω_0 whose restoring coefficient is modulated at angular frequency γ obeys $\ddot{u} + \omega_0^2[1 + \epsilon\cos\gamma t]u = 0$. Substituting $x = \gamma t/2$ turns it into Equation (9.42) with

$$a = \frac{4\omega_0^2}{\gamma^2}\,, \qquad 2h = -\frac{4\omega_0^2\epsilon}{\gamma^2}\,, \tag{9.45}$$

so Equation (9.44) becomes $\gamma = 2\omega_0/n$ with $n \geq 1$: the modulation destabilises the oscillator when it is driven at twice the natural frequency, or at an integer submultiple of that. The $n = 1$ tongue is the widest and is the one observed; the others narrow rapidly with n, which is the quantitative statement that a slowly-varying-amplitude argument cannot make and this theorem can. Chapter 28 derives the width of the first tongue and the damping threshold, and Chapter 35 measures the effect on a string.

9.4 Orthonormal systems of functions

9.4.1 Orthonormality

Definition 9.45 (Orthonormal set of functions)**.** Let $\{\phi_i\}$ be a collection of functions

$$\begin{aligned}\phi_i : I \subset \mathbb{R} &\longrightarrow \mathbb{C}\\ x &\longmapsto \phi_i(x)\,.\end{aligned}$$

The functions ϕ_i form an *orthonormal set of functions* if and only if

$$\int_I \overline{\phi_i(x)}\,\phi_j(x)\,\mathrm{d}x = \delta_{ij}\,. \tag{9.46}$$

Remark 9.46. For real-valued functions the conjugation in Equation (9.46) is immaterial and the relation reduces to $\int_I \phi_i\phi_j\,\mathrm{d}x = \delta_{ij}$, which is the form in which the Legendre and Bessel relations below are stated.

9.4.2 Expansion in series of orthonormal functions

Definition 9.47 (Orthonormal series expansion)**.** The *expansion of a function f in a series of orthonormal functions* $\{\phi_i\}$ is

$$f(x) = \sum_{i=1}^{\infty} c_i\,\phi_i(x)\,. \tag{9.47}$$

Rests on Definition 9.45.

Proposition 9.48 (Expansion coefficients)**.** *The coefficients of the expansion Equation (9.47) are*

$$c_i = \int_I f(x)\,\overline{\phi_i(x)}\,\mathrm{d}x\,. \tag{9.48}$$

Rests on Definitions 9.45 and 9.47.

Derivation. Derives Proposition 9.48.

Multiply Equation (9.47) by $\overline{\phi_j(x)}$ and integrate over I:

$$\begin{aligned}f(x) &= \sum_{i=1}^{\infty} c_i\,\phi_i(x)\,,\\ f(x)\,\overline{\phi_j(x)} &= \sum_{i=1}^{\infty} c_i\,\phi_i(x)\,\overline{\phi_j(x)}\,,\\ \int_I f(x)\,\overline{\phi_j(x)}\,\mathrm{d}x &= \sum_{i=1}^{\infty} c_i \int_I \overline{\phi_j(x)}\,\phi_i(x)\,\mathrm{d}x = \sum_{i=1}^{\infty} c_i\,\delta_{ji} = c_j\,,\end{aligned}$$

where the orthonormality relation Equation (9.46) collapsed the sum. □

9.4.3 Expansion of a product

Consider two functions f_1 and f_2, each expanded in the same orthonormal set, together with the expansion of their pointwise product:

$$f_1(x) = \sum_{i=1}^{\infty} c_i^{(1)}\, \phi_i(x)\,,$$
$$f_2(x) = \sum_{i=1}^{\infty} c_i^{(2)}\, \phi_i(x)\,,$$
$$f_1(x)\, f_2(x) = \sum_{i=1}^{\infty} c_i^{(12)}\, \phi_i(x)\,,$$

where $c_i^{(1)}$ and $c_i^{(2)}$ are the expansion coefficients of f_1 and f_2, and $c_i^{(12)}$ those of the product $f_1 f_2$.

Definition 9.49 (Structure constants of an orthonormal set)**.** The *structure constants* of the orthonormal set $\{\phi_i\}$ are its triple overlap integrals

$$T_{ijk} = \int_I \overline{\phi_i(x)}\, \phi_j(x)\, \phi_k(x)\, \mathrm{d}x\,. \tag{9.49}$$

Rests on Definition 9.45.

Proposition 9.50 (Coefficients of a product)**.** *Whenever the three expansions above are valid and the double series below converges absolutely, the coefficients of the product are the values of one fixed bilinear form on the two coefficient sequences,*

$$c_i^{(12)} = \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} T_{ijk}\, c_j^{(1)}\, c_k^{(2)}\,, \tag{9.50}$$

with T_{ijk} the structure constants Equation (9.49).
Rests on Proposition 9.48 and Definition 9.49.

Derivation. *Derives Proposition 9.50.*
Applying Equation (9.48) to the product and substituting the two series,

$$\begin{aligned} c_i^{(12)} &= \int_I f_1(x)\, f_2(x)\, \overline{\phi_i(x)}\, \mathrm{d}x \\ &= \int_I \left(\sum_{j=1}^{\infty} c_j^{(1)} \phi_j(x) \right) \left(\sum_{k=1}^{\infty} c_k^{(2)} \phi_k(x) \right) \overline{\phi_i(x)}\, \mathrm{d}x \\ &= \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} c_j^{(1)} c_k^{(2)} \int_I \overline{\phi_i(x)}\, \phi_j(x)\, \phi_k(x)\, \mathrm{d}x\,, \end{aligned}$$

and the remaining integral is T_{ijk} by Equation (9.49). □

Remark 9.51 (This is the closed form). No further reduction is available for a general orthonormal set, and none should be looked for: the numbers T_{ijk} are independent data attached to the set — they measure exactly how far it is from being closed under multiplication — and Equation (9.50) is the statement that pointwise multiplication, read in coefficients, is the bilinear map they define. What makes a particular set useful is that its structure constants are sparse. The complex exponentials are the extreme case: a single term of the double sum survives and the bilinear map degenerates into a convolution.

Proposition 9.52 (Product coefficients for the Fourier system)**.** *Take the complex exponentials $\phi_n(x) = \mathrm{e}^{\mathrm{i}nx}$ on $[-\pi, \pi]$ in the normalisation of Equations (9.110) and (9.111), that is with every integral of Section 9.4 — and in particular the triple overlap Equation (9.49) — read against the normalised measure $\mathrm{d}x/(2\pi)$ of Remark 9.91, which is what makes them an orthonormal set at all. Their structure constants are then $T_{njk} = \delta_{n,\,j+k}$ and Equation (9.50) becomes the discrete convolution*

$$c^{(12)}_n = \sum_{m=-\infty}^{\infty} c^{(1)}_m \, c^{(2)}_{n-m} \,, \tag{9.51}$$

absolutely convergent whenever both coefficient sequences are absolutely summable.

Rests on Proposition 9.50 and Definition 9.49.

Derivation. *Derives Proposition 9.52.*

Every integral carries the measure $\mathrm{d}x/(2\pi)$ (Remark 9.91), which is also what puts the factor into Equation (9.111), so the triple overlap to be computed is

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} \mathrm{e}^{-\mathrm{i}nx}\,\mathrm{e}^{\mathrm{i}jx}\,\mathrm{e}^{\mathrm{i}kx}\,\mathrm{d}x = \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathrm{e}^{\mathrm{i}(j+k-n)x}\,\mathrm{d}x = \delta_{n,\,j+k}\,,$$

by Equation (9.109) applied to the integer $j + k - n$. Inserting this in Equation (9.50) collapses the double sum to the single sum over $j = m$, $k = n - m$, which is Equation (9.51). Absolute convergence, and with it the right to rearrange the double series into that single one, is the Cauchy product of two absolutely convergent series (Proposition 7.49).

The other reading of Remark 9.91 gives the same answer, as it must. For the set $\phi_n = \mathrm{e}^{\mathrm{i}nx}/\sqrt{2\pi}$ with plain $\mathrm{d}x$ the same integral yields $T_{njk} = \delta_{n,\,j+k}/\sqrt{2\pi}$ while every coefficient is multiplied by $\sqrt{2\pi}$, and the three factors cancel in Equation (9.50), leaving Equation (9.51) unchanged. □

9.4.4 Parseval relation

Let f be a function whose expansion Equation (9.47) in the orthonormal set $\{\phi_i\}$ converges to f in the mean square. The *Parseval relation* then equates the norm of the function to the norm of its coefficient sequence,

$$\int_I |f(x)|^2 \,\mathrm{d}x = \sum_{i=1}^{\infty} |c_i|^2 \,. \tag{9.52}$$

Derivation. *Derives Equation (9.52).*

Mean-square convergence permits the series to be integrated term by term against its own conjugate:

$$\begin{aligned}\int_I |f(x)|^2 \,\mathrm{d}x &= \int_I \left(\sum_{i=1}^{\infty} c_i\,\phi_i(x)\right)\overline{\left(\sum_{j=1}^{\infty} c_j\,\phi_j(x)\right)}\,\mathrm{d}x \\ &= \sum_{i=1}^{\infty}\sum_{j=1}^{\infty} c_i\,\overline{c_j}\int_I \overline{\phi_j(x)}\,\phi_i(x)\,\mathrm{d}x = \sum_{i=1}^{\infty}\sum_{j=1}^{\infty} c_i\,\overline{c_j}\,\delta_{ji} = \sum_{i=1}^{\infty}|c_i|^2 \,,\end{aligned}$$

the orthonormality relation Equation (9.46) collapsing the double sum to its diagonal. □

Remark 9.53. The hypothesis is not decoration: it is exactly the statement that the orthonormal set is *complete* for f. For an arbitrary orthonormal set only an inequality holds, and it costs one line: expanding the non-negative quantity $\int_I \big|f - \sum_{i\le N} c_i\phi_i\big|^2\mathrm{d}x =$

$\int_I |f|^2\,\mathrm{d}x - \sum_{i\le N} |c_i|^2 \ge 0$, where the cross terms collapse by orthonormality and the definition $c_i = \int_I \bar{\phi}_i f\,\mathrm{d}x$, and letting $N \to \infty$ gives

$$\sum_i |c_i|^2 \le \int_I |f|^2\,\mathrm{d}x\,, \tag{9.53}$$

Bessel's inequality, with equality for every square integrable f being the definition of completeness. (Proposition 17.4 is this same argument carried out for the trigonometric system, where it also identifies the partial sum as the least-squares approximant; it does not by itself cover an arbitrary orthonormal set, which is why the general statement is given here.) The two systems used in this chapter are complete, and each is proved so: Theorem 17.34 for the trigonometric system of Section 9.7, and Theorem 17.36 for the Fourier integral of Section 9.7.5. The statement in the abstract, for an orthonormal basis of an arbitrary Hilbert space, belongs to Chapter 12.

9.5 The Sturm–Liouville operator

Definition 9.54 (Sturm–Liouville differential operator)**.** Let y be a function

$$\begin{aligned} y : \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto y(x)\,. \end{aligned}$$

The *Sturm–Liouville differential operator* acting on y is defined as

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[p(x)\,\frac{\mathrm{d}y}{\mathrm{d}x}(x)\right] + \left[q(x) + \lambda^2\, r(x)\right] y(x)\,, \tag{9.54}$$

where p, q and r are given real functions and λ^2 is a parameter.

Remark 9.55. Setting the expression Equation (9.54) equal to zero yields the *Sturm–Liouville equation*. Wherever $r > 0$ it may be rewritten as

$$-\frac{1}{r(x)}\left\{\frac{\mathrm{d}}{\mathrm{d}x}\left[p(x)\,\frac{\mathrm{d}y}{\mathrm{d}x}(x)\right] + q(x)\,y(x)\right\} = \lambda^2\, y(x)\,, \tag{9.55}$$

an eigenvalue problem with eigenvalue λ^2 and *weight function* r. Each classical family of special functions treated below is obtained by one specific choice of the data (p, q, λ^2, r); the identifications are collected in Table 9.2.

9.5.1 Self-adjointness and orthogonality

The whole force of the Sturm–Liouville form is one identity. Because the second-order part of Equation (9.54) is written as the derivative of $p\,\mathrm{d}y/\mathrm{d}x$ and not as $p\,\mathrm{d}^2y/\mathrm{d}x^2$, two solutions can be played off against each other under the integral sign, and every orthogonality relation proved in this chapter follows from that single manoeuvre rather than from a separate trick per family.

Lemma 9.56 (Lagrange identity)**.** *Write* $L[y] = \frac{\mathrm{d}}{\mathrm{d}x}\left[p\,\frac{\mathrm{d}y}{\mathrm{d}x}\right] + q\,y$ *for the part of Equation* (9.54) *that does not carry the spectral parameter. For any twice differentiable* u *and* v*,*

$$u\,L[v] - v\,L[u] = \frac{\mathrm{d}}{\mathrm{d}x}\left[p\left(u\,\frac{\mathrm{d}v}{\mathrm{d}x} - v\,\frac{\mathrm{d}u}{\mathrm{d}x}\right)\right]\,. \tag{9.56}$$

Rests on Definition 9.54.

Derivation. *Derives Lemma 9.56.*

The terms carrying q cancel, and by the Leibniz rule Equation (7.16),

$$u\frac{\mathrm{d}}{\mathrm{d}x}\left[p\frac{\mathrm{d}v}{\mathrm{d}x}\right]-v\frac{\mathrm{d}}{\mathrm{d}x}\left[p\frac{\mathrm{d}u}{\mathrm{d}x}\right]=\frac{\mathrm{d}}{\mathrm{d}x}\left[u\,p\frac{\mathrm{d}v}{\mathrm{d}x}\right]-p\frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x}-\frac{\mathrm{d}}{\mathrm{d}x}\left[v\,p\frac{\mathrm{d}u}{\mathrm{d}x}\right]+p\frac{\mathrm{d}v}{\mathrm{d}x}\frac{\mathrm{d}u}{\mathrm{d}x},$$

in which the two products of first derivatives cancel, leaving Equation (9.56). □

Theorem 9.57 (Orthogonality of Sturm–Liouville eigenfunctions)**.** *Let u and v be real solutions of the Sturm–Liouville equation Equation (9.55) on $[a,b]$ belonging to different eigenvalues, $\lambda_u^2\neq\lambda_v^2$, and suppose the boundary term vanishes,*

$$\left[p\left(u\frac{\mathrm{d}v}{\mathrm{d}x}-v\frac{\mathrm{d}u}{\mathrm{d}x}\right)\right]_a^b=0\,. \tag{9.57}$$

Then u and v are orthogonal with respect to the weight r,

$$\int_a^b u(x)\,v(x)\,r(x)\,\mathrm{d}x=0\,. \tag{9.58}$$

Rests on Lemma 9.56 and Equation (9.55).

Derivation. *Derives Theorem 9.57.*

By hypothesis $L[u]=-\lambda_u^2\,r\,u$ and $L[v]=-\lambda_v^2\,r\,v$, so that $u\,L[v]-v\,L[u]=(\lambda_u^2-\lambda_v^2)\,r\,u\,v$. Integrating Equation (9.56) over $[a,b]$ therefore gives

$$(\lambda_u^2-\lambda_v^2)\int_a^b u\,v\,r\,\mathrm{d}x=\left[p\left(u\frac{\mathrm{d}v}{\mathrm{d}x}-v\frac{\mathrm{d}u}{\mathrm{d}x}\right)\right]_a^b,$$

which is zero by Equation (9.57). Dividing by the non-zero factor $\lambda_u^2-\lambda_v^2$ gives Equation (9.58). □

Remark 9.58 (The three ways the boundary term dies). Equation (9.57) is satisfied in each of the situations met below, and they are worth naming because they are the only ones used. *Separated boundary conditions*: u and v each satisfy $\alpha\,y(a)+\beta\,\frac{\mathrm{d}y}{\mathrm{d}x}(a)=0$ with the same pair (α,β), and similarly at b; the bracket then vanishes at each endpoint separately, because $(u,\mathrm{d}u/\mathrm{d}x)$ and $(v,\mathrm{d}v/\mathrm{d}x)$ are proportional there. This is the Fourier–Bessel problem of Section 9.8.4, where the condition is $y(a)=0$. *A vanishing coefficient function*: $p(a)=0$ or $p(b)=0$ kills the bracket at that endpoint with no condition on y beyond boundedness of y and $\mathrm{d}y/\mathrm{d}x$ there, which is what happens at $x=0$ for Bessel and at $x=\pm1$ for Legendre and its associated equation. *Decay at infinity*: on an unbounded interval it suffices that $p\,y\,\mathrm{d}y/\mathrm{d}x$ tend to zero, which the Gaussian and exponential weights of Sections 9.10 and 9.11 guarantee for polynomial solutions. The second mechanism is the one that requires care: p vanishing is not by itself enough if the solutions are unbounded there, and Remark 9.112 is a worked instance in which the bracket survives.

9.6 The semiclassical approximation

The families catalogued in the sections that follow solve the Sturm–Liouville equation exactly, one closed form for each choice of the data (p,q,λ^2,r). Almost no potential met in a laboratory is one of them. What survives when the exact solution does not exist is an asymptotic one: whenever the coefficient multiplying the unknown in a second-order linear equation is large, the equation has a universal approximate solution, an oscillation whose

local wavelength and local amplitude are both read off that coefficient. Jeffreys obtained it for the general second-order equation [526], and Wentzel, Kramers and Brillouin obtained it independently of him and of each other, within months, for the wave equation of quantum mechanics [535, 549, 563] — which is why the method is called WKB by most authors and JWKB by the careful ones. This section derives the approximation, the formulae that carry a solution across the points where it fails, the tunnelling exponent that follows from them — the Gamow factor [600, 603] — and the quantisation condition of the old quantum theory [395, 441], which the same machinery delivers with its half-integer correction attached rather than postulated.

9.6.1 The equation and its Sturm–Liouville data

The equation treated is the stationary wave equation of a particle of mass m moving on a line in a potential V [557],

$$-\frac{\hbar^2}{2m}\frac{\mathrm{d}^2\psi}{\mathrm{d}x^2}(x) + V(x)\,\psi(x) = E\,\psi(x)\,, \tag{9.59}$$

with x in m, m in kg, V and E in J, and $\hbar = 1.054\,571\,817 \times 10^{-34}$ J s exactly (Appendix B). In the template of Definition 9.54 this is a Sturm–Liouville equation with coefficient function 1, potential term $-2mV(x)/\hbar^2$, weight 1 and eigenvalue $\lambda^2 = 2mE/\hbar^2$. The potential term and the eigenvalue both carry the SI dimension of an inverse squared length, as they must, being added to a second derivative with respect to x; the coefficient function and the weight are dimensionless.

Dividing Equation (9.59) by $-\hbar^2/(2m)$ puts it in the form used throughout this section,

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}x^2}(x) + \frac{P(x)^2}{\hbar^2}\,\psi(x) = 0\,, \qquad P(x) = \sqrt{2m\,[E - V(x)]}\,, \tag{9.60}$$

where $P(x)$, in kg m/s, is the momentum a classical particle of energy E would have at x. It is real on the *classically allowed* set $\{x : V(x) < E\}$ and imaginary on the *classically forbidden* set $\{x : V(x) > E\}$, where the real quantity

$$\kappa(x) = \sqrt{2m\,[V(x) - E]} = |P(x)| \tag{9.61}$$

is used instead. A point a with $V(a) = E$, where the two sets meet, is a *turning point*: classically the particle stops there and reverses.

Remark 9.59 (Notation). Throughout this section P denotes the local momentum Equation (9.60) and not the coefficient function called p in Definition 9.54, which for this equation is the constant 1 and plays no further role. The capital is a deliberate departure from the usual lower-case p of the semiclassical literature, adopted here only to keep the two meanings apart inside one chapter.

9.6.2 The expansion in powers of $\hbar$

Write the solution as a single exponential,

$$\psi(x) = \exp\left[\frac{\mathrm{i}\,S(x)}{\hbar}\right], \tag{9.62}$$

with S carrying the SI dimension of an action, J s, so that the exponent is dimensionless. Nothing is approximated yet: any nowhere-vanishing ψ can be written this way with a complex S.

Proposition 9.60 (Exact Riccati form)**.** *The function ψ of Equation (9.62) solves Equation (9.60) if and only if*

$$\left(\frac{\mathrm{d}S}{\mathrm{d}x}\right)^2 - \mathrm{i}\hbar\,\frac{\mathrm{d}^2 S}{\mathrm{d}x^2} = P(x)^2\,. \tag{9.63}$$

Rests on Equations (9.60) and (9.62).

Derivation. *Derives Proposition 9.60.*

Differentiating Equation (9.62) twice,

$$\frac{\mathrm{d}\psi}{\mathrm{d}x} = \frac{\mathrm{i}}{\hbar}\frac{\mathrm{d}S}{\mathrm{d}x}\,\psi\,, \qquad \frac{\mathrm{d}^2\psi}{\mathrm{d}x^2} = \left[\frac{\mathrm{i}}{\hbar}\frac{\mathrm{d}^2 S}{\mathrm{d}x^2} - \frac{1}{\hbar^2}\left(\frac{\mathrm{d}S}{\mathrm{d}x}\right)^2\right]\psi\,.$$

Substituting into Equation (9.60) and cancelling the nowhere-vanishing factor ψ leaves

$$\frac{\mathrm{i}}{\hbar}\frac{\mathrm{d}^2 S}{\mathrm{d}x^2} - \frac{1}{\hbar^2}\left(\frac{\mathrm{d}S}{\mathrm{d}x}\right)^2 + \frac{P^2}{\hbar^2} = 0\,,$$

and multiplication by $-\hbar^2$ gives Equation (9.63). □

The substitution has traded a linear equation of second order for a non-linear one of first order in $\mathrm{d}S/\mathrm{d}x$ — a Riccati equation — and that is a bad bargain except for one feature: $\hbar$ now appears in exactly one place, multiplying the highest derivative. The equation is therefore a singular perturbation problem in $\hbar$, and its natural treatment is a power series in that constant,

$$S(x) = S_0(x) + \hbar\,S_1(x) + \hbar^2 S_2(x) + \cdots\,, \tag{9.64}$$

in which S_0 has the dimension of an action, S_1 is dimensionless, S_2 has the dimension of a reciprocal action, and so on. Equation (9.64) is the one place in this treatise where a physical constant is treated as a formal expansion parameter; the whole structure of the method is the ordering of Equation (9.63) by powers of $\hbar$, so a convention that gave that constant the numerical value one would not simplify the argument but abolish it.

Proposition 9.61 (Eikonal and transport equations)**.** *Substituting Equation (9.64) into Equation (9.63) and collecting powers of $\hbar$ gives, at the first three orders,*

$$\left(\frac{\mathrm{d}S_0}{\mathrm{d}x}\right)^2 = P(x)^2 \qquad \textit{(eikonal)}\,, \tag{9.65}$$

$$2\,\frac{\mathrm{d}S_0}{\mathrm{d}x}\,\frac{\mathrm{d}S_1}{\mathrm{d}x} = \mathrm{i}\,\frac{\mathrm{d}^2 S_0}{\mathrm{d}x^2} \qquad \textit{(transport)}\,, \tag{9.66}$$

$$2\,\frac{\mathrm{d}S_0}{\mathrm{d}x}\,\frac{\mathrm{d}S_2}{\mathrm{d}x} + \left(\frac{\mathrm{d}S_1}{\mathrm{d}x}\right)^2 = \mathrm{i}\,\frac{\mathrm{d}^2 S_1}{\mathrm{d}x^2} \qquad \textit{(first correction)}\,. \tag{9.67}$$

Their solutions are

$$S_0(x) = \pm\int_{x_0}^{x} P(x')\,\mathrm{d}x'\,, \qquad S_1(x) = \frac{\mathrm{i}}{2}\,\ln P(x) + \textit{const}\,. \tag{9.68}$$

Rests on Proposition 9.60 and Equation (9.64).

Derivation. *Derives Proposition 9.61.*

Insert Equation (9.64) in Equation (9.63). The squared term contributes $(S_0')^2 + 2\hbar S_0' S_1' + \hbar^2\left[(S_1')^2 + 2S_0' S_2'\right] + \cdots$, and the second term contributes $-\mathrm{i}\hbar S_0'' - \mathrm{i}\hbar^2 S_1'' - \cdots$; the right-hand side P^2 is of order $\hbar^0$. Equating coefficients of $\hbar^0$, $\hbar^1$ and $\hbar^2$ gives Equations (9.65) to (9.67). The eikonal equation is solved by quadrature, with the two signs corresponding to the two directions of classical motion, which is the first equality of Equation (9.68). Dividing Equation (9.66) by $2S_0'$ turns it into

$$\frac{\mathrm{d}S_1}{\mathrm{d}x} = \frac{\mathrm{i}}{2}\,\frac{S_0''}{S_0'} = \frac{\mathrm{i}}{2}\,\frac{\mathrm{d}}{\mathrm{d}x}\ln\left|\frac{\mathrm{d}S_0}{\mathrm{d}x}\right|\,,$$

and $|S_0'| = P$ by Equation (9.65), so integrating gives the second equality. □

Corollary 9.62 (The semiclassical wave)**.** *Truncating Equation* (9.64) *after the term of order ħ, the general solution of Equation* (9.60) *in a classically allowed region free of turning points is*

$$\psi(x) \approx \frac{C_+}{\sqrt{P(x)}} \exp\left[\frac{\mathrm{i}}{\hbar}\int_{x_0}^{x} P\,\mathrm{d}x'\right] + \frac{C_-}{\sqrt{P(x)}} \exp\left[-\frac{\mathrm{i}}{\hbar}\int_{x_0}^{x} P\,\mathrm{d}x'\right], \tag{9.69}$$

and in a classically forbidden region, with κ of Equation (9.61)*,*

$$\psi(x) \approx \frac{D_+}{\sqrt{\kappa(x)}} \exp\left[\frac{1}{\hbar}\int_{x_0}^{x} \kappa\,\mathrm{d}x'\right] + \frac{D_-}{\sqrt{\kappa(x)}} \exp\left[-\frac{1}{\hbar}\int_{x_0}^{x} \kappa\,\mathrm{d}x'\right]. \tag{9.70}$$

Rests on Proposition 9.61 and Equations (9.61) *and* (9.62)*.*

Derivation. *Derives Corollary 9.62.*

By Equation (9.62) and Equation (9.68),

$$\psi = \exp\left[\frac{\mathrm{i}S_0}{\hbar}\right] \exp\left[\mathrm{i}S_1\right] = \exp\left[\pm\frac{\mathrm{i}}{\hbar}\int^{x} P\,\mathrm{d}x'\right] \exp\left[-\tfrac{1}{2}\ln P\right],$$

because $\mathrm{i}S_1 = \mathrm{i}\cdot\frac{\mathrm{i}}{2}\ln P = -\frac{1}{2}\ln P$, and the second factor is $P^{-1/2}$. Linear superposition of the two signs gives Equation (9.69). In a forbidden region $P = \mathrm{i}\kappa$, the two exponents become real, and absorbing the constant phase of $P^{-1/2}$ into the coefficients gives Equation (9.70). □

The amplitude factor is not decoration. It is the exact content of the transport equation, and it says something physical.

Proposition 9.63 (The transport equation is flux conservation)**.** *For the single travelling wave* $\psi = C_+ P^{-1/2}\exp\left[(\mathrm{i}/\hbar)\int^x P\,\mathrm{d}x'\right]$ *of Equation* (9.69)*, the probability current*

$$j = \frac{\hbar}{m}\,\Im\left[\overline{\psi(x)}\,\frac{\mathrm{d}\psi}{\mathrm{d}x}(x)\right] = \frac{|C_+|^2}{m} \tag{9.71}$$

is independent of x.

Rests on Corollary 9.62.

Derivation. *Derives Proposition 9.63.*

Write $\psi = C_+ P^{-1/2}\mathrm{e}^{\mathrm{i}\theta}$ with $\theta(x) = \hbar^{-1}\int^x P\,\mathrm{d}x'$, so that $\mathrm{d}\theta/\mathrm{d}x = P/\hbar$. Then

$$\overline{\psi}\,\frac{\mathrm{d}\psi}{\mathrm{d}x} = |C_+|^2\left[-\frac{1}{2}\,\frac{1}{P^2}\,\frac{\mathrm{d}P}{\mathrm{d}x} + \frac{\mathrm{i}}{\hbar}\right],$$

the first term inside the bracket being real because P is real in the allowed region. Taking the imaginary part and multiplying by $\hbar/m$ gives Equation (9.71). Had the amplitude been anything other than $P^{-1/2}$ the bracket would have carried an x-dependent imaginary part and the current would not have been constant, which for a stationary state on a line is impossible. □

If ψ is normalised so that $|\psi|^2$ is a probability per unit length, in 1/m, then $|C_+|^2$ is in kg/s and j in 1/s: a probability per unit time, as a current must be. Since the classical speed is $v = P/m$, Equation (9.71) reads $|\psi|^2 v =$ constant — the particle is most likely to be found where it moves slowest, which is the classical statement the approximation reproduces.

9.6.3 Where the approximation is valid, and where it is not

Definition 9.64 (Reduced de Broglie wavelength)**.** For the local momentum of Equation (9.60),

$$\bar{\lambda}(x) = \frac{\hbar}{P(x)}\,, \tag{9.72}$$

in m: the de Broglie wavelength [521] of the local motion, divided by 2π.

Rests on Equation (9.60).

Proposition 9.65 (Validity criterion)**.** *The term of order $\hbar$ in Equation (9.64) is a small correction to the leading term, in the sense that $|\hbar\,\mathrm{d}S_1/\mathrm{d}x| \ll |\mathrm{d}S_0/\mathrm{d}x|$, if and only if*

$$\left|\frac{\mathrm{d}\bar{\lambda}}{\mathrm{d}x}(x)\right| \ll 1\,, \qquad \textit{equivalently} \qquad \frac{\hbar\, m\,|V'(x)|}{P(x)^3} \ll 1\,. \tag{9.73}$$

Both expressions are dimensionless.

Rests on Proposition 9.61, Equation (9.64), and Definition 9.64.

Derivation. *Derives Proposition 9.65.*

By Equation (9.68), $\hbar\,S_1' = \mathrm{i}\hbar P'/(2P)$ and $S_0' = \pm P$, so

$$\left|\frac{\hbar\,S_1'}{S_0'}\right| = \frac{\hbar\,|P'|}{2P^2} = \frac{1}{2}\left|\frac{\mathrm{d}\bar{\lambda}}{\mathrm{d}x}\right|\,,$$

the last equality because $\mathrm{d}\bar{\lambda}/\mathrm{d}x = -\hbar P'/P^2$ from Equation (9.72). Differentiating $P^2 = 2m(E-V)$ gives $2PP' = -2mV'$, hence $P' = -mV'/P$ and $\hbar\,|P'|/P^2 = \hbar m\,|V'|/P^3$. □

The first form of Equation (9.73) is the statement usually quoted: the local wavelength must change by much less than itself over a distance of one wavelength, so that the wave sees an essentially constant potential over each oscillation. The second form makes the same point in terms of the potential, and shows that the criterion is not a smallness condition on V' alone — a gentle slope still defeats the approximation where P is small.

Remark 9.66 (Failure at a turning point). At a turning point a the momentum vanishes, so $\bar{\lambda}$ diverges and Equation (9.73) fails however smooth V may be. The failure is written on the face of the solution: the amplitudes $P^{-1/2}$ and $\kappa^{-1/2}$ in Equations (9.69) and (9.70) become infinite there, whereas the true solution of Equation (9.59) is perfectly finite. Quantitatively, near a simple turning point — one at which $F = V'(a) \neq 0$ — one has $P(x)^2 \approx 2mF(a-x)$, so the second form of Equation (9.73) behaves as $|a-x|^{-3/2}$ and reaches unity at a distance of order

$$\ell = \left(\frac{\hbar^2}{2m\,|F|}\right)^{1/3}\,, \tag{9.74}$$

in m. Outside a neighbourhood of a few ℓ the semiclassical forms are good; inside it they are worthless, and something else must be put there. That is the business of the next subsection.

Remark 9.67 (The series is asymptotic, not convergent). Equation (9.64) is an asymptotic expansion. Carrying it to high order does not converge to the exact solution and generally makes matters worse beyond an optimal truncation, in the same way as the perturbation series of the anharmonic oscillator [1392]. All statements below therefore use the first two terms only, and the accuracy claimed is the one certified by Proposition 9.65.

9.6.4 Connection across a simple turning point

Let a be a simple turning point, $V(a) = E$ with $F = V'(a) \neq 0$, and take $F > 0$, so that $x < a$ is classically allowed and $x > a$ is forbidden. On the scale ℓ of Equation (9.74) the potential may be replaced by its tangent, $V(x) \approx E + F\,(x - a)$, and Equation (9.60) becomes

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}x^2} = \frac{2mF}{\hbar^2}\,(x - a)\,\psi\,. \tag{9.75}$$

From Equation (9.60) (linearise V about the turning point).

Introducing the dimensionless variable $z = (x - a)/\ell$ turns Equation (9.75) into

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}z^2} = z\,\psi\,, \tag{9.76}$$

the *Airy equation*, whose solutions Airy introduced to describe the intensity of light near a caustic — the optical turning point, and the same mathematics [103]. Its two standard solutions are fixed by a contour integral, and it is their behaviour far from the turning point that the connection formulae are made of.

Definition 9.68 (Airy functions)**.** For $z \in \mathbb{C}$,

$$\mathrm{Ai}(z) = \frac{1}{2\pi\mathrm{i}} \int_C \exp\left[\frac{t^3}{3} - z\,t\right] \mathrm{d}t\,, \tag{9.77}$$

where C comes in from infinity along the direction $\arg t = -\pi/3$ and returns to infinity along $\arg t = +\pi/3$, and

$$\mathrm{Bi}(z) = \mathrm{e}^{\mathrm{i}\pi/6}\,\mathrm{Ai}\big(z\,\mathrm{e}^{2\pi\mathrm{i}/3}\big) + \mathrm{e}^{-\mathrm{i}\pi/6}\,\mathrm{Ai}\big(z\,\mathrm{e}^{-2\pi\mathrm{i}/3}\big)\,. \tag{9.78}$$

Proposition 9.69 (The integral solves the Airy equation)**.** *The functions of Definition 9.68 are entire, both solve Equation (9.76), both are real on the real axis, and they are linearly independent.*

Rests on Definition 9.68 and Equation (9.76).

Derivation. *Derives Proposition 9.69.*

The integrand is entire in t and decays superexponentially as $|t| \to \infty$ in each of the three open sectors where $\Re(t^3) < 0$, namely those centred on $\arg t = \pi/3$, $\arg t = \pi$ and $\arg t = -\pi/3$. Both ends of C lie in such sectors, so Equation (9.77) converges and may be differentiated under the integral sign. Since

$$\frac{\mathrm{d}}{\mathrm{d}t} \exp\left[\frac{t^3}{3} - z\,t\right] = \left(t^2 - z\right) \exp\left[\frac{t^3}{3} - z\,t\right],$$

one has

$$\frac{\mathrm{d}^2\mathrm{Ai}}{\mathrm{d}z^2}(z) - z\,\mathrm{Ai}(z) = \frac{1}{2\pi\mathrm{i}} \int_C \left(t^2 - z\right) \exp\left[\frac{t^3}{3} - z\,t\right] \mathrm{d}t = \frac{1}{2\pi\mathrm{i}} \left[\exp\left(\frac{t^3}{3} - z\,t\right)\right]_C = 0\,,$$

the bracket vanishing because both ends of C lie in decay sectors. If $\omega^3 = 1$ then $w(z) = \mathrm{Ai}(\omega z)$ satisfies $\mathrm{d}^2w/\mathrm{d}z^2 = \omega^2\,\mathrm{Ai}''(\omega z) = \omega^3\,z\,\mathrm{Ai}(\omega z) = z\,w$, so each term of Equation (9.78) solves the equation and so does their sum. Reflection: conjugating Equation (9.77) maps C onto itself with reversed orientation and sends the integrand to $\exp[t^3/3 - \bar{z}t]$, while $\overline{1/(2\pi\mathrm{i})} = -1/(2\pi\mathrm{i})$; the two sign changes cancel and $\overline{\mathrm{Ai}(z)} = \mathrm{Ai}(\bar{z})$. Hence Ai is real on the real axis, and for real z the two terms of Equation (9.78) are complex conjugates of each other, so Bi is real there too. Independence follows from Theorem 9.70 below: one solution decays and the other grows as $z \to +\infty$, so neither is a multiple of the other. □

Theorem 9.70 (Asymptotics of the Airy functions)**.** *As the real variable z tends to $+\infty$,*

$$\mathrm{Ai}(z) \sim \frac{1}{2\sqrt{\pi}\, z^{1/4}}\, \mathrm{e}^{-\frac{2}{3}z^{3/2}}, \qquad \mathrm{Ai}(-z) \sim \frac{1}{\sqrt{\pi}\, z^{1/4}} \sin\left(\tfrac{2}{3}z^{3/2} + \tfrac{\pi}{4}\right), \tag{9.79}$$

$$\mathrm{Bi}(z) \sim \frac{1}{\sqrt{\pi}\, z^{1/4}}\, \mathrm{e}^{+\frac{2}{3}z^{3/2}}, \qquad \mathrm{Bi}(-z) \sim \frac{1}{\sqrt{\pi}\, z^{1/4}} \cos\left(\tfrac{2}{3}z^{3/2} + \tfrac{\pi}{4}\right). \tag{9.80}$$

The first of these holds in the whole sector $|\arg z| < \pi$, with the principal branches of $z^{3/2}$ and $z^{1/4}$.

Rests on Definition 9.68 and Proposition 9.69.

Derivation. *Derives Theorem 9.70.*

Write the exponent of Equation (9.77) as $\varphi(t) = t^3/3 - z\,t$, so that $\varphi'(t) = t^2 - z$ and $\varphi''(t) = 2t$; the saddle points are $t = \pm\sqrt{z}$. By Cauchy's theorem and the deformation corollary (Theorem 8.12 and Corollary 8.15) the contour may be moved at will, the integrand being entire, provided its ends stay in the decay sectors. The method of steepest descent chooses the deformation on which $\Im\varphi$ is constant: the integrand then does not oscillate, its modulus has a sharp maximum at the saddle, and the whole contribution comes from a neighbourhood of it whose width shrinks as $|\varphi''|^{-1/2}$.

Positive argument. Let $z = x > 0$. The two saddles are at $t = \pm\sqrt{x}$, with $\varphi(\sqrt{x}) = -\frac{2}{3}x^{3/2}$ and $\varphi(-\sqrt{x}) = +\frac{2}{3}x^{3/2}$. The ends of C lie in the two sectors adjacent to the positive real axis, so C is deformed through the saddle at $t = +\sqrt{x}$ alone. There $\varphi'' = 2\sqrt{x}$ is real and positive, so putting $t = \sqrt{x} + \mathrm{i}u$ with u real makes $\frac{1}{2}\varphi''\,(t-\sqrt{x})^2 = -\sqrt{x}\,u^2$: the vertical line through the saddle is the path of steepest descent. On it $\mathrm{d}t = \mathrm{i}\,\mathrm{d}u$, and

$$\mathrm{Ai}(x) \approx \frac{1}{2\pi\mathrm{i}}\, \mathrm{e}^{-\frac{2}{3}x^{3/2}} \int_{-\infty}^{\infty} \mathrm{e}^{-\sqrt{x}\,u^2}\, \mathrm{i}\,\mathrm{d}u = \frac{\mathrm{e}^{-\frac{2}{3}x^{3/2}}}{2\pi} \sqrt{\frac{\pi}{\sqrt{x}}} = \frac{\mathrm{e}^{-\frac{2}{3}x^{3/2}}}{2\sqrt{\pi}\, x^{1/4}},$$

the first member of Equation (9.79). Nothing in this computation used z real: the same deformation is available, and the same result holds, for every z with $|\arg z| < \pi$.

Negative argument. Let $z = -x$ with $x > 0$, so that $\varphi(t) = t^3/3 + x\,t$ and the saddles sit at $t = \pm\mathrm{i}\sqrt{x}$ with $\varphi(\pm\mathrm{i}\sqrt{x}) = \pm\mathrm{i}\,\frac{2}{3}x^{3/2}$, purely imaginary: neither dominates the other, and both must be kept. The bookkeeping is topological. Call V_1, V_2, V_3 the decay sectors around $\arg t = \pi/3$, π and $-\pi/3$; the contour runs from V_3 to V_1. At a saddle s the steepest descent direction $\mathrm{e}^{\mathrm{i}\theta}$ is fixed by requiring $\frac{1}{2}\varphi''(s)\,\mathrm{e}^{2\mathrm{i}\theta}$ to be real and negative. At $s = -\mathrm{i}\sqrt{x}$, where $\varphi'' = 2\sqrt{x}\,\mathrm{e}^{-\mathrm{i}\pi/2}$, this gives $\theta = -\pi/4$ or $\theta = 3\pi/4$, so that descent path joins V_3 to V_2; at $s = +\mathrm{i}\sqrt{x}$, where $\varphi'' = 2\sqrt{x}\,\mathrm{e}^{\mathrm{i}\pi/2}$, it gives $\theta = \pi/4$ or $\theta = 5\pi/4$, joining V_2 to V_1. Their concatenation runs from V_3 to V_1 and is therefore a legitimate deformation of C. Each saddle contributes $\mathrm{e}^{\varphi(s)}\,\mathrm{e}^{\mathrm{i}\theta}\sqrt{\pi/\sqrt{x}}$ with θ the direction in which it is traversed — $3\pi/4$ at the lower saddle and $\pi/4$ at the upper one. Writing $\zeta = \frac{2}{3}x^{3/2}$,

$$\begin{aligned}\mathrm{Ai}(-x) &\approx \frac{1}{2\pi\mathrm{i}}\sqrt{\frac{\pi}{\sqrt{x}}}\left[\mathrm{e}^{-\mathrm{i}\zeta}\,\mathrm{e}^{3\mathrm{i}\pi/4} + \mathrm{e}^{\mathrm{i}\zeta}\,\mathrm{e}^{\mathrm{i}\pi/4}\right] \\ &= \frac{1}{2\pi\mathrm{i}}\sqrt{\frac{\pi}{\sqrt{x}}}\,\mathrm{e}^{\mathrm{i}\pi/2}\left[\mathrm{e}^{\mathrm{i}(\pi/4-\zeta)} + \mathrm{e}^{-\mathrm{i}(\pi/4-\zeta)}\right] = \frac{\cos\left(\zeta - \pi/4\right)}{\sqrt{\pi}\, x^{1/4}},\end{aligned}$$

and $\cos(\zeta - \pi/4) = \sin(\zeta + \pi/4)$, which is the second member of Equation (9.79).

The second solution. Equation (9.78) reduces both members of Equation (9.80) to the result already obtained. For $z = x > 0$ the two arguments are $x\,\mathrm{e}^{\pm 2\pi\mathrm{i}/3}$, inside the sector $|\arg z| < \pi$ where the first expansion holds; there $\left(x\mathrm{e}^{\pm 2\pi\mathrm{i}/3}\right)^{3/2} = x^{3/2}\mathrm{e}^{\pm\mathrm{i}\pi} = -x^{3/2}$ and $\left(x\mathrm{e}^{\pm 2\pi\mathrm{i}/3}\right)^{1/4} = x^{1/4}\mathrm{e}^{\pm\mathrm{i}\pi/6}$, so each term of Equation (9.78) equals $\mathrm{e}^{\pm\mathrm{i}\pi/6}\,\mathrm{e}^{+\frac{2}{3}x^{3/2}} \,/\, (2\sqrt{\pi}\, x^{1/4}\,\mathrm{e}^{\pm\mathrm{i}\pi/6})$: the phases cancel, the two terms are equal, and their sum is the first

member of Equation (9.80). For $z=-x$ the two arguments are $x\,\mathrm{e}^{\mp\mathrm{i}\pi/3}$, again inside the sector, and now $\left(x\mathrm{e}^{\mp\mathrm{i}\pi/3}\right)^{3/2}=\mp\mathrm{i}\,x^{3/2}$ and $\left(x\mathrm{e}^{\mp\mathrm{i}\pi/3}\right)^{1/4}=x^{1/4}\mathrm{e}^{\mp\mathrm{i}\pi/12}$, so the two terms are $\mathrm{e}^{\pm\mathrm{i}\pi/4}\,\mathrm{e}^{\pm\mathrm{i}\zeta}\,/\,\left(2\sqrt{\pi}\,x^{1/4}\right)$ and their sum is $\cos(\zeta+\pi/4)\,/\,\left(\sqrt{\pi}\,x^{1/4}\right)$, the second member of Equation (9.80). □

Remark 9.71 (What "asymptotic" means here). Each result above is the leading term of a full asymptotic expansion, and the expansion is obtained from the same contour. On the steepest-descent path the exponent is $\varphi(s)+\frac{1}{2}\varphi''(s)(t-s)^2+\frac{1}{6}\varphi'''(s)(t-s)^3$ *exactly*, because φ is a cubic and $\varphi'''=2$; the quadratic term is the Gaussian already used, and expanding the cubic term and integrating the Gaussian moments one by one produces a series in inverse powers of $\zeta=\frac{2}{3}z^{3/2}$, whose first correction to Ai is the relative factor $-5/(72\zeta)$. The series does not converge — it is asymptotic in the sense of Remark 9.67 — but truncating it after any fixed number of terms commits an error of the order of the first term omitted, uniformly on $|\arg z|\le\pi-\delta$ for each fixed $\delta>0$. Only the leading term is used in this chapter, and the connection formulae inherit exactly its accuracy: they are correct to relative order ζ^{-1}, which is small precisely where the semiclassical forms they connect are themselves good.

Theorem 9.72 (Connection formulae)**.** *With a a simple turning point and $F=V'(a)>0$, the semiclassical solutions on the two sides of a are related by*

$$\frac{C}{\sqrt{\kappa(x)}}\exp\left[-\frac{1}{\hbar}\int_a^x\kappa\,\mathrm{d}x'\right]\leftrightarrow\frac{2C}{\sqrt{P(x)}}\sin\left[\frac{1}{\hbar}\int_x^a P\,\mathrm{d}x'+\frac{\pi}{4}\right],\tag{9.81}$$

$$\frac{D}{\sqrt{\kappa(x)}}\exp\left[+\frac{1}{\hbar}\int_a^x\kappa\,\mathrm{d}x'\right]\leftrightarrow\frac{D}{\sqrt{P(x)}}\cos\left[\frac{1}{\hbar}\int_x^a P\,\mathrm{d}x'+\frac{\pi}{4}\right],\tag{9.82}$$

the left-hand member holding for $x>a$ and the right-hand member for $x<a$. If instead $F<0$, so that the allowed region lies to the right of a, the same formulae hold with the roles of the two sides interchanged and every integral taken outward from a.

Rests on Corollary 9.62 and Equations (9.74), (9.76), (9.79) and (9.80).

Derivation. *Derives Theorem 9.72.*

Work with the linearised equation, for which the exact solution is a combination of $\mathrm{Ai}(z)$ and $\mathrm{Bi}(z)$, and evaluate the two sides of Equation (9.81) on it. For $x>a$, that is $z>0$, Equation (9.61) gives $\kappa(x)=\sqrt{2mF(x-a)}=\sqrt{2mF\ell}\,z^{1/2}$, hence

$$\frac{1}{\hbar}\int_a^x\kappa\,\mathrm{d}x'=\frac{\ell^{3/2}\sqrt{2mF}}{\hbar}\int_0^z\sqrt{z'}\,\mathrm{d}z'=\frac{2}{3}\,z^{3/2},$$

because $\ell^{3/2}=\hbar/\sqrt{2mF}$ by Equation (9.74). So on the forbidden side the decaying semiclassical form is $C\,(2mF\ell)^{-1/4}z^{-1/4}\mathrm{e}^{-\frac{2}{3}z^{3/2}}$, which by Equation (9.79) is $2\sqrt{\pi}\,C\,(2mF\ell)^{-1/4}$ times $\mathrm{Ai}(z)$. For $x<a$ put $z=-u$ with $u>0$; then $P(x)=\sqrt{2mF\ell}\,u^{1/2}$ and, by the same computation, $\hbar^{-1}\int_x^a P\,\mathrm{d}x'=\frac{2}{3}u^{3/2}$. The second relation of Equation (9.79) therefore gives

$$2\sqrt{\pi}\,C\,(2mF\ell)^{-1/4}\,\mathrm{Ai}(-u)\sim 2C\,(2mF\ell)^{-1/4}u^{-1/4}\sin\left(\tfrac{2}{3}u^{3/2}+\tfrac{\pi}{4}\right)=\frac{2C}{\sqrt{P}}\sin\left[\frac{1}{\hbar}\int_x^a P\,\mathrm{d}x'+\frac{\pi}{4}\right],$$

which is Equation (9.81). The factor 2 is nothing but the ratio of the two prefactors in Equation (9.79), and the phase $\pi/4$ is the constant carried across by the same pair. Repeating the computation with Bi in place of Ai, whose two prefactors in Equation (9.80) are equal, gives Equation (9.82) with no factor of 2. The case $F<0$ is the reflection $x\mapsto 2a-x$, which leaves Equation (9.60) invariant. □

Remark 9.73 (The formulae are not symmetric in practice). Equation (9.81) may be read reliably only from left to right, and Equation (9.82) only from right to left. The reason is that an exponentially small admixture of the growing solution is invisible beside the

decaying one on the forbidden side, yet dominates once traced back to the allowed side; the asymptotic representation of a solution therefore changes discontinuously as the turning point is crossed in the complex plane. This is the Stokes phenomenon, and ignoring it is the commonest error in applications of the method. Every connection made below is therefore labelled with its direction: the quantisation condition of Section 9.6.7 uses only the safe one, and the single delicate step in the tunnelling derivation is flagged where it occurs and its cost accounted for in Remark 9.77.

9.6.5 Turning points of higher order

The linearisation Equation (9.75) presumed $F = V'(a) \neq 0$. Where the potential meets the energy level tangentially that derivative vanishes too and the Airy problem is empty, so let $\mu \geq 1$ be the order of contact,

$$V(x) - E \approx F_\mu \, (x-a)^\mu \,, \qquad F_\mu = \frac{V^{(\mu)}(a)}{\mu!} \neq 0 \,, \tag{9.83}$$

F_μ carrying the SI unit of an energy divided by the μ-th power of a length, so that F_1 is the force F of Section 9.6.4 in J/m. The odd and even cases are genuinely different, and only the odd one is a turning point at all.

Proposition 9.74 (Connection at a turning point of odd order)**.** *Let μ be odd and $F_\mu > 0$ in Equation (9.83), so that $x < a$ is classically allowed and $x > a$ forbidden. Then the decaying solution on the forbidden side connects to*

$$\frac{C}{\sqrt{\kappa(x)}} \exp\left[-\frac{1}{\hbar}\int_a^x \kappa \,\mathrm{d}x'\right] \quad \leftrightarrow \quad \frac{C}{\sin\left[\pi/\left(2\mu+4\right)\right]} \frac{1}{\sqrt{P(x)}} \sin\left[\frac{1}{\hbar}\int_x^a P \,\mathrm{d}x' + \frac{\pi}{4}\right] . \tag{9.84}$$

The phase $\pi/4$ is the same as in Equation (9.81) for every odd μ; only the amplitude changes, and at $\mu = 1$ the factor is $1/\sin(\pi/6) = 2$, which recovers Theorem 9.72.

Rests on Theorem 9.72 and Equation (9.83).

Derivation. *Derives Proposition 9.74.*

Put $s = x - a$ and $k = \sqrt{2mF_\mu}/\hbar$, a positive constant. Near a, Equation (9.60) reads

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}s^2} = k^2 \, s^\mu \, \psi \,,$$

and for $s > 0$ the substitution $\zeta = 2k\, s^q/(\mu+2)$ with $q = (\mu+2)/2$, together with $\psi = \sqrt{s}\,\chi(\zeta)$, turns it by a direct computation into the modified Bessel equation of order $\nu = 1/(\mu+2)$. A basis of local solutions is therefore $\sqrt{s}\, I_{\pm\nu}(\zeta)$, and the decaying combination is $\sqrt{s}\,[I_{-\nu}(\zeta) - I_\nu(\zeta)]$, proportional to $\sqrt{s}\, K_\nu(\zeta)$. Note that $\zeta = \hbar^{-1}\int_a^x \kappa \,\mathrm{d}x'$ exactly for the local potential, since $\kappa = \hbar k\, s^{\mu/2}$ there.

Continue to the allowed side by rotating $s = u\,\mathrm{e}^{\mathrm{i}\pi}$ with $u = a - x > 0$. Then $\zeta = w\,\mathrm{e}^{\mathrm{i}\pi q}$ with $w = 2k\,u^q/(\mu+2) = \hbar^{-1}\int_x^a P \,\mathrm{d}x'$. In the power series

$$I_\sigma(\zeta) = \sum_{j\geq 0} \frac{1}{j!\,\Gamma(j+\sigma+1)} \left(\frac{\zeta}{2}\right)^{2j+\sigma}$$

the rotation multiplies the j-th term by $\mathrm{e}^{2\pi\mathrm{i}qj} = \mathrm{e}^{\mathrm{i}\pi(\mu+2)j} = (-1)^j$, because $\mu+2$ is odd; and an alternating sign is exactly what turns the modified Bessel series into the ordinary one. Hence $I_\sigma(w\,\mathrm{e}^{\mathrm{i}\pi q}) = \mathrm{e}^{\mathrm{i}\pi q\sigma}\, J_\sigma(w)$. With $q\nu = \tfrac{1}{2}$ and $\sqrt{s} = \mathrm{e}^{\mathrm{i}\pi/2}\sqrt{u}$ the two basis solutions continue to $\mathrm{e}^{\mathrm{i}\pi/2}\mathrm{e}^{\pm\mathrm{i}\pi/2}\sqrt{u}\, J_{\pm\nu}(w)$, that is to $-\sqrt{u}\, J_\nu(w)$ and $+\sqrt{u}\, J_{-\nu}(w)$, so the decaying solution continues to $\sqrt{u}\,[J_{-\nu}(w) + J_\nu(w)]$. This much is exact.

It remains to read off the two amplitudes, and for that one classical fact is imported: the large-argument behaviour of the Bessel functions, $K_\nu(\zeta) \sim \sqrt{\pi/(2\zeta)}\ \mathrm{e}^{-\zeta}$ and $J_\sigma(w) \sim \sqrt{2/(\pi w)}\cos(w - \sigma\pi/2 - \pi/4)$ [1023]. The prefactors $\sqrt{s/\zeta}$ and $\sqrt{u/w}$ are the same function of $|s|$ with the same constant in front, and each reproduces the semiclassical amplitude, $\kappa^{-1/2}$ on one side and $P^{-1/2}$ on the other, so only the pure numbers matter. On the forbidden side $I_{-\nu} - I_\nu = (2\sin\nu\pi/\pi)\,K_\nu$ leaves the number $(2\sin\nu\pi/\pi)\sqrt{\pi/2} = \sqrt{2/\pi}\,\sin\nu\pi$. On the allowed side

$$J_\nu(w) + J_{-\nu}(w) \sim \sqrt{\frac{2}{\pi w}}\,2\cos\left(\frac{\nu\pi}{2}\right)\cos\left(w - \frac{\pi}{4}\right),$$

the two phase shifts $\mp\nu\pi/2$ averaging away and leaving the universal $-\pi/4$. The ratio of the two numbers is

$$\frac{2\cos(\nu\pi/2)\sqrt{2/\pi}}{\sqrt{2/\pi}\,\sin\nu\pi} = \frac{2\cos(\nu\pi/2)}{2\sin(\nu\pi/2)\cos(\nu\pi/2)} = \frac{1}{\sin(\nu\pi/2)},$$

which with $\nu = 1/(\mu+2)$ is the factor in Equation (9.84); and $\cos(w-\pi/4) = \sin(w+\pi/4)$ completes it. □

Remark 9.75 (Even order is tangency, not a turning point). For even μ the difference $V - E$ does not change sign at a, so a is not a turning point at all: the motion is either forbidden on both sides of it or allowed on both, and there are no two regimes to connect. The rotation argument above fails at exactly that point — $\mu+2$ is then even, $\mathrm{e}^{2\pi\mathrm{i}qj} = +1$, and the modified Bessel series is not turned into the ordinary one. The instance that matters physically is $\mu = 2$ with $F_2 < 0$: the top of a barrier sitting exactly at the energy of the incident particle. There the local equation is the parabolic-cylinder equation rather than Equation (9.76), and the transmission coefficient passes smoothly through the barrier top instead of jumping. That regime is outside the linear connection theory of this section, and Remark 9.77 has already recorded that $\gamma \lesssim 1$ is precisely where the formulae derived here are not entitled to be used.

The other place where the semiclassical treatment fails for a reason that is not a simple turning point is the origin of the radial equation, where the centrifugal term diverges. That case has its own repair, and it is derived in Section 9.6.10.

9.6.6 Barrier penetration and the Gamow factor

Theorem 9.76 (Semiclassical transmission through a barrier)**.** *Let $V > E$ on an interval (a,b) and $V < E$ outside it, with simple turning points at a and b. Write*

$$\gamma = \frac{1}{\hbar}\int_a^b \sqrt{2m\,[V(x) - E]}\,\mathrm{d}x\,, \tag{9.85}$$

a dimensionless number, the integrand being in kg m/s *and $\hbar$ in* J s*. Then the transmission coefficient — the ratio of transmitted to incident probability current — is*

$$T = \left(\mathrm{e}^{\gamma} + \tfrac{1}{4}\mathrm{e}^{-\gamma}\right)^{-2}, \tag{9.86}$$

which for a thick barrier, $\gamma \gg 1$, reduces to

$$T \approx \mathrm{e}^{-2\gamma} = \exp\left[-\frac{2}{\hbar}\int_a^b \sqrt{2m\,[V(x) - E]}\,\mathrm{d}x\right], \tag{9.87}$$

the correction being of relative size $\mathrm{e}^{-2\gamma}/2$. The exponent 2γ is the Gamow factor.

Rests on Corollary 9.62, Theorem 9.72, and Proposition 9.63.

Derivation. *Derives Theorem 9.76.*

Beyond the barrier, for $x > b$, impose a purely outgoing wave and write it with the phase measured from b,

$$\psi(x) = \frac{\mathcal{A}}{\sqrt{P(x)}} \exp\left\{ \mathrm{i} \left[\frac{1}{\hbar} \int_b^x P \, \mathrm{d}x' + \frac{\pi}{4} \right] \right\} = \frac{\mathcal{A}}{\sqrt{P}} \left[\cos\Theta + \mathrm{i} \sin\Theta \right] ,$$

with $\Theta(x) = \hbar^{-1} \int_b^x P \, \mathrm{d}x' + \pi/4$. At b the forbidden region lies to the left, so Theorem 9.72 is used in its reflected form. The direction has to be said carefully, because "growing towards b" and "growing away from b" name opposite solutions: measured *into* the barrier, the way Equations (9.81) and (9.82) measure it, the $\cos\Theta$ part comes from the exponential growing away from b and the $\sin\Theta$ part from the one decaying away from it, with the coefficients read off Equation (9.82) and Equation (9.81) respectively. Hence inside the barrier

$$\psi(x) = \frac{\mathcal{A}}{\sqrt{\kappa}} \exp\left[+\frac{1}{\hbar} \int_x^b \kappa \, \mathrm{d}x' \right] + \frac{\mathrm{i}\mathcal{A}/2}{\sqrt{\kappa}} \exp\left[-\frac{1}{\hbar} \int_x^b \kappa \, \mathrm{d}x' \right] .$$

The first of these two readings is in the safe direction of Remark 9.73; the second is not, and it is the sole source of the order-unity ambiguity recorded in Remark 9.77 — it is the term that carries the coefficient $\frac{1}{4}$ into Equation (9.86), and it does not affect the exponent.

Now re-express the exponents about the other turning point using $\int_x^b \kappa = \hbar\gamma - \int_a^x \kappa$, which turns the first term into $\mathcal{A}\mathrm{e}^{\gamma}$ times the exponential decaying away from a and the second into $(\mathrm{i}\mathcal{A}/2)\mathrm{e}^{-\gamma}$ times the one growing away from a. At a the allowed region lies to the left, which is exactly the configuration of Theorem 9.72, so with $\Xi(x) = \hbar^{-1} \int_x^a P \, \mathrm{d}x' + \pi/4$,

$$\psi(x) = \frac{1}{\sqrt{P}} \left[2\mathcal{A}\mathrm{e}^{\gamma} \sin\Xi + \frac{\mathrm{i}\mathcal{A}}{2} \mathrm{e}^{-\gamma} \cos\Xi \right] , \qquad x < a \, .$$

Writing $\sin\Xi = (\mathrm{e}^{\mathrm{i}\Xi} - \mathrm{e}^{-\mathrm{i}\Xi})/(2\mathrm{i})$ and $\cos\Xi = (\mathrm{e}^{\mathrm{i}\Xi} + \mathrm{e}^{-\mathrm{i}\Xi})/2$ and collecting,

$$\psi(x) = \frac{\mathrm{i}\mathcal{A}}{\sqrt{P}} \left[\left(\mathrm{e}^{\gamma} + \tfrac{1}{4}\mathrm{e}^{-\gamma} \right) \mathrm{e}^{-\mathrm{i}\Xi} - \left(\mathrm{e}^{\gamma} - \tfrac{1}{4}\mathrm{e}^{-\gamma} \right) \mathrm{e}^{\mathrm{i}\Xi} \right] .$$

Since $\mathrm{d}\Xi/\mathrm{d}x = -P/\hbar$, the term in $\mathrm{e}^{-\mathrm{i}\Xi}$ advances in phase with increasing x and is the incident wave, while $\mathrm{e}^{\mathrm{i}\Xi}$ is the reflected one. The amplitude $P^{-1/2}$ has already made $|\cdot|^2$ proportional to the current, by Proposition 9.63, so the transmission coefficient is the ratio of the squared coefficients of the transmitted and incident waves,

$$T = \frac{|\mathcal{A}|^2}{|\mathcal{A}|^2 \left(\mathrm{e}^{\gamma} + \frac{1}{4}\mathrm{e}^{-\gamma} \right)^2} ,$$

which is Equation (9.86). Expanding, $T = \mathrm{e}^{-2\gamma}\left(1 + \frac{1}{4}\mathrm{e}^{-2\gamma}\right)^{-2} = \mathrm{e}^{-2\gamma}\left[1 - \frac{1}{2}\mathrm{e}^{-2\gamma} + \cdots\right]$. □

Remark 9.77 (How much of the prefactor is real). Only the exponential in Equation (9.87) is a reliable output of the method. The order-unity factor multiplying it depends on how the two turning points are treated, and Equation (9.86) is not exact: the linear connection formulae assume the two turning points are far apart on the scale ℓ of Equation (9.74), and a uniform treatment that does not gives $T = \left(1 + \mathrm{e}^{2\gamma}\right)^{-1}$ instead. The place where the two disagree is worth being exact about, because it is the opposite of what one might guess. Both tend to $\mathrm{e}^{-2\gamma}$ with the *same* unit prefactor as γ grows, and they are numerically indistinguishable in the regime a barrier problem usually lives in: their ratio is 1.009 at $\gamma = 2$, and 1 to ten significant figures at the $\gamma = 33.6$ of Example 9.81. They part company only near the top of the barrier, $\gamma \lesssim 1$, where the ratio reaches 1.28 at $\gamma = 0$ — and that is precisely the regime in which the two turning points are no longer far apart on the scale ℓ, so the linear connection formulae were never entitled to be used there. The exponent is the whole physical content, and it is the part the method actually determines.

The exponential is the result Gamow, and independently Gurney and Condon, put to work on the escape of a charged particle from a nucleus [600, 603, 625]; the same expression, with a triangular barrier, is Fowler and Nordheim's account of electron emission from a cold metal in a strong field [599]. What this section supplies is the mathematics: a formula for the exponent, its derivation, and an honest statement of what it does and does not determine.

9.6.7 Bohr–Sommerfeld quantisation and the Maslov index

Theorem 9.78 (Semiclassical quantisation of a well)**.** *Let $V < E$ on an interval (a, b) and $V > E$ outside it, with simple turning points at a and b. A solution of Equation (9.59) that decays in both forbidden regions exists only for those energies satisfying*

$$\frac{1}{\hbar}\int_a^b P(x)\,\mathrm{d}x = \left(n+\frac{1}{2}\right)\pi\,, \qquad n = 0, 1, 2, \dots\,. \tag{9.88}$$

Equivalently, in terms of the action accumulated over one full classical period, with $h = 2\pi\hbar$ the Planck constant,

$$\oint P\,\mathrm{d}x = 2\int_a^b P(x)\,\mathrm{d}x = \left(n+\frac{\mu}{4}\right)h\,, \qquad \mu = 2\,. \tag{9.89}$$

Rests on Equation (9.59), Theorem 9.72, and Corollary 9.62.

Derivation. Derives Theorem 9.78.

Decay in the left forbidden region, $x < a$, is the configuration of Theorem 9.72 reflected, and connects to

$$\psi(x) = \frac{2C}{\sqrt{P}}\sin\left[\frac{1}{\hbar}\int_a^x P\,\mathrm{d}x' + \frac{\pi}{4}\right]$$

inside the well. Decay in the right forbidden region, $x > b$, connects by Equation (9.81) to

$$\psi(x) = \frac{2C'}{\sqrt{P}}\sin\left[\frac{1}{\hbar}\int_x^b P\,\mathrm{d}x' + \frac{\pi}{4}\right]\,.$$

These are two expressions for the same function, so they must agree up to sign for every x in (a, b). Write $\theta(x) = \hbar^{-1}\int_a^x P\,\mathrm{d}x'$ and $\Phi = \hbar^{-1}\int_a^b P\,\mathrm{d}x'$, so that $\hbar^{-1}\int_x^b P\,\mathrm{d}x' = \Phi - \theta$, and expand

$$\sin\left(\Phi - \theta + \tfrac{\pi}{4}\right) = \sin\left(\Phi + \tfrac{\pi}{2}\right)\cos\left(\theta + \tfrac{\pi}{4}\right) - \cos\left(\Phi + \tfrac{\pi}{2}\right)\sin\left(\theta + \tfrac{\pi}{4}\right)\,.$$

For this to be a constant multiple of $\sin(\theta + \pi/4)$ for all θ, the coefficient of the independent function $\cos(\theta + \pi/4)$ must vanish, that is $\cos\Phi = 0$, whence $\Phi = (n + \frac{1}{2})\pi$ with n a non-negative integer, which is Equation (9.88). The remaining coefficient is then $-\cos(\Phi + \pi/2) = \sin\Phi = (-1)^n$, so $C' = (-1)^n C$ and the two expressions do agree. Doubling and multiplying by $\hbar$ gives $\oint P\,\mathrm{d}x = (2n+1)\pi\hbar = (n + \frac{1}{2})h$, which is Equation (9.89). □

Remark 9.79 (Where the one half comes from)*.* The old quantum theory quantised the phase integral as $\oint P\,\mathrm{d}x = nh$ [441], generalising Bohr's quantisation of the angular momentum of a circular orbit [395], and had no account of the additional $h/2$. Theorem 9.78 shows that it is not an empirical patch but an accounting of turning points: each of the two simple turning points contributed a phase $\pi/4$ through Equation (9.81), and $2 \times \pi/4 = \pi/2$ is exactly the half-integer. The integer μ of Equation (9.89) counts those contributions — one per turning point for a one-dimensional well, so $\mu = 2$ — and is the *Maslov index*. Keller identified the same index as the count of caustics traversed by the classical trajectory, and thereby extended the condition to systems of more than one degree of freedom, where the quantisation applies to each independent circuit of an invariant torus [1150]. A turning point at an infinitely steep wall, where the wave function must simply vanish, contributes $\pi/2$ rather than $\pi/4$ and so counts twice in μ.

Example 9.80 (The harmonic oscillator)**.** For $V(x) = \frac{1}{2}m\omega^2 x^2$, with m in kg and ω in rad/s, the turning points of energy E are at $x = \pm x_E$ with $x_E = \sqrt{2E/(m\omega^2)}$, and

$$\oint P\,\mathrm{d}x = 2\int_{-x_E}^{x_E} \sqrt{2mE - m^2\omega^2 x^2}\,\mathrm{d}x = \frac{2\pi E}{\omega}\,, \tag{9.90}$$

the integral being the area of an ellipse with semi-axes x_E and $\sqrt{2mE}$ in the phase plane. Equation (9.89) then gives $2\pi E/\omega = (n + \frac{1}{2})\,2\pi\hbar$, that is

$$E_n = \left(n + \frac{1}{2}\right)\hbar\omega\,, \qquad n = 0, 1, 2, \ldots\,, \tag{9.91}$$

in J. These are the exact eigenvalues of Equation (9.59) for this potential, zero-point energy included — an accident of the harmonic case, not a general property of the approximation, but a reassuring one. For a vibrational mode of angular frequency $\omega = 5.0 \times 10^{14}\,\mathrm{rad/s}$, typical of a diatomic molecule, the spacing is $\hbar\omega = 5.3 \times 10^{-20}\,\mathrm{J} = 0.33\,\mathrm{eV}$.

Rests on Theorem 9.78.

9.6.8 Worked example: a charged particle against a Coulomb barrier

Example 9.81 (Gamow factor for an alpha particle, in SI)**.** Take a particle of charge ze and mass m inside a spherical region of radius R whose boundary it must cross against the electrostatic repulsion of a residual charge Ze. Outside R the potential energy is

$$V(r) = \frac{zZe^2}{4\pi\varepsilon_0\, r}\,, \qquad r > R\,, \tag{9.92}$$

in J, with $e = 1.602\,176\,634 \times 10^{-19}\,\mathrm{C}$ exactly and $\varepsilon_0 = 8.854\,187\,812\,8 \times 10^{-12}\,\mathrm{F/m}$ [2392]. Take the alpha particle, $z = 2$ and $m_\alpha = 6.644\,657\,335\,7 \times 10^{-27}\,\mathrm{kg}$ [2392], with $Z = 82$, $R = 9.0\,\mathrm{fm}$ and a kinetic energy at infinity of

$$E = 5.00\,\mathrm{MeV} = 8.0109 \times 10^{-13}\,\mathrm{J}\,.$$

The charge factor is $zZe^2/(4\pi\varepsilon_0) = 3.7836 \times 10^{-26}\,\mathrm{J\,m}$, so the outer turning point, where $V(b) = E$, sits at

$$b = \frac{zZe^2}{4\pi\varepsilon_0 E} = 4.7231 \times 10^{-14}\,\mathrm{m} = 47.23\,\mathrm{fm}\,,$$

five times the radius of the source region. Only b is a turning point here: at $r = R$ the model potential is cut off discontinuously by the nuclear surface, and $V(R) = 26.24\,\mathrm{MeV}$ is far above E (Example 9.82), so the momentum does not vanish there and no connection formula can be applied at R. That puts the configuration *outside* the hypothesis of Theorem 9.76, which asks for simple turning points at both ends of the barrier and performs one connection at each: here the inner end is a hard wall, off which the incident amplitude is reflected rather than matched to an Airy function. What is taken from that theorem is therefore its exponent alone. The barrier integral Equation (9.85) is taken from the edge of the source region to the single turning point b, while the order-unity factor multiplying $\mathrm{e}^{-2\gamma}$ — which Equation (9.86) determines only in the two-turning-point case, and there only to the accuracy Remark 9.77 records — is not fixed by anything proved here. Since $V(r) - E = E\,(b/r - 1)$ by Equation (9.92), the exponent Equation (9.85) taken between R and b is $\hbar^{-1}\sqrt{2mE}\int_R^b \sqrt{b/r - 1}\,\mathrm{d}r$, and the substitution $r = b\cos^2\vartheta$ evaluates it in closed form: with $\xi = R/b = 0.1906$,

$$\gamma = \frac{\sqrt{2mE}\,b}{\hbar}\left[\arccos\sqrt{\xi} - \sqrt{\xi\,(1-\xi)}\right]. \tag{9.93}$$

Numerically $\sqrt{2mE} = 1.0318 \times 10^{-19}\,\mathrm{kg\,m/s}$, $\arccos\sqrt{\xi} = 1.1191$, $\sqrt{\xi(1-\xi)} = 0.3927$, and the bracket is 0.7263, so

$$\gamma = \frac{1.0318 \times 10^{-19}\,\mathrm{kg\,m/s} \times 4.7231 \times 10^{-14}\,\mathrm{m} \times 0.7263}{1.054\,571\,817 \times 10^{-34}\,\mathrm{J\,s}} = 33.56\,,$$

dimensionless as required, since kg m/s × m divided by J s is a pure number. The Gamow factor is $2\gamma = 67.13$, and the exponential of Equation (9.87) gives

$$T \approx \mathrm{e}^{-67.13} = 7.0 \times 10^{-30}\,, \tag{9.94}$$

about one crossing in 1.4×10^{29} attempts — an order-of-magnitude statement, the prefactor being undetermined here for the reason given above. Two checks are worth recording. First, letting $R \to 0$ replaces the bracket of Equation (9.93) by $\pi/2$ and gives $2\gamma \to 2\pi\eta$ with $\eta = zZe^2/(4\pi\varepsilon_0\hbar v)$ and $v = \sqrt{2E/m} = 1.553 \times 10^7\,\mathrm{m/s}$; here $\eta = 23.11$ and $2\pi\eta = 145.2$, more than twice the actual exponent, so the finite size of the source region is not a detail. Second, with $c = 299\,792\,458\,\mathrm{m/s}$ exactly, $v/c = 0.052$, which justifies using the non-relativistic Equation (9.59) at all.

Rests on Theorem 9.76.

Example 9.82 (Checking the validity criterion for the barrier above)**.** Return to the data of Example 9.81. At the inner edge $r = R$ the potential energy is $V(R) = 26.24\,\mathrm{MeV}$, so $V(R) - E = 21.24\,\mathrm{MeV}$, $\kappa(R) = 2.1266 \times 10^{-19}\,\mathrm{kg\,m/s}$ and $\bar{\lambda}(R) = \hbar/\kappa(R) = 0.496\,\mathrm{fm}$. With $|V'(R)| = zZe^2/(4\pi\varepsilon_0 R^2) = 467\,\mathrm{J/m}$, the criterion Equation (9.73) evaluates to

$$\frac{\hbar\, m_\alpha\, |V'(R)|}{\kappa(R)^3} = 0.034\,,$$

comfortably small. It grows without bound on approach to b, where $|V'(b)| = 16.96\,\mathrm{J/m}$ gives an Airy scale Equation (9.74) of $\ell = 3.67\,\mathrm{fm}$: the semiclassical forms are worthless over a few femtometres at the outer turning point, of order a tenth of the barrier width $b - R = 38\,\mathrm{fm}$. That region is precisely the one handled by Theorem 9.72 and not by Equation (9.70). Finally, the free momentum $\sqrt{2mE}$ corresponds to $\bar{\lambda} = 1.02\,\mathrm{fm}$ outside the barrier, small against that same width, which is the qualitative statement the criterion makes quantitative.

Rests on Proposition 9.65 and Example 9.81.

9.6.9 The radial equation

In three-dimensional space with a potential depending only on the radius, separation of variables (Chapter 10) writes a stationary state as $\psi = u(r)\,Y(\theta,\varphi)/r$, with Y a spherical harmonic of degree n (Equation (9.163)). The azimuthal index of Y does not enter the radial equation, which is why it is not displayed here beside the mass m; the radial factor u obeys

$$-\frac{\hbar^2}{2m}\frac{\mathrm{d}^2u}{\mathrm{d}r^2}(r) + \left[V(r) + \frac{\hbar^2\, n(n+1)}{2m\, r^2}\right] u(r) = E\,u(r)\,, \qquad r > 0\,, \tag{9.95}$$

with $u(0) = 0$. This is Equation (9.59) on the half-line with the centrifugal term added to the potential, so everything derived above applies verbatim once V is replaced by the bracket. For $n = 0$ the bracket is V itself, which is the case used in Example 9.81. For $n \geq 1$ the replacement is legitimate away from the origin but not at it: the centrifugal term diverges as r^{-2}, the criterion Equation (9.73) fails there however smooth V is, and the naive substitution gives the wrong energies. The repair, due to Langer, is to replace $n(n+1)$ by $\left(n + \tfrac{1}{2}\right)^2$ before applying the approximation, and it is derived next.

9.6.10 The Langer substitution

Theorem 9.83 (Langer transformation of the radial equation)**.** *Fix a reference length r_0 in* m *and let u solve the radial equation Equation (9.95) on $r > 0$. Under the change of independent and dependent variable*

$$r = r_0\,\mathrm{e}^{\varrho}\,, \qquad u(r) = \mathrm{e}^{\varrho/2}\,w(\varrho)\,, \qquad \varrho \in \mathbb{R}\,, \tag{9.96}$$

the radial equation becomes, exactly and with no approximation,

$$\frac{\mathrm{d}^2 w}{\mathrm{d}\varrho^2}(\varrho) + \frac{Q(\varrho)^2}{\hbar^2}\,w(\varrho) = 0\,, \qquad Q^2 = 2m\,[E - V(r)]\,r^2 - \hbar^2\left(n+\tfrac{1}{2}\right)^2\,, \tag{9.97}$$

a problem of the form Equation (9.60) on the whole line, with Q in J s *and ϱ dimensionless. Its semiclassical phase integral, transported back to the radial variable, is*

$$\frac{1}{\hbar}\int Q\,\mathrm{d}\varrho = \frac{1}{\hbar}\int \sqrt{2m\,[E - V(r)] - \frac{\hbar^2\left(n+\tfrac{1}{2}\right)^2}{r^2}}\;\mathrm{d}r\,, \tag{9.98}$$

which is the radial phase integral with $n(n+1)$ replaced by $\left(n+\tfrac{1}{2}\right)^2$.

Rests on Equations (9.60) and (9.95).

Derivation. *Derives Theorem 9.83.*

From Equation (9.96), $\mathrm{d}/\mathrm{d}r = r^{-1}\mathrm{d}/\mathrm{d}\varrho$ with $r = r_0\mathrm{e}^{\varrho}$, so

$$\frac{\mathrm{d}u}{\mathrm{d}r} = \frac{1}{r_0}\,\mathrm{e}^{-\varrho/2}\left(\frac{\mathrm{d}w}{\mathrm{d}\varrho} + \frac{w}{2}\right)\,, \qquad \frac{\mathrm{d}^2 u}{\mathrm{d}r^2} = \frac{1}{r_0^2}\,\mathrm{e}^{-3\varrho/2}\left(\frac{\mathrm{d}^2 w}{\mathrm{d}\varrho^2} - \frac{w}{4}\right)\,,$$

the cross terms in $\mathrm{d}w/\mathrm{d}\varrho$ cancelling in the second derivative, which is what the factor $\mathrm{e}^{\varrho/2}$ in Equation (9.96) was chosen to arrange. Substituting into Equation (9.95) written as

$$\frac{\mathrm{d}^2 u}{\mathrm{d}r^2} + \left[\frac{2m\,(E-V)}{\hbar^2} - \frac{n(n+1)}{r^2}\right]u = 0$$

and multiplying through by $r_0^2\,\mathrm{e}^{3\varrho/2}$ gives

$$\frac{\mathrm{d}^2 w}{\mathrm{d}\varrho^2} - \frac{w}{4} + \frac{2m\,(E-V)}{\hbar^2}\,r^2\,w - n(n+1)\,w = 0\,,$$

because $r_0^2\mathrm{e}^{2\varrho} = r^2$. The two constant terms combine as $n(n+1) + \tfrac{1}{4} = \left(n+\tfrac{1}{2}\right)^2$, which is Equation (9.97). For Equation (9.98), $\mathrm{d}\varrho = \mathrm{d}r/r$, so

$$Q\,\mathrm{d}\varrho = \sqrt{2m\,(E-V)\,r^2 - \hbar^2\left(n+\tfrac{1}{2}\right)^2}\;\frac{\mathrm{d}r}{r} = \sqrt{2m\,(E-V) - \frac{\hbar^2\left(n+\tfrac{1}{2}\right)^2}{r^2}}\;\mathrm{d}r\,.$$

Both terms of Q^2 carry the square of J s — the first because $2m\,(E-V)\,r^2$ is a mass times an energy times an area, the second manifestly — so $Q/\hbar$ is dimensionless, as an exponent per unit of ϱ must be; the arbitrary r_0 has cancelled out of both Equation (9.97) and Equation (9.98), as it must, since shifting it only translates ϱ. □

Remark 9.84 (Why the replacement is not optional). Three things are settled at once by Theorem 9.83. First, the half-line $r > 0$, whose endpoint at the origin is singular, becomes the whole line, on which Q^2 tends to the finite constant $-\hbar^2\left(n+\tfrac{1}{2}\right)^2$ as $\varrho \to -\infty$: the coefficient no longer diverges, the criterion Equation (9.73) is satisfied there, and

the semiclassical solution $w \sim \exp\left[\pm\left(n+\tfrac{1}{2}\right)\varrho\right]$ reproduces through Equation (9.96) the exact behaviours $u \sim r^{n+1}$ and $u \sim r^{-n}$ of Equation (9.95) at the origin — which the untransformed approximation does not, since with $n(n+1)$ in place of $\left(n+\tfrac{1}{2}\right)^2$ the same computation returns $u \sim r^{1/2\pm\sqrt{n(n+1)}}$, a pair of irrational exponents that agree with the exact ones only in the limit of large n. Second, the transformation is exact, so nothing has been assumed: the substitution $n(n+1) \to \left(n+\tfrac{1}{2}\right)^2$ is not a patch applied to the answer but the statement that the approximation had been made in the wrong variable. Third, the turning points of the transformed problem are simple for a potential of the usual kind, so Theorem 9.72 applies to it unchanged and Equation (9.88) may be used with the phase integral Equation (9.98). The Coulomb potential is the standard check [1023]: with the corrected coefficient the quantisation condition returns the exact hydrogen levels, and with $n(n+1)$ it does not.

Rests on Theorem 9.83.

Remark 9.85 (The $\hbar = 1$ convention of the literature). Most treatments of this material set $\hbar = 1$ and write the semiclassical exponent as $\int P\,\mathrm{d}x$ and the Gamow factor as $2\int \kappa\,\mathrm{d}x$. This treatise does not, for the reason given after Equation (9.64): $\hbar$ is the expansion parameter, and a convention that hides it hides the structure of the method. A reader coming from such a text restores the SI form of every expression above by the single rule that each exponent must be dimensionless: divide any integral of a momentum over a length by $\hbar$, in J s, and any energy by $\hbar$ before comparing it with an angular frequency. Momenta are then in kg m/s, lengths in m and energies in J, and no formula in this section needs any other change.

9.6.11 Boundary layers and matched asymptotic expansions

The semiclassical expansion is one half of the theory of a small parameter multiplying the highest derivative. It is the half in which the reduced problem is oscillatory and the small parameter sets a wavelength. The other half is the one in which the reduced problem is of lower order and *cannot meet all the boundary conditions*: the neglected derivative then reasserts itself in a thin region, a *boundary layer*, whose thickness is set by the small parameter and inside which the solution turns rapidly to meet the condition the outer solution had to abandon. The technique for handling that case is the same in outline — expand, and match — and is set out here because the physical parts need it and because a reader who has followed Section 9.6 has already done the harder half.

Definition 9.86 (Outer and inner expansions; matching)**.** Consider a problem containing a small parameter $\varepsilon > 0$ on a fixed interval. An *outer expansion* is a series in ε solving the problem with ε set to zero at leading order, valid where the solution varies on the scale of the interval. An *inner expansion* is a series solving the problem rewritten in a stretched variable $\xi = (x - x_c)/\delta(\varepsilon)$ about a point x_c, with $\delta \to 0$; the choice of δ for which the rewritten equation retains its highest derivative in a non-trivial balance is the *distinguished limit*. The two are joined by the *matching condition*

$$\lim_{\xi\to\infty} y_{\mathrm{in}}(\xi) = \lim_{x\to x_c} y_{\mathrm{out}}(x)\,, \tag{9.99}$$

which says that the inner solution far out and the outer solution close in describe the same thing, and the *composite* approximation is

$$y_{\mathrm{c}}(x) = y_{\mathrm{out}}(x) + y_{\mathrm{in}}\!\left(\frac{x-x_c}{\delta}\right) - (\text{their common limit})\,, \tag{9.100}$$

the subtraction removing the part they both already carry.

Rests on Definitions 7.16 and 9.1.

Proposition 9.87 (The distinguished limit, and which end carries the layer)**.** *Let a and b be continuous on $[0,1]$ with $a(x) \geq a_0 > 0$, and consider*

$$\varepsilon \frac{\mathrm{d}^2 y}{\mathrm{d}x^2}(x) + a(x) \frac{\mathrm{d}y}{\mathrm{d}x}(x) + b(x)\, y(x) = 0\,, \qquad y(0) = A\,, \quad y(1) = B\,. \tag{9.101}$$

Then (i) *the only stretching $x = x_c + \delta\xi$ under which the second-derivative term is retained in a balance with a term at least as large as every neglected one is $\delta = \varepsilon$;* (ii) *at that scaling the leading inner equation is $\mathrm{d}^2Y/\mathrm{d}\xi^2 + a(x_c)\,\mathrm{d}Y/\mathrm{d}\xi = 0$, whose solutions are constants and $\mathrm{e}^{-a(x_c)\xi}$; and* (iii) *that exponential decays away from x_c into the interval only at $x_c = 0$. The layer therefore sits at the left endpoint, and the outer solution — the solution of the first-order reduced equation $a\,y' + b\,y = 0$ — must carry the condition at $x = 1$.*

Rests on Equation (9.101), Theorem 9.23, and Proposition 9.18.

Derivation. Derives Proposition 9.87.

Under $x = x_c + \delta\xi$ the three terms of Equation (9.101) carry the factors ε/δ^2, $1/\delta$ and 1. Suppose the first is retained. If it balances the third, $\varepsilon/\delta^2 \sim 1$ and $\delta \sim \sqrt{\varepsilon}$, whereupon the second term is of order $\varepsilon^{-1/2}$ and dominates both retained terms — so the balance is inconsistent. If it balances the second, $\varepsilon/\delta^2 \sim 1/\delta$, that is $\delta \sim \varepsilon$, and the third term, of order 1, is smaller by a factor ε than the two retained ones: consistent. That is (i), and substituting $\delta = \varepsilon$ and $a(x_c + \varepsilon\xi) \to a(x_c)$ gives (ii), whose solutions are read off Theorem 9.23 for the constant-coefficient equation — or directly from Proposition 9.18 applied to $\mathrm{d}Y/\mathrm{d}\xi$.

For (iii): at $x_c = 0$ the interval is $\xi \geq 0$ and $\mathrm{e}^{-a(0)\xi} \to 0$ as $\xi \to \infty$, so the inner solution settles to a constant and Equation (9.99) can be imposed. At $x_c = 1$ the interval is $\xi \leq 0$ and $\mathrm{e}^{-a(1)\xi} \to \infty$ as $\xi \to -\infty$: the inner solution grows without bound where it should match, so no matching is possible and there is no layer there. The reduced equation is of first order and therefore accepts exactly one boundary condition, which must then be the one at $x = 1$. □

Proposition 9.88 (The model problem, and the error of the composite)**.** *Let $A, B \in \mathbb{R}$ and consider Equation (9.101) with $a \equiv 1$, $b \equiv 1$: $\varepsilon y'' + y' + y = 0$, $y(0) = A$, $y(1) = B$. Its outer solution is $y_{\mathrm{out}}(x) = B\,\mathrm{e}^{1-x}$, its inner solution is $y_{\mathrm{in}}(\xi) = (A - B\mathrm{e})\mathrm{e}^{-\xi} + B\mathrm{e}$, and the composite Equation (9.100) is*

$$y_{\mathrm{c}}(x) = B\,\mathrm{e}^{1-x} + (A - B\mathrm{e})\,\mathrm{e}^{-x/\varepsilon}\,. \tag{9.102}$$

There is a constant C, depending only on $|A|$ and $|B|$, with

$$\sup_{0 \leq x \leq 1} |y(x) - y_{\mathrm{c}}(x)| \leq C\,\varepsilon \tag{9.103}$$

for every $\varepsilon \in (0, 1/8]$. The approximation is therefore uniform: it is correct both inside the layer and outside it.

Rests on Propositions 9.28 and 9.87 and Theorem 7.38.

Derivation. Derives Proposition 9.88.

The equation has constant coefficients, so by Proposition 9.28 its solutions are combinations of $\mathrm{e}^{\lambda_\pm x}$ with $\lambda_\pm = \left[-1 \pm \sqrt{1 - 4\varepsilon}\right]/(2\varepsilon)$, real and distinct for $\varepsilon < 1/4$. Taylor's theorem (Theorem 7.38) applied to $\sqrt{1-u}$ at $u = 4\varepsilon$ gives $\left|\sqrt{1-4\varepsilon} - (1 - 2\varepsilon)\right| \leq c_0\varepsilon^2$ on $(0, 1/8]$, whence

$$\lambda_+ = -1 + r\,, \quad |r| \leq c_0\varepsilon/2\,, \qquad \lambda_- = -\frac{1}{\varepsilon} + s\,, \quad |s| \leq 1 + c_0\varepsilon/2 \leq 2\,. \tag{9.104}$$

In particular $\lambda_- \leq -1/(2\varepsilon)$, so $\eta = \mathrm{e}^{\lambda_-} \leq \mathrm{e}^{-1/(2\varepsilon)}$ is smaller than any power of ε.

Write $y = C_+\mathrm{e}^{\lambda_+ x} + C_-\mathrm{e}^{\lambda_- x}$. The boundary conditions give $C_+ + C_- = A$ and $C_+\mathrm{e}^{\lambda_+} + C_-\eta = B$, so $C_+ = (B - A\eta)/(\mathrm{e}^{\lambda_+} - \eta)$. Since $\mathrm{e}^{\lambda_+} = \mathrm{e}^{-1}\mathrm{e}^{r} = \mathrm{e}^{-1}(1 + O(\varepsilon))$ by

Equation (9.104) and η is negligible beside it, $C_+ = B\mathrm{e} + O(\varepsilon)$ and hence $C_- = A - B\mathrm{e} + O(\varepsilon)$, every implied constant depending only on $|A|$, $|B|$ and c_0.

Now compare term by term. For the outer term, on $0 \le x \le 1$,

$$\left| C_+ \mathrm{e}^{\lambda_+ x} - B\mathrm{e}^{1-x} \right| \le |C_+ - B\mathrm{e}|\ \mathrm{e}^{|\lambda_+|} + B\mathrm{e}\ \mathrm{e}^{-x}\,|\mathrm{e}^{rx} - 1| \le C_1 \varepsilon\,,$$

using $|\mathrm{e}^{rx} - 1| \le |r|\, x\mathrm{e}^{|r|}$ and Equation (9.104). For the layer term, writing $\mathrm{e}^{\lambda_- x} = \mathrm{e}^{-x/\varepsilon}\mathrm{e}^{sx}$ and using $\mathrm{e}^{\lambda_- x} \le 1$ for $x \ge 0$,

$$\left| C_- \mathrm{e}^{\lambda_- x} - (A - B\mathrm{e})\mathrm{e}^{-x/\varepsilon} \right| \le |C_- - (A - B\mathrm{e})| + |A - B\mathrm{e}|\ \mathrm{e}^{-x/\varepsilon}\,|\mathrm{e}^{sx} - 1|\,.$$

The first term is $O(\varepsilon)$. In the second, $|\mathrm{e}^{sx} - 1| \le |s|\, x\mathrm{e}^{|s|} \le 2\mathrm{e}^2 x$ on $[0,1]$, and $x\,\mathrm{e}^{-x/\varepsilon}$ attains its maximum ε/e at $x = \varepsilon$; so the second term is $O(\varepsilon)$ too. Adding the two comparisons gives Equation (9.103). □

Remark 9.89 (Two singular perturbations, and where each belongs). Section 9.6 and this subsection treat the same syntactic situation — a small parameter on the highest derivative — and produce different objects, because the sign of the coefficient of the undifferentiated term decides whether the neglected derivative buys oscillation or a layer. Where the reduced problem is oscillatory the rapid variation is spread over the whole interval and the expansion is in the phase, which is Corollary 9.62; where the reduced problem is of lower order the rapid variation is confined to a region of thickness ε and the expansion is the two-region one of Definition 9.86. The turning point of Theorem 9.72 is the same matching problem in the first setting: an inner solution — there the Airy function of Definition 9.68 — joined to two outer ones by their common asymptotics.

Nothing above is specific to one dimension or to linear equations. The reduction of the equations of a viscous fluid to Prandtl's boundary-layer equations [315] is Proposition 9.87 carried out on a partial differential equation, with the Reynolds number in place of $1/\varepsilon$: the inviscid outer flow cannot satisfy the no-slip condition at a wall, the viscous term is restored in a layer whose thickness the same balance fixes, and Equation (9.99) is what hands the outer pressure gradient to the inner problem. Chapter 36 carries that computation and its measurement.

9.7 The one-dimensional Helmholtz equation

9.7.1 Sturm–Liouville data

The functions p, q and r of the operator are

$$p(x) = 1\,, \qquad q(x) = 0\,, \qquad r(x) = 1\,, \tag{9.105}$$

with λ^2 the free eigenvalue parameter.

9.7.2 Homogeneous solution

The homogeneous equation becomes

$$\frac{\mathrm{d}^2 y}{\mathrm{d}x^2}(x) + \lambda^2\, y(x) = 0\,, \tag{9.106}$$

whose solution is

$$y(x) = A\,\mathrm{e}^{\mathrm{i}\lambda x} + B\,\mathrm{e}^{-\mathrm{i}\lambda x}\,. \tag{9.107}$$

Remark 9.90. Using Euler's formula, $\mathrm{e}^{\pm \mathrm{i}t} = \cos t \pm \mathrm{i}\sin t$, the solution Equation (9.107) may equivalently be written in the real form

$$y(x) = A'\cos(\lambda x) + B'\sin(\lambda x)\,. \tag{9.108}$$

9.7.3 Orthonormality

On the interval $[-\pi, \pi]$, and for integer values $\lambda = n \in \mathbb{Z}$, the solution functions satisfy

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \mathrm{e}^{\mathrm{i}(m-n)x} \, \mathrm{d}x = \delta_{mn} \, . \tag{9.109}$$

Equation (9.109) is Lemma 17.2, proved there by direct integration: the integrand is $\mathrm{e}^{\mathrm{i}(m-n)x}$, which equals 1 when $m = n$ and, when $m \neq n$, has an antiderivative that returns to its starting value over a full period, so the integral vanishes.

Remark 9.91 (Which measure makes the exponentials orthonormal). The factor $1/(2\pi)$ in Equation (9.109) is not cosmetic, and it is worth placing once. Against the plain $\mathrm{d}x$ of Equation (9.46) the bare exponentials are merely *orthogonal*: $\int_{-\pi}^{\pi} \overline{\mathrm{e}^{\mathrm{i}nx}} \, \mathrm{e}^{\mathrm{i}nx} \, \mathrm{d}x = 2\pi$, not 1, so $\{\mathrm{e}^{\mathrm{i}nx}\}$ is not an orthonormal set in the sense of Definition 9.45. Two readings repair this, and they are one statement written twice: either keep $\mathrm{d}x$ and take the normalised functions $\phi_n(x) = \mathrm{e}^{\mathrm{i}nx}/\sqrt{2\pi}$, or keep the bare exponentials $\phi_n(x) = \mathrm{e}^{\mathrm{i}nx}$ and read every integral of Section 9.4 — Equation (9.46), the coefficient formula Equation (9.48) and the triple overlap Equation (9.49) alike — against the normalised measure $\mathrm{d}x/(2\pi)$. The Fourier sections of this chapter take the second reading throughout, which is exactly what puts the $1/(2\pi)$ into Equation (9.111) and the $1/L$ into Equation (9.113). The choice cancels out of every expansion, since the factor a coefficient gains is the one its basis function loses; what must not happen is the two readings being mixed inside one calculation.

9.7.4 Fourier series

Expanding a function on $[-\pi, \pi]$ in the complex exponentials — orthonormal in the second sense of Remark 9.91 — gives the *Fourier series*

$$f(x) = \sum_{n=-\infty}^{\infty} c_n \, \mathrm{e}^{\mathrm{i}nx} \, , \tag{9.110}$$

$$c_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) \, \mathrm{e}^{-\mathrm{i}nx} \, \mathrm{d}x \, , \tag{9.111}$$

an instance of the general coefficient formula Equation (9.48).

Under a *change of interval* to an arbitrary interval $[a, b]$ of length $L = b - a$, the series and its coefficients become

$$f(x) = \sum_{n=-\infty}^{\infty} f_n \, \mathrm{e}^{\mathrm{i}k_n x} \, , \qquad k_n = \frac{2n\pi}{L} \, , \tag{9.112}$$

$$f_n = \frac{1}{L} \int_{a}^{b} f(x) \, \mathrm{e}^{-\mathrm{i}k_n x} \, \mathrm{d}x \, . \tag{9.113}$$

Trigonometric form

On the symmetric interval $[-L, L]$ the cosine and sine functions satisfy the orthonormality relations

$$\frac{1}{L} \int_{-L}^{L} \cos\left(\frac{m\pi x}{L}\right) \cos\left(\frac{n\pi x}{L}\right) \mathrm{d}x = \delta_{mn} \, , \tag{9.114}$$

$$\frac{1}{L} \int_{-L}^{L} \sin\left(\frac{m\pi x}{L}\right) \sin\left(\frac{n\pi x}{L}\right) \mathrm{d}x = \delta_{mn} \, , \tag{9.115}$$

$$\int_{-L}^{L} \cos\left(\frac{m\pi x}{L}\right) \sin\left(\frac{n\pi x}{L}\right) \mathrm{d}x = 0 \, , \tag{9.116}$$

with $m, n \geq 1$, and the Fourier series takes the real form

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left[a_n \cos \frac{n\pi x}{L} + b_n \sin \frac{n\pi x}{L} \right] , \tag{9.117}$$

$$a_n = \frac{1}{L} \int_{-L}^{L} f(x) \cos \frac{n\pi x}{L} \, \mathrm{d}x \, , \tag{9.118}$$

$$b_n = \frac{1}{L} \int_{-L}^{L} f(x) \sin \frac{n\pi x}{L} \, \mathrm{d}x \, . \tag{9.119}$$

The relations Equations (9.114) to (9.116) are proved at Equation (17.9), where the product formulas of trigonometry reduce each of them to Lemma 17.2: the identity $\cos A \cos B = \frac{1}{2}[\cos(A-B) + \cos(A+B)]$ turns the first into δ_{mn}, since the second index coincidence $m = -n$ is impossible for positive m and n; the sine relation is the same identity with the opposite sign; and the mixed integral vanishes as that of an odd function over a symmetric interval. The coefficient formulas Equations (9.118) and (9.119) are Equation (17.7) written with $T = 2L$.

9.7.5 The Fourier transform

Consider a function that can be expanded in the Fourier series Equation (9.112). If $L \to +\infty$, the sum over the discrete wavenumbers k_n passes into a Riemann integral, and one obtains

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(k) \, \mathrm{e}^{\mathrm{i}kx} \, \mathrm{d}k \, , \tag{9.120}$$

where $g(k)$, called the *Fourier transform* of $f(x)$, is defined by

$$g(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) \, \mathrm{e}^{-\mathrm{i}kx} \, \mathrm{d}x \, . \tag{9.121}$$

The Riemann-sum argument sketched above is carried out at Equation (17.33), in the same normalisation: the coefficients of the series on $[-L, L]$ are $\sqrt{2\pi}$ times the transform sampled at the harmonics k_n, divided by the interval length, and the mesh of the sum is $\Delta k = 2\pi/L \to 0$. That argument is heuristic, because the summand depends on L as well as on the mesh; the inversion formula Equation (9.120) is established properly, by Gaussian regularisation, in Theorem 17.32, and the injectivity it implies is Corollary 17.33.

Properties

Transform of derivatives. If f is n times differentiable, $f^{(n)}$ is absolutely integrable, and every derivative below the top one vanishes at infinity,

$$\lim_{x \to \pm\infty} f^{(j)}(x) = 0 \qquad \text{for } j = 0, 1, \ldots, n-1 \, ,$$

then the transform g_n of the n-th derivative $f^{(n)}$ satisfies

$$g_n(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f^{(n)}(x) \, \mathrm{e}^{-\mathrm{i}kx} \, \mathrm{d}x = (\mathrm{i}k)^n \, g(k) \, . \tag{9.122}$$

The case $n = 1$ is Equation (17.38) of Proposition 17.30, proved there by a single integration by parts: the boundary term $[f \, \mathrm{e}^{-\mathrm{i}kx}]_{-\infty}^{\infty}$ vanishes because f tends to zero, and what is left is $\mathrm{i}k$ times the transform of f. The general n follows by induction, applying that result to $f^{(j)}$ in turn — which is exactly why the hypothesis above is imposed on *every* derivative below the top one and not on f alone: each step of the induction consumes one boundary term. This is the property that turns a constant-coefficient differential operator into a polynomial and is the reason the transform is a method at all.

Convolution. The convolution of two functions and the theorem that its transform is the product of theirs are Definition 17.50 and Theorem 17.53: in the normalisation of Equation (9.121) the transform of $f * g$ is $\sqrt{2\pi}$ times the product of the transforms, and dually the transform of a product is $(2\pi)^{-1/2}$ times the convolution of the transforms. The derivation is a single application of Fubini's theorem to the double integral, justified by the bound Equation (17.64).

Parseval relation. The transform preserves the norm,

$$\int_{-\infty}^{\infty} |f(x)|^2 \, \mathrm{d}x = \int_{-\infty}^{\infty} |g(k)|^2 \, \mathrm{d}k \,. \tag{9.123}$$

Equation (9.123) is Plancherel's theorem, Theorem 17.36: the transform of Equation (9.121) is an isometry on the smooth rapidly decreasing functions, by Theorem 17.32 and an exchange of integrals, and extends uniquely to a unitary map of the square-integrable functions onto themselves. The statement for the Fourier *series* — the completeness of the harmonics, and hence Equation (9.52) for that system — is Theorem 17.34.

9.8 The Bessel equation

9.8.1 Sturm–Liouville data

The identification of the operator data is

$$p(x) = x \,, \qquad q(x) = x \,, \qquad \lambda^2 = -\nu^2 \,, \qquad r(x) = \frac{1}{x} \,. \tag{9.124}$$

9.8.2 General solution

The homogeneous equation becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[x \, \frac{\mathrm{d}y}{\mathrm{d}x}(x)\right] + \left[x - \frac{\nu^2}{x}\right] y(x) = 0 \,, \tag{9.125}$$

whose solution is

$$y(x) = A \, J_\nu(x) + B \, N_\nu(x) \,, \tag{9.126}$$

with J_ν the Bessel functions of the first kind and N_ν (also written Y_ν) the Neumann functions, the Bessel functions of the second kind [1976].

Remark 9.92. Expanding the derivative in Equation (9.125) and multiplying by x puts the equation into its familiar form $x^2 y'' + x y' + (x^2 - \nu^2)\, y = 0$.

Definition 9.93 (Bessel functions of the first kind)**.** For $\nu \geq 0$ and $x > 0$,

$$J_\nu(x) = \sum_{j=0}^{\infty} \frac{(-1)^j}{j! \, \Gamma(j + \nu + 1)} \left(\frac{x}{2}\right)^{2j+\nu} \,, \tag{9.127}$$

a series convergent for every x by the ratio test (Proposition 7.48). For non-integer ν the same formula with ν replaced by $-\nu$ defines a second, independent solution $J_{-\nu}$. At integer $\nu = n$ the reciprocal gamma function vanishes at the non-positive integers, so the first n terms of that series drop out and $J_{-n} = (-1)^n J_n$ is not independent; the second solution is then the Neumann function $N_\nu = \big[J_\nu \cos \nu\pi - J_{-\nu}\big] / \sin \nu\pi$, read at integer order as the limit of that expression.

Proposition 9.94 (The series solves the Bessel equation)**.** *J_ν of Equation (9.127) satisfies Equation (9.125).*

Rests on Definition 9.93 and Equation (9.125).

Derivation. *Derives Proposition 9.94.*

Use the expanded form of Remark 9.92 and substitute Equation (9.127) term by term, which is legitimate inside the disc of convergence (Theorem 7.51). Write $J_\nu = \sum_j c_j x^{2j+\nu}$ with $c_j = (-1)^j \big[j!\,\Gamma(j+\nu+1)\,2^{2j+\nu}\big]^{-1}$. The operator $x^2\mathrm{d}^2/\mathrm{d}x^2 + x\,\mathrm{d}/\mathrm{d}x - \nu^2$ sends $x^{2j+\nu}$ to $\big[(2j+\nu)^2 - \nu^2\big]x^{2j+\nu} = 4j(j+\nu)\,x^{2j+\nu}$, while the remaining term $x^2 J_\nu$ shifts the index by one. The coefficient of $x^{2j+\nu}$ in the whole expression is therefore $4j(j+\nu)\,c_j + c_{j-1}$, and this vanishes: by $j!\,\Gamma(j+\nu+1) = j\,(j-1)!\,(j+\nu)\,\Gamma(j+\nu)$ and $2^{2j+\nu} = 4\cdot 2^{2(j-1)+\nu}$,

$$4j(j+\nu)\,c_j = \frac{4\,(-1)^j}{(j-1)!\,\Gamma(j+\nu)\,2^{2j+\nu}} = -c_{j-1}\,.$$

The term $j=0$ has no partner and vanishes on its own, because $4j(j+\nu)=0$ there. □

9.8.3 Recurrence relations

Proposition 9.95 (The two ladder identities)**.** *For every order ν and every $x>0$,*

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[x^{-\nu}\,J_\nu(x)\right] = -x^{-\nu}\,J_{\nu+1}(x)\,, \tag{9.128}$$

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[x^{\nu}\,J_\nu(x)\right] = x^{\nu}\,J_{\nu-1}(x)\,. \tag{9.129}$$

Rests on Definition 9.93.

Derivation. *Derives Proposition 9.95.*

Both are term-by-term computations on Equation (9.127). For Equation (9.128),

$$x^{-\nu}J_\nu(x) = \sum_{j\ge 0} \frac{(-1)^j\,x^{2j}}{j!\,\Gamma(j+\nu+1)\,2^{2j+\nu}}\,,$$

whose derivative is $\sum_{j\ge1}(-1)^j\,2j\,x^{2j-1}\big[j!\,\Gamma(j+\nu+1)2^{2j+\nu}\big]^{-1}$; putting $j=i+1$ and cancelling the factor $2(i+1)$ against $(i+1)!$ turns this into $-\sum_{i\ge0}(-1)^i x^{2i+1}\big[i!\,\Gamma(i+\nu+2)\,2^{2i+\nu+1}\big]^{-1}$, which is $-x^{-\nu}J_{\nu+1}(x)$ by Equation (9.127) at order $\nu+1$. For Equation (9.129), the derivative of $x^\nu J_\nu = \sum_j (-1)^j x^{2j+2\nu}\big[j!\,\Gamma(j+\nu+1)2^{2j+\nu}\big]^{-1}$ carries the factor $2j+2\nu = 2(j+\nu)$, which cancels against $\Gamma(j+\nu+1) = (j+\nu)\Gamma(j+\nu)$ and lowers the power of two by one, giving $\sum_j (-1)^j x^{2j+2\nu-1}\big[j!\,\Gamma(j+\nu)2^{2j+\nu-1}\big]^{-1} = x^\nu J_{\nu-1}(x)$. □

Corollary 9.96 (Recurrence relations)**.** *For every order ν,*

$$J_{\nu-1}(x) + J_{\nu+1}(x) = \frac{2\nu}{x}\,J_\nu(x)\,, \tag{9.130}$$

$$J_{\nu-1}(x) - J_{\nu+1}(x) = 2\,\frac{\mathrm{d}J_\nu}{\mathrm{d}x}(x)\,. \tag{9.131}$$

In particular $\frac{\mathrm{d}J_\nu}{\mathrm{d}x} = -J_{\nu+1}$ at every zero of J_ν.

Rests on Proposition 9.95.

Derivation. *Derives Corollary 9.96.*

Carrying out the differentiations on the left of Equations (9.128) and (9.129) and dividing by $x^{-\nu}$ and x^ν respectively gives

$$\frac{\mathrm{d}J_\nu}{\mathrm{d}x} - \frac{\nu}{x}J_\nu = -J_{\nu+1}\,, \qquad \frac{\mathrm{d}J_\nu}{\mathrm{d}x} + \frac{\nu}{x}J_\nu = J_{\nu-1}\,.$$

Subtracting gives Equation (9.130) and adding gives Equation (9.131). At a zero of J_ν the first of the two displayed identities reduces to $\mathrm{d}J_\nu/\mathrm{d}x = -J_{\nu+1}$. □

9.8.4 Orthogonality

Remark 9.97 (Which eigenvalue problem the orthogonality belongs to). Equation (9.124) reads Equation (9.125) as a Sturm–Liouville equation in which the order ν carries the spectral parameter. The orthogonality relation below belongs to the other reading of the same equation, the one the applications use: fix ν, and let $y(x) = J_\nu(\alpha x/a)$ on $[0, a]$. Rescaling Equation (9.125) gives

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[x\,\frac{\mathrm{d}y}{\mathrm{d}x}(x)\right] + \left[-\frac{\nu^2}{x} + \frac{\alpha^2}{a^2}\,x\right] y(x) = 0\,, \tag{9.132}$$

which is Equation (9.54) with $p(x) = x$, $q(x) = -\nu^2/x$, weight $r(x) = x$ and eigenvalue $\lambda^2 = \alpha^2/a^2$. It is that spectral parameter, and not ν, which distinguishes the functions appearing in Equation (9.133).

Theorem 9.98 (Orthogonality of the Bessel functions)**.** *Let $\nu \geq 0$ and let $\alpha_{\nu m}$ denote the m-th positive zero of J_ν. On the interval $[0, a]$ the rescaled Bessel functions are orthogonal with weight x:*

$$\int_0^a J_\nu\left(\frac{\alpha_{\nu m}x}{a}\right) J_\nu\left(\frac{\alpha_{\nu n}x}{a}\right) x\,\mathrm{d}x = \frac{a^2}{2}\left[J_{\nu+1}(\alpha_{\nu m})\right]^2 \delta_{mn}\,. \tag{9.133}$$

Rests on Theorem 9.57, Corollary 9.96, and Equation (9.132).

Derivation. Derives Theorem 9.98.

Take $u(x) = J_\nu(\lambda x)$ and $v(x) = J_\nu(\mu x)$ with $\lambda, \mu > 0$, both solutions of Equation (9.132) with $p(x) = x$, weight x and eigenvalues λ^2 and μ^2. Integrating the Lagrange identity Equation (9.56) over $[0, a]$ gives

$$\left(\lambda^2 - \mu^2\right) \int_0^a J_\nu(\lambda x)\, J_\nu(\mu x)\, x\,\mathrm{d}x = a\left[\mu\, J_\nu(\lambda a)\, J'_\nu(\mu a) - \lambda\, J_\nu(\mu a)\, J'_\nu(\lambda a)\right]\,, \tag{9.134}$$

the prime denoting the derivative of J_ν with respect to its own argument. The contribution at $x = 0$ vanishes because $p(x) = x$ does while J_ν behaves there as x^ν by Equation (9.127) — the second mechanism of Remark 9.58. Taking $\lambda = \alpha_{\nu m}/a$ and $\mu = \alpha_{\nu n}/a$ with $m \neq n$ makes both Bessel values on the right vanish while the factor on the left does not, which is the off-diagonal statement; it is Theorem 9.57 with the boundary condition $y(a) = 0$, the first mechanism of Remark 9.58.

For the diagonal, fix $\lambda = \alpha_{\nu m}/a$, keep μ free and use $J_\nu(\lambda a) = 0$ in Equation (9.134):

$$\int_0^a J_\nu(\lambda x)\, J_\nu(\mu x)\, x\,\mathrm{d}x = \frac{-a\,\lambda\, J_\nu(\mu a)\, J'_\nu(\lambda a)}{\lambda^2 - \mu^2}\,.$$

Let $\mu \to \lambda$. The numerator vanishes like $J_\nu(\mu a) = (\mu - \lambda)\, a\, J'_\nu(\lambda a) + \ldots$ and the denominator like $-(\mu - \lambda)\, 2\lambda$, so the quotient tends to $\frac{1}{2}a^2\left[J'_\nu(\lambda a)\right]^2$. Finally $J'_\nu(\alpha_{\nu m}) = -J_{\nu+1}(\alpha_{\nu m})$ by Corollary 9.96, and squaring removes the sign. □

9.8.5 Generating function

For integer order the Bessel functions of the first kind are generated by

$$g(x, t) = \mathrm{e}^{\frac{x}{2}\left(t - \frac{1}{t}\right)} = \sum_{n=-\infty}^{\infty} J_n(x)\, t^n\,. \tag{9.135}$$

Proposition 9.99 (Generating function)**.** *Equation (9.135) holds for every x and every complex $t \neq 0$.*

Rests on Definition 9.93.

Derivation. *Derives Proposition 9.99.*

Both factors of $g(x,t) = \mathrm{e}^{xt/2}\,\mathrm{e}^{-x/(2t)}$ are entire in their arguments, so the two exponential series may be multiplied out and the resulting double series rearranged absolutely (Proposition 7.49):

$$\begin{aligned}\mathrm{e}^{\frac{x}{2}t}\,\mathrm{e}^{-\frac{x}{2t}} &= \left[\sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{x}{2}\right)^{j}t^{j}\right]\left[\sum_{k=0}^{\infty}\frac{(-1)^{k}}{k!}\left(\frac{x}{2}\right)^{k}t^{-k}\right]\\ &= \sum_{n=-\infty}^{\infty}t^{n}\sum_{k}\frac{(-1)^{k}}{(k+n)!\,k!}\left(\frac{x}{2}\right)^{2k+n},\end{aligned}$$

the outer index being $n = j-k$ and the inner sum running over those $k \geq 0$ with $k+n \geq 0$. Comparing with Equation (9.127) at integer order, where $\Gamma(k+n+1) = (k+n)!$ and the reciprocal factorial is zero whenever $k+n<0$, the inner sum is exactly $J_n(x)$, which is Equation (9.135). □

9.8.6 The Fourier–Bessel series

Proposition 9.100 (Fourier–Bessel coefficients)**.** *Let $\nu \geq 0$, and let f on $[0,a]$ admit an expansion*

$$f(x) = \sum_{m=1}^{\infty} c_m\,J_\nu\left(\frac{\alpha_{\nu m}\,x}{a}\right), \tag{9.136}$$

convergent in the mean with respect to the weight x. Then

$$c_m = \frac{2}{a^2\left[J_{\nu+1}(\alpha_{\nu m})\right]^2}\int_0^a f(x)\,J_\nu\left(\frac{\alpha_{\nu m}\,x}{a}\right)x\,\mathrm{d}x\,. \tag{9.137}$$

Rests on Theorem 9.98 and Definition 9.47.

Derivation. *Derives Proposition 9.100.*

Multiply Equation (9.136) by $J_\nu(\alpha_{\nu n}x/a)\,x$ and integrate over $[0,a]$. Mean convergence permits the exchange of sum and integral, and Equation (9.133) leaves the single term $m=n$ carrying the constant $a^2\left[J_{\nu+1}(\alpha_{\nu n})\right]^2/2$. This is the argument of Proposition 9.48 run for a set that is orthogonal but not normalised, the normalising constant being divided out at the end instead of absorbed into the functions. □

Remark 9.101 (Completeness is a separate theorem). That an expansion Equation (9.136) exists at all — that the system $\{J_\nu(\alpha_{\nu m}x/a)\}_{m\geq 1}$ is complete in the square-integrable functions on $[0,a]$ with weight x — is a statement about the Sturm–Liouville problem of Remark 9.97, not about Bessel functions in particular, and it is not proved here; the general statement belongs to Chapter 12 [1222]. What Proposition 9.100 does establish is that if the expansion exists then it is this one — the same division of labour as in Remark 9.53.

9.8.7 The zeros

The orthogonality relation of Theorem 9.98 and the Fourier–Bessel series of Section 9.8.6 are indexed by the positive zeros of J_ν, and every eigenfrequency of a circular membrane or a cylindrical cavity is one of them. Their existence, their simplicity and their spacing are therefore not decoration.

Proposition 9.102 (Liouville normal form of the Bessel equation)**.** *On $x>0$ the substitution $y(x) = x^{-1/2}u(x)$ turns Equation (9.125) into*

$$\frac{\mathrm{d}^2u}{\mathrm{d}x^2}(x) + \left[1 - \frac{\nu^2-\frac{1}{4}}{x^2}\right]u(x) = 0\,. \tag{9.138}$$

The first-derivative term is gone, and for large x the equation is a vanishing perturbation of $u'' + u = 0$.

Rests on Equation (9.125) and Remark 9.92.

Derivation. *Derives Proposition 9.102.*

Use the expanded form $x^2y'' + xy' + (x^2 - \nu^2)y = 0$ of Remark 9.92. With $y = x^{-1/2}u$,

$$y' = -\tfrac{1}{2}x^{-3/2}u + x^{-1/2}u' , \qquad y'' = \tfrac{3}{4}x^{-5/2}u - x^{-3/2}u' + x^{-1/2}u'' ,$$

so $x^2y'' = \tfrac{3}{4}x^{-1/2}u - x^{1/2}u' + x^{3/2}u''$ and $xy' = -\tfrac{1}{2}x^{-1/2}u + x^{1/2}u'$. The terms in u' cancel, and adding $(x^2 - \nu^2)x^{-1/2}u$ leaves

$$x^{3/2}u'' + x^{3/2}u + \left(\tfrac{3}{4} - \tfrac{1}{2} - \nu^2\right) x^{-1/2}u = 0 ,$$

which is Equation (9.138) after division by $x^{3/2}$, since $\tfrac{3}{4} - \tfrac{1}{2} = \tfrac{1}{4}$. □

Proposition 9.103 (The positive zeros and their spacing)**.** *Let $\nu \geq 0$. Every zero of J_ν in $x > 0$ is simple, and there are infinitely many of them; writing $j_{\nu,n}$ for the n-th in increasing order,*

$$j_{\nu,n} = \left(n + \frac{\nu}{2} - \frac{1}{4}\right)\pi + O\left(\frac{1}{n}\right) , \qquad n \to \infty . \tag{9.139}$$

Successive zeros are therefore asymptotically π apart, whatever the order.

Rests on Proposition 9.102 and Corollaries 9.9 and 9.96.

Derivation. *Derives Proposition 9.103.*

Simplicity. On $x > 0$ the Bessel equation is regular — its leading coefficient x^2 does not vanish — so Corollary 9.9 applies: a solution with $y(x_*) = y'(x_*) = 0$ at some $x_* > 0$ is identically zero. Since J_ν is not, no positive zero of it can be a zero of its derivative. (Equivalently, by Corollary 9.96, $J_\nu' = -J_{\nu+1}$ at a zero of J_ν, and the two functions have no common positive zero.)

Location. Proposition 9.102 writes $J_\nu(x) = x^{-1/2}u(x)$ with u solving an equation that tends to $u'' + u = 0$: the solutions oscillate with asymptotic half-period π, and the classical large-argument form quoted in Section 9.6.5 from [1023],

$$J_\nu(x) = \sqrt{\frac{2}{\pi x}}\left[\cos\left(x - \frac{\nu\pi}{2} - \frac{\pi}{4}\right) + O\left(\frac{1}{x}\right)\right] , \qquad x \to \infty , \tag{9.140}$$

makes the phase explicit. The cosine vanishes where $x - \nu\pi/2 - \pi/4 = \pi/2 + (n-1)\pi$, that is at $x = (n + \nu/2 - \tfrac{1}{4})\pi$, and it crosses each of those points with slope of modulus 1. A perturbation of size $O(1/x)$ of a function crossing zero with unit slope displaces the crossing by $O(1/x)$, and the amplitude $\sqrt{2/\pi x}$, being non-zero, cannot create or destroy a crossing; so for large n there is exactly one zero of J_ν within $O(1/n)$ of each of those points, which is Equation (9.139), and there are infinitely many of them. □

Remark 9.104 (What is imported, and how much rests on it)*.* Equation (9.140) is not proved in this treatise; it is the same imported fact that Section 9.6.5 uses to fix the connection coefficients at a turning point of higher order, and it is flagged there for the same reason. Only the constant $-\pi/4$ in the phase depends on it. The π spacing — which is what converts a count of nodal circles into a frequency, and is all that Chapter 35 needs for the square law of a circular plate — follows from Equation (9.138) alone, since the coefficient there tends to 1 and the oscillation of $u'' + u = 0$ has half-period exactly π.

9.8.8 The modified Bessel functions

Replacing x by $\mathrm{i}x$ in Equation (9.125) reverses the sign of the term that makes the solutions oscillate, and produces the equation obeyed by the radial part of a field that decays rather than propagates — the evanescent interior of a waveguide below cutoff, the screened potential around a charge, the edge-localised part of the deflection of a vibrating plate. This treatise has already used its solutions, in Section 9.6.5; they are defined here.

Definition 9.105 (Modified Bessel functions)**.** The *modified Bessel equation* of order ν is

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[x\,\frac{\mathrm{d}y}{\mathrm{d}x}(x)\right]-\left[x+\frac{\nu^2}{x}\right]y(x)=0\,, \tag{9.141}$$

equivalently $x^2y''+xy'-(x^2+\nu^2)y=0$. Its Sturm–Liouville data in the convention of Definition 9.54 are $p(x)=x$, $q(x)=-x$, $\lambda^2=-\nu^2$, $r(x)=1/x$. The *modified Bessel function of the first kind* is

$$I_\nu(x)=\sum_{j=0}^{\infty}\frac{1}{j!\,\Gamma(j+\nu+1)}\left(\frac{x}{2}\right)^{2j+\nu}\,,\qquad x>0\,, \tag{9.142}$$

the series of Equation (9.127) with the alternating sign removed, so that $I_\nu(x)=\mathrm{i}^{-\nu}J_\nu(\mathrm{i}x)$. The *modified Bessel function of the second kind* is

$$K_\nu(x)=\frac{\pi}{2}\,\frac{I_{-\nu}(x)-I_\nu(x)}{\sin\nu\pi}\,, \tag{9.143}$$

read at integer order as the limit of that expression, exactly as N_ν is in Definition 9.93.

Rests on Definitions 9.54 and 9.93.

Proposition 9.106 (The modified series and what it does not do)**.** *I_ν of Equation (9.142) converges for every x and solves Equation (9.141). For $\nu\geq 0$ it is positive and strictly increasing on $x>0$, with $I_\nu(0^+)=0$ for $\nu>0$ and $I_0(0)=1$; in particular it has no positive zero, so it carries no oscillation and no eigenvalue condition. Together with K_ν it spans the solution space of Equation (9.141).*

Rests on Definition 9.105, Proposition 9.94, and Theorem 9.13.

Derivation. *Derives Proposition 9.106.*

Convergence is the ratio test (Proposition 7.48) exactly as for Equation (9.127), the moduli of the terms being the same. For the equation, run the computation of Proposition 9.94 with $c_j=\left[j!\,\Gamma(j+\nu+1)2^{2j+\nu}\right]^{-1}$ and with the sign of the term x^2y reversed: the coefficient of $x^{2j+\nu}$ becomes $4j(j+\nu)c_j-c_{j-1}$, and the identity $j!\,\Gamma(j+\nu+1)=j\,(j-1)!\,(j+\nu)\,\Gamma(j+\nu)$ used there gives $4j(j+\nu)c_j=c_{j-1}$, so it vanishes; the term $j=0$ vanishes on its own.

Every coefficient in Equation (9.142) is strictly positive for $\nu\geq 0$, and so is every term for $x>0$; the same is true of the term-by-term derivative, legitimate inside the radius of convergence (Theorem 7.51). Hence $I_\nu>0$ and $I_\nu'>0$ on $x>0$, which forbids a zero there. The leading power is $(x/2)^\nu/\Gamma(\nu+1)$, giving the stated behaviour at the origin. Finally I_ν and K_ν are independent — one is bounded at infinity and the other is not, by Remark 9.107 — so by Theorem 9.13 they span the two-dimensional solution space. □

Remark 9.107 (Growth, and where it is imported from)*.* The large-argument behaviour

$$I_\nu(x)\sim\frac{\mathrm{e}^x}{\sqrt{2\pi x}}\,,\qquad K_\nu(x)\sim\sqrt{\frac{\pi}{2x}}\,\mathrm{e}^{-x}\,,\qquad x\to\infty\,, \tag{9.144}$$

is quoted from [1023]; the second half of it is the fact already imported in Section 9.6.5, so nothing new is being taken on credit. The qualitative half of Equation (9.144) — that I_ν

grows without bound and K_ν decays — does not depend on the import: I_ν is a positive increasing function whose terms already exceed those of $e^x/2^\nu$ term by term for ν an integer, and K_ν is the solution that Proposition 9.106 leaves over. This is what licenses the reading used in the physical parts: in a superposition $A\,J_m(kr) + B\,I_m(kr)$ on a disc, the second term is negligible except within a few $1/k$ of the rim, so the interior nodal pattern is that of J_m alone.

9.9 The Legendre equation and spherical harmonics

9.9.1 The Legendre equation

Sturm–Liouville data

The identification of the operator data is

$$p(x) = 1 - x^2\,, \qquad q(x) = n(n+1)\,, \qquad \lambda^2 = 0\,, \qquad r(x) = 1\,. \tag{9.145}$$

This is the source's identification and it is the one reproduced in Table 9.2, but with $\lambda^2 = 0$ it is not an eigenvalue problem: nothing in it distinguishes one degree from another. Theorem 9.111 therefore reads the same equation the other way round, with $q = 0$ and $\lambda^2 = n(n+1)$, exactly as Remark 9.97 does for the Bessel equation.

Homogeneous solution

The homogeneous equation becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[(1-x^2)\,\frac{\mathrm{d}y}{\mathrm{d}x}(x)\right] + n(n+1)\,y(x) = 0\,, \tag{9.146}$$

whose solution is

$$y(x) = A\,P_n(x) + B\,Q_n(x)\,, \tag{9.147}$$

with P_n the Legendre polynomials and Q_n the Legendre functions of the second kind.

The Legendre polynomials

Definition 9.108 (Rodrigues formula)**.** The *Legendre polynomial* of degree n is

$$P_n(x) = \frac{1}{2^n\,n!}\,\frac{\mathrm{d}^n}{\mathrm{d}x^n}\left(x^2-1\right)^n\,, \qquad n = 0, 1, 2, \dots \tag{9.148}$$

Proposition 9.109 (Rodrigues' polynomials solve the equation)**.** *P_n of Equation (9.148) is a polynomial of degree n with leading coefficient $(2n)!/\left[2^n (n!)^2\right]$, it satisfies $P_n(1) = 1$, and it solves the Legendre equation Equation (9.146).*

Rests on Definition 9.108 and Equation (9.146).

Derivation. *Derives Proposition 9.109.*

Write $v = \left(x^2-1\right)^n$, a polynomial of degree $2n$ whose n-th derivative has degree n; the coefficient of x^n comes from $\mathrm{d}^n x^{2n}/\mathrm{d}x^n = [(2n)!/n!]\,x^n$, which after the division by $2^n n!$ gives the stated leading coefficient. For the value at 1, factor $v = (x-1)^n (x+1)^n$: in the Leibniz expansion of $\mathrm{d}^n v/\mathrm{d}x^n$ every term retains at least one factor $x-1$ except the one in which all n derivatives fall on $(x-1)^n$, so at $x = 1$ only $n!\,(x+1)^n = n!\,2^n$ survives, and division by $2^n n!$ gives $P_n(1) = 1$.

For the equation, start from the identity $\left(x^2-1\right)\frac{\mathrm{d}v}{\mathrm{d}x} = 2n\,x\,v$, which is immediate from the definition of v, and differentiate it $n+1$ times by the Leibniz rule Equation (7.16). On the left only three terms survive, because x^2-1 is quadratic:

$$\left(x^2-1\right)v^{(n+2)} + (n+1)\,2x\,v^{(n+1)} + \frac{(n+1)n}{2}\,2\,v^{(n)}\,,$$

and on the right only two, because x is linear: $2n\,x\,v^{(n+1)} + 2n(n+1)\,v^{(n)}$. Writing $u = v^{(n)}$ and collecting,

$$\left(x^2 - 1\right)\frac{\mathrm{d}^2 u}{\mathrm{d}x^2} + 2x\,\frac{\mathrm{d}u}{\mathrm{d}x} - n(n+1)\,u = 0\,,$$

which on multiplication by -1 is $\left[(1-x^2)u'\right]' + n(n+1)u = 0$, that is Equation (9.146). Since P_n is a constant multiple of u, it solves the same linear equation. □

Lemma 9.110 (The polynomial solution is unique up to scale)**.** *Every polynomial solution of Equation (9.146) is a constant multiple of P_n.*

Rests on Proposition 9.109.

Derivation. *Derives Lemma 9.110.*

Let $\Lambda[y] = \left[(1-x^2)y'\right]'$. On monomials

$$\Lambda\left[x^k\right] = \frac{\mathrm{d}}{\mathrm{d}x}\left[k\,x^{k-1} - k\,x^{k+1}\right] = -k(k+1)\,x^k + k(k-1)\,x^{k-2}\,,$$

so Λ maps the space of polynomials of degree at most N into itself and is triangular in the monomial basis ordered by degree, with diagonal entries $-k(k+1)$ for $k = 0, \dots, N$. Those entries are pairwise distinct, so each eigenvalue of Λ on that space is simple and its eigenspace is one-dimensional. A polynomial solution of Equation (9.146) of degree at most N is an eigenvector for the eigenvalue $-n(n+1)$, and P_n is one such by Proposition 9.109; taking N at least as large as the degree of the given solution identifies the two up to a constant. □

Orthogonality

Theorem 9.111 (Orthogonality of the Legendre polynomials)**.** *The Legendre polynomials are orthogonal on $[-1, 1]$:*

$$\int_{-1}^{1} P_m(x)\,P_n(x)\,\mathrm{d}x = \frac{2}{2n+1}\,\delta_{mn}\,. \tag{9.149}$$

Rests on Theorem 9.57 and Proposition 9.109.

Derivation. *Derives Theorem 9.111.*

For the off-diagonal terms read Equation (9.146) as the eigenvalue problem it is: $p(x) = 1 - x^2$, $q = 0$, weight $r = 1$ and eigenvalue $\lambda^2 = n(n+1)$, distinct for distinct non-negative degrees. The coefficient function p vanishes at both endpoints while P_m, P_n and their derivatives are polynomials and hence bounded there, so Equation (9.57) holds by the second mechanism of Remark 9.58 and Theorem 9.57 gives the vanishing of the integral for $m \neq n$.

For the diagonal use Equation (9.148) and integrate by parts n times (Equation (7.28)). At each step the integrated term carries a factor $\mathrm{d}^j(x^2-1)^n/\mathrm{d}x^j$ with $j < n$, which retains a factor (x^2-1) and so vanishes at $x = \pm 1$. Hence

$$\int_{-1}^{1} P_n^2\,\mathrm{d}x = \frac{(-1)^n}{(2^n n!)^2}\int_{-1}^{1}\left(x^2-1\right)^n\frac{\mathrm{d}^{2n}}{\mathrm{d}x^{2n}}\left(x^2-1\right)^n\mathrm{d}x = \frac{(2n)!}{(2^n n!)^2}\int_{-1}^{1}\left(1-x^2\right)^n\mathrm{d}x\,,$$

since the $2n$-th derivative of a monic-leading polynomial of degree $2n$ is the constant $(2n)!$ and $(-1)^n(x^2-1)^n = (1-x^2)^n$. Write $I_n = \int_{-1}^{1}(1-x^2)^n\,\mathrm{d}x$. Integration by parts gives

$$I_n = \left[x\left(1-x^2\right)^n\right]_{-1}^{1} + 2n\int_{-1}^{1} x^2\left(1-x^2\right)^{n-1}\mathrm{d}x = 2n\left(I_{n-1} - I_n\right)\,,$$

the boundary term vanishing and $x^2 = 1 - (1 - x^2)$ splitting the integral; hence $I_n = [2n/(2n+1)]I_{n-1}$, and with $I_0 = 2$,

$$I_n = 2\prod_{k=1}^{n} \frac{2k}{2k+1} = \frac{2^{2n+1}\,(n!)^2}{(2n+1)!}\,,$$

the closed form following from $\prod_{k\le n} 2k = 2^n n!$ and $\prod_{k\le n}(2k+1) = (2n+1)!/\,(2^n n!)$. Multiplying,

$$\int_{-1}^{1} P_n^2\,\mathrm{d}x = \frac{(2n)!}{2^{2n}\,(n!)^2}\cdot\frac{2^{2n+1}\,(n!)^2}{(2n+1)!} = \frac{2\,(2n)!}{(2n+1)!} = \frac{2}{2n+1}\,.$$

□

Remark 9.112 (There is no such relation for the Q_n). The source reserves headings for an orthogonality relation of the second-kind solutions Q_n, and for one of the general solution Equation (9.147). Neither exists, and the reason is the warning at the end of Remark 9.58: p vanishing at an endpoint is not enough when the solutions do not stay bounded there. The Q_n diverge logarithmically at $x = \pm 1$ — $Q_0(x) = \frac{1}{2}\ln[(1+x)/(1-x)]$ and $Q_n = P_nQ_0 -$ (a polynomial) — and a short computation with $u = Q_0$, $v = Q_2$ shows that the surviving part of the bracket is $\frac{3}{2}\,p\,\mathrm{d}Q_0/\mathrm{d}x = \frac{3}{2}$ at $x \to 1$ and $-\frac{3}{2}$ at $x \to -1$, so Equation (9.57) equals 3 and not 0. The identity in the proof of Theorem 9.57 then returns $\int_{-1}^{1} Q_0Q_2\,\mathrm{d}x = -\frac{1}{2}$ rather than zero. Orthogonality on $[-1,1]$ is a property of the solutions that remain bounded at the two singular endpoints, and that requirement is exactly what selects the P_n and makes the Legendre problem a self-adjoint one.

Generating function

Theorem 9.113 (Generating function)**.** *For $|x| \le 1$ and $|t| < 1$ the Legendre polynomials are generated by*

$$g(x,t) = \frac{1}{\sqrt{1-2xt+t^2}} = \sum_{n=0}^{\infty} P_n(x)\,t^n\,. \tag{9.150}$$

Rests on Lemma 9.110 and Proposition 9.109.

Derivation. *Derives Theorem 9.113.*

Write $W = 1 - 2xt + t^2$, so that $g = W^{-1/2}$. For $|x| \le 1$ the roots of W in t are $\mathrm{e}^{\pm\mathrm{i}\theta}$ with $x = \cos\theta$, both of modulus one, so g is holomorphic in t on $|t| < 1$ and has there a Taylor expansion $g = \sum_{n\ge 0} p_n(x)\,t^n$ (Theorem 8.20). Expanding $[1 - t(2x - t)]^{-1/2}$ by the binomial series and collecting powers of t shows each p_n to be a polynomial in x of degree at most n.

Next, g satisfies the identity

$$\frac{\partial}{\partial x}\left[\left(1-x^2\right)\frac{\partial g}{\partial x}\right] + \frac{\partial}{\partial t}\left[t^2\,\frac{\partial g}{\partial t}\right] = 0\,.$$

Indeed $\partial g/\partial x = t\,W^{-3/2}$ and $\partial g/\partial t = (x-t)\,W^{-3/2}$, so the first bracket differentiates to $-2xt\,W^{-3/2} + 3\,(1-x^2)\,t^2W^{-5/2}$ and the second to $2t(x-t)W^{-3/2} - t^2W^{-3/2} + 3t^2(x-t)^2W^{-5/2}$. The terms in $W^{-3/2}$ add to $-3t^2W^{-3/2}$, and those in $W^{-5/2}$ add to $3t^2[(1-x^2) + (x-t)^2]W^{-5/2} = 3t^2W\cdot W^{-5/2}$, which cancels the first.

Substituting the Taylor series in that identity and equating coefficients of t^n, using $\partial_t[t^2\partial_t g] = \sum_n n(n+1)p_nt^n$, gives

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[\left(1-x^2\right)\frac{\mathrm{d}p_n}{\mathrm{d}x}\right] + n(n+1)\,p_n = 0\,,$$

which is Equation (9.146). So p_n is a polynomial solution of the Legendre equation of that degree, hence a constant multiple of P_n by Lemma 9.110. The constant is 1 because $g(1,t) = (1-t)^{-1} = \sum_n t^n$ gives $p_n(1) = 1$, and $P_n(1) = 1$ by Proposition 9.109. □

Legendre series and recurrence relations

Proposition 9.114 (Recurrence relations)**.** *For $n \geq 1$,*

$$(n+1)\,P_{n+1}(x) = (2n+1)\,x\,P_n(x) - n\,P_{n-1}(x)\,, \tag{9.151}$$

$$\frac{\mathrm{d}P_{n+1}}{\mathrm{d}x}(x) - \frac{\mathrm{d}P_{n-1}}{\mathrm{d}x}(x) = (2n+1)\,P_n(x)\,, \tag{9.152}$$

with $P_0(x) = 1$ and $P_1(x) = x$.

Rests on Theorem 9.113.

Derivation. *Derives Proposition 9.114.*

Differentiating Equation (9.150) with respect to t gives $W\,\partial g/\partial t = (x-t)\,g$, and with respect to x gives $W\,\partial g/\partial x = t\,g$. Substituting the series and reading off the coefficient of t^n turns the first into

$$(n+1)P_{n+1} - 2n\,x\,P_n + (n-1)P_{n-1} = x\,P_n - P_{n-1}\,,$$

which is Equation (9.151), and the second into

$$\frac{\mathrm{d}P_n}{\mathrm{d}x} - 2x\,\frac{\mathrm{d}P_{n-1}}{\mathrm{d}x} + \frac{\mathrm{d}P_{n-2}}{\mathrm{d}x} = P_{n-1}\,. \tag{9.153}$$

Differentiating Equation (9.151) gives $(n+1)P'_{n+1} = (2n+1)P_n + (2n+1)xP'_n - nP'_{n-1}$, and Equation (9.153) at index $n+1$ gives $2xP'_n = P'_{n+1} + P'_{n-1} - P_n$. Eliminating xP'_n between the two leaves $\frac{1}{2}P'_{n+1} = \frac{1}{2}(2n+1)P_n + \frac{1}{2}P'_{n-1}$, which is Equation (9.152). The initial values follow from $g(x,t) = 1 + xt + O\,(t^2)$. □

Proposition 9.115 (Legendre series)**.** *Let f on $[-1,1]$ admit an expansion*

$$f(x) = \sum_{n=0}^{\infty} a_n\,P_n(x) \tag{9.154}$$

convergent in the mean. Then

$$a_n = \frac{2n+1}{2}\int_{-1}^{1} f(x)\,P_n(x)\,\mathrm{d}x\,. \tag{9.155}$$

Rests on Theorem 9.111 and Definition 9.47.

Derivation. *Derives Proposition 9.115.*

Multiply Equation (9.154) by P_m and integrate over $[-1,1]$; mean convergence permits the exchange of sum and integral, and Equation (9.149) leaves the single term $n = m$ with the factor $2/(2m+1)$, which inverts to Equation (9.155). That an expansion exists for every square-integrable f — the completeness of the system — is again a Sturm–Liouville theorem and not proved here, exactly as in Remark 9.101. □

9.9.2 The associated Legendre equation

Sturm–Liouville data

The identification of the operator data is

$$p(x) = 1 - x^2\,, \qquad q(x) = n(n+1)\,, \qquad \lambda^2 = -m^2\,, \qquad r(x) = \frac{1}{1-x^2}\,. \tag{9.156}$$

General solution

The homogeneous equation becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[(1-x^2)\,\frac{\mathrm{d}y}{\mathrm{d}x}(x)\right]+\left[n(n+1)-\frac{m^2}{1-x^2}\right]y(x)=0\,, \tag{9.157}$$

whose solution is

$$y(x)=A\,P_n^m(x)+B\,Q_n^m(x)\,, \tag{9.158}$$

with P_n^m the associated Legendre functions and Q_n^m the associated Legendre functions of the second kind.

Construction from the Legendre polynomials

Definition 9.116 (Associated Legendre functions)**.** For integers $0\le m\le n$ and $|x|\le 1$,

$$P_n^m(x)=\left(1-x^2\right)^{m/2}\,\frac{\mathrm{d}^m P_n}{\mathrm{d}x^m}(x)\,, \tag{9.159}$$

so that $P_n^0=P_n$ and $P_n^m=0$ for $m>n$, the m-th derivative of a polynomial of degree n then vanishing.

Rests on Definition 9.108.

Lemma 9.117 (The differentiated Legendre equation)**.** *If y solves Equation (9.146) then $u=\mathrm{d}^m y/\mathrm{d}x^m$ solves*

$$\left(1-x^2\right)\frac{\mathrm{d}^2u}{\mathrm{d}x^2}-2(m+1)\,x\,\frac{\mathrm{d}u}{\mathrm{d}x}+\left[n(n+1)-m(m+1)\right]u=0\,. \tag{9.160}$$

Rests on Equation (9.146).

Derivation. *Derives Lemma 9.117.*

Differentiate $(1-x^2)\,y''-2xy'+n(n+1)y=0$ exactly m times by the Leibniz rule Equation (7.16). The first term contributes $(1-x^2)\,y^{(m+2)}-2mx\,y^{(m+1)}-m(m-1)y^{(m)}$, the second $-2x\,y^{(m+1)}-2m\,y^{(m)}$, and the third $n(n+1)y^{(m)}$; only three and two terms survive respectively because $1-x^2$ is quadratic and x linear. Collecting, the coefficient of $y^{(m+1)}$ is $-2(m+1)x$ and that of $y^{(m)}$ is $n(n+1)-m(m-1)-2m=n(n+1)-m(m+1)$. □

Proposition 9.118 (The construction solves the associated equation)**.** *P_n^m of Equation (9.159) solves Equation (9.157).*

Rests on Definition 9.116 and Lemma 9.117.

Derivation. *Derives Proposition 9.118.*

Put $\varpi=(1-x^2)^{m/2}$ and $y=\varpi\,u$ with $u=\mathrm{d}^m P_n/\mathrm{d}x^m$, so that $\varpi'/\varpi=-mx/\left(1-x^2\right)$ and

$$\frac{\varpi''}{\varpi}=-\frac{m}{1-x^2}+\frac{(m^2-2m)\,x^2}{(1-x^2)^2}\,.$$

Substituting $y=\varpi u$ into the associated equation Equation (9.157), written out as $(1-x^2)\,y''-2xy'+\left[n(n+1)-m^2/(1-x^2)\right]y=0$, and dividing by ϖ leaves an equation for u whose coefficient of $\mathrm{d}u/\mathrm{d}x$ is $2\,(1-x^2)\,\varpi'/\varpi-2x=-2(m+1)x$ and whose coefficient of u is

$$\left(1-x^2\right)\frac{\varpi''}{\varpi}-2x\,\frac{\varpi'}{\varpi}+n(n+1)-\frac{m^2}{1-x^2}=-m+n(n+1)+\frac{m^2\,(x^2-1)}{1-x^2}\,,$$

that is $n(n+1)-m(m+1)$. The result is exactly Equation (9.160), which u satisfies by Lemma 9.117. □

Orthogonality

Theorem 9.119 (Orthogonality at fixed order)**.** *At fixed order m, the associated Legendre functions are orthogonal on $[-1,1]$:*

$$\int_{-1}^{1} P_n^m(x)\, P_{n'}^m(x)\,\mathrm{d}x = \frac{2}{2n+1}\,\frac{(n+m)!}{(n-m)!}\,\delta_{nn'}\,. \tag{9.161}$$

Rests on Theorems 9.57 and 9.111 and Proposition 9.118.

Derivation. *Derives Theorem 9.119.*

For $n \neq n'$ read Equation (9.157) at fixed m as the eigenvalue problem with $p(x) = 1-x^2$, $q(x) = -m^2/(1-x^2)$, weight $r = 1$ and eigenvalue $\lambda^2 = n(n+1)$. The functions P_n^m carry the factor $(1-x^2)^{m/2}$, so for $m \geq 1$ both they and p times their derivatives vanish at $x = \pm 1$, while for $m = 0$ the argument is that of Theorem 9.111; either way Equation (9.57) holds and Theorem 9.57 applies.

For the diagonal put $I_m = \int_{-1}^{1} (1-x^2)^m \left[u_m(x)\right]^2 \mathrm{d}x$ with $u_m = \mathrm{d}^m P_n/\mathrm{d}x^m$, which is the integral to be computed because $(P_n^m)^2 = (1-x^2)^m\, u_m^2$. For $m \geq 1$ write $u_m = \mathrm{d}u_{m-1}/\mathrm{d}x$ and integrate by parts (Equation (7.28)); the boundary term carries the factor $(1-x^2)^m$ and vanishes, so

$$I_m = -\int_{-1}^{1} u_{m-1}\,\frac{\mathrm{d}}{\mathrm{d}x}\left[\left(1-x^2\right)^m \frac{\mathrm{d}u_{m-1}}{\mathrm{d}x}\right]\mathrm{d}x = -\int_{-1}^{1} \left(1-x^2\right)^{m-1} u_{m-1}\,\Theta\,\mathrm{d}x\,,$$

where $\Theta = (1-x^2)\,\mathrm{d}^2u_{m-1}/\mathrm{d}x^2 - 2m\,x\,\mathrm{d}u_{m-1}/\mathrm{d}x$. By Equation (9.160) at order $m-1$ that combination is $-\left[n(n+1) - m(m-1)\right]u_{m-1}$, so

$$I_m = \left[n(n+1) - m(m-1)\right] I_{m-1} = (n+m)(n-m+1)\, I_{m-1}\,.$$

Iterating from $I_0 = 2/(2n+1)$, which is Theorem 9.111, gives

$$I_m = \frac{2}{2n+1}\prod_{k=1}^{m}(n+k)(n-k+1) = \frac{2}{2n+1}\cdot\frac{(n+m)!}{n!}\cdot\frac{n!}{(n-m)!}\,,$$

which is Equation (9.161). □

Recurrence relations

Proposition 9.120 (Recurrence in the degree at fixed order)**.** *For $1 \leq m \leq n$,*

$$(n-m+1)\,P_{n+1}^m(x) = (2n+1)\,x\,P_n^m(x) - (n+m)\,P_{n-1}^m(x)\,. \tag{9.162}$$

Rests on Proposition 9.114 and Definition 9.116.

Derivation. *Derives Proposition 9.120.*

Write $D = \mathrm{d}/\mathrm{d}x$. Applying D^m to Equation (9.151) by the Leibniz rule Equation (7.16), in which the factor x contributes only two terms,

$$(n+1)\,D^m P_{n+1} = (2n+1)\left[x\,D^m P_n + m\,D^{m-1}P_n\right] - n\,D^m P_{n-1}\,,$$

while applying D^{m-1} to Equation (9.152) gives $D^m P_{n+1} - D^m P_{n-1} = (2n+1)\,D^{m-1}P_n$. Substituting the second into the first eliminates $D^{m-1}P_n$ and leaves

$$(n-m+1)\,D^m P_{n+1} = (2n+1)\,x\,D^m P_n - (n+m)\,D^m P_{n-1}\,,$$

and multiplying through by $(1-x^2)^{m/2}$ turns each $D^m P_k$ into P_k^m by Equation (9.159). □

9.9.3 Spherical harmonics

The associated Legendre functions in $\cos\theta$, combined with the complex exponentials of Section 9.7 in the azimuthal angle φ, form the *spherical harmonics*

$$Y_n^m(\theta,\varphi) = \sqrt{\frac{2n+1}{4\pi}\,\frac{(n-m)!}{(n+m)!}}\;P_n^m(\cos\theta)\,\mathrm{e}^{\mathrm{i}m\varphi}\,, \tag{9.163}$$

which are orthonormal on the unit sphere [1976],

$$\int_0^{2\pi}\mathrm{d}\varphi\int_0^{\pi}\overline{Y_{n'}^{m'}(\theta,\varphi)}\,Y_n^m(\theta,\varphi)\,\sin\theta\,\mathrm{d}\theta = \delta_{nn'}\,\delta_{mm'}\,. \tag{9.164}$$

Proposition 9.121 (Where the construction comes from)**.** *Separating the angular part of the Laplace operator on the unit sphere as $Y(\theta,\varphi)=\Theta(\theta)\,\Phi(\varphi)$ forces $\Phi(\varphi)=\mathrm{e}^{\mathrm{i}m\varphi}$ with m an integer, and $\Theta(\theta)=P_n^m(\cos\theta)$ with n a non-negative integer and $|m|\le n$. Every other choice of the two separation constants gives a solution that is either multivalued in φ or unbounded at one of the poles.*

Rests on Equations (9.107) and (9.157).

Derivation. Derives Proposition 9.121.

The angular eigenvalue equation is

$$\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left[\sin\theta\,\frac{\partial Y}{\partial\theta}\right]+\frac{1}{\sin^2\theta}\,\frac{\partial^2 Y}{\partial\varphi^2} = -\Lambda\,Y\,.$$

Substituting the product and dividing by $\Theta\Phi/\sin^2\theta$ separates it: the φ part is $\mathrm{d}^2\Phi/\mathrm{d}\varphi^2 = -m^2\Phi$, whose solutions are the exponentials Equation (9.107), and single-valuedness under $\varphi\mapsto\varphi+2\pi$ restricts m to the integers. The θ part, in the variable $x=\cos\theta$ — for which $\mathrm{d}/\mathrm{d}\theta = -\sin\theta\,\mathrm{d}/\mathrm{d}x$ and $\sin^2\theta = 1-x^2$ — is exactly the associated Legendre equation Equation (9.157) with $n(n+1)$ replaced by Λ. Boundedness at the two poles $x=\pm1$, the singular endpoints of that equation in the sense of Remark 9.17, selects the solutions P_n^m: for $\Lambda=n(n+1)$ with n a non-negative integer and $|m|\le n$ these are bounded by Equation (9.159), and the second solution Q_n^m diverges there, as does every solution for any other value of Λ. □

Theorem 9.122 (Normalisation and orthonormality)**.** *With the constant displayed in Equation (9.163) the functions Y_n^m satisfy Equation (9.164), and that constant is the only positive one that does so.*

Rests on Theorem 9.119 and Equation (9.109).

Derivation. Derives Theorem 9.122.

The integral factorises. The azimuthal factor is

$$\int_0^{2\pi}\mathrm{e}^{\mathrm{i}(m-m')\varphi}\,\mathrm{d}\varphi = 2\pi\,\delta_{mm'}\,,$$

which is Equation (9.109) on an interval of one period, so every term with $m\neq m'$ vanishes whatever the polar factor does. At $m=m'$ the polar factor is, substituting $x=\cos\theta$ and $\mathrm{d}x=-\sin\theta\,\mathrm{d}\theta$,

$$\int_0^{\pi}P_{n'}^m(\cos\theta)\,P_n^m(\cos\theta)\,\sin\theta\,\mathrm{d}\theta = \int_{-1}^{1}P_{n'}^m(x)\,P_n^m(x)\,\mathrm{d}x = \frac{2}{2n+1}\,\frac{(n+m)!}{(n-m)!}\,\delta_{nn'}$$

by Theorem 9.119. The product of the two factors is $2\pi\cdot 2(n+m)!/\big[(2n+1)(n-m)!\big]$ times $\delta_{nn'}\delta_{mm'}$, and the squared modulus of the constant in Equation (9.163) is the reciprocal of that number, which gives Equation (9.164). Since the constant enters squared and is required positive, it is unique. □

Remark 9.123 (Negative order, and completeness). Equation (9.159) defines P_n^m for $m \geq 0$ only, and Equation (9.163) is extended to $-n \leq m < 0$ by

$$P_n^{-m}(x) = (-1)^m \, \frac{(n-m)!}{(n+m)!} \, P_n^m(x) \,, \qquad 0 \leq m \leq n \,, \tag{9.165}$$

a convention — the Condon–Shortley one — chosen so that Equation (9.163) then satisfies $\overline{Y_n^m} = (-1)^m \, Y_n^{-m}$ and so that Theorem 9.122 continues to hold with the same formula, as substituting Equation (9.165) into the two factorials shows. That the Y_n^m are moreover *complete* in the square-integrable functions on the sphere — so that every such function has an expansion in them — is not proved here: it is the statement that the angular Laplace operator has no other eigenfunctions, which belongs with the general spectral theory of Chapter 12 [1222]. The addition theorem, which expresses $P_n(\cos\gamma)$ for the angle γ between two directions as a sum of products of spherical harmonics of those two directions, rests on the rotation behaviour of the space spanned by the Y_n^m at fixed n and is not derived here either; it is used in this treatise only through [1976].

9.10 The Hermite equation

The source announces the Hermite family with the same systematic headings as the families above — Sturm–Liouville data p, q and r, general solution, recurrence relations, orthonormality, and Hermite series — but every one of those subsections is empty, so they are supplied here. This family governs the stationary states of the quantum harmonic oscillator, where the Hermite polynomials appear multiplied by a Gaussian weight [1593, 2313].

9.10.1 Sturm–Liouville data

The Hermite equation is

$$\frac{\mathrm{d}^2 y}{\mathrm{d}x^2}(x) - 2x \, \frac{\mathrm{d}y}{\mathrm{d}x}(x) + 2n \, y(x) = 0 \,, \qquad x \in \mathbb{R} \,. \tag{9.166}$$

Multiplying it by the integrating factor e^{-x^2} puts it in the form Equation (9.54), since $\frac{\mathrm{d}}{\mathrm{d}x}\left[\mathrm{e}^{-x^2} \mathrm{d}y/\mathrm{d}x\right] = \mathrm{e}^{-x^2}\left[y'' - 2xy'\right]$, with data

$$p(x) = \mathrm{e}^{-x^2} \,, \qquad q(x) = 0 \,, \qquad \lambda^2 = 2n \,, \qquad r(x) = \mathrm{e}^{-x^2} \,, \tag{9.167}$$

on the whole line. The weight is the Gaussian, and the interval is unbounded, so the third mechanism of Remark 9.58 is the one that will apply.

9.10.2 Solutions and generating function

Definition 9.124 (Hermite polynomials)**.**

$$H_n(x) = (-1)^n \, \mathrm{e}^{x^2} \, \frac{\mathrm{d}^n}{\mathrm{d}x^n} \, \mathrm{e}^{-x^2} \,, \qquad n = 0, 1, 2, \ldots \tag{9.168}$$

Proposition 9.125 (Generating function and first properties)**.** *The polynomials Equation (9.168) are generated by*

$$\mathrm{e}^{2xt - t^2} = \sum_{n=0}^{\infty} \frac{H_n(x)}{n!} \, t^n \,, \tag{9.169}$$

and H_n is a polynomial of degree n with leading coefficient 2^n and parity $(-1)^n$.
Rests on Definition 9.124.

Derivation. *Derives Proposition 9.125.*

Complete the square: $2xt-t^2 = x^2-(x-t)^2$, so the left of Equation (9.169) is $\mathrm{e}^{x^2}\,\mathrm{e}^{-(x-t)^2}$. The second factor is a function of $x-t$ alone, so $\partial/\partial t$ acting on it equals $-\partial/\partial x$; hence its n-th t-derivative at $t=0$ is $(-1)^n \mathrm{d}^n\mathrm{e}^{-x^2}/\mathrm{d}x^n$, and the Taylor expansion in t of a function entire in t (Theorem 8.20) gives

$$\mathrm{e}^{x^2}\mathrm{e}^{-(x-t)^2} = \sum_{n\geq 0} \frac{t^n}{n!}\,(-1)^n\,\mathrm{e}^{x^2}\,\frac{\mathrm{d}^n\mathrm{e}^{-x^2}}{\mathrm{d}x^n}\,,$$

which is Equation (9.169) with Equation (9.168). Differentiating Equation (9.168) once more, and using $\mathrm{d}\mathrm{e}^{-x^2}/\mathrm{d}x = -2x\,\mathrm{e}^{-x^2}$, gives $H_{n+1} = 2x\,H_n - \mathrm{d}H_n/\mathrm{d}x$; with $H_0 = 1$ this shows by induction that H_n is a polynomial of degree n whose leading coefficient doubles at each step, hence equals 2^n. The parity follows from $\mathrm{e}^{2(-x)t-t^2} = \mathrm{e}^{2x(-t)-(-t)^2}$, which sends $H_n(-x)$ to $(-1)^n H_n(x)$. □

Proposition 9.126 (Recurrence relations and the equation)**.** *For $n \geq 1$,*

$$\frac{\mathrm{d}H_n}{\mathrm{d}x}(x) = 2n\,H_{n-1}(x)\,, \tag{9.170}$$

$$H_{n+1}(x) = 2x\,H_n(x) - 2n\,H_{n-1}(x)\,, \tag{9.171}$$

and H_n solves the Hermite equation Equation (9.166).

Rests on Proposition 9.125 and Equation (9.166).

Derivation. *Derives Proposition 9.126.*

Differentiating Equation (9.169) with respect to x gives $2t\,\mathrm{e}^{2xt-t^2} = \sum_n (\mathrm{d}H_n/\mathrm{d}x)t^n/n!$, and comparing coefficients of t^n gives $\mathrm{d}H_n/\mathrm{d}x \;/\; n! = 2H_{n-1}/(n-1)!$, which is Equation (9.170). Combining it with $H_{n+1} = 2xH_n - \mathrm{d}H_n/\mathrm{d}x$, established in the proof of Proposition 9.125, gives Equation (9.171). For the equation, differentiate that same relation: $\mathrm{d}H_{n+1}/\mathrm{d}x = 2H_n + 2x\,\mathrm{d}H_n/\mathrm{d}x - \mathrm{d}^2H_n/\mathrm{d}x^2$, and use Equation (9.170) on the left, which turns it into $2(n+1)H_n$. Cancelling $2H_n$ from both sides leaves $\mathrm{d}^2H_n/\mathrm{d}x^2 - 2x\,\mathrm{d}H_n/\mathrm{d}x + 2n\,H_n = 0$. □

9.10.3 Orthogonality and Hermite series

Theorem 9.127 (Orthogonality)**.**

$$\int_{-\infty}^{\infty} H_m(x)\,H_n(x)\,\mathrm{e}^{-x^2}\,\mathrm{d}x = 2^n\,n!\,\sqrt{\pi}\,\delta_{mn}\,. \tag{9.172}$$

Rests on Theorem 9.57, Proposition 9.126, and Equation (9.167).

Derivation. *Derives Theorem 9.127.*

For $m \neq n$ apply Theorem 9.57 with the data Equation (9.167): the eigenvalues $2m$ and $2n$ differ, and the boundary term Equation (9.57) vanishes because $p = \mathrm{e}^{-x^2}$ multiplies polynomials and e^{-x^2} beats every polynomial at both ends of the line — the third mechanism of Remark 9.58.

For $m = n$ insert Equation (9.168) for one factor and integrate by parts n times (Equation (7.28)), every boundary term vanishing for the same reason:

$$\int_{-\infty}^{\infty} H_n^2\,\mathrm{e}^{-x^2}\,\mathrm{d}x = (-1)^n \int_{-\infty}^{\infty} H_n(x)\,\frac{\mathrm{d}^n\mathrm{e}^{-x^2}}{\mathrm{d}x^n}\,\mathrm{d}x = \int_{-\infty}^{\infty} \frac{\mathrm{d}^n H_n}{\mathrm{d}x^n}\,\mathrm{e}^{-x^2}\,\mathrm{d}x\,.$$

By Proposition 9.125 the n-th derivative of H_n is the constant $2^n n!$, and the Gaussian integral $\int_{-\infty}^{\infty}\mathrm{e}^{-x^2}\mathrm{d}x = \sqrt{\pi}$ — its square being $\int\int \mathrm{e}^{-x^2-y^2}\mathrm{d}x\,\mathrm{d}y = \pi$ in plane polar coordinates — completes Equation (9.172). □

Proposition 9.128 (Hermite series)**.** *Let f admit an expansion $f(x) = \sum_{n\geq 0} a_n H_n(x)$ convergent in the mean with respect to the weight e^{-x^2}. Then*

$$a_n = \frac{1}{2^n\, n!\, \sqrt{\pi}} \int_{-\infty}^{\infty} f(x)\, H_n(x)\, \mathrm{e}^{-x^2}\, \mathrm{d}x\,. \tag{9.173}$$

Rests on Theorem 9.127 and Definition 9.47.

Derivation. *Derives Proposition 9.128.*

Multiply by $H_m(x)\mathrm{e}^{-x^2}$, integrate over the line, exchange sum and integral by mean convergence, and use Equation (9.172); the surviving term is $n = m$ and carries the constant $2^m m!\sqrt{\pi}$. Completeness of the system carries the same caveat as Remark 9.101. □

Remark 9.129 (The quantum oscillator, in SI). For the potential $V(x) = \frac{1}{2}m_0\omega^2 x^2$ of Example 9.80, with m_0 in kg and ω in rad/s, the substitution $\xi = x/\ell_0$ with $\ell_0 = \sqrt{\hbar/(m_0\omega)}$ in m turns Equation (9.59) into $\mathrm{d}^2\psi/\mathrm{d}\xi^2 + [2E/(\hbar\omega) - \xi^2]\psi = 0$, and the substitution $\psi = \mathrm{e}^{-\xi^2/2}H(\xi)$ turns that into Equation (9.166) for H with $2n = 2E/(\hbar\omega) - 1$. Square integrability forces the series solution to terminate, that is n to be a non-negative integer, which returns the levels Equation (9.91) $E_n = (n + \frac{1}{2})\hbar\omega$ in J — there exactly, not semiclassically. The mass is written m_0 here only because m is the order of the associated Legendre functions elsewhere in this chapter.

9.11 The Laguerre equation

The source likewise reserves the full set of systematic headings for the Laguerre family — Sturm–Liouville data p, q and r, general solution, recurrence relations, orthonormality, and Laguerre series — all of them empty, and they are supplied here. The associated Laguerre polynomials furnish the radial eigenfunctions of the hydrogen atom [1593, 2313].

9.11.1 Sturm–Liouville data

The Laguerre equation is

$$x\,\frac{\mathrm{d}^2y}{\mathrm{d}x^2}(x) + (1-x)\,\frac{\mathrm{d}y}{\mathrm{d}x}(x) + n\,y(x) = 0\,, \qquad x > 0\,. \tag{9.174}$$

Multiplying by e^{-x} puts it in the form Equation (9.54), since $\frac{\mathrm{d}}{\mathrm{d}x}[x\mathrm{e}^{-x}\mathrm{d}y/\mathrm{d}x] = \mathrm{e}^{-x}[xy'' + (1-x)y']$, with data

$$p(x) = x\,\mathrm{e}^{-x}\,, \qquad q(x) = 0\,, \qquad \lambda^2 = n\,, \qquad r(x) = \mathrm{e}^{-x}\,, \tag{9.175}$$

on the half-line. Here p vanishes at the origin and decays at infinity, so the boundary term dies at both ends at once.

9.11.2 Solutions and generating function

Definition 9.130 (Laguerre polynomials)**.**

$$L_n(x) = \frac{\mathrm{e}^x}{n!}\,\frac{\mathrm{d}^n}{\mathrm{d}x^n}\left(x^n\,\mathrm{e}^{-x}\right)\,, \qquad n = 0, 1, 2, \ldots \tag{9.176}$$

Proposition 9.131 (Explicit form and generating function)**.** *The Rodrigues formula Equation (9.176) evaluates to*

$$L_n(x) = \sum_{j=0}^{n} \binom{n}{j}\,\frac{(-1)^j}{j!}\,x^j\,, \tag{9.177}$$

a polynomial of degree n with leading coefficient $(-1)^n/n!$ and $L_n(0) = 1$, and these polynomials are generated by

$$\frac{1}{1-t}\,\exp\left[-\frac{x\,t}{1-t}\right] = \sum_{n=0}^{\infty} L_n(x)\,t^n\,, \qquad |t|<1\,. \tag{9.178}$$

Rests on Definition 9.130.

Derivation. Derives Proposition 9.131.

By the Leibniz rule Equation (7.16),

$$\frac{\mathrm{d}^n}{\mathrm{d}x^n}\left(x^n \mathrm{e}^{-x}\right) = \sum_{k=0}^{n} \binom{n}{k} \frac{n!}{(n-k)!}\, x^{n-k}\,(-1)^{n-k}\,\mathrm{e}^{-x}\,,$$

and dividing by $n!\,\mathrm{e}^{-x}$ and putting $j = n-k$ gives Equation (9.177); the term $j=n$ gives the leading coefficient and the term $j=0$ gives $L_n(0)=1$. For the generating function expand the exponential and then each factor $(1-t)^{-1-j}$ by the binomial series,

$$\frac{1}{1-t}\exp\left[-\frac{xt}{1-t}\right] = \sum_{j\ge 0}\frac{(-x)^j}{j!}\,\frac{t^j}{(1-t)^{j+1}} = \sum_{j\ge 0}\frac{(-x)^j}{j!}\,t^j \sum_{i\ge 0}\binom{i+j}{j} t^i\,,$$

both series being absolutely convergent for $|t|<1$, so that they may be rearranged (Proposition 7.49). The coefficient of t^n collects $i=n-j$ and is $\sum_{j\le n}\binom{n}{j}(-x)^j/j!$, which is Equation (9.177). □

Proposition 9.132 (The equation and the recurrence)**.** *L_n solves Equation (9.174), and for $n \ge 1$*

$$(n+1)\,L_{n+1}(x) = (2n+1-x)\,L_n(x) - n\,L_{n-1}(x)\,. \tag{9.179}$$

Rests on Proposition 9.131 and Equation (9.174).

Derivation. Derives Proposition 9.132.

Write $v = x^n\mathrm{e}^{-x}$, which satisfies $x\,\mathrm{d}v/\mathrm{d}x = (n-x)\,v$. Differentiating that identity $n+1$ times by the Leibniz rule Equation (7.16), each side producing only two terms because x and $n-x$ are linear, gives for $u = v^{(n)}$

$$x\,\frac{\mathrm{d}^2u}{\mathrm{d}x^2} + (n+1)\,\frac{\mathrm{d}u}{\mathrm{d}x} = (n-x)\,\frac{\mathrm{d}u}{\mathrm{d}x} - (n+1)\,u\,,$$

that is $x\,u'' + (1+x)\,u' + (n+1)\,u = 0$. Now $u = n!\,\mathrm{e}^{-x}L_n$ by Equation (9.176), so $u' = n!\,\mathrm{e}^{-x}\,(L_n' - L_n)$ and $u'' = n!\,\mathrm{e}^{-x}\,(L_n'' - 2L_n' + L_n)$; substituting and cancelling $n!\mathrm{e}^{-x}$,

$$x\,L_n'' + L_n'\,(-2x+1+x) + L_n\,(x-1-x+n+1) = x\,L_n'' + (1-x)L_n' + n\,L_n = 0\,,$$

which is Equation (9.174). For the recurrence, write G for the left of Equation (9.178); then $\ln G = -\ln(1-t) - xt/(1-t)$ gives $\partial G/\partial t = G\big[(1-t)^{-1} - x(1-t)^{-2}\big]$, that is $(1-t)^2\,\partial G/\partial t = (1-t-x)\,G$. Substituting the series and reading off the coefficient of t^n gives $(n+1)L_{n+1} - 2n\,L_n + (n-1)L_{n-1} = L_n - L_{n-1} - x\,L_n$, which rearranges to Equation (9.179). □

9.11.3 Orthogonality and Laguerre series

Theorem 9.133 (Orthonormality)**.** *The Laguerre polynomials are orthonormal on the half-line with weight e^{-x}:*

$$\int_0^{\infty} L_m(x)\,L_n(x)\,\mathrm{e}^{-x}\,\mathrm{d}x = \delta_{mn}\,. \tag{9.180}$$

Rests on Theorem 9.57, Proposition 9.131, and Equation (9.175).

Derivation. *Derives Theorem 9.133.*

For $m \neq n$ apply Theorem 9.57 with the data Equation (9.175): the eigenvalues m and n differ, and $p(x) = x\mathrm{e}^{-x}$ vanishes at the origin and decays at infinity while the solutions are polynomials, so Equation (9.57) holds.

For $m = n$ use Equation (9.176) on one factor and integrate by parts n times (Equation (7.28)). Every boundary term vanishes: at infinity because of e^{-x}, and at the origin because each derivative $\mathrm{d}^k(x^n\mathrm{e}^{-x})/\mathrm{d}x^k$ with $k < n$ still carries a positive power of x. Hence

$$\int_0^\infty L_n^2\,\mathrm{e}^{-x}\,\mathrm{d}x = \frac{1}{n!}\int_0^\infty L_n(x)\,\frac{\mathrm{d}^n}{\mathrm{d}x^n}\left(x^n\mathrm{e}^{-x}\right)\mathrm{d}x = \frac{(-1)^n}{n!}\int_0^\infty \frac{\mathrm{d}^n L_n}{\mathrm{d}x^n}\,x^n\,\mathrm{e}^{-x}\,\mathrm{d}x\,.$$

By Equation (9.177) the n-th derivative of L_n is the constant $(-1)^n$, and $\int_0^\infty x^n\mathrm{e}^{-x}\mathrm{d}x = \Gamma(n+1) = n!$, so the whole expression is $[(-1)^n]^2\,n!/n! = 1$. □

Proposition 9.134 (Laguerre series)**.** *Let f on $(0,\infty)$ admit an expansion $f(x) = \sum_{n\geq 0} a_n L_n(x)$ convergent in the mean with respect to the weight e^{-x}. Then $a_n = \int_0^\infty f(x)\,L_n(x)\,\mathrm{e}^{-x}\,\mathrm{d}x$.*

Rests on Theorem 9.133 and Definition 9.47.

Derivation. *Derives Proposition 9.134.*

This is Proposition 9.48 verbatim: the system $\{L_n\}$ is already orthonormal for the weight e^{-x} by Equation (9.180), so no normalising constant appears. Completeness carries the caveat of Remark 9.101. □

Remark 9.135 (The associated polynomials and the hydrogen atom). The radial eigenfunctions of the hydrogen atom involve not L_n but the *associated* Laguerre polynomials $L_n^k = (-1)^k\,\mathrm{d}^k L_{n+k}/\mathrm{d}x^k$, which stand to Definition 9.130 as the associated Legendre functions of Definition 9.116 stand to the Legendre polynomials. They solve $x\,y'' + (k+1-x)\,y' + n\,y = 0$, which is Equation (9.174) with $1-x$ replaced by $k+1-x$ — a Sturm–Liouville problem with $p(x) = x^{k+1}\mathrm{e}^{-x}$ and weight $x^k\mathrm{e}^{-x}$ on the same half-line, so that the boundary term dies at both ends exactly as it does here. Their orthogonality, recurrences and generating function are established by the arguments used above, and they are used in Chapter 81 [1593, 2313].

9.12 Elliptic integrals and the Jacobi elliptic functions

Every family treated so far arose from separating a linear partial differential equation. The family of this section arises differently and is needed just as often: whenever a one-degree-of-freedom conservative system is integrated by energy conservation, the result is a quadrature $t = \int \mathrm{d}u/\sqrt{f(u)}$, and when f is a cubic or a quartic that quadrature is an elliptic integral. The pendulum at finite amplitude, the nutation of a heavy symmetric top, the free rotation of a body with three unequal moments of inertia and the shape of an elastic strip under end thrust are all of this kind, and each stops at a quadrature the reader cannot invert without the functions defined here. They are due to Legendre, who reduced every such integral to three normal forms, and to Jacobi and Abel, who saw that the fruitful object is the *inverse* of the integral.

9.12.1 The three normal forms

Lemma 9.136 (Wallis integrals)**.** *For every integer $n \geq 0$,*

$$\int_0^{\pi/2} \sin^{2n}\theta\,\mathrm{d}\theta = \frac{\pi}{2}\,\frac{(2n)!}{4^n\,(n!)^2}\,. \tag{9.181}$$

Rests on Corollary 7.44 and Lemma 7.59.

Derivation. *Derives Lemma 9.136.*

Write W_n for the integral. Integrating by parts (Corollary 7.44) with $u = \sin^{2n-1}\theta$ and $\mathrm{d}v = \sin\theta\,\mathrm{d}\theta$, the boundary term $\left[-\sin^{2n-1}\theta\cos\theta\right]_0^{\pi/2}$ vanishes at both ends for $n \geq 1$, leaving

$$W_n = (2n-1)\int_0^{\pi/2} \sin^{2n-2}\theta\,\cos^2\theta\,\mathrm{d}\theta = (2n-1)(W_{n-1} - W_n)\,,$$

by $\cos^2 = 1 - \sin^2$ (Lemma 7.59). Hence $2n\,W_n = (2n-1)W_{n-1}$, and with $W_0 = \pi/2$ induction gives

$$W_n = \frac{\pi}{2}\prod_{j=1}^{n}\frac{2j-1}{2j} = \frac{\pi}{2}\,\frac{(2n)!}{4^n(n!)^2}\,,$$

the last step because $\prod_{j\leq n}(2j-1) = (2n)!/(2^n n!)$ and $\prod_{j\leq n}(2j) = 2^n n!$. □

Definition 9.137 (Elliptic integrals of the three kinds)**.** Let $0 \leq k < 1$ be the *modulus* and $\varphi \in \mathbb{R}$ the *amplitude*. The incomplete elliptic integrals of the first, second and third kind are

$$F(\varphi,k) = \int_0^{\varphi} \frac{\mathrm{d}\theta}{\sqrt{1-k^2\sin^2\theta}}\,, \tag{9.182}$$

$$E(\varphi,k) = \int_0^{\varphi} \sqrt{1-k^2\sin^2\theta}\,\mathrm{d}\theta\,, \tag{9.183}$$

$$\Pi(n;\varphi,k) = \int_0^{\varphi} \frac{\mathrm{d}\theta}{(1-n\sin^2\theta)\sqrt{1-k^2\sin^2\theta}}\,, \tag{9.184}$$

with n the *characteristic*. The *complete* integrals are their values at $\varphi = \pi/2$,

$$K(k) = F\!\left(\frac{\pi}{2},k\right), \qquad E(k) = E\!\left(\frac{\pi}{2},k\right). \tag{9.185}$$

Rests on Definition 7.93 and Theorem 7.40.

Remark 9.138 (Modulus, parameter, and a trap in the literature). Three conventions are in use and they are not distinguished by the symbol K. This treatise writes $K(k)$ with the *modulus* k, so that k^2 appears in Equation (9.182). Much of the mathematical literature, and most computer-algebra systems, write $K(m)$ with the *parameter* $m = k^2$; a third convention uses the *modular angle* α with $k = \sin\alpha$. The three disagree by a squaring, so a formula copied across conventions without checking is wrong by an amount that vanishes at small amplitude and is therefore not caught by the obvious limit. Where a result of this treatise is quoted elsewhere — the pendulum period Equation (9.199) is the case that matters — the argument is stated as $\sin(\theta_0/2)$, a modulus.

Proposition 9.139 (Series for the complete integral of the first kind)**.** *For $0 \leq k < 1$,*

$$K(k) = \frac{\pi}{2}\sum_{n=0}^{\infty}\left[\frac{(2n)!}{4^n(n!)^2}\right]^2 k^{2n} = \frac{\pi}{2}\left[1 + \frac{k^2}{4} + \frac{9k^4}{64} + \frac{25k^6}{256} + \cdots\right], \tag{9.186}$$

the series converging for every k with $|k| < 1$. Moreover K is strictly increasing on $[0,1)$ and $K(k) \to +\infty$ as $k \to 1^-$.

Rests on Definition 9.137 and Lemmas 9.6 and 9.136.

Derivation. *Derives Proposition 9.139.*

The binomial series $(1-u)^{-1/2} = \sum_{n\geq 0}\left[(2n)!/(4^n(n!)^2)\right]u^n$ converges for $|u| < 1$ (Theorem 7.50, Proposition 7.48: the ratio of successive coefficients is $(2n+1)/(2n+2) \to 1$). Put $u = k^2\sin^2\theta$, so that $0 \leq u \leq k^2 < 1$ uniformly in θ. The n-th term is bounded on $[0,\pi/2]$ by $M_n = \left[(2n)!/(4^n(n!)^2)\right]k^{2n}$, and $\sum_n M_n = (1-k^2)^{-1/2}$ is finite, so by Lemma 9.6 the series converges uniformly on $[0,\pi/2]$ and may be integrated term by term. Each

term contributes $[(2n)!/(4^n(n!)^2)]k^{2n}W_n$ with W_n the Wallis integral Equation (9.181), and substituting Equation (9.181) produces the square in Equation (9.186). The first coefficients are 1, $(1/2)^2 = 1/4$, $(3/8)^2 = 9/64$ and $(5/16)^2 = 25/256$.

Monotonicity is immediate: the integrand of Equation (9.182) increases with k at every $\theta \in (0, \pi/2]$. For the divergence, use $1 - k^2\sin^2\theta = (1-k^2) + k^2\cos^2\theta \le c^2 + \cos^2\theta$ with $c = \sqrt{1-k^2}$, and substitute $w = \pi/2 - \theta$, so $\cos\theta = \sin w \le w$:

$$K(k) \ge \int_0^{\pi/2} \frac{\mathrm{d}w}{\sqrt{c^2 + w^2}} = \ln\left[\frac{\pi}{2c} + \sqrt{1 + \frac{\pi^2}{4c^2}}\right],$$

which tends to $+\infty$ as $c \to 0^+$, that is as $k \to 1^-$. □

9.12.2 The Jacobi elliptic functions

Definition 9.140 (Amplitude and the Jacobi elliptic functions)**.** Fix $0 \le k < 1$. The integrand of Equation (9.182) is positive and π-periodic in θ, so $\varphi \mapsto F(\varphi, k)$ is a strictly increasing bijection of $\mathbb{R}$ onto $\mathbb{R}$ satisfying $F(\varphi + \pi, k) = F(\varphi, k) + 2K(k)$. Its inverse is the *amplitude* $\operatorname{am}(u, k)$, and the *Jacobi elliptic functions* are

$$\operatorname{sn}(u,k) = \sin\operatorname{am}(u,k), \quad \operatorname{cn}(u,k) = \cos\operatorname{am}(u,k), \quad \operatorname{dn}(u,k) = \sqrt{1 - k^2\operatorname{sn}^2(u,k)}. \tag{9.187}$$

Rests on Definition 9.137 and Proposition 7.32.

Proposition 9.141 (First properties)**.** *With $K = K(k)$ and the argument k suppressed,*

$$\operatorname{sn}^2 u + \operatorname{cn}^2 u = 1, \qquad \operatorname{dn}^2 u + k^2\operatorname{sn}^2 u = 1, \tag{9.188}$$

$$\frac{\mathrm{d}}{\mathrm{d}u}\operatorname{sn} u = \operatorname{cn} u\,\operatorname{dn} u, \qquad \frac{\mathrm{d}}{\mathrm{d}u}\operatorname{cn} u = -\operatorname{sn} u\,\operatorname{dn} u, \tag{9.189}$$

and $\mathrm{d}(\operatorname{dn} u)/\mathrm{d}u = -k^2\operatorname{sn} u\,\operatorname{cn} u$. *Furthermore* sn *is odd and* cn, dn *are even;* $\operatorname{sn} 0 = 0$, $\operatorname{cn} 0 = \operatorname{dn} 0 = 1$, $\operatorname{sn} K = 1$*; and*

$$\operatorname{sn}(u+2K) = -\operatorname{sn} u, \quad \operatorname{cn}(u+2K) = -\operatorname{cn} u, \quad \operatorname{dn}(u+2K) = \operatorname{dn} u, \tag{9.190}$$

so sn *and* cn *have period* $4K$ *and* dn *has period* $2K$*. At* $k = 0$ *they reduce to* $\sin u$, $\cos u$ *and* 1.

Rests on Definition 9.140, Proposition 7.32, and Lemma 7.59.

Derivation. *Derives Proposition 9.141.*

The first identity in Equation (9.188) is the Pythagorean identity (Lemma 7.59) applied to am, and the second is Equation (9.187) squared. Since $\partial F/\partial\varphi = (1 - k^2\sin^2\varphi)^{-1/2}$ is positive and continuous, Proposition 7.32 gives

$$\frac{\mathrm{d}}{\mathrm{d}u}\operatorname{am}(u,k) = \sqrt{1 - k^2\sin^2\operatorname{am}(u,k)} = \operatorname{dn}(u,k), \tag{9.191}$$

and the chain rule (Proposition 7.31) turns Equation (9.187) into Equation (9.189). Differentiating $\operatorname{dn}^2 = 1 - k^2\operatorname{sn}^2$ and dividing by $2\operatorname{dn}$ gives the third derivative, $-k^2\operatorname{sn}\operatorname{cn}$.

F is odd in φ because its integrand is even, so am is odd and the parities follow. The values at $u = 0$ are those at $\varphi = 0$, and $\operatorname{am}(K) = \pi/2$ by Equation (9.185), giving $\operatorname{sn} K = 1$. Finally $F(\varphi + \pi) = F(\varphi) + 2K$ inverts to $\operatorname{am}(u + 2K) = \operatorname{am}(u) + \pi$, and Equation (9.190) is what sin, cos and $\sin^2$ do under a shift by π. At $k = 0$, Equation (9.182) gives $F(\varphi, 0) = \varphi$ and hence $\operatorname{am}(u, 0) = u$. □

Proposition 9.142 (The differential equation of the sine amplitude)**.** *The function* $y(u) = \operatorname{sn}(u,k)$ *satisfies*

$$\left(\frac{\mathrm{d}y}{\mathrm{d}u}\right)^2 = (1-y^2)(1-k^2y^2)\,, \tag{9.192}$$

and therefore the second-order equation

$$\frac{\mathrm{d}^2y}{\mathrm{d}u^2} = -(1+k^2)\,y + 2k^2\,y^3\,, \tag{9.193}$$

with $y(0)=0$ *and* $y'(0)=1$*. Conversely Equation* (9.193) *with those initial data has* $\operatorname{sn}(\cdot,k)$ *as its unique solution.*

Rests on Proposition 9.141 and Theorem 9.8.

Derivation. *Derives Proposition 9.142.*

Squaring Equation (9.189) and eliminating cn and dn by Equation (9.188) gives Equation (9.192). Differentiating $\operatorname{sn}' = \operatorname{cn}\operatorname{dn}$ once more and using the three derivative formulas,

$$\operatorname{sn}'' = -\operatorname{sn}\operatorname{dn}^2 - k^2\operatorname{sn}\operatorname{cn}^2 = -\operatorname{sn}(1-k^2\operatorname{sn}^2) - k^2\operatorname{sn}(1-\operatorname{sn}^2)\,,$$

which is Equation (9.193). The initial values are those of Proposition 9.141, with $\operatorname{sn}'(0) = \operatorname{cn}0\,\operatorname{dn}0 = 1$. The right-hand side of Equation (9.193) is a polynomial and therefore locally Lipschitz, so Theorem 9.8 makes the solution unique. Note that Equation (9.192), whose right-hand side has a square root at the turning points, does *not* by itself determine the solution there; the second-order form does. □

9.12.3 Quadratures that reduce to elliptic integrals

Proposition 9.143 (A cubic quadrature between two turning points)**.** *Let* $f(v) = c\,(v-e_1)(v-e_2)(v-e_3)$ *with* $c>0$ *and* $e_1<e_2<e_3$*, so that* $f>0$ *on* (e_1,e_2)*. Put*

$$k^2 = \frac{e_2-e_1}{e_3-e_1} \in (0,1)\,, \qquad \omega = \tfrac{1}{2}\sqrt{c\,(e_3-e_1)}\,. \tag{9.194}$$

Then for $u \in [e_1,e_2]$*,*

$$\int_{e_1}^{u} \frac{\mathrm{d}v}{\sqrt{f(v)}} = \frac{1}{\omega}\,F(\varphi,k)\,, \qquad \sin^2\varphi = \frac{u-e_1}{e_2-e_1}\,, \tag{9.195}$$

so the integral is finite at both endpoints, its value over the whole interval is $K(k)/\omega$*, and the function* $t \mapsto u(t)$ *inverting it is*

$$u(t) = e_1 + (e_2-e_1)\,\operatorname{sn}^2(\omega t,k)\,, \tag{9.196}$$

which oscillates between e_1 *and* e_2 *with period* $2K(k)/\omega$ *and satisfies* $(\mathrm{d}u/\mathrm{d}t)^2 = f(u)$*.*

Rests on Definition 9.140, Proposition 9.141, and Corollary 7.44.

Derivation. *Derives Proposition 9.143.*

Substitute $v = e_1 + (e_2-e_1)\sin^2\theta$ (Corollary 7.44), which increases from e_1 to e_2 as θ runs over $[0,\pi/2]$. Then

$$v-e_1 = (e_2-e_1)\sin^2\theta\,, \qquad v-e_2 = -(e_2-e_1)\cos^2\theta\,,$$

and, using Equation (9.194), $v-e_3 = -(e_3-e_1)\,[1-k^2\sin^2\theta]$. Hence

$$f(v) = c\,(e_2-e_1)^2(e_3-e_1)\,\sin^2\theta\,\cos^2\theta\,[1-k^2\sin^2\theta]\,,$$

whose square root is $2\omega(e_2-e_1)\sin\theta\cos\theta\sqrt{1-k^2\sin^2\theta}$ on $[0,\pi/2]$, every factor being non-negative there. Since $\mathrm{d}v = 2(e_2-e_1)\sin\theta\cos\theta\,\mathrm{d}\theta$, everything cancels except

$$\frac{\mathrm{d}v}{\sqrt{f(v)}} = \frac{1}{\omega}\,\frac{\mathrm{d}\theta}{\sqrt{1-k^2\sin^2\theta}}\,,$$

and integrating from 0 to φ gives Equation (9.195), finite at both ends because the integrand of Equation (9.182) is bounded for $k<1$. Taking $\varphi=\pi/2$ gives $K(k)/\omega$.

Inverting Equation (9.195) means $\varphi=\mathrm{am}(\omega t,k)$, hence $\sin^2\varphi=\mathrm{sn}^2(\omega t,k)$, which is Equation (9.196). Differentiating it with Equation (9.189), $\mathrm{d}u/\mathrm{d}t = 2\omega(e_2-e_1)\,\mathrm{sn}\,\mathrm{cn}\,\mathrm{dn}$, whose square is $4\omega^2(e_2-e_1)^2\,\mathrm{sn}^2\,\mathrm{cn}^2\,\mathrm{dn}^2$; and the same substitutions that produced $f(v)$ above, now with $\sin\theta=\mathrm{sn}$, give $f(u)=c(e_2-e_1)^2(e_3-e_1)\,\mathrm{sn}^2\,\mathrm{cn}^2\,\mathrm{dn}^2$. The two agree precisely when $4\omega^2=c(e_3-e_1)$, which is Equation (9.194). Finally sn^2 has period $2K$ by Equation (9.190), so u has period $2K/\omega$. □

Proposition 9.144 (The pendulum equation at finite amplitude)**.** *Let $\omega_0>0$ and let θ solve*

$$\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}(t)+\omega_0^2\,\sin\theta(t)=0 \tag{9.197}$$

with $\theta(0)=0$ and $\mathrm{d}\theta/\mathrm{d}t(0)=2\omega_0\sin(\theta_0/2)$ for some $\theta_0\in(0,\pi)$. Then the motion is periodic between $-\theta_0$ and $+\theta_0$, with

$$\sin\frac{\theta(t)}{2} = k\;\mathrm{sn}(\omega_0 t,k)\,,\qquad k=\sin\frac{\theta_0}{2}\,, \tag{9.198}$$

and its period is

$$T(\theta_0)=\frac{4}{\omega_0}\,K\!\left(\sin\frac{\theta_0}{2}\right)=T_0\,\frac{2}{\pi}\,K\!\left(\sin\frac{\theta_0}{2}\right),\qquad T_0=\frac{2\pi}{\omega_0}\,, \tag{9.199}$$

which for small amplitude expands as

$$T(\theta_0)=T_0\left[1+\frac{\theta_0^2}{16}+\frac{11\,\theta_0^4}{3072}+O\!\left(\theta_0^6\right)\right]. \tag{9.200}$$

Rests on Proposition 9.139, Definition 9.140, and Corollary 7.44.

Derivation. *Derives Proposition 9.144.*

Multiplying Equation (9.197) by $\mathrm{d}\theta/\mathrm{d}t$ and integrating once gives the first integral $\tfrac12\dot\theta^2-\omega_0^2\cos\theta=\text{const}$. The stated initial data fix the constant so that $\dot\theta$ vanishes at $\theta=\pm\theta_0$, and with $\cos\theta=1-2\sin^2(\theta/2)$,

$$\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2=4\omega_0^2\left[k^2-\sin^2\frac{\theta}{2}\right],\qquad k=\sin\frac{\theta_0}{2}\,. \tag{9.201}$$

The right-hand side is negative beyond $|\theta|=\theta_0$, so the motion is confined there and reverses at the two turning points. Equation (9.197) is unchanged under $t\mapsto -t$, and also under $\theta\mapsto-\theta$ because the sine is odd, so the four quarters of the motion are congruent and the period is four times the time from $\theta=0$ to $\theta=\theta_0$.

On that quarter $\dot\theta>0$. Substitute $\sin(\theta/2)=k\sin\varphi$, which carries $\theta:0\to\theta_0$ into $\varphi:0\to\pi/2$ and gives $\tfrac12\cos(\theta/2)\,\mathrm{d}\theta=k\cos\varphi\,\mathrm{d}\varphi$ with $\cos(\theta/2)=\sqrt{1-k^2\sin^2\varphi}$, while Equation (9.201) gives $\dot\theta=2\omega_0 k\cos\varphi$. Hence

$$\mathrm{d}t=\frac{\mathrm{d}\theta}{\dot\theta}=\frac{2k\cos\varphi\,\mathrm{d}\varphi}{\sqrt{1-k^2\sin^2\varphi}}\,\frac{1}{2\omega_0 k\cos\varphi}=\frac{1}{\omega_0}\,\frac{\mathrm{d}\varphi}{\sqrt{1-k^2\sin^2\varphi}}\,,$$

so $\omega_0 t = F(\varphi, k)$, that is $\varphi = \operatorname{am}(\omega_0 t, k)$, which is Equation (9.198); and $\varphi = \pi/2$ at the turning point gives $T/4 = K(k)/\omega_0$, which is Equation (9.199).

For Equation (9.200), expand $k = \sin(\theta_0/2)$ by Taylor's theorem (Theorem 7.38): $k^2 = \theta_0^2/4 - \theta_0^4/48 + O(\theta_0^6)$ and $k^4 = \theta_0^4/16 + O(\theta_0^6)$. Substituting into Equation (9.186) truncated at k^4,

$$\frac{2}{\pi}K = 1 + \frac{k^2}{4} + \frac{9k^4}{64} = 1 + \frac{\theta_0^2}{16} - \frac{\theta_0^4}{192} + \frac{9\theta_0^4}{1024} + O\left(\theta_0^6\right) ,$$

and $-1/192 + 9/1024 = (-16 + 27)/3072 = 11/3072$. □

Remark 9.145 (What this section is for). Proposition 9.143 is the general shape of the answer whenever a conservative system with one degree of freedom is reduced to a quadrature whose radicand is a cubic with three real roots and the motion runs between the lower two. That is the case of the heavy symmetric top, whose nutation angle satisfies exactly such an equation in the variable $\cos\theta$, so its nutation is Equation (9.196) and its nutation period is the complete integral $2K(k)/\omega$; the same reduction applies to the free rotation of a body with three distinct moments of inertia. The quartic case is reached from the cubic by the substitution that sends one root to infinity, and the case of two real and two complex roots by a different linear fractional substitution; those reductions are not carried out here, and no statement of this treatise depends on them. Proposition 9.144 is the second standard instance and is used directly by Chapter 28 and Chapter 34: Equation (9.199) is what a pendulum clock's rate depends on, Equation (9.200) is the correction a swinging amplitude introduces, and the two together are the quantitative content of the isochronism experiment. Note that Equation (9.200) is an expansion of an exact formula, not an independent approximation: the exact period is available at every amplitude below π, and the series is quoted only because it is what an error budget uses.

9.13 The Laplace transform

Beside the Fourier transform of Section 9.7.5, the source reserves a section for the Laplace transform — the integral transform adapted to initial-value problems on the half-line — but leaves it empty. The material is developed in full in Section 17.4, and this section records only what it is for and where each piece of it is proved.

The Fourier transform requires a function to decay at both ends of the line. A physical initial-value problem supplies neither condition: the system is switched on at $t = 0$ and its response may grow. Restricting the integral to $t > 0$ and inserting the convergence factor e^{-st} with $\Re s$ large enough repairs both defects at once, and gives the one-sided Laplace transform of Definition 17.65. Three facts make it a method rather than a definition. It converges on a half-plane $\Re s > \sigma_c$ and nowhere to the left of it (Theorem 17.66), and it is holomorphic there (Proposition 17.67); on each vertical line it is literally a Fourier transform, of the causal signal damped by $\mathrm{e}^{-\sigma t}$ (Proposition 17.68), which is what reduces its inversion to Theorem 17.32 and produces the Bromwich contour integral (Theorem 17.69), evaluable by residues (Corollary 17.71). And it converts differentiation into multiplication while swallowing the initial data, which enter the transformed equation as extra polynomial terms rather than as conditions imposed afterwards (Equation (17.87)).

That last rule is what makes the transform the natural tool for the constant-coefficient equations of Section 9.1: a linear ordinary differential equation becomes an algebraic one, its solution is a rational function of s, and the inverse transform is read off the poles by Heaviside's expansion theorem (Corollary 17.76). The location of those poles is the stability of the system (Proposition 17.77), and the requirement that the response be causal, applied to the same half-plane of holomorphy, yields the Kramers–Kronig dispersion relations (Theorem 17.78).

9.14 Summary of the classical families

Table 9.2 collects the Sturm–Liouville data (p, q, λ^2, r) of every family treated above, together with the pair of independent solutions. Three of the rows have to be read with Remark 9.97 in mind: the Bessel, Legendre and associated Legendre equations each admit two Sturm–Liouville readings. In the first the order or the degree sits in q — the source's identification, reproduced in the table — and in the second a scaling parameter or the degree carries the spectral parameter instead. It is the second reading to which the orthogonality relations of Theorems 9.98, 9.111 and 9.119 belong, since orthogonality of eigenfunctions needs distinct eigenvalues to separate them. The Legendre row is where the swap is bluntest, and it is the reason the table alone cannot be read as an eigenvalue problem: it carries $q = n(n+1)$ and $\lambda^2 = 0$, so Equation (9.55) has no spectral parameter left, whereas the proof of Theorem 9.111 reads the same equation with $q = 0$ and $\lambda^2 = n(n+1)$, distinct for distinct degrees.

Two rows of Table 9.2 are of a different character and are included because later parts of the book need them by name. The modified Bessel row (Definition 9.105) is the ordinary Bessel row with the sign of q reversed, which is exactly the difference between oscillation and monotone growth, and its solutions therefore carry no zeros and no eigenvalue condition (Proposition 9.106). The Mathieu row Equation (9.43) is the only entry whose coefficient q is periodic rather than polynomial or exponential: its eigenvalue problem is not a boundary-value problem on an interval but the stability question of Corollary 9.41, and its named solutions ce_n and se_n are the periodic solutions that exist only on the boundaries of the instability regions (Proposition 9.43). Finally, the elliptic integrals and Jacobi functions of Section 9.12 appear in no row at all, and deliberately: they do not solve a linear Sturm–Liouville equation but invert a quadrature, and Equation (9.193) — the equation sn does satisfy — is nonlinear.

Table 9.2: Sturm–Liouville data of the classical equations, in the convention of Definition 9.54: the operator is $\frac{\mathrm{d}}{\mathrm{d}x}\big[p\,y'\big] + \big[q + \lambda^2 r\big]y$.

Equation	$p(x)$	$q(x)$	λ^2	$r(x)$	Solutions
Helmholtz (1D)	1	0	λ^2	1	$\mathrm{e}^{\pm \mathrm{i}\lambda x}$

Chapter 10

Partial Differential Equations

A *partial differential equation* (PDE) relates a function of several variables to its partial derivatives. The fundamental equations of physics are of this kind: the wave equation, the heat equation, the Laplace and Poisson equations, and the Schrödinger equation are all linear second-order PDEs, and their boundary- and initial-value problems occupy the rest of this treatise.

Three facts organise the whole subject and are established below. The first is that a second-order equation carries an invariant — the inertia of its principal coefficient matrix — which sorts the equations of physics into three families with entirely different behaviour, and which no change of coordinates can alter. The second is that each family admits its own kind of side condition and no other: asking an elliptic equation for initial data, or a parabolic one for a solution running backwards in time, is not merely difficult but ill posed in Hadamard's precise sense. The third is that a linear problem is solved once the response to a point source is known, which is what a Green's function is.

The general theory followed here — classification, characteristics, well-posedness and the canonical equations — is that of Courant–Hilbert [1222]; the operator-by-operator catalogue of separable coordinates and Green's functions is Morse–Feshbach [1023].

Throughout, Ω denotes a nonempty open subset of $\mathbb{R}^N$, repeated indices are summed from 1 to N, and $\partial_i = \partial/\partial x^i$. The Laplacian is written $\nabla^2 = \partial_i \partial_i$ in Cartesian coordinates, and the wave operator of speed c is

$$\Box = \frac{1}{c^2}\,\partial_t^2 - \nabla^2 \,. \tag{10.1}$$

10.1 Definitions

Definition 10.1 (Partial differential equation; order)**.** Let $u : \Omega \longrightarrow \mathbb{R}$ be the unknown. For a multi-index $\alpha = (\alpha_1, \dots, \alpha_N) \in \mathbb{N}^N$ write $|\alpha| = \alpha_1 + \cdots + \alpha_N$ and

$$\partial^\alpha = \partial_1^{\alpha_1} \cdots \partial_N^{\alpha_N} \,, \qquad \xi^\alpha = \xi_1^{\alpha_1} \cdots \xi_N^{\alpha_N} \,. \tag{10.2}$$

A *partial differential equation of order* m on Ω is a relation

$$F\big(x,\; u(x),\; \{\partial^\alpha u(x)\}_{1 \le |\alpha| \le m}\big) = 0 \,, \qquad x \in \Omega \,, \tag{10.3}$$

in which F depends nontrivially on at least one derivative of order exactly m. A *classical solution* is a function $u \in C^m(\Omega)$ satisfying Equation (10.3) at every point of Ω.

Rests on Definitions 6.2 and 7.66.

Definition 10.2 (Linear, semilinear, quasilinear)**.** The equation Equation (10.3) is

1. *linear* if it reads $\sum_{|\alpha| \le m} a_\alpha(x)\, \partial^\alpha u = f(x)$, and *homogeneous* if in addition $f \equiv 0$;

2. *semilinear* if the terms of order m are linear with coefficients depending on x alone, the remaining dependence being arbitrary;

3. *quasilinear* if it is linear in the derivatives of order m with coefficients that may depend on x, on u and on derivatives of order below m;

4. *fully nonlinear* otherwise.

Rests on Definition 10.1.

Linearity is what makes superposition available, and superposition is what every method of this chapter rests on: if u_1 and u_2 solve a homogeneous linear equation, so does $\lambda_1 u_1 + \lambda_2 u_2$, because a linear differential operator is a linear map on the vector space $C^m(\Omega)$ (Chapter 5). The last section of the chapter shows what breaks when it is unavailable.

Definition 10.3 (Principal part and principal symbol)**.** For a linear operator $L = \sum_{|\alpha|\le m} a_\alpha(x)\,\partial^\alpha$ the *principal part* is $\sum_{|\alpha|=m} a_\alpha \partial^\alpha$ and the *principal symbol* is the homogeneous polynomial

$$\sigma_L(x,\xi) = \sum_{|\alpha|=m} a_\alpha(x)\,\xi^\alpha\,, \qquad \xi \in \mathbb{R}^N\,. \tag{10.4}$$

Rests on Definition 10.2 and Equation (10.2).

The symbol is obtained by the substitution $\partial^\alpha \longmapsto \xi^\alpha$, which is exactly what the Fourier transform performs up to a factor i per derivative (Equation (17.38)): for constant coefficients, $\widehat{Lu}(\xi) = \sigma_L(\mathrm{i}\xi)\,\hat{u}(\xi)$ modulo the lower-order terms. Everything in this section is therefore a statement about a polynomial.

Definition 10.4 (The second-order operator)**.** The general linear second-order operator on Ω is

$$Lu = a^{ij}(x)\,\partial_i\partial_j u + b^i(x)\,\partial_i u + c(x)\,u\,, \tag{10.5}$$

with real coefficients and $a^{ij} = a^{ji}$. Its principal symbol is the quadratic form $\sigma_L(x,\xi) = a^{ij}(x)\,\xi_i\xi_j$, and $A(x)$ denotes the symmetric matrix $\big(a^{ij}(x)\big)$.

Rests on Definition 10.3 and Proposition 7.73.

Remark 10.5. The symmetry $a^{ij} = a^{ji}$ costs nothing. For $u \in C^2$ one has $\partial_i\partial_j u = \partial_j\partial_i u$ (Proposition 7.73), so only the symmetric part $\frac{1}{2}(a^{ij} + a^{ji})$ of the coefficient array acts on the solution; the antisymmetric part is invisible and is discarded. This is why the classification below is a statement about a *symmetric* matrix, and hence about its inertia.

10.1.1 Classification and characteristics

Definition 10.6 (Type of a second-order operator)**.** Let (n_+, n_-, n_0) be the inertia of $A(x)$ — the numbers of positive, negative and zero eigenvalues, so that $n_+ + n_- + n_0 = N$. At the point x the operator L of Equation (10.5) is

1. *elliptic* if $n_0 = 0$ and $n_+ n_- = 0$, that is if $A(x)$ is definite;

2. *hyperbolic* if $n_0 = 0$ and $\min(n_+, n_-) = 1$;

3. *ultrahyperbolic* if $n_0 = 0$ and $\min(n_+, n_-) \ge 2$;

4. *parabolic* if $n_0 \ge 1$, that is if $A(x)$ is singular.

L is elliptic (hyperbolic, …) *on* Ω if it is so at every point of Ω.

Rests on Definition 10.4 and Theorem 5.112.

Remark 10.7. Case (iv) as stated is only degeneracy of the principal part; the heat operator $\partial_t - D\nabla^2$ is the case that matters, in which $n_0 = 1$ exactly and the first-order part supplies a derivative in the one direction the principal part cannot see. An equation with $n_0 \geq 1$ and no such first-order term — $\partial_x^2 u = 0$ in two variables — is degenerate rather than parabolic. Ultrahyperbolic operators do not occur in this treatise: they need at least two time-like directions, and the observed world has one.

The classification would be worthless if it depended on the coordinates used to write the equation down. It does not, and the reason is Sylvester's law of inertia.

Theorem 10.8 (The type is a coordinate invariant)**.** *Let $y = y(x)$ be a C^2 change of coordinates on Ω with invertible Jacobian $J^a{}_i = \partial y^a / \partial x^i$, and let $\tilde{A}$ be the principal coefficient matrix of the transformed operator. Then*

$$\tilde{A} = J\, A\, (J)^{\mathsf{T}}, \tag{10.6}$$

and the inertia (n_+, n_-, n_0) of A is unchanged. The type of a second-order operator at a point is therefore an attribute of the equation, not of the chart in which it is written.

Rests on Definition 10.6, Theorem 5.112, and Proposition 7.31.

Proof. *Derives Theorem 10.8.*

Write $u(x) = \tilde{u}(y(x))$ and let $\tilde{\partial}_a = \partial/\partial y^a$. The chain rule (Proposition 7.31) gives $\partial_i u = J^a{}_i\, \tilde{\partial}_a \tilde{u}$ and, differentiating once more,

$$\partial_i \partial_j u = J^a{}_i J^b{}_j\, \tilde{\partial}_a \tilde{\partial}_b \tilde{u} + (\partial_i \partial_j y^a)\, \tilde{\partial}_a \tilde{u}\,. \tag{10.7}$$

The second term carries only one derivative of $\tilde{u}$, so it joins the first-order part and cannot affect the principal coefficients. Contracting the first term with a^{ij} gives $\tilde{a}^{ab} = J^a{}_i\, a^{ij}\, J^b{}_j$, which is Equation (10.6). Since J is invertible, this is a congruence of symmetric matrices, and by Sylvester's law of inertia (Theorem 5.112) congruent real symmetric matrices have the same triple (n_+, n_-, n_0); Equation (5.142) is the normal form both reach. □

Example 10.9. In $\mathbb{R}^4$ with coordinates (ct, x^1, x^2, x^3) the wave operator Equation (10.1) has $A = \operatorname{diag}(1, -1, -1, -1)$, inertia $(1, 3, 0)$: hyperbolic. The Laplacian ∇^2 on $\mathbb{R}^3$ has $A = \operatorname{diag}(1, 1, 1)$, inertia $(3, 0, 0)$: elliptic. The heat operator $\partial_t - D\nabla^2$ on $\mathbb{R} \times \mathbb{R}^3$ has $A = \operatorname{diag}(0, -D, -D, -D)$, inertia $(0, 3, 1)$: parabolic, with the single null direction the time direction, exactly as in Remark 10.7.

Rests on Definition 10.6 and Equation (10.1).

Definition 10.10 (Characteristic surface)**.** Let $\phi \in C^1(\Omega)$ with $\nabla\phi \neq 0$, and let $S = \{x \in \Omega \mid \phi(x) = 0\}$. The hypersurface S is *characteristic* for L at $x \in S$ if and only if

$$\sigma_L\big(x, \nabla\phi(x)\big) = a^{ij}(x)\, \partial_i \phi(x)\, \partial_j \phi(x) = 0\,. \tag{10.8}$$

Rests on Definitions 10.3 and 10.4.

Proposition 10.11 (What a characteristic surface is)**.** *Let S be a C^2 hypersurface and let Cauchy data — the values of u and of its normal derivative on S — be prescribed. Every second-order derivative of u on S is then determined by the data together with the equation $Lu = f$ if and only if S is non-characteristic at the point in question.*

Rests on Definition 10.10 and Theorem 10.8.

Proof. *Derives Proposition 10.11.*

Choose coordinates $y = (y^1, \ldots, y^N)$ near the point with $y^N = \phi$, so that S is the slice $\{y^N = 0\}$; this is admissible because $\nabla\phi \neq 0$. The Cauchy data are $\tilde{u}$ and $\tilde{\partial}_N \tilde{u}$ on the slice. Differentiating those two functions *along* the slice determines every derivative $\tilde{\partial}_a \tilde{\partial}_b \tilde{u}$ with

$a, b < N$ and every $\tilde{\partial}_a \tilde{\partial}_N \tilde{u}$ with $a < N$. The only second derivative not so obtained is $\tilde{\partial}_N^2 \tilde{u}$, and the equation reads

$$\tilde{a}^{NN}\, \tilde{\partial}_N^2 \tilde{u} = f - (\text{determined terms})\,, \tag{10.9}$$

because every other principal term carries at least one index below N. By Equation (10.6), $\tilde{a}^{NN} = a^{ij} \partial_i \phi\, \partial_j \phi = \sigma_L(x, \nabla\phi)$. Hence Equation (10.9) determines $\tilde{\partial}_N^2 \tilde{u}$ if and only if that symbol is nonzero, which by Equation (10.8) is exactly non-characteristic. □

Corollary 10.12 (Characteristics of the three canonical operators)**.** *An elliptic operator has no real characteristic surface. The characteristics of* $\Box$ *are the surfaces with* $|\nabla\phi|^2 = c^{-2}(\partial_t \phi)^2$*, that is the light cones* $|\boldsymbol{x} - \boldsymbol{x}_0| = c\,|t - t_0|$*. The characteristics of* $\partial_t - D\nabla^2$ *are the slices* $t =$ *constant.*

Rests on Proposition 10.11 and Equation (10.1).

Proof. *Derives Corollary 10.12.*

Ellipticity means A definite, so $a^{ij}\xi_i\xi_j = 0$ forces $\xi = 0$, which $\nabla\phi \neq 0$ excludes. For $\Box$ the symbol is $c^{-2}(\partial_t\phi)^2 - |\nabla\phi|^2$, and the stated cones are the level sets of $\phi = c(t - t_0) - |\boldsymbol{x} - \boldsymbol{x}_0|$, which annihilate it. For the heat operator the principal symbol is $-D\,|\boldsymbol{\xi}|^2$, with no dependence on the time component of the conormal; it vanishes precisely when $\nabla_{\boldsymbol{x}}\phi = 0$, i.e. when ϕ is a function of t alone. □

That the slices of constant time are characteristic for the heat operator is not a technicality: it is the reason a parabolic problem takes one initial condition and not two, and it will reappear as the one-sided character of diffusion in Section 10.5.2.

Proposition 10.13 (Canonical form in two variables)**.** *Let* $Lu = a\,u_{xx} + 2b\,u_{xy} + c\,u_{yy} + \cdots$ *have* C^1 *coefficients near a point where* $(a, b, c) \neq (0, 0, 0)$*, and set* $\Delta = b^2 - ac$*. There are new coordinates* (ξ, η) *in which the principal part becomes*

$$u_{\xi\eta} \quad (\Delta > 0)\,, \qquad u_{\eta\eta} \quad (\Delta = 0)\,, \qquad u_{\xi\xi} + u_{\eta\eta} \quad (\Delta < 0)\,, \tag{10.10}$$

up to a nonvanishing factor. The three cases are respectively hyperbolic, parabolic and elliptic in the sense of Definition 10.6.

Rests on Theorem 10.8 and Definition 10.10.

Proof. *Derives Proposition 10.13.*

Here the principal coefficient matrix is

$$A = \begin{pmatrix} a & b \\ b & c \end{pmatrix}, \qquad \det A = ac - b^2 = -\Delta\,, \tag{10.11}$$

so the sign of Δ is the sign pattern of the eigenvalues of A, which is Definition 10.6 for $N = 2$: two eigenvalues of opposite sign when $\Delta > 0$, one zero eigenvalue when $\Delta = 0$, and two of the same sign when $\Delta < 0$. Under $\xi = \xi(x, y)$, $\eta = \eta(x, y)$ with Jacobian $J_0 = \xi_x\eta_y - \xi_y\eta_x \neq 0$, Equation (10.6) gives

$$\tilde{a} = a\xi_x^2 + 2b\xi_x\xi_y + c\xi_y^2\,, \qquad \tilde{c} = a\eta_x^2 + 2b\eta_x\eta_y + c\eta_y^2\,, \tag{10.12}$$

with $\tilde{b}$ the associated polarisation, and taking determinants of Equation (10.6) yields $\tilde{b}^2 - \tilde{a}\tilde{c} = J_0^2\,\Delta$.

Now $\tilde{a}$ vanishes exactly when $\xi =$ constant is a characteristic, by Equation (10.8). Suppose first that $a \neq 0$. On such a curve $\xi_y \neq 0$, since $\xi_y = 0$ would reduce Equation (10.12) to $a\xi_x^2 = 0$ and force $\nabla\xi = 0$, which Definition 10.10 excludes; dividing Equation (10.12)

by ξ_y^2 and writing $m = \mathrm{d}y/\mathrm{d}x = -\xi_x/\xi_y$ for the slope of such a curve, the condition is the quadratic

$$a\,m^2 - 2b\,m + c = 0\,, \qquad m = \frac{b \pm \sqrt{\Delta}}{a} \quad (a \neq 0)\,. \tag{10.13}$$

If $a = 0$ the closed form is empty and the families must be read off Equation (10.12) directly, which then factorises as $\tilde{a} = \xi_y(2b\,\xi_x + c\,\xi_y)$: the vertical family $x =$ constant, of infinite slope and so invisible to m, is always characteristic, and if $b \neq 0$ a second family of slope $m = c/(2b)$ accompanies it — two families, as $\Delta = b^2 > 0$ demands. If $a = b = 0$ then $\Delta = 0$, only the vertical family survives, and the principal part is already $c\,u_{yy}$ with $c \neq 0$, which is the parabolic normal form. The archetype of the first of these degenerate cases is $Lu = 2u_{xy}$, whose two characteristic families are the coordinate lines themselves and which is already in hyperbolic canonical form. With the vertical family admitted, the count of real families in each of the three cases is the one the sign of Δ dictates, and the constructions below apply verbatim.

If $\Delta > 0$ there are two real families; take ξ and η to be first integrals of the two, so $\tilde{a} = \tilde{c} = 0$ and $\tilde{b}^2 = J_0^2\Delta > 0$, leaving $2\tilde{b}\,u_{\xi\eta}$ as the principal part. If $\Delta = 0$ the two families coincide; take ξ to be a first integral of it and η any independent function, so $\tilde{a} = 0$ and then $\tilde{b}^2 = \tilde{a}\tilde{c} = 0$, leaving $\tilde{c}\,u_{\eta\eta}$ with $\tilde{c} \neq 0$: otherwise the whole transformed principal matrix would vanish, and by Equation (10.6) with J invertible so would A, contradicting $(a, b, c) \neq (0, 0, 0)$. If $\Delta < 0$ then $ac > b^2 \geq 0$, so $a \neq 0$ and the roots of Equation (10.13) are a complex-conjugate pair. Assume for this branch that the coefficients are real analytic. Complexifying y and integrating $\mathrm{d}y/\mathrm{d}x = (b + \mathrm{i}\sqrt{-\Delta})/a$ then supplies a complex first integral ζ with $a\zeta_x^2 + 2b\zeta_x\zeta_y + c\zeta_y^2 = 0$ and with $\Re\zeta$, $\Im\zeta$ functionally independent; setting $\xi = \Re\zeta$, $\eta = \Im\zeta$ turns that one complex condition into the real pair $\tilde{a} = \tilde{c}$, $\tilde{b} = 0$, which is $\tilde{a}\,(u_{\xi\xi} + u_{\eta\eta})$. Remark 10.14 records how the same branch is settled at C^1. □

Remark 10.14 (Regularity in the elliptic branch). The hyperbolic and parabolic branches of the proof are complete at C^1: their characteristic equations are real, and Theorem 9.8 integrates them under exactly that hypothesis. The elliptic branch is not. A complex first integral is not delivered by any real ordinary differential equation theorem, because the object sought is a function ζ of two real variables solving a Beltrami equation with non-vanishing Jacobian; complexifying the independent variable and integrating the characteristic equation constructs it when the coefficients are real analytic, and that is the hypothesis under which the classical argument of Courant and Hilbert is stated [1222]. For merely C^1 — hence locally Hölder — coefficients the existence of ζ is a separate and much harder statement, the Korn–Lichtenstein theorem on the local solvability of the Beltrami equation. The conclusion of Proposition 10.13 does hold at C^1, and the appendix supplies it: the reduction of the canonical form to a Beltrami equation, and the construction of its solution, are carried out there from a single quoted singular-integral estimate. Two things should be carried away from that section. The map (ξ, η) it produces is $C^{1,\alpha}$ and not C^2, so at merely Hölder coefficients the canonical form is a statement about the *principal part* alone — which is all Equation (10.6) ever needed, since that congruence involves the Jacobian and no second derivative; and one more derivative on the coefficients buys a $C^{2,\alpha}$ map and the classical reading of Equation (10.10), first-order remainder included.

Full derivation: Appendix A.13 (p. 2817).
Derives Proposition 10.13.

Proposition 10.15 (Method of characteristics, first order)**.** *Let u be a C^1 solution of the quasilinear equation*

$$a(x, y, u)\,\partial_x u + b(x, y, u)\,\partial_y u = c(x, y, u)\,. \tag{10.14}$$

Then along every solution of the characteristic system $\dot{x} = a$, $\dot{y} = b$, $\dot{u} = c$ the graph of u is swept out; the equation is thus reduced to a system of ordinary differential equations.

Rests on Definition 10.2 and Proposition 7.31.

Proof. *Derives Proposition 10.15.*

Let $s \longmapsto (x(s), y(s))$ solve $\dot{x} = a(x, y, u(x, y))$, $\dot{y} = b(x, y, u(x, y))$ and put $U(s) = u(x(s), y(s))$. The chain rule (Proposition 7.31) gives $\dot{U} = \partial_x u\,\dot{x} + \partial_y u\,\dot{y} = a\,\partial_x u + b\,\partial_y u = c$, which is the third equation. The converse is the statement that the surface swept by the characteristic curves through a non-characteristic initial curve is a solution surface, since its tangent plane contains the vector (a, b, c) at every point. □

The equation of a mechanical principal function is not of the quasilinear form Equation (10.14): the Hamiltonian is quadratic in the derivatives. What covers that case is Cauchy's method, in which the derivatives are carried along the curve as unknowns of their own, so that a curve in $\mathbb{R}^n$ is replaced by a *strip* — a point, the value there, and the tangent plane there.

Proposition 10.16 (Cauchy's characteristic strips)**.** *Let $F(\boldsymbol{x}, u, \boldsymbol{p})$ be of class C^2 on an open subset of $\mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n$ and let u be a C^2 solution of the fully nonlinear first-order equation*

$$F(\boldsymbol{x}, u(\boldsymbol{x}), \nabla u(\boldsymbol{x})) = 0\,. \tag{10.15}$$

Fix $\boldsymbol{x}_0$ and let $s \longmapsto (\boldsymbol{x}(s), U(s), \boldsymbol{p}(s))$ solve the characteristic strip system

$$\dot{x}^i = \partial_{p_i} F\,, \qquad \dot{U} = p_j\,\partial_{p_j} F\,, \qquad \dot{p}_i = -\partial_{x^i} F - p_i\,\partial_u F\,, \tag{10.16}$$

with data $\boldsymbol{x}(0) = \boldsymbol{x}_0$, $U(0) = u(\boldsymbol{x}_0)$ and $\boldsymbol{p}(0) = \nabla u(\boldsymbol{x}_0)$. Then $U(s) = u(\boldsymbol{x}(s))$ and $\boldsymbol{p}(s) = \nabla u(\boldsymbol{x}(s))$ for as long as the solution exists, and F keeps the value zero along the strip. The system Equation (10.16) is closed*: its right-hand sides involve only $(\boldsymbol{x}, U, \boldsymbol{p})$, so it can be integrated without knowing u beforehand, and that is what makes it a method of solution rather than an identity satisfied by a solution already found.*

Rests on Propositions 7.73 and 10.15 and Theorem 9.8.

Proof. *Derives Proposition 10.16.*

Let $s \longmapsto \boldsymbol{x}(s)$ solve $\dot{x}^i = \partial_{p_i} F(\boldsymbol{x}, u(\boldsymbol{x}), \nabla u(\boldsymbol{x}))$ with $\boldsymbol{x}(0) = \boldsymbol{x}_0$; the right-hand side is C^1 in $\boldsymbol{x}$, so Theorem 9.8 supplies a unique solution on some interval about $s = 0$. Put $U(s) = u(\boldsymbol{x}(s))$ and $p_i(s) = \partial_i u(\boldsymbol{x}(s))$. The chain rule (Proposition 7.72) gives $\dot{U} = \partial_j u\,\dot{x}^j = p_j\,\partial_{p_j} F$, which is the second equation, and $\dot{p}_i = \partial_j \partial_i u\,\dot{x}^j = \partial_i \partial_j u\,\partial_{p_j} F$, the order of the two derivatives being immaterial by Proposition 7.73. Differentiating Equation (10.15) with respect to x^i,

$$\partial_{x^i} F + \partial_u F\,\partial_i u + \partial_{p_j} F\,\partial_i \partial_j u = 0\,, \tag{10.17}$$

so that $\partial_i \partial_j u\,\partial_{p_j} F = -\partial_{x^i} F - p_i\,\partial_u F$, which is the third equation. The triple $(\boldsymbol{x}, U, \boldsymbol{p})$ therefore solves the closed system Equation (10.16) with the stated data; that system has a C^1 right-hand side because F is C^2, so Theorem 9.8 applied to it says the triple is the only solution with those data, which is the claim. Finally, along any solution of Equation (10.16),

$$\frac{\mathrm{d}}{\mathrm{d}s} F = \partial_{x^i} F\,\dot{x}^i + \partial_u F\,\dot{U} + \partial_{p_i} F\,\dot{p}_i = \partial_{x^i} F\,\partial_{p_i} F + \partial_u F\,p_j\,\partial_{p_j} F - \partial_{p_i} F\,(\partial_{x^i} F + p_i\,\partial_u F) = 0\,, \tag{10.18}$$

so F retains its initial value, which is zero. □

Remark 10.17 (Two special cases). For $F = a^i(\boldsymbol{x}, u)\,p_i - c(\boldsymbol{x}, u)$ the first two equations of Equation (10.16) read $\dot{x}^i = a^i$ and $\dot{U} = c$, and the third is not needed: that is Proposition 10.15 again, in n variables. For $F = p_0 + H(\boldsymbol{x}, \boldsymbol{p})$ — the shape the Hamilton–Jacobi

equation of Chapter 23 takes when the time is written as one further coordinate x^0, so that $p_0 = \partial S/\partial t$ — one has $\partial_u F = 0$ and $\partial_{p_0} F = 1$, so s may be identified with t and the remaining equations of Equation (10.16) are $\dot{x}^i = \partial H/\partial p_i$ and $\dot{p}_i = -\partial H/\partial x^i$: Hamilton's equations themselves. The characteristics of the Hamilton–Jacobi equation are the trajectories of the mechanical system, and this is the calculation that establishes it.

A complete integral is a family of solutions large enough to generate the rest by a purely algebraic operation. The operation is the formation of an envelope, and the one thing that has to be proved about it is that it does not leave the equation.

Definition 10.18 (Complete integral; envelope)**.** Let $u = \varphi(\boldsymbol{x}; \boldsymbol{a})$ be a family of C^2 solutions of Equation (10.15), one for each $\boldsymbol{a}$ in an open set $A \subseteq \mathbb{R}^n$, with φ of class C^2 in both arguments jointly. The family is a *complete integral* when the $n \times (n+1)$ matrix whose rows are $\left(\partial\varphi/\partial a_k,\ \partial^2\varphi/\partial a_k \partial x^1, \dots, \partial^2\varphi/\partial a_k \partial x^n\right)$ has rank n everywhere, so that distinct parameters give genuinely distinct solutions. Given a C^1 map $\boldsymbol{x} \longmapsto \boldsymbol{a}(\boldsymbol{x})$ into A with

$$\frac{\partial \varphi}{\partial a_k}\big(\boldsymbol{x}; \boldsymbol{a}(\boldsymbol{x})\big) = 0\,, \qquad k = 1, \dots, n\,, \tag{10.19}$$

the function $v(\boldsymbol{x}) = \varphi(\boldsymbol{x}; \boldsymbol{a}(\boldsymbol{x}))$ is an *envelope* of the family: at each point it touches one member of the family and has the same tangent plane there.

Rests on Equation (10.15) *and Proposition 7.72.*

Proposition 10.19 (An envelope of solutions is a solution)**.** *Every envelope in the sense of Definition 10.18 solves Equation* (10.15)*.*

Rests on Definition 10.18 and Proposition 7.72.

Proof. *Derives Proposition 10.19.*

By the chain rule (Proposition 7.72),

$$\partial_i v(\boldsymbol{x}) = \frac{\partial \varphi}{\partial x^i} + \frac{\partial \varphi}{\partial a_k}\,\frac{\partial a_k}{\partial x^i} = \frac{\partial \varphi}{\partial x^i}\big(\boldsymbol{x}; \boldsymbol{a}(\boldsymbol{x})\big)\,, \tag{10.20}$$

the second group of terms vanishing by Equation (10.19). Hence the triple $(\boldsymbol{x}, v(\boldsymbol{x}), \nabla v(\boldsymbol{x}))$ is exactly the triple $(\boldsymbol{x}, \varphi, \nabla_{\boldsymbol{x}}\varphi)$ formed from the single member $\varphi(\cdot\,; \boldsymbol{a}(\boldsymbol{x}))$ of the family, and F vanishes on it because that member is a solution. □

Remark 10.20 (What the envelope construction is for)*.* Proposition 10.19 is what makes a complete integral worth having. Restricting the parameters by $n-1$ arbitrary relations and enveloping over what is left produces, from the n-parameter family, a solution containing an arbitrary function — the *general integral* of the equation; enveloping over all n parameters at once produces the *singular* solution, which belongs to no member of the family and is where the family's members touch one another. In Chapter 23 this is the sense in which a caustic is the envelope of a family of solutions, and Equation (10.19) is the condition that chapter writes as the vanishing of a Jacobian. The construction and its use for first-order equations are Cauchy's; the classical account, with the strip system Equation (10.16) and the envelope theorem side by side, is [1222], chapter II.

Remark 10.21*.* Proposition 10.16 is the mechanism behind the Hamilton–Jacobi equation of Chapter 23: there the first-order PDE for the principal function is integrated along the characteristic strips, and those strips are, by Remark 10.17, the trajectories of the mechanical system carried together with their momenta. Its quasilinear predecessor Proposition 10.15 does not cover that equation, and the distinction matters: a Hamiltonian is quadratic in $\partial S/\partial q^a$, so the derivatives do not enter linearly. The quasilinear construction reappears below as the mechanism of shock formation (Section 10.6.3), where the characteristics cross.

Theorem 10.22 (Cauchy–Kovalevskaya)**.** *If the coefficients and the data of a normal Cauchy problem are real analytic near a point, and the initial surface is non-characteristic there, then the problem has a solution analytic in a neighbourhood of that point, and it is unique among analytic solutions.*

Rests on Proposition 10.11 and Definition 10.2.

Full derivation: Appendix A.14 (p. 2825).

Derives Theorem 10.22.

Remark 10.23. The theorem is due to Kovalevskaya [190], and its hypotheses cannot be relaxed casually. Analyticity is essential: Lewy exhibited a linear equation of first order with polynomial coefficients and a smooth right-hand side possessing no solution whatever, in any neighbourhood of any point [1122]. Nor does the theorem say anything useful about physics even when it applies, because analytic data cannot be prescribed independently in disjoint regions: the Cauchy problem it solves for the Laplace equation is the ill-posed one of Section 10.1.2. Existence and well-posedness are different questions, and only the second is physical.

10.1.2 Well-posedness in the sense of Hadamard

Definition 10.24 (Well-posed problem)**.** A problem consisting of a differential equation together with side conditions, with data d in a normed space $\mathcal{D}$ and solutions u in a normed space $\mathcal{U}$, is *well posed in the sense of Hadamard* if and only if

1. a solution exists for every admissible d;
2. it is unique;
3. it depends continuously on the data: $d_n \to d$ in $\mathcal{D}$ implies $u_n \to u$ in $\mathcal{U}$.

A problem failing any one of the three is *ill posed*.

Rests on Definitions 6.24 and 10.1.

Hadamard introduced the three conditions together, and insisted on the third [305]; the systematic development is in his Yale lectures [502]. The third condition is the one that carries the physics. Data are measured, hence known only to within an experimental uncertainty, and a problem that fails (iii) converts an arbitrarily small uncertainty into an arbitrarily large one: its solution is not a prediction. The following is the standard example, and it is the heat equation run backwards.

Proposition 10.25 (The backward heat problem is ill posed)**.** *Consider $\partial_t u = D\,\partial_x^2 u$ on $(0,\pi)\times(0,T)$ with $u(0,t) = u(\pi,t) = 0$, and let the datum be the final profile $u(\cdot,T) = g$, the unknown being the initial profile $u(\cdot,0)$. With the supremum norm on both, this problem violates condition (iii) of Definition 10.24.*

Rests on Definitions 10.6 and 10.24.

Proof. *Derives Proposition 10.25.*

For $n \in \mathbb{N}$ put

$$u_n(x,t) = \frac{1}{n}\,\mathrm{e}^{Dn^2(T-t)}\,\sin(nx)\,. \tag{10.21}$$

Then $\partial_t u_n = -Dn^2 u_n$ and $D\partial_x^2 u_n = -Dn^2 u_n$, so each u_n solves the equation and vanishes at $x = 0, \pi$. Its datum is $g_n = u_n(\cdot,T) = n^{-1}\sin(nx)$, with $\|g_n\|_\infty = 1/n \longrightarrow 0$, so g_n tends to the zero datum, whose solution is $u \equiv 0$. But $\|u_n(\cdot,0)\|_\infty = n^{-1}\mathrm{e}^{Dn^2T} \longrightarrow \infty$. Data differing by ε therefore admit initial profiles differing by any prescribed amount, and no continuity estimate can hold. □

Remark 10.26 (Hadamard's example). The same phenomenon forbids Cauchy data for an elliptic equation. Take $\partial_x^2 u + \partial_y^2 u = 0$ on the half-plane $y > 0$ with $u(x,0) = 0$ and $\partial_y u(x,0) = n^{-1}\sin(nx)$. The solution is $u = n^{-2}\sin(nx)\sinh(ny)$, and while the Cauchy data tend uniformly to zero, $\sup_x |u(x,y)| = n^{-2}\sinh(ny)$ diverges for every fixed $y > 0$. An elliptic equation accepts data on a closed boundary — Dirichlet or Neumann — and nothing else; a hyperbolic equation accepts Cauchy data on a non-characteristic surface; a parabolic equation accepts one initial condition and boundary conditions, forward in time only. The match between type and side condition is not a convention but a theorem about which problems are well posed.

Remark 10.27 (Where ill-posedness is unavoidable). Ill-posed problems cannot simply be avoided, because some of them are the questions one wants to ask: reconstructing a source from its field, deconvolving an instrumental response from a measured spectrum, or inferring a past state from a present one. The Fourier analysis of the same difficulty is Remark 17.55: the forward map annihilates high frequencies, so its inverse amplifies them without bound, and the practical answer is regularisation — solving a nearby well-posed problem and quantifying the difference.

10.1.3 The equations of physics

The equations this chapter serves are five, and between them they cover almost every field equation of the treatise.

The *wave equation*

$$\Box u = \frac{1}{c^2}\,\partial_t^2 u - \nabla^2 u = 0\,, \tag{10.22}$$

with c a speed in m/s, is hyperbolic (Example 10.9). It was written down by d'Alembert for the vibrating string [25] and returns for sound (Chapter 28), for light (Chapter 61) and for gravitational radiation (Chapter 46).

The *heat* or *diffusion equation*

$$\partial_t u - D\,\nabla^2 u = 0\,, \tag{10.23}$$

with diffusivity D in $\mathrm{m^2/s}$, is parabolic. It is Fourier's [72], and it governs conduction, molecular diffusion (Chapter 119) and the transport coefficients of Chapter 124.

The *Laplace* and *Poisson equations*

$$\nabla^2 u = 0\,, \qquad \nabla^2 u = -\varrho\,, \tag{10.24}$$

are elliptic. The homogeneous form is the potential equation of Laplace's celestial mechanics [45]; Poisson added the source term valid inside the distribution [57]. They govern electrostatics (Chapter 58) and Newtonian gravity.

The *Helmholtz equation*

$$\nabla^2 \psi + k^2 \psi = 0\,, \tag{10.25}$$

with k a wavenumber in 1/m, is elliptic and is the common time-reduced form of the first two: separating the time dependence out of Equation (10.22) or Equation (10.23) leaves Equation (10.25) for the spatial factor, as Section 10.2 shows. Its separable coordinate systems are catalogued by Morse and Feshbach [1023].

The *Schrödinger equation*

$$\mathrm{i}\hbar\,\partial_t \psi = -\frac{\hbar^2}{2m}\,\nabla^2 \psi + V(\boldsymbol{x})\,\psi\,, \tag{10.26}$$

with $\hbar$ in J s and m in kg, is the equation of Chapter 77 [557]. Its principal coefficients are imaginary, so the real trichotomy of Definition 10.6 does not apply to it directly: it has the shape of a diffusion equation with imaginary diffusivity $\mathrm{i}\hbar/2m$, and behaves like neither, propagating wave packets that spread without damping. Its relativistic counterparts in Chapter 92 are genuinely hyperbolic.

10.2 From partial to ordinary differential equations

The link between this chapter and the preceding one is the method of *separation of variables*: writing the unknown as a product of single-variable factors decomposes a linear PDE, in coordinates adapted to the boundary, into ordinary differential equations of Sturm–Liouville type. It is by this route that the classical families of Chapter 9 enter physics: the one-dimensional Helmholtz equation and its Fourier system arise on intervals (Section 9.7), the Bessel functions in cylindrical problems (Section 9.8), and the Legendre functions and spherical harmonics in spherical ones (Section 9.9) [1976].

The whole method rests on one elementary observation.

Lemma 10.28 (The separation constant)**.** *Let I_1, I_2 be intervals and let $F : I_1 \to \mathbb{R}$, $G : I_2 \to \mathbb{R}$ satisfy $F(s) = G(t)$ for every $(s,t) \in I_1 \times I_2$. Then F and G are one and the same constant.*

Rests on Definition 10.2.

Proof. *Derives Lemma 10.28.*

Fix $t_0 \in I_2$. Then $F(s) = G(t_0)$ for every $s \in I_1$, so F is the constant $G(t_0)$; symmetrically G is the constant $F(s_0)$, and the two constants agree. □

Proposition 10.29 (Time separation reduces the canonical equations to Helmholtz)**.** *Let $u(\boldsymbol{x}, t) = T(t)\,\psi(\boldsymbol{x})$ with T, ψ not identically zero. Then u solves Equation (10.23) if and only if there is a constant λ with*

$$\nabla^2\psi + \lambda\,\psi = 0\,, \qquad \frac{\mathrm{d}T}{\mathrm{d}t} = -D\lambda\,T\,, \tag{10.27}$$

and it solves Equation (10.22) if and only if

$$\nabla^2\psi + \lambda\,\psi = 0\,, \qquad \frac{\mathrm{d}^2T}{\mathrm{d}t^2} = -c^2\lambda\,T\,. \tag{10.28}$$

In both cases the spatial factor obeys the Helmholtz equation Equation (10.25) with $k^2 = \lambda$.

Rests on Lemma 10.28 and Equation (10.25).

Proof. *Derives Proposition 10.29.*

Substituting $u = T\psi$ into Equation (10.23) and dividing by $DT\psi$ where it is nonzero gives

$$\frac{1}{D}\,\frac{T'(t)}{T(t)} = \frac{\nabla^2\psi(\boldsymbol{x})}{\psi(\boldsymbol{x})}\,. \tag{10.29}$$

The left side depends on t alone and the right on $\boldsymbol{x}$ alone, so by Lemma 10.28 both equal a constant, written $-\lambda$; that is Equation (10.27). The wave case is identical with T'/D replaced by T''/c^2. Conversely a pair satisfying Equation (10.27) reassembles into a solution by direct substitution, and likewise for Equation (10.28). □

Remark 10.30 (What the ansatz is, and what it can miss). The product form is not an assumption about the solution sought. It is a device for manufacturing a supply of exact solutions, each of which is then a legitimate solution of the linear homogeneous equation; the solution of the actual problem is assembled from them by superposition, and the assembly is what has to be justified. Two things can go wrong. The separated solutions may fail to span the data — the question of completeness, settled for a regular Sturm–Liouville problem in Chapter 9 and in the abstract in Section 12.2; and the boundary may fail to be a coordinate surface of any system in which the operator separates, in which case the method does not start at all. Superposition also requires linearity, so nothing in this section survives into Section 10.6.3.

10.2.1 Separable coordinate systems

The three systems this treatise uses are worked out here; the general classification follows.

Example 10.31 (Cartesian separation)**.** Put $\psi = X(x)Y(y)Z(z)$ in Equation (10.25) and divide by ψ:

$$\frac{X''}{X} + \frac{Y''}{Y} + \frac{Z''}{Z} + k^2 = 0\,. \tag{10.30}$$

Each quotient depends on one variable alone, so each is a constant by Lemma 10.28: $X'' = -\alpha^2 X$, $Y'' = -\beta^2 Y$, $Z'' = -\gamma^2 Z$ with $\alpha^2 + \beta^2 + \gamma^2 = k^2$. Each factor obeys the one-dimensional Helmholtz equation Equation (9.106), whose eigenfunctions on an interval are the Fourier system (Section 9.7.4).

Rests on Lemma 10.28 and Equation (9.106).

Example 10.32 (Cylindrical separation)**.** In circular cylindrical coordinates (ρ, φ, z),

$$\nabla^2 = \frac{1}{\rho}\,\partial_\rho(\rho\,\partial_\rho) + \frac{1}{\rho^2}\,\partial_\varphi^2 + \partial_z^2\,. \tag{10.31}$$

With $\psi = R(\rho)\Phi(\varphi)Z(z)$, single-valuedness forces $\Phi'' = -m^2\Phi$ with $m \in \mathbb{Z}$, and $Z'' = -\gamma^2 Z$; the radial factor then obeys

$$\frac{1}{\rho}\frac{\mathrm{d}}{\mathrm{d}\rho}\left(\rho\,\frac{\mathrm{d}R}{\mathrm{d}\rho}\right) + \left(k^2 - \gamma^2 - \frac{m^2}{\rho^2}\right) R = 0\,, \tag{10.32}$$

which is Bessel's equation Equation (9.125) of order m in the variable $\sqrt{k^2-\gamma^2}\,\rho$.

Rests on Lemma 10.28 and Equation (9.125).

Example 10.33 (Spherical separation)**.** In spherical coordinates (r, θ, φ),

$$\nabla^2 = \frac{1}{r^2}\,\partial_r(r^2\,\partial_r) + \frac{1}{r^2}\left[\frac{1}{\sin\theta}\,\partial_\theta(\sin\theta\,\partial_\theta) + \frac{1}{\sin^2\theta}\,\partial_\varphi^2\right]. \tag{10.33}$$

With $\psi = R(r)\,Y(\theta,\varphi)$ the bracket acting on Y must be a constant multiple of Y; regularity on the whole sphere fixes that constant to be $-l(l+1)$ with $l \in \mathbb{N}$, and Y is a spherical harmonic Equation (9.163), its polar factor obeying the associated Legendre equation Equation (9.157) in $\cos\theta$. The radial factor obeys

$$\frac{1}{r^2}\frac{\mathrm{d}}{\mathrm{d}r}\left(r^2\frac{\mathrm{d}R}{\mathrm{d}r}\right) + \left(k^2 - \frac{l(l+1)}{r^2}\right) R = 0\,, \tag{10.34}$$

the spherical Bessel equation, which the substitution $R = r^{-1/2}\,W$ turns into Equation (9.125) of order $l + \frac{1}{2}$. For $k = 0$ this is the Laplace equation and Equation (10.34) is solved by r^l and r^{-l-1}: the multipole expansion of Chapter 58, and, with the Coulomb potential restored, the radial problem of Chapter 81.

Rests on Lemma 10.28 and Equations (9.157) and (9.163).

Theorem 10.34 (Separable systems for the Helmholtz operator)**.** *In three dimensions the Helmholtz equation Equation (10.25) separates in exactly eleven orthogonal coordinate systems: Cartesian, circular cylindrical, elliptic cylindrical, parabolic cylindrical, spherical, prolate spheroidal, oblate spheroidal, parabolic, conical, ellipsoidal and paraboloidal. Separation holds if and only if the metric coefficients of the system satisfy the Stäckel conditions, which state that the reciprocals of the scale factors are expressible through a matrix whose rows depend each on one coordinate alone.*

Rests on Equation (10.25) and Lemma 10.28.

Full derivation: Appendix A.15 (p. 2831).
Derives Theorem 10.34.

The Stäckel conditions are derived there — both their necessity and their sufficiency — by substituting the product ansatz into the Laplacian of an orthogonal system and demanding that the three separation constants enter the separated equations linearly; the ellipsoidal system, of which the three examples above are degenerate limits, is verified against them outright, and the eleven systems are obtained as the degenerations of one confocal quadric family. Only the completeness of that list — that no orthogonal system outside the confocal scheme separates — is quoted, from the catalogue of Morse and Feshbach [1023], whose tables give the separated equations system by system.

Remark 10.35. The Laplace equation, being the case $k = 0$, separates in strictly more systems than the Helmholtz equation — bispherical and toroidal coordinates among them — because it also admits *R-separation*, in which the product ansatz is preceded by division by a fixed function of position. A Stäckel matrix of the same shape governs the separability of the Hamilton–Jacobi equation of Chapter 23, which is not a coincidence: both ask when a single operator falls apart along the coordinate directions. The two statements are nevertheless different, the Hamilton–Jacobi equation being of first order and nonlinear, and it is Theorem 23.17 that carries that case; Remark 23.19 sets the two side by side and explains why the eleven systems above coincide with the separable systems of a free particle. In practice the coordinate system is chosen by the boundary, not by the operator: one separates in the system whose surfaces the boundary is made of, and the worked boundary-value problems appear in Chapter 58 and Chapter 81.

10.2.2 Eigenfunction expansions

Separation supplies a family of solutions indexed by the separation constants; the data are matched by superposing them, which is possible exactly when the separated eigenfunctions are complete.

Theorem 10.36 (Solution of the heat problem on an interval)**.** *Let f be continuous on $[0, L]$ with $f(0) = f(L) = 0$ and let*

$$c_n = \frac{2}{L}\int_0^L f(x)\,\sin\!\left(\frac{n\pi x}{L}\right)\mathrm{d}x\,. \tag{10.35}$$

Then

$$u(x,t) = \sum_{n=1}^{\infty} c_n\,\mathrm{e}^{-Dn^2\pi^2 t/L^2}\,\sin\!\left(\frac{n\pi x}{L}\right) \tag{10.36}$$

converges for $t > 0$ together with all its derivatives, solves Equation (10.23) on $(0, L)\times(0,\infty)$ with $u(0,t) = u(L,t) = 0$, and satisfies $u(\cdot,t) \to f$ in the mean square as $t \to 0^+$.
Rests on Proposition 10.29 and Remark 9.53.

Proof. *Derives Theorem 10.36.*

Each summand is a separated solution: by Proposition 10.29 with $\lambda = n^2\pi^2/L^2$ the spatial factor $\sin(n\pi x/L)$ solves the one-dimensional Helmholtz equation with the stated boundary values and the temporal factor solves $T' = -D\lambda T$. Bessel's inequality Equation (9.53) bounds the coefficients, $|c_n| \le C$ uniformly in n; for $t \ge t_0 > 0$ the factor $\mathrm{e}^{-Dn^2\pi^2 t/L^2}$ then dominates any fixed power of n, so the series and every series obtained from it by differentiating term by term in x or t converge absolutely and uniformly on $[0, L]\times[t_0,\infty)$. Term-by-term differentiation is therefore legitimate there and each term satisfies the equation, so u does. Since $t_0 > 0$ was arbitrary, this holds for every $t > 0$. Finally the partial sums of Equation (10.36) at $t = 0$ are the partial sums of the sine series of f, which converge to f in the mean square by completeness of the Sturm–Liouville eigenfunctions (Remark 9.53);

the exponential factors are bounded by 1 and tend to 1 for each fixed n, whence the stated limit. □

Remark 10.37 (Smoothing). The proof shows more than it was asked for. The initial datum was merely continuous, yet for every $t > 0$ the solution is infinitely differentiable, because the factor $\mathrm{e}^{-Dn^2\pi^2 t/L^2}$ kills the high harmonics faster than differentiation can excite them. Diffusion destroys the information carried by the fine structure of the datum, and that destruction is exactly the obstruction met in Proposition 10.25.

Example 10.38 (The vibrating string)**.** The same separation applied to Equation (10.22) on $[0, L]$ with fixed ends gives, by Equation (10.28),

$$u(x,t) = \sum_{n=1}^{\infty} \left[a_n \cos\!\left(\frac{n\pi c t}{L}\right) + b_n \sin\!\left(\frac{n\pi c t}{L}\right) \right] \sin\!\left(\frac{n\pi x}{L}\right), \tag{10.37}$$

with a_n and $n\pi c\, b_n/L$ the sine coefficients of the initial displacement and velocity. Here the exponentials of Theorem 10.36 are replaced by oscillations of the same magnitude for all n, so nothing is damped and no smoothing occurs: the wave equation remembers. That the general motion is a superposition of such modes is Daniel Bernoulli's claim [28], contested at the time and vindicated only by Fourier's theory of the coefficients [72]; the physical reading, in which the n-th term is a normal mode, is developed in Chapter 28.

Rests on Proposition 10.29 and Equation (10.28).

10.2.3 Integral-transform methods

On an unbounded domain the eigenfunctions are not discrete and the sum of Section 10.2.2 becomes an integral. The machinery is that of Chapter 17, and the principle is one line: a transform that converts differentiation into multiplication converts a PDE in $N+1$ variables into a problem in one.

Proposition 10.39 (Fourier reduction on the line)**.** *Let $P(\partial_x)$ be a constant-coefficient operator in x and consider $\partial_t u = P(\partial_x)u$ for $x \in \mathbb{R}$, $t > 0$, with $u(\cdot, 0) = f$ absolutely integrable. Then the transform $\hat{u}(\xi, t)$ of u in x satisfies the ordinary differential equation*

$$\partial_t \hat{u}(\xi,t) = P(\mathrm{i}\xi)\,\hat{u}(\xi,t), \qquad \hat{u}(\xi,0) = \hat{f}(\xi), \tag{10.38}$$

one equation for each ξ, whose solution is $\hat{u} = \hat{f}\,\mathrm{e}^{P(\mathrm{i}\xi)t}$.

Rests on Equation (17.38) *and Definition 17.29.*

Proof. *Derives Proposition 10.39.*

Each x-derivative contributes a factor $\mathrm{i}\xi$ under the transform (Equation (17.38)), so $\widehat{P(\partial_x)u} = P(\mathrm{i}\xi)\hat{u}$; the t-derivative passes through the x-integral. What remains is a linear first-order ordinary differential equation in t with ξ as a parameter, and Equation (10.38) is its statement. The inversion Equation (17.34) returns u. □

Remark 10.40 (Laplace on the half-line). When the variable runs over a half-line — as time does, a system being switched on at $t = 0$ — the Laplace transform of Definition 17.65 is the right tool, because its derivative rule Equation (17.87) does not merely multiply by s but absorbs the initial values into the transformed equation as polynomial terms. The initial conditions are thus imposed automatically rather than fitted afterwards, and the solution is recovered from the Bromwich integral Theorem 17.69 by residues. The choice of transform is therefore dictated by the domain and the side conditions, not by taste: Fourier for a whole line with decay at both ends, Laplace for a half-line with data at its origin, a series for a bounded interval.

Remark 10.41 (Dispersion relations). Substituting the plane wave $u = \mathrm{e}^{\mathrm{i}(\boldsymbol{k}\cdot\boldsymbol{x}-\omega t)}$ into a constant-coefficient linear equation reduces it to an algebraic relation between ω and $\boldsymbol{k}$ — the dispersion relation, which is the symbol Equation (10.4) evaluated on the wave. For Equation (10.22) it is $\omega = \pm c\,|\boldsymbol{k}|$: all wavelengths travel at the same speed and a signal keeps its shape. For Equation (10.23) it is $\omega = -\mathrm{i}D\,|\boldsymbol{k}|^2$, purely imaginary, so nothing propagates and everything decays, the finer structure faster. For Equation (10.26) with $V = 0$ it is $\hbar\omega = \hbar^2\,|\boldsymbol{k}|^2\,/2m$, real but nonlinear in $|\boldsymbol{k}|$: propagation with spreading. The three types of Definition 10.6 are visible in these three answers, and the physical consequences are drawn in Chapter 28 and Chapter 71.

10.3 Green's functions

For an inhomogeneous linear problem, the *Green's function* — the response of the differential operator to a point source — converts the equation into an integral representation of the solution. Green introduced both the function and the reciprocity it obeys, for the potential equation, in a privately printed essay [83].

Definition 10.42 (Green's function)**.** Let L be a linear differential operator on Ω together with homogeneous boundary conditions. A *Green's function* for the pair is a function $G(\boldsymbol{x}, \boldsymbol{x}')$ satisfying, in the sense of distributions in $\boldsymbol{x}$ for each fixed $\boldsymbol{x}' \in \Omega$,

$$L\,G(\boldsymbol{x}, \boldsymbol{x}') = \delta(\boldsymbol{x} - \boldsymbol{x}')\,, \tag{10.39}$$

and the boundary conditions in the variable $\boldsymbol{x}$.

Rests on Definitions 10.4 and 17.40.

Proposition 10.43 (Representation of the solution)**.** *If G is a Green's function for L with the given homogeneous boundary conditions and f is such that the integral converges, then*

$$u(\boldsymbol{x}) = \int_\Omega G(\boldsymbol{x}, \boldsymbol{x}')\, f(\boldsymbol{x}')\, \mathrm{d}^3x' \tag{10.40}$$

solves $Lu = f$ with those boundary conditions.

Rests on Definitions 10.2 and 10.42.

Proof. *Derives Proposition 10.43.*

L acts on $\boldsymbol{x}$ and the integration is over $\boldsymbol{x}'$, so L may be taken under the integral sign: $Lu(\boldsymbol{x}) = \int_\Omega [LG(\boldsymbol{x}, \boldsymbol{x}')] f(\boldsymbol{x}')\mathrm{d}^3x' = \int_\Omega \delta(\boldsymbol{x} - \boldsymbol{x}') f(\boldsymbol{x}')\mathrm{d}^3x' = f(\boldsymbol{x})$ by Equation (10.39) and the defining property of the Dirac distribution (Definition 17.38). Each $G(\cdot, \boldsymbol{x}')$ satisfies the homogeneous boundary conditions, and so therefore does the superposition. □

The content of the method is thus entirely in the construction of G, to which the next two subsections are devoted. Note what has been gained: one function of two points, computed once, solves the problem for every source.

10.3.1 The Green's function of a boundary-value problem

Lemma 10.44 (Green's identities)**.** *Let $V \subset \mathbb{R}^3$ be a bounded region with piecewise-smooth boundary and let $u, v \in C^2(\overline{V})$, $p \in C^1$. Then*

$$\int_V \left[v\,\nabla\cdot(p\nabla u) - u\,\nabla\cdot(p\nabla v)\right] \mathrm{d}^3x = \oint_{\partial V} p\,(v\,\partial_\nu u - u\,\partial_\nu v)\,\mathrm{d}S\,, \tag{10.41}$$

where ∂_ν is the outward normal derivative.

Rests on Theorem 7.101 and Definition 7.66.

Proof. *Derives Lemma 10.44.*

Apply the divergence theorem Equation (7.123) to the vector field $\boldsymbol{A} = p\,(v\nabla u - u\nabla v)$. Its divergence is $v\,\nabla\cdot(p\nabla u) - u\,\nabla\cdot(p\nabla v)$, the two terms $p\nabla v\cdot\nabla u$ produced by the product rule cancelling; and $\boldsymbol{A}\cdot\mathrm{d}\boldsymbol{S} = p(v\partial_\nu u - u\partial_\nu v)\mathrm{d}S$. □

Theorem 10.45 (Symmetry of the Green's function)**.** *Let $Lu = \nabla\cdot(p\nabla u) + q\,u$ with p, q real, and let the boundary conditions be homogeneous of the form $\alpha u + \beta\,\partial_\nu u = 0$ on ∂V with real α, β not both zero. Then the Green's function is symmetric,*

$$G(\boldsymbol{x}_1, \boldsymbol{x}_2) = G(\boldsymbol{x}_2, \boldsymbol{x}_1)\,. \tag{10.42}$$

Rests on Lemma 10.44 and Definition 10.42.

Proof. *Derives Theorem 10.45.*

Put $u(\boldsymbol{x}) = G(\boldsymbol{x}, \boldsymbol{x}_1)$ and $v(\boldsymbol{x}) = G(\boldsymbol{x}, \boldsymbol{x}_2)$ in Equation (10.41). The terms in q are symmetric in u and v and cancel, so the left-hand side is

$$\int_V \left[v\,\delta(\boldsymbol{x} - \boldsymbol{x}_1) - u\,\delta(\boldsymbol{x} - \boldsymbol{x}_2)\right]\mathrm{d}^3x = G(\boldsymbol{x}_1, \boldsymbol{x}_2) - G(\boldsymbol{x}_2, \boldsymbol{x}_1)\,. \tag{10.43}$$

On the boundary both u and v satisfy $\alpha w + \beta\partial_\nu w = 0$. If $\beta \neq 0$ then $\partial_\nu w = -(\alpha/\beta)w$ for both, and $v\partial_\nu u - u\partial_\nu v = -(\alpha/\beta)(vu - uv) = 0$; if $\beta = 0$ then $u = v = 0$ there and the same combination vanishes. So the right-hand side of Equation (10.41) is zero, and Equation (10.43) gives Equation (10.42). □

Remark 10.46. The hypothesis is exactly that L is formally self-adjoint and that the boundary conditions make it symmetric on its domain — the Sturm–Liouville form Equation (9.54) of Chapter 9, in one dimension. The symmetry of G is therefore not an accident of the potential problem but the kernel-level shadow of self-adjointness, and it is the statement Green called reciprocity: the field at $\boldsymbol{x}_1$ due to a unit source at $\boldsymbol{x}_2$ equals the field at $\boldsymbol{x}_2$ due to a unit source at $\boldsymbol{x}_1$. The operator-theoretic setting, in which a self-adjoint operator is diagonalised by the spectral theorem, is Chapter 12.

Proposition 10.47 (Bilinear expansion)**.** *Let $\{\psi_n\}$ be a complete orthonormal system of eigenfunctions of L on V satisfying the boundary conditions, with $L\psi_n = \lambda_n\psi_n$ and $\lambda_n \neq \mu$ for all n. Then the Green's function of $L - \mu$ is*

$$G_\mu(\boldsymbol{x}, \boldsymbol{x}') = \sum_n \frac{\psi_n(\boldsymbol{x})\,\overline{\psi_n(\boldsymbol{x}')}}{\lambda_n - \mu}\,. \tag{10.44}$$

Rests on Definition 10.42 and Remark 9.53.

Proof. *Derives Proposition 10.47.*

Apply $L - \mu$ term by term in $\boldsymbol{x}$: the n-th term becomes $\psi_n(\boldsymbol{x})\overline{\psi_n(\boldsymbol{x}')}$, and completeness of the system is the closure relation $\sum_n \psi_n(\boldsymbol{x})\overline{\psi_n(\boldsymbol{x}')} = \delta(\boldsymbol{x} - \boldsymbol{x}')$ (Remark 9.53), which is Equation (10.39) for $L - \mu$. Each term satisfies the boundary conditions, hence so does the sum. □

Remark 10.48. Equation (10.44) displays the Green's function as a meromorphic function of the parameter μ whose poles are exactly the eigenvalues and whose residues are the eigenprojections. This is the resolvent operator of Chapter 12 written as a kernel, and it is why the analytic structure of a response function encodes a spectrum — the observation that drives the contour techniques of Chapter 8 and, in Chapter 65, the identification of resonances with poles.

Example 10.49 (The method of images)**.** For $L = \nabla^2$ on the half-space $z > 0$ with $G = 0$ on the plane $z = 0$, write $\boldsymbol{x}'^{*}$ for the mirror image of $\boldsymbol{x}'$ in that plane. Then

$$G(\boldsymbol{x}, \boldsymbol{x}') = -\frac{1}{4\pi}\left(\frac{1}{|\boldsymbol{x} - \boldsymbol{x}'|} - \frac{1}{|\boldsymbol{x} - \boldsymbol{x}'^{*}|}\right). \tag{10.45}$$

The second term is harmonic throughout $z > 0$, since its singularity lies outside; so Equation (10.39) holds by Proposition 10.67, proved below, which identifies $-1/4\pi r$ as the fundamental solution of the Laplacian. On $z = 0$ the two distances are equal and G vanishes. The construction succeeds whenever the boundary is a plane or a sphere, and fails otherwise; the electrostatic reading is in Chapter 58 [1976], and the catalogue of Green's functions for the standard operators and domains is Morse–Feshbach [1023].

Rests on Proposition 10.67 and Definition 10.42.

10.3.2 Causal Green's functions and Duhamel's principle

Definition 10.50 (Retarded and advanced Green's functions)**.** The *retarded* and *advanced* Green's functions of the wave operator Equation (10.1) in three space dimensions are

$$G_{\pm}(\boldsymbol{x}, t) = \frac{\delta\left(t \mp |\boldsymbol{x}|/c\right)}{4\pi\,|\boldsymbol{x}|}, \tag{10.46}$$

each satisfying $\Box G_{\pm} = \delta(\boldsymbol{x})\,\delta(t)$, with G_+ supported on the future light cone of the source and G_- on its past cone.

Rests on Definition 10.42 and Equation (10.1).

Both solve the same equation, so the equation does not choose between them; the choice is a physical postulate, that an effect follows its cause. Selecting G_+ turns Equation (10.40) into the retarded potentials of Chapter 60 and the radiation fields of Chapter 65: the field at $(\boldsymbol{x}, t)$ is the source evaluated at the earlier time $t - |\boldsymbol{x} - \boldsymbol{x}'|/c$, integrated over space.

Remark 10.51 (The causal choice as a contour prescription). Transforming Equation (10.39) for $\Box$ in space and time gives $(|\boldsymbol{k}|^2 - \omega^2/c^2)\hat{G} = 1$, whose right-hand side is finite while the left vanishes on the light cone $\omega = \pm c\,|\boldsymbol{k}|$: the inverse transform is an integral through two poles on the real ω axis and is undefined until they are avoided. Which way to close the contour is fixed by the synthesis kernel of Equation (17.34), which in the convention of Definition 17.29 is $\mathrm{e}^{+\mathrm{i}\omega t}$: on a large semicircle at $\Im\omega = \tau$ its modulus is $\mathrm{e}^{-\tau t}$, so the contour must be closed in the upper half-plane for $t > 0$ and in the lower for $t < 0$. Displacing the poles by $\omega \to \omega - \mathrm{i}\varepsilon$ in the denominator moves them to $\omega = \pm c\,|\boldsymbol{k}| + \mathrm{i}\varepsilon$, both in the upper half-plane, so closing downward encloses nothing and gives zero for $t < 0$ (Corollary 8.15) while closing upward gives the retarded function for $t > 0$; the opposite displacement gives the advanced one. Causality is thus one of the two possible pole prescriptions, and the Sokhotski–Plemelj formula Equation (17.54) is the statement that the difference between them is a delta function on the light cone. The residue calculus that evaluates either is Theorem 8.24.

The sign of ε is convention-dependent and is quoted the other way round in much of the physics literature, which synthesises with $\mathrm{e}^{-\mathrm{i}\omega t}$ — the kernel of the plane-wave ansatz $\mathrm{e}^{\mathrm{i}(\boldsymbol{k}\cdot\boldsymbol{x} - \omega t)}$ of Remark 10.41 — rather than with the $\mathrm{e}^{+\mathrm{i}\omega t}$ fixed for this treatise in Definition 17.29. Under that reading the half-planes are exchanged and the retarded prescription is $\omega \to \omega + \mathrm{i}\varepsilon$. What is convention-independent, and is the content of the remark, is that the retarded function is the one whose poles lie on the side of the real axis that the closure for $t > 0$ encircles.

Theorem 10.52 (Duhamel's principle)**.** *Let $\mathcal{A}$ be a linear operator acting on the space variables only. Suppose that for each $s \geq 0$ the function $v(\cdot, t; s)$ solves the homogeneous*

problem $\partial_t v = \mathcal{A} v$ *for* $t > s$ *with* $v(\cdot, s; s) = f(\cdot, s)$. *Then*

$$u(\boldsymbol{x}, t) = \int_0^t v(\boldsymbol{x}, t; s)\, \mathrm{d}s \tag{10.47}$$

solves the driven problem $\partial_t u = \mathcal{A} u + f$ *with* $u(\cdot, 0) = 0$.

Rests on Definition 10.2 and Theorem 7.42.

Proof. *Derives Theorem 10.52.*

Differentiating Equation (10.47) in t, the upper limit contributes the integrand evaluated at $s = t$ and the integrand contributes its own t-derivative (Theorem 7.42):

$$\partial_t u(\boldsymbol{x}, t) = v(\boldsymbol{x}, t; t) + \int_0^t \partial_t v(\boldsymbol{x}, t; s)\, \mathrm{d}s = f(\boldsymbol{x}, t) + \int_0^t \mathcal{A} v(\boldsymbol{x}, t; s)\, \mathrm{d}s\,, \tag{10.48}$$

using the initial condition of v in the first term and its equation in the second. Since $\mathcal{A}$ does not act on s, the remaining integral is $\mathcal{A} u$. That $u(\cdot, 0) = 0$ is immediate from Equation (10.47). □

Corollary 10.53 (Duhamel for the wave equation)**.** *If* $w(\cdot, t; s)$ *solves* $\partial_t^2 w = c^2 \nabla^2 w$ *for* $t > s$ *with* $w(\cdot, s; s) = 0$ *and* $\partial_t w(\cdot, s; s) = f(\cdot, s)$, *then* $u = \int_0^t w(\boldsymbol{x}, t; s) \mathrm{d}s$ *solves* $\partial_t^2 u - c^2 \nabla^2 u = f$ *with vanishing initial data.*

Rests on Theorem 10.52 and Equation (10.22).

Proof. *Derives Corollary 10.53.*

The first derivative is $\partial_t u = w(\boldsymbol{x}, t; t) + \int_0^t \partial_t w\, \mathrm{d}s = \int_0^t \partial_t w\, \mathrm{d}s$, since w vanishes on the diagonal. Differentiating once more, $\partial_t^2 u = \partial_t w(\boldsymbol{x}, t; t) + \int_0^t \partial_t^2 w\, \mathrm{d}s = f + c^2 \nabla^2 u$, by the second initial condition and the equation for w. □

Remark 10.54. Duhamel's principle is superposition in the time variable: a distributed source is a continuum of impulses, and the response is the integral of the impulse responses. It is the same statement as Proposition 10.43 with the causal Green's function inserted, and in the language of Chapter 17 it is the convolution Equation (17.66) of the source with the impulse response of a time-invariant linear system.

10.4 The canonical equations and their fundamental solutions

10.4.1 The wave equation

Theorem 10.55 (d'Alembert's formula)**.** *Let* $f \in C^2(\mathbb{R})$ *and* $g \in C^1(\mathbb{R})$. *The unique* C^2 *solution of* $\partial_t^2 u = c^2 \partial_x^2 u$ *on* $\mathbb{R} \times \mathbb{R}$ *with* $u(x, 0) = f(x)$ *and* $\partial_t u(x, 0) = g(x)$ *is*

$$u(x, t) = \frac{f(x - ct) + f(x + ct)}{2} + \frac{1}{2c} \int_{x - ct}^{x + ct} g(y)\, \mathrm{d}y\,. \tag{10.49}$$

Rests on Proposition 10.13 and Theorem 7.43.

Proof. *Derives Theorem 10.55.*

Introduce the characteristic coordinates $\xi = x - ct$, $\eta = x + ct$ of Proposition 10.13. Then $\partial_x = \partial_\xi + \partial_\eta$ and $\partial_t = c\,(\partial_\eta - \partial_\xi)$, so

$$\partial_t^2 - c^2 \partial_x^2 = c^2\,(\partial_\eta - \partial_\xi)^2 - c^2\,(\partial_\xi + \partial_\eta)^2 = -4c^2\, \partial_\xi \partial_\eta\,. \tag{10.50}$$

The equation is therefore $\partial_\xi \partial_\eta u = 0$. Integrating in η shows $\partial_\xi u$ is a function of ξ alone, and integrating in ξ (Theorem 7.43) gives $u = F(\xi) + G(\eta)$ with $F, G \in C^2$; conversely every such u solves the equation, so this is the general solution.

Imposing the data at $t = 0$, where $\xi = \eta = x$, gives $F(x) + G(x) = f(x)$ and $c\,(G'(x) - F'(x)) = g(x)$. Integrating the second from a fixed x_0, $G(x) - F(x) = c^{-1}\int_{x_0}^{x} g + A$ for a constant A. Solving the pair,

$$F(x) = \frac{f(x)}{2} - \frac{1}{2c}\int_{x_0}^{x} g - \frac{A}{2}\,, \qquad G(x) = \frac{f(x)}{2} + \frac{1}{2c}\int_{x_0}^{x} g + \frac{A}{2}\,, \tag{10.51}$$

and $u = F(x - ct) + G(x + ct)$ is Equation (10.49), the constant A cancelling and the two partial integrals combining into one over $[x - ct, x + ct]$. Uniqueness follows because every solution has the form $F(\xi) + G(\eta)$ and the data determine F and G up to the constant that cancels. □

Corollary 10.56 (Domain of dependence and influence)**.** *The value $u(x_0, t_0)$ with $t_0 > 0$ depends on the data only through their restriction to the interval $[x_0 - ct_0,\ x_0 + ct_0]$. Conversely the data near a point x_1 influence the solution only inside the forward cone $|x - x_1| \le c\,t$. In particular no signal travels faster than c.*

Rests on Theorem 10.55.

Proof. *Derives Corollary 10.56.*

Read Equation (10.49): f enters only at the two endpoints of the interval and g only through its integral over the interval. The converse statement is the contrapositive, since x_1 lies in the interval of dependence of (x, t) if and only if $|x - x_1| \le ct$. □

The same conclusion holds in three space dimensions, and is proved there without any formula, by an energy estimate that will also give uniqueness.

Proposition 10.57 (Energy in a backward cone)**.** *Let $u \in C^2$ solve $\partial_t^2 u = c^2 \nabla^2 u$ on $\mathbb{R}^3 \times (0, \infty)$, fix $(\boldsymbol{x}_0, t_0)$ and set*

$$e(t) = \frac{1}{2}\int_{B(\boldsymbol{x}_0,\, c(t_0 - t))} \Big[(\partial_t u)^2 + c^2\,|\nabla u|^2\Big]\,\mathrm{d}^3x\,, \qquad 0 \le t < t_0\,. \tag{10.52}$$

Then e is non-increasing. Consequently, if u and $\partial_t u$ vanish at $t = 0$ on the ball $B(\boldsymbol{x}_0, ct_0)$, then u vanishes throughout the backward cone, and solutions of the Cauchy problem are unique.

Rests on Theorem 7.101 and Equation (10.22).

Proof. *Derives Proposition 10.57.*

Write $R(t) = c(t_0 - t)$ and differentiate Equation (10.52). The integrand's own t-derivative gives, on using the equation and the divergence theorem Equation (7.123) on $\nabla \cdot (\partial_t u\,\nabla u)$,

$$\int_B \Big[\partial_t u\,\partial_t^2 u + c^2 \nabla u \cdot \nabla \partial_t u\Big]\,\mathrm{d}^3x = c^2 \oint_{\partial B} \partial_t u\,\partial_\nu u\,\mathrm{d}S\,, \tag{10.53}$$

because the remaining volume term is $\int \partial_t u\,(\partial_t^2 u - c^2\nabla^2 u) = 0$. The shrinking of the ball, $\dot R = -c$, contributes $-\frac{c}{2}\oint_{\partial B}\Big[(\partial_t u)^2 + c^2\,|\nabla u|^2\Big]\,\mathrm{d}S$. Now for real numbers $a = \partial_t u$ and $b = |\nabla u|$ one has $c^2 ab \le \frac{c}{2}\,(a^2 + c^2 b^2)$, since the difference is $\frac{c}{2}(a - cb)^2 \ge 0$; and $|\partial_\nu u| \le |\nabla u|$. The surface term of Equation (10.53) is therefore dominated by the negative one, so $\dot e(t) \le 0$.

If the data vanish on $B(\boldsymbol{x}_0, ct_0)$ then $e(0) = 0$, and since $e \ge 0$ and e is non-increasing, $e \equiv 0$: both $\partial_t u$ and ∇u vanish in the cone, so u is constant there, and the constant is zero. Uniqueness follows by applying this to the difference of two solutions, whose data vanish everywhere. □

Lemma 10.58 (Darboux's equation for spherical means)**.** *For $h \in C^2(\mathbb{R}^3)$ define the spherical mean*

$$M_h(\boldsymbol{x}, r) = \frac{1}{4\pi} \int_{S^2} h(\boldsymbol{x} + r\boldsymbol{n}) \, \mathrm{d}\Omega \,, \tag{10.54}$$

the integral running over the unit sphere with total solid angle 4π. Then $M_h(\boldsymbol{x}, r) \to h(\boldsymbol{x})$ as $r \to 0$ and

$$\partial_r M_h = \frac{1}{4\pi r^2} \int_{B_r(\boldsymbol{x})} \nabla^2 h \, \mathrm{d}^3 y \,, \qquad \left(\partial_r^2 + \frac{2}{r}\partial_r\right) M_h = M_{\nabla^2 h} = \nabla_{\boldsymbol{x}}^2 M_h \,. \tag{10.55}$$

Rests on Theorem 7.101 and Definition 7.66.

Proof. *Derives Lemma 10.58.*

Differentiating Equation (10.54) under the integral sign, $\partial_r M_h = \frac{1}{4\pi} \int_{S^2} \boldsymbol{n} \cdot \nabla h(\boldsymbol{x} + r\boldsymbol{n}) \mathrm{d}\Omega$, which on rewriting the solid angle as a surface element, $\mathrm{d}S = r^2 \mathrm{d}\Omega$, is $\frac{1}{4\pi r^2} \oint_{\partial B_r} \partial_\nu h \, \mathrm{d}S$; the divergence theorem Equation (7.123) turns this into the first half of Equation (10.55). Multiplying by r^2 and differentiating again,

$$\partial_r \left(r^2 \partial_r M_h\right) = \frac{1}{4\pi} \partial_r \int_{B_r} \nabla^2 h \, \mathrm{d}^3 y = \frac{1}{4\pi} \oint_{\partial B_r} \nabla^2 h \, \mathrm{d}S = r^2 \, M_{\nabla^2 h} \,, \tag{10.56}$$

which is the second half after dividing by r^2. The last equality in Equation (10.55) holds because $\nabla_{\boldsymbol{x}}^2$ commutes with the average over $\boldsymbol{n}$. The limit $r \to 0$ is the continuity of h. □

Theorem 10.59 (Kirchhoff's formula)**.** *Let $f \in C^3(\mathbb{R}^3)$ and $g \in C^2(\mathbb{R}^3)$. The solution of $\partial_t^2 u = c^2 \nabla^2 u$ with $u(\cdot, 0) = f$ and $\partial_t u(\cdot, 0) = g$ is*

$$u(\boldsymbol{x}, t) = \partial_t \left[t \, M_f(\boldsymbol{x}, ct)\right] + t \, M_g(\boldsymbol{x}, ct) \,, \tag{10.57}$$

with M the spherical mean Equation (10.54).

Rests on Lemma 10.58 and Theorem 10.55.

Proof. *Derives Theorem 10.59.*

Fix $\boldsymbol{x}$ and write $M(r, t) = M_{u(\cdot,t)}(\boldsymbol{x}, r)$. Averaging the equation over the sphere of radius r and using Equation (10.55),

$$\partial_t^2 M = c^2 M_{\nabla^2 u} = c^2 \left(\partial_r^2 + \frac{2}{r}\partial_r\right) M \,. \tag{10.58}$$

Set $W(r, t) = r \, M(r, t)$. Then $\partial_r^2 W = r \left(\partial_r^2 M + \frac{2}{r}\partial_r M\right)$, so Equation (10.58) becomes the one-dimensional wave equation $\partial_t^2 W = c^2 \partial_r^2 W$ on $r > 0$, with $W(0, t) = 0$ and data $W(r, 0) = r \, M_f(\boldsymbol{x}, r)$, $\partial_t W(r, 0) = r \, M_g(\boldsymbol{x}, r)$. Extending both data as odd functions of r — which is consistent with the boundary condition at the origin — d'Alembert's formula Equation (10.49) applies. Writing $\tilde{F}(s) = s \, M_f(\boldsymbol{x}, s)$ and $\tilde{G}(s) = s \, M_g(\boldsymbol{x}, s)$ for the odd extensions,

$$W(r, t) = \frac{\tilde{F}(r + ct) - \tilde{F}(ct - r)}{2} + \frac{1}{2c} \int_{ct-r}^{ct+r} \tilde{G}(s) \, \mathrm{d}s \,, \tag{10.59}$$

for $0 < r < ct$, the oddness having been used to replace $\tilde{F}(r - ct)$ by $-\tilde{F}(ct - r)$. Now $u(\boldsymbol{x}, t) = \lim_{r \to 0^+} M(r, t) = \lim_{r \to 0^+} W(r, t)/r$. The first term of Equation (10.59) divided by r tends to $\tilde{F}'(ct)$ by the definition of the derivative, and the second to $\tilde{G}(ct)/c$ by continuity of $\tilde{G}$. Hence $u = \tilde{F}'(ct) + t \, M_g(\boldsymbol{x}, ct)$, and since $\partial_t \left[t \, M_f(\boldsymbol{x}, ct)\right] = M_f(ct) + ct \, \partial_s M_f(s)\big|_{s=ct} = \tilde{F}'(ct)$, this is Equation (10.57). □

Corollary 10.60 (Huygens' principle in three space dimensions)**.** *The value of u at $(\boldsymbol{x}, t)$ depends on the initial data only through their values on the sphere $|\boldsymbol{y} - \boldsymbol{x}| = ct$, and not at all on their values inside it. A signal emitted at one instant from one point is therefore received at one instant, with no trailing wake.*

Rests on Theorem 10.59 and Corollary 10.12.

Proof. *Derives Corollary 10.60.*

Every term of Equation (10.57) is an average over the sphere of radius ct, or a t-derivative of such an average, and no integration over the interior occurs. □

Remark 10.61. Huygens stated the sharp propagation of light as a construction of wave fronts [15]; Kirchhoff turned it into the formula Equation (10.57) [224], and Hadamard identified the property as special — it holds for the wave operator in three space dimensions and fails in general [502]. It is what makes hearing and vision possible: sound arrives when it arrives, and the acoustic and optical consequences are drawn in Chapter 28 and Chapter 61. The support of the solution on the characteristic cone of Corollary 10.12 is the same statement in the language of the classification.

10.4.2 The heat equation

Theorem 10.62 (The heat kernel)**.** *Let f be bounded and continuous on $\mathbb{R}$. Then*

$$K(x,t) = \frac{1}{\sqrt{4\pi D t}}\,\exp\!\left(-\frac{x^2}{4Dt}\right), \qquad t>0\,, \tag{10.60}$$

satisfies $\int_{\mathbb{R}} K(x,t)\mathrm{d}x = 1$ for every $t>0$, and $u = K(\cdot,t) * f$ solves Equation (10.23) on $\mathbb{R}\times(0,\infty)$ with $u(\cdot,t)\to f$ pointwise as $t\to 0^{+}$. In three dimensions the kernel is the product of three such factors, $K_3(\boldsymbol{x},t) = (4\pi Dt)^{-3/2}\exp\left(-|\boldsymbol{x}|^2/4Dt\right)$.

Rests on Proposition 10.39, Equation (17.42), and Theorem 17.53.

Proof. *Derives Theorem 10.62.*

By Proposition 10.39 with $P(\partial_x) = D\partial_x^2$, the transform of the solution is

$$\hat{u}(\xi,t) = \hat{f}(\xi)\,\mathrm{e}^{-D\xi^2 t}\,. \tag{10.61}$$

The convolution theorem Equation (17.66) says that a product of transforms is $(2\pi)^{-1/2}$ times the transform of the convolution, so $u = K * f$ with $\hat{K}(\xi) = (2\pi)^{-1/2}\mathrm{e}^{-Dt\xi^2}$. The Gaussian pair Equation (17.42) with $a = \sqrt{2Dt}$ reads $\widehat{\mathrm{e}^{-x^2/(4Dt)}}(\xi) = \sqrt{2Dt}\,\mathrm{e}^{-Dt\xi^2}$, whence $K = (2\pi)^{-1/2}(2Dt)^{-1/2}\mathrm{e}^{-x^2/(4Dt)}$, which is Equation (10.60). Its integral is $\hat{K}(0)\sqrt{2\pi} = 1$. That u solves the equation may now be checked directly: K is smooth for $t>0$ and differentiation under the integral sign is justified by the Gaussian decay, while $\partial_t K = D\partial_x^2 K$ is a computation from Equation (10.60). For the initial values, $K(\cdot,t)$ is a nonnegative kernel of unit mass concentrating on the origin, so $(K*f)(x)\to f(x)$ wherever f is continuous. In three dimensions the transformed solution is $\hat{f}\,\mathrm{e}^{-D|\boldsymbol{\xi}|^2 t}$, which factorises over the three coordinates, and so does the kernel. □

Proposition 10.63 (Infinite propagation speed)**.** *Let $f\geq 0$ be continuous, not identically zero, and supported in a bounded set. Then the solution of Equation (10.23) given by Theorem 10.62 satisfies $u(x,t)>0$ for every $x\in\mathbb{R}$ and every $t>0$.*

Rests on Theorem 10.62.

Proof. *Derives Proposition 10.63.*

$u(x,t) = \int_{\mathbb{R}} K(x-y,t)f(y)\mathrm{d}y$ with $K>0$ everywhere for $t>0$ by Equation (10.60), and $f\geq 0$ is strictly positive on some interval. The integrand is therefore nonnegative and strictly positive on a set of positive measure. □

Remark 10.64 (What the infinite speed means). The disturbance is felt everywhere immediately, in flat contradiction with Corollary 10.56 for the wave equation. The contradiction is with relativity, not with observation: at distance x and time t the response is suppressed by $\exp(-x^2/4Dt)$, which for any laboratory value of D is unmeasurably small outside the diffusion length. The heat equation is a macroscopic limit of a kinetic description with a finite mean free path (Chapter 124), and the limit is where the infinite speed comes from.

Remark 10.65 (The spreading law). The kernel Equation (10.60) is a Gaussian of variance $2Dt$, so a point release spreads as

$$\left\langle x^2 \right\rangle = \int_{\mathbb{R}} x^2 K(x,t)\,\mathrm{d}x = 2Dt\,, \tag{10.62}$$

and the diffusion length grows as $\sqrt{t}$, not as t: a random walk, not a flight. With D in m^2/s the dimensions are those of Equation (10.62) as written. This is Einstein's relation for Brownian motion, whose molecular origin and measurement are Chapter 119. Time enters Equation (10.60) only through Dt and only for $t > 0$: the equation is not invariant under $t \to -t$, and running it backwards is the ill-posed problem of Proposition 10.25.

10.4.3 The Laplace and Poisson equations

Definition 10.66 (Harmonic function)**.** A function $u \in C^2(\Omega)$ is *harmonic* on Ω if and only if $\nabla^2 u = 0$ there; it is *subharmonic* if $\nabla^2 u \geq 0$ and *superharmonic* if $\nabla^2 u \leq 0$.

Rests on Equation (10.24) and Definition 7.66.

Proposition 10.67 (The Newtonian potential is the fundamental solution)**.** *In $\mathbb{R}^3$ the function*

$$\Phi(\boldsymbol{x}) = -\frac{1}{4\pi\,|\boldsymbol{x}|} \tag{10.63}$$

is harmonic away from the origin and satisfies $\nabla^2\Phi = \delta(\boldsymbol{x})$ in the sense of distributions.

Rests on Lemma 10.44 and Definition 17.38.

Proof. *Derives Proposition 10.67.*

For $r = |\boldsymbol{x}| > 0$ the radial part of Equation (10.33) gives $\nabla^2 r^{-1} = r^{-2}\partial_r\left(r^2\partial_r r^{-1}\right) = r^{-2}\partial_r(-1) = 0$, so Φ is harmonic there. Let φ be a test function (Definition 17.38). Then

$$\int_{\mathbb{R}^3} \Phi\,\nabla^2\varphi\,\mathrm{d}^3x = \lim_{\varepsilon\to 0^+} \int_{r>\varepsilon} \Phi\,\nabla^2\varphi\,\mathrm{d}^3x\,, \tag{10.64}$$

the integral converging absolutely because Φ is integrable near the origin. On the region $r > \varepsilon$ apply Equation (10.41) with $p = 1$, $u = \varphi$, $v = \Phi$; the term $\varphi\nabla^2\Phi$ vanishes there, and only the inner boundary contributes, with outward normal $-\boldsymbol{n}$ pointing towards the origin. The two surface terms are

$$\frac{1}{4\pi\varepsilon}\oint_{r=\varepsilon} \partial_r\varphi\,\mathrm{d}S = O(\varepsilon)\,, \qquad \frac{1}{4\pi\varepsilon^2}\oint_{r=\varepsilon} \varphi\,\mathrm{d}S \longrightarrow \varphi(\boldsymbol{0})\,, \tag{10.65}$$

the first because the sphere has area $4\pi\varepsilon^2$ and $\nabla\varphi$ is bounded, the second because the factor is exactly the reciprocal of that area and φ is continuous. Hence Equation (10.64) equals $\varphi(\boldsymbol{0})$, which by Equation (17.50) says $\nabla^2\Phi = \delta$. □

Remark 10.68. Combining Proposition 10.67 with Proposition 10.43, the solution of $\nabla^2 u = -\varrho$ on all of $\mathbb{R}^3$ decaying at infinity is $u(\boldsymbol{x}) = \frac{1}{4\pi}\int \varrho(\boldsymbol{x}')\,|\boldsymbol{x}-\boldsymbol{x}'|^{-1}\,\mathrm{d}^3x'$: the superposition of $1/r$ potentials that Laplace and Poisson wrote down [45], [57], and the electrostatic potential of a charge density once ϱ is ρ/ε_0 (Chapter 58).

Theorem 10.69 (Mean-value property)**.** *Let u be harmonic on Ω and let $\overline{B(\boldsymbol{x},r)} \subset \Omega$. Then*

$$u(\boldsymbol{x}) = \frac{1}{4\pi}\int_{S^2} u(\boldsymbol{x}+r\boldsymbol{n})\,\mathrm{d}\Omega = \frac{3}{4\pi r^3}\int_{B(\boldsymbol{x},r)} u(\boldsymbol{y})\,\mathrm{d}^3y\,. \tag{10.66}$$

Conversely a function of class C^2 with the first of these properties for every admissible ball is harmonic.

Rests on Lemma 10.58 and Definition 10.66.

Proof. *Derives Theorem 10.69.*

By Equation (10.55), $\partial_r M_u(\boldsymbol{x}, r)$ is $(4\pi r^2)^{-1}$ times the integral of $\nabla^2 u$ over the ball, which vanishes. So $M_u(\boldsymbol{x}, \cdot)$ is constant on $(0, r]$, and its limit as the radius tends to zero is $u(\boldsymbol{x})$: that is the first equality. Multiplying it by $4\pi s^2$ and integrating over $s \in [0, r]$ converts the spherical average into the solid one, since $\int_0^r 4\pi s^2 \mathrm{d}s = \frac{4}{3}\pi r^3$: that is the second. For the converse, if $\nabla^2 u(\boldsymbol{x}_0) > 0$ then by continuity $\nabla^2 u > 0$ on a small ball, and Equation (10.55) makes $\partial_r M_u > 0$ there, so M_u is not constant — contradicting the mean-value property; the case $\nabla^2 u < 0$ is symmetric. Both $\nabla^2 u(\boldsymbol{x}_0)$ and the appeal to Equation (10.55) use the hypothesis $u \in C^2$, which is why the converse is stated for that class. □

Remark 10.70 (The converse for merely continuous functions). The converse in Theorem 10.69 is in fact true for a function only assumed continuous, but not by the argument above: that argument decides the sign of a Laplacian whose existence is what is to be proved. The route taken in the appendix first establishes smoothness — averaging a continuous function with the mean-value property against a radial bump reproduces the function itself, exactly and on every compact subset, so it is automatically infinitely differentiable — and only then runs the sign argument. That smoothing step needs a mollifier, which is built there from scratch, together with the one calculus lemma it consumes; nothing is quoted, and the whole construction stays inside the Riemann integral of Chapter 7, every integrand being continuous on a compact region. Everything the chapter subsequently uses, including Theorem 10.77, needs only the C^2 form; what the continuous form adds is that the mean-value property may be taken as the *definition* of harmonicity, and with it the stability of the class under locally uniform limits.

Full derivation: Appendix A.16 (p. 2841).
Derives Theorem 10.69.

Proposition 10.71 (Green's representation formula)**.** *Let V be a bounded region with piecewise-smooth boundary and let $u \in C^2(\overline{V})$. Then for $\boldsymbol{x}$ in the interior,*

$$u(\boldsymbol{x}) = \int_V \Phi(\boldsymbol{x} - \boldsymbol{y})\, \nabla^2 u(\boldsymbol{y})\, \mathrm{d}^3 y + \oint_{\partial V} \left[u\, \partial_\nu \Phi - \Phi\, \partial_\nu u\right] \mathrm{d}S_y\,, \tag{10.67}$$

with Φ the Newtonian potential Equation (10.63) and the normal derivatives taken in $\boldsymbol{y}$.
Rests on Proposition 10.67 and Lemma 10.44.

Proof. *Derives Proposition 10.71.*

Apply Equation (10.41) with $p = 1$ on the region V punctured by a ball of radius ε about $\boldsymbol{x}$, where $\Phi(\cdot - \boldsymbol{x})$ is harmonic. The inner boundary contributes, in the limit $\varepsilon \to 0$, exactly the two terms evaluated in Equation (10.65), the first vanishing and the second producing $-u(\boldsymbol{x})$ with the orientation of the punctured region; rearranging gives Equation (10.67). □

Remark 10.72 (From the representation to the Green's function). Equation (10.67) is not yet a solution of the Dirichlet problem, because it uses both u and $\partial_\nu u$ on the boundary while the problem prescribes only the first. Adding to Φ a harmonic correction that cancels it on ∂V produces the Green's function of Definition 10.42 and removes the unwanted term — Equation (10.45) is the case where the correction can be written down. That such a correction always exists is the solvability of the Dirichlet problem, argued by Riemann from the existence of a minimiser of the energy $\int |\nabla v|^2$, criticised by Weierstrass for assuming the minimum attained, and rehabilitated by Hilbert [314]. The variational side of the story is Chapter 16, and the modern form of the argument is Section 10.6.2.

10.4.4 The Helmholtz decomposition

The Newtonian potential solves Poisson's equation one scalar at a time. Applied to each Cartesian component of a vector field it yields a structural statement about vector fields

themselves, and it is the statement most often wanted in physics: that a field splits into a part carrying all of its divergence and a part carrying all of its curl. That statement is Theorem 7.105, and this chapter is where its engine lives: each Cartesian component of the vector potential Equation (7.130) is a Newtonian potential, so $\nabla^2 \boldsymbol{w} = \boldsymbol{u}$ by Proposition 10.67, and the identity $\nabla \times (\nabla \times \boldsymbol{w}) = \nabla(\nabla \cdot \boldsymbol{w}) - \nabla^2 \boldsymbol{w}$ read backwards turns that Laplacian into a gradient plus a curl. The analysis the step needs — convergence of the singular integral, differentiation under it, and the decay that forces uniqueness — is Appendix A.45.

Remark 10.73 (What compact support is doing, and the rate that replaces it). Theorem 7.105 is stated for a field that is *smooth* and of *compact* support, and both words are load-bearing: smoothness is inherited by the potentials, which the theorem asserts to be smooth as well, and compact support is what makes the singular integral converge and lets it be differentiated under the sign. Compact support is nonetheless a convenience rather than a necessity, and Remark A.527 says exactly how much of it is needed: the same argument runs for a smooth field decaying faster than $|\boldsymbol{x}|^{-2}$ whose first derivatives decay faster than $|\boldsymbol{x}|^{-3}$, that is, for some $\varepsilon > 0$,

$$|\boldsymbol{u}(\boldsymbol{x})| + |\boldsymbol{x}| \max_{i,j} |\partial_j u_i(\boldsymbol{x})| = O\big(|\boldsymbol{x}|^{-2-\varepsilon}\big)\,, \qquad |\boldsymbol{x}| \longrightarrow \infty\,. \tag{10.68}$$

What that relaxation does *not* buy is a drop in differentiability: the proof obtains the potentials from Proposition A.521, which returns C^k potentials for a C^k field, so a merely C^2 field would give a C^1 vector potential and not the smooth one the theorem states. Some condition at infinity is indispensable, and the failure is immediate rather than technical — the constant field $\hat{\boldsymbol{z}}$ is both a gradient and a curl, so the split is not unique for it. That case is worked in the same appendix remark.

Rests on Theorem 7.105 and Proposition 10.67.

Remark 10.74 (Where the decomposition is used, and what it costs). Theorem 7.105 is the reason a wave in an elastic solid splits into one longitudinal and two transverse polarizations (Chapter 30): the irrotational part and the solenoidal part obey wave equations with different speeds, so a general disturbance separates into a pressure wave and a shear wave. It is also what lies behind the Coulomb gauge of Chapter 60, where $\boldsymbol{A}$ is chosen divergence-free, and behind the split of a fluid velocity field into a potential flow and a vortical part (Chapter 31). Some hypothesis at infinity is not decoration: without one the uniqueness fails outright, since a constant field is both a gradient and a curl, and on a bounded region the statement acquires boundary terms and a third, harmonic, summand. Both the compact support of Theorem 7.105 and the rate Equation (10.68) are convenient sufficient conditions, and both are comfortably met by the fields the physical chapters decompose, which are compactly supported or exponentially localised. Sharper hypotheses exist and are not needed here.

Rests on Theorem 7.105.

10.5 Maximum principles

10.5.1 Elliptic maximum principles

Theorem 10.75 (Weak maximum principle)**.** *Let $\Omega \subset \mathbb{R}^3$ be bounded and open and let $u \in C^2(\Omega)$ be continuous on $\overline{\Omega}$ with $\nabla^2 u \geq 0$. Then*

$$\max_{\overline{\Omega}} u = \max_{\partial\Omega} u\,. \tag{10.69}$$

The same holds for the minimum of a superharmonic function, and a harmonic function attains both its extremes on the boundary.

Rests on Definition 10.66 and Theorem 6.11.

Proof. *Derives Theorem 10.75.*

Suppose first that $\nabla^2 u > 0$ strictly. If u attained an interior maximum at $\boldsymbol{x}_0$, then each second pure derivative $\partial_i^2 u(\boldsymbol{x}_0)$ would be non-positive, since $x^i \longmapsto u$ has an interior maximum along each coordinate line; summing, $\nabla^2 u(\boldsymbol{x}_0) \le 0$, a contradiction. So the maximum is attained on the boundary, which is where it must be, both sets being compact and u continuous.

In general set $u_\varepsilon = u + \varepsilon\,|\boldsymbol{x}|^2$ for $\varepsilon > 0$. Then $\nabla^2 u_\varepsilon = \nabla^2 u + 6\varepsilon > 0$, so the strict case applies: $\max_{\overline{\Omega}} u_\varepsilon = \max_{\partial\Omega} u_\varepsilon$. Since Ω is bounded there is R with $|\boldsymbol{x}| \le R$ on $\overline{\Omega}$, and therefore

$$\max_{\overline{\Omega}} u \le \max_{\overline{\Omega}} u_\varepsilon = \max_{\partial\Omega} u_\varepsilon \le \max_{\partial\Omega} u + \varepsilon R^2 \,. \tag{10.70}$$

Letting $\varepsilon \to 0$ gives $\le$ in Equation (10.69), and the reverse inequality is trivial. The minimum statement follows on replacing u by $-u$. □

Corollary 10.76 (Uniqueness and stability for the Dirichlet problem)**.** *Let Ω be bounded and let u_1, u_2 solve $\nabla^2 u_i = f$ in Ω with boundary values g_i. Then*

$$\max_{\overline{\Omega}} |u_1 - u_2| = \max_{\partial\Omega} |g_1 - g_2| \,. \tag{10.71}$$

In particular the solution is unique, and the Dirichlet problem is well posed in the sense of Definition 10.24 with respect to the supremum norm.

Rests on Theorem 10.75 and Definition 10.24.

Proof. *Derives Corollary 10.76.*

$w = u_1 - u_2$ is harmonic, so by Equation (10.69) applied to w and to $-w$ its maximum and its minimum are attained on $\partial\Omega$; hence $\max|w|$ is attained there and equals $\max_{\partial\Omega}|g_1 - g_2|$. With $g_1 = g_2$ this gives $w \equiv 0$. □

Theorem 10.77 (Strong maximum principle for harmonic functions)**.** *Let Ω be open and connected and let u be harmonic on Ω. If u attains its supremum at some point of Ω, then u is constant.*

Rests on Theorem 10.69 and Definition 6.13.

Proof. *Derives Theorem 10.77.*

Let $M = \sup_\Omega u$ and $E = \{\boldsymbol{x} \in \Omega \mid u(\boldsymbol{x}) = M\}$, nonempty by hypothesis and closed in Ω by continuity. Let $\boldsymbol{x}_0 \in E$ and let $\overline{B(\boldsymbol{x}_0, r)} \subset \Omega$. By the solid mean-value property Equation (10.66), $M = u(\boldsymbol{x}_0)$ is the average of u over the ball, and $u \le M$ there; a continuous function no greater than its own average must equal it everywhere on the ball, since otherwise $u < M$ on a nonempty open subset and the average would be strictly less than M. So $B(\boldsymbol{x}_0, r) \subseteq E$ and E is open. Being nonempty, open and closed in the connected set Ω (Definition 6.13), $E = \Omega$. □

Remark 10.78 (Hopf's extension). Hopf proved the strong principle for general second-order elliptic operators, without the mean-value property, by a barrier construction [578]. The boundary-point lemma that usually travels with it — at a boundary point where the maximum is attained, the outward normal derivative is strictly positive unless the solution is constant — is not in that paper, whose content is the strong principle alone; Hopf published the boundary lemma a quarter of a century later [1002], and Oleinik obtained it independently the same year, in a paper this bibliography does not carry (*Matematicheskii Sbornik* 30(72) (1952) 695–702). The physical reading of both results is that a static temperature or potential field has no interior hot spot: an extreme in the interior requires a source there, and where there is no source the field is controlled entirely by its boundary values. It is also why Equation (10.66) is sometimes taken as the definition of harmonicity — legitimately, by the converse of Theorem 10.69 for twice-differentiable functions and, with the smoothing step quoted in Remark 10.70, for merely continuous ones.

10.5.2 Parabolic maximum principles

Definition 10.79 (Parabolic boundary)**.** For $\Omega \subset \mathbb{R}^3$ bounded and open and $T > 0$ put $\Omega_T = \Omega \times (0, T]$. The *parabolic boundary* is

$$\Gamma_T = \left(\overline{\Omega} \times \{0\}\right) \cup (\partial\Omega \times [0, T]) \,, \tag{10.72}$$

the initial slice together with the lateral wall. The final slice $\Omega \times \{T\}$ belongs to Ω_T and not to Γ_T.

Rests on Definitions 6.3 and 10.6.

The asymmetry is the content: a parabolic problem is posed on the parabolic boundary and predicts the final slice, never the reverse.

Theorem 10.80 (Parabolic maximum principle)**.** *Let u be continuous on $\overline{\Omega_T}$, with $\partial_t u$ and the second space derivatives continuous in Ω_T, and suppose $\partial_t u - D\nabla^2 u \le 0$ there. Then*

$$\max_{\overline{\Omega_T}} u = \max_{\Gamma_T} u \,. \tag{10.73}$$

Rests on Definition 10.79 and Theorem 10.75.

Proof. *Derives Theorem 10.80.*

Assume first the strict inequality $\partial_t u - D\nabla^2 u < 0$ in Ω_T, and suppose the maximum over the compact set $\overline{\Omega_T}$ were attained at a point $(\boldsymbol{x}_0, t_0) \in \Omega_T$, so $\boldsymbol{x}_0$ interior and $0 < t_0 \le T$. Spatially the point is an interior maximum, so $\nabla^2 u(\boldsymbol{x}_0, t_0) \le 0$ by the argument of Theorem 10.75. In time, if $t_0 < T$ then $\partial_t u = 0$ there, while if $t_0 = T$ then $\partial_t u \ge 0$, because u cannot decrease on approach to a maximum at the end of the interval. Either way $\partial_t u - D\nabla^2 u \ge 0$, contradicting the strict inequality.

For the general case put $u_\varepsilon = u - \varepsilon t$ with $\varepsilon > 0$. Then $\partial_t u_\varepsilon - D\nabla^2 u_\varepsilon = (\partial_t u - D\nabla^2 u) - \varepsilon < 0$, so $\max_{\overline{\Omega_T}} u_\varepsilon = \max_{\Gamma_T} u_\varepsilon$, whence $\max_{\overline{\Omega_T}} u \le \max_{\Gamma_T} u + \varepsilon T$. Let $\varepsilon \to 0$. □

Corollary 10.81 (Uniqueness for the heat equation)**.** *The initial-boundary-value problem $\partial_t u = D\nabla^2 u + f$ in Ω_T, with u prescribed on Γ_T, has at most one solution, and two solutions whose data differ by at most ε on Γ_T differ by at most ε everywhere.*

Rests on Theorem 10.80 and Definition 10.24.

Proof. *Derives Corollary 10.81.*

The difference w of two solutions satisfies $\partial_t w - D\nabla^2 w = 0$, so Equation (10.73) applies to w and to $-w$, giving $\max_{\overline{\Omega_T}} |w| = \max_{\Gamma_T} |w|$. □

Remark 10.82. Theorem 10.80 says that the extremes of a temperature field can only shrink: no interior point ever becomes hotter than the hottest point of the initial datum or of the wall. Together with Remark 10.37 this is the analytic face of the irreversibility of diffusion — the equation has a preferred direction of time built into its type, and the statistical account of why the world's diffusion equations run that way rather than the other is Chapter 118. The analogy should not be pressed into an identification: the maximum principle is a theorem about a parabolic PDE, while entropy growth is a statement about ensembles.

10.6 Weak solutions

10.6.1 Distributional solutions and Sobolev spaces

Every construction above has assumed a classical solution, differentiable as many times as the equation demands. Three things force that requirement to be relaxed: the fundamental solutions themselves are not twice differentiable at the source; the data of a physical problem may be discontinuous; and, as Section 10.6.3 shows, a perfectly smooth initial condition may produce a solution that ceases to be differentiable in finite time. The remedy is to move the derivatives off the solution and onto a test function.

Definition 10.83 (Weak solution)**.** Let $L = \sum_{|\alpha|\le m} a_\alpha \partial^\alpha$ have smooth coefficients and let its *formal adjoint* be

$$L^*\varphi = \sum_{|\alpha|\le m} (-1)^{|\alpha|}\, \partial^\alpha (a_\alpha \varphi)\,. \tag{10.74}$$

A locally integrable u is a *weak solution* of $Lu = f$ on Ω if and only if

$$\int_\Omega u\, L^*\varphi \,\mathrm{d}^N x = \int_\Omega f\,\varphi \,\mathrm{d}^N x \tag{10.75}$$

for every smooth φ with compact support in Ω.

Rests on Definitions 10.3 and 17.38.

Proposition 10.84 (Consistency)**.** *Every classical solution is a weak solution. Conversely a weak solution of class C^m is a classical solution.*

Rests on Definition 10.83 and Equation (7.28).

Proof. *Derives Proposition 10.84.*

For $u \in C^m$, integrating by parts $|\alpha|$ times (Equation (7.28), applied in each variable) moves each ∂^α from u onto $a_\alpha\varphi$ with a sign $(-1)^{|\alpha|}$; the boundary terms vanish because φ has compact support. Hence $\int uL^*\varphi = \int (Lu)\varphi$, and Equation (10.75) says $\int (Lu - f)\varphi = 0$ for all test φ. It remains to show that a continuous h with $\int h\varphi = 0$ for all such φ vanishes. If $h(\boldsymbol{x}_0) > 0$, continuity gives a ball on which $h > h(\boldsymbol{x}_0)/2$; choosing $\varphi \ge 0$ smooth, supported in that ball and not identically zero makes $\int h\varphi > 0$, a contradiction, and $h(\boldsymbol{x}_0) < 0$ is symmetric. This proves both directions at once. □

Definition 10.85 (Sobolev space)**.** For $\Omega \subseteq \mathbb{R}^N$ open, $H^1(\Omega)$ is the space of square-integrable u whose first-order distributional derivatives $\partial_i u$ are again square-integrable, with the norm

$$\|u\|_{H^1}^2 = \int_\Omega \left(|u|^2 + |\nabla u|^2 \right) \mathrm{d}^N x\,, \tag{10.76}$$

and $H^1_0(\Omega)$ is the closure in this norm of the smooth functions of compact support — the functions "vanishing on $\partial\Omega$" in the only sense available.

Rests on Definitions 10.83 and 12.2.

Remark 10.86. H^1 is complete, hence a Hilbert space (Chapter 12); the generalised derivatives are Sobolev's, introduced precisely to handle the Cauchy problem for hyperbolic equations [787], and the systematic theory in which they and the Dirac distribution are the same kind of object is Schwartz's [971], developed in this treatise at Section 17.2.3. In that language every Green's function of Section 10.3 is a genuine solution of its equation: Φ of Equation (10.63) has no second derivative at the origin as a function, yet Proposition 10.67 exhibits $\nabla^2\Phi$ as the Dirac distribution, and $G_\pm$ of Equation (10.46) is not a function at all. A fundamental solution is a distribution or it is nothing.

10.6.2 Variational formulation

Definition 10.87 (Weak form of an elliptic problem)**.** For p, q bounded and measurable on a bounded Ω, define on $H^1_0(\Omega)$ the bilinear form and the linear functional

$$a(u,v) = \int_\Omega \left(p\,\nabla u \cdot \nabla v + q\,u\,v \right) \mathrm{d}^N x\,, \qquad \ell(v) = \int_\Omega f\,v\,\mathrm{d}^N x\,. \tag{10.77}$$

A *weak solution* of $-\nabla\cdot(p\nabla u) + qu = f$ with vanishing boundary values is a $u \in H^1_0(\Omega)$ with $a(u,v) = \ell(v)$ for every $v \in H^1_0(\Omega)$.

Rests on Definitions 10.83 and 10.85.

The form is obtained from the equation by multiplying by v and integrating by parts once: the divergence theorem Equation (7.123) moves one derivative from u to v and produces a boundary term $\oint p\, v\, \partial_\nu u$, which vanishes because v vanishes on the boundary. Only one derivative of u now appears, which is why H^1 is the natural space.

Theorem 10.88 (Lax–Milgram)**.** *Let H be a real Hilbert space and $a : H \times H \to \mathbb{R}$ bilinear with*

$$|a(u,v)| \le C\, \|u\|\, \|v\|\,, \qquad a(u,u) \ge \alpha\, \|u\|^2\,, \tag{10.78}$$

for constants C and $\alpha > 0$, and let ℓ be a bounded linear functional on H. Then there is exactly one $u \in H$ with $a(u,v) = \ell(v)$ for every $v \in H$, and $\|u\| \le \|\ell\|\,/\alpha$.

Rests on Definitions 10.87 and 12.2.

Proof. *Derives Theorem 10.88.*

For fixed u the map $v \longmapsto a(u,v)$ is a bounded linear functional, so by the Riesz representation theorem (Chapter 12) there is a unique $Au \in H$ with $a(u,v) = \langle Au, v\rangle$ for all v; uniqueness makes A linear, and the first hypothesis of Equation (10.78) gives $\|Au\| \le C\,\|u\|$.

Coercivity gives $\alpha\,\|u\|^2 \le a(u,u) = \langle Au, u\rangle \le \|Au\|\,\|u\|$, hence

$$\|Au\| \ge \alpha\, \|u\|\,, \qquad u \in H\,. \tag{10.79}$$

So A is injective. Its range is closed: if $Au_n \to w$ then Equation (10.79) applied to $u_n - u_m$ shows (u_n) is Cauchy, so $u_n \to u$ by completeness, and $Au = w$ by continuity. The range is also dense: if $w \perp A(H)$ then in particular $\langle Aw, w\rangle = 0$, so $\alpha\,\|w\|^2 \le a(w,w) = 0$ and $w = 0$. A closed dense subspace is the whole space, so A is a bijection.

Riesz again gives F with $\ell(v) = \langle F, v\rangle$, and $u = A^{-1}F$ is the unique solution. Finally $\alpha\,\|u\|^2 \le a(u,u) = \ell(u) \le \|\ell\|\,\|u\|$. □

Corollary 10.89 (Existence for the elliptic problem)**.** *If $p \ge p_0 > 0$ and $q \ge q_0 > 0$ almost everywhere and f is square-integrable, the problem of Definition 10.87 has exactly one weak solution $u \in H^1_0(\Omega)$, and $\|u\|_{H^1} \le \|f\| \,/\, \min(p_0, q_0)$.*

Rests on Theorem 10.88 and Definition 10.87.

Proof. *Derives Corollary 10.89.*

Boundedness of a follows from the boundedness of p and q and the Cauchy–Schwarz inequality; coercivity is immediate, $a(u,u) \ge \min(p_0,q_0)\,\|u\|^2_{H^1}$ by Equation (10.76); and ℓ is bounded because $|\ell(v)| \le \|f\|\,\|v\| \le \|f\|\,\|v\|_{H^1}$. Theorem 10.88 applies with $\alpha = \min(p_0, q_0)$. □

Remark 10.90. The hypothesis $q \ge q_0 > 0$ was used only to control the term $\int u^2$ in Equation (10.76). For the Dirichlet problem proper, $q = 0$, coercivity instead follows from the Poincaré inequality — on a bounded Ω the H^1_0 norm is equivalent to $\|\nabla u\|$ alone — and the conclusion is unchanged.

Proposition 10.91 (Dirichlet principle)**.** *Let a be symmetric in addition to the hypotheses of Theorem 10.88, and set $J(v) = \tfrac12 a(v,v) - \ell(v)$. Then u is the weak solution if and only if u minimises J over H.*

Rests on Theorem 10.88 and Definition 10.87.

Proof. *Derives Proposition 10.91.*

For $v \in H$ and $t \in \mathbb{R}$, bilinearity and symmetry give

$$J(u + tv) = J(u) + t\,[a(u,v) - \ell(v)] + \frac{t^2}{2}\, a(v,v)\,. \tag{10.80}$$

If $a(u,v) = \ell(v)$ for all v, the linear term vanishes and $a(v,v) \ge \alpha\,\|v\|^2 \ge 0$, so $J(u+tv) \ge J(u)$ with equality only for $v = 0$: u is the strict minimiser. Conversely if u minimises then the derivative of Equation (10.80) at $t = 0$ vanishes for every v, which is $a(u,v) = \ell(v)$. □

Remark 10.92. The three conclusions of Theorem 10.88 are exactly Hadamard's three conditions (Definition 10.24): existence, uniqueness, and the energy estimate $\|u\| \le \|\ell\|/\alpha$, which is continuous dependence because the map $\ell \longmapsto u$ is linear. Coercivity is thus the hypothesis that carries well-posedness, and the Euler–Lagrange correspondence of Proposition 10.91 is the one developed in general in Chapter 16. The functional-analytic ingredients — completeness, the Riesz theorem, orthogonality — are Chapter 12.

10.6.3 Shocks and conservation laws

Weak solutions were introduced above to accommodate irregular data. For nonlinear equations they are unavoidable for a stronger reason: the classical solution can destroy itself.

Definition 10.93 (Scalar conservation law)**.** Given a flux $F \in C^1(\mathbb{R})$, the associated *conservation law* is

$$\partial_t u + \partial_x F(u) = 0\,, \tag{10.81}$$

equivalently $\partial_t u + F'(u)\,\partial_x u = 0$ for smooth u. The case $F(u) = \tfrac{1}{2}u^2$, that is $\partial_t u + u\,\partial_x u = 0$, is *Burgers' equation*.

Rests on Definition 10.2 and Proposition 10.15.

The name is the content: integrating Equation (10.81) over an interval shows that $\int u\,\mathrm{d}x$ changes only through the flux at the two ends, so u is the density of a conserved quantity.

Proposition 10.94 (Gradient catastrophe)**.** *Let $u_0 \in C^1(\mathbb{R})$ and let u solve Burgers' equation with $u(\cdot,0) = u_0$. Then u is constant along each straight characteristic $x = x_0 + u_0(x_0)\,t$, and*

$$\partial_x u(x_0 + u_0(x_0)t,\ t) = \frac{u_0'(x_0)}{1 + u_0'(x_0)\,t}\,. \tag{10.82}$$

If $u_0' < 0$ somewhere, no C^1 solution exists beyond

$$t_* = \frac{-1}{\min_{x_0 \in \mathbb{R}} u_0'(x_0)}\,. \tag{10.83}$$

Rests on Proposition 10.15 and Definition 10.93.

Proof. *Derives Proposition 10.94.*

By Proposition 10.15 with $a = 1$ in the time variable, $b = u$ and $c = 0$, the solution is constant along the curves $\mathrm{d}x/\mathrm{d}t = u$; being constant there, those curves have constant slope and are the stated straight lines. Hence $u\,(x_0 + u_0(x_0)t,\, t) = u_0(x_0)$. Differentiating this identity with respect to x_0,

$$\partial_x u \cdot \big(1 + u_0'(x_0)\,t\big) = u_0'(x_0)\,, \tag{10.84}$$

which is Equation (10.82). Where $u_0'(x_0) < 0$ the denominator vanishes at $t = -1/u_0'(x_0)$, and the earliest such time is Equation (10.83); as $t \to t_*^-$ the slope diverges. Equivalently, two characteristics with u_0 decreasing between them meet at that time, and the classical solution would have to take two values at once. □

Definition 10.95 (Weak solution of a conservation law)**.** A bounded measurable u on $\mathbb{R} \times [0,\infty)$ is a weak solution of Equation (10.81) with datum u_0 if and only if

$$\int_0^\infty \!\! \int_{\mathbb{R}} \big[u\,\partial_t \varphi + F(u)\,\partial_x \varphi\big]\,\mathrm{d}x\,\mathrm{d}t + \int_{\mathbb{R}} u_0(x)\,\varphi(x,0)\,\mathrm{d}x = 0 \tag{10.85}$$

for every smooth φ of compact support in $\mathbb{R} \times [0,\infty)$.

Rests on Definitions 10.83 and 10.93.

Theorem 10.96 (Rankine–Hugoniot condition)**.** *Let u be a weak solution which is C^1 on either side of a C^1 curve $x = s(t)$ and has one-sided limits $u_\pm$ across it. Then at every point of the curve*

$$\frac{\mathrm{d}s}{\mathrm{d}t} = \frac{F(u_+) - F(u_-)}{u_+ - u_-}\,. \tag{10.86}$$

Rests on Definition 10.95 and Theorem 7.99.

Proof. *Derives Theorem 10.96.*

Let φ be supported in a small disc B meeting the curve and no other singularity, and away from $t = 0$. Split B into $B_- = B \cap \{x < s(t)\}$ and $B_+ = B \cap \{x > s(t)\}$. On B_-,

$$\int_{B_-} \left[u\,\partial_t\varphi + F(u)\partial_x\varphi\right] = \int_{B_-} \left[\partial_t(u\varphi) + \partial_x(F(u)\varphi)\right] - \int_{B_-} \varphi\left[\partial_t u + \partial_x F(u)\right]\,, \tag{10.87}$$

and the last integral vanishes because u is a classical solution there. The first is a divergence in the plane (t, x), so by the divergence form of Green's theorem (Theorem 7.99) it equals the flux of $(u\varphi,\ F(u)\varphi)$ through ∂B_-; only the part of the boundary lying on the curve contributes, since φ vanishes on ∂B. There the outward normal of B_- is proportional to $(-\dot s,\,1)$ and the arclength element is $\sqrt{1+\dot s^2}\,\mathrm{d}t$, so the contribution is $\int \left[F(u_-) - \dot s\,u_-\right]\varphi\,\mathrm{d}t$. The region B_+ gives the same expression with u_+ and the opposite sign. Adding, and using Equation (10.85),

$$\int \left\{\left[F(u_-) - F(u_+)\right] - \dot s\left[u_- - u_+\right]\right\}\varphi\,\mathrm{d}t = 0 \tag{10.88}$$

for every such φ, and the bracket, being continuous, must vanish identically; that is Equation (10.86). □

Example 10.97 (Burgers shock)**.** For $F(u) = u^2/2$, Equation (10.86) gives

$$\frac{\mathrm{d}s}{\mathrm{d}t} = \frac{u_+^2/2 - u_-^2/2}{u_+ - u_-} = \frac{u_- + u_+}{2}\,, \tag{10.89}$$

the shock travels at the arithmetic mean of the states it separates. Riemann obtained the same relation for finite-amplitude sound waves and identified the steepening that produces it [156]; the jump conditions across a shock in a compressible fluid are Rankine's [178] and Hugoniot's [242], and the gas-dynamical form is developed in Chapter 31.

Rests on Theorem 10.96 and Definition 10.93.

Example 10.98 (Weak solutions are not unique)**.** Take Burgers' equation with $u_0 = 0$ for $x < 0$ and $u_0 = 1$ for $x > 0$. Both of

$$u_{\mathrm{r}} = \begin{cases} 0\,, & x \le 0\,,\\ x/t\,, & 0 < x < t\,,\\ 1\,, & x \ge t\,, \end{cases} \qquad\qquad u_{\mathrm{s}} = \begin{cases} 0\,, & x < t/2\,,\\ 1\,, & x > t/2\,, \end{cases} \tag{10.90}$$

are weak solutions in the sense of Definition 10.95: the first is continuous and solves the equation classically wherever it is smooth, and the second satisfies Equation (10.89) with $u_- = 0$, $u_+ = 1$. The weak formulation alone therefore does not determine the evolution.

Rests on Theorem 10.96 and Definition 10.95.

Definition 10.99 (Entropy condition)**.** A discontinuity of a weak solution of Equation (10.81) is *admissible* if and only if

$$F'(u_-) \ge \frac{\mathrm{d}s}{\mathrm{d}t} \ge F'(u_+)\,, \tag{10.91}$$

that is, if the characteristics on both sides run *into* the discontinuity as time increases. For Burgers' equation this reads $u_- > u_+$.

Rests on Theorem 10.96 and Definition 10.95.

Remark 10.100. In Example 10.98 the jump of u_{s} has $u_- = 0 < 1 = u_+$ and is inadmissible, so the entropy condition rejects it and keeps the rarefaction u_{r}. The criterion is not an extra postulate but a limit: adding a viscous term $\varepsilon\,\partial_x^2 u$ to Equation (10.81) makes the problem parabolic and its solution unique, and as $\varepsilon \to 0^+$ the solutions converge to the weak solution satisfying Equation (10.91) and to no other [1222]. The name records that for the equations of gas dynamics the admissible jumps are exactly those across which the entropy of a fluid element does not decrease, which is why a compression shock exists in nature and a rarefaction shock does not (Chapter 31).

Definition 10.101 (Entropy pair; entropy inequality)**.** An *entropy pair* for Equation (10.81) is a pair (η, q) with η of class C^2 and convex and q of class C^1 with $q' = \eta' F'$. A weak solution u in the sense of Definition 10.95 is an *entropy solution* if and only if

$$\int_0^\infty \!\! \int_{\mathbb{R}} \left[\eta(u)\,\partial_t \varphi + q(u)\,\partial_x \varphi\right] \mathrm{d}x\,\mathrm{d}t + \int_{\mathbb{R}} \eta(u_0(x))\,\varphi(x,0)\,\mathrm{d}x \geq 0 \tag{10.92}$$

for every entropy pair and every non-negative smooth φ of compact support in $\mathbb{R} \times [0,\infty)$; briefly, $\partial_t \eta(u) + \partial_x q(u) \leq 0$ in the sense of distributions.

Rests on Definitions 10.95 and 10.99.

Equation (10.91) is a statement about the one-sided limits across a curve of discontinuity, so it presupposes that those limits exist. A bounded measurable weak solution need not be piecewise C^1 and its set of discontinuities need not be a union of curves at all, so for such a solution the jump condition selects nothing; Equation (10.92) is meaningful for every weak solution and says the same thing wherever both do.

Proposition 10.102 (Jump form of the entropy inequality)**.** *Let F be convex and let u be a weak solution which is C^1 on either side of a C^1 curve $x = s(t)$, with one-sided limits $u_\pm$. Then Equation (10.92) holds for every test function supported near the curve and away from $t = 0$ if and only if*

$$q(u_-) - q(u_+) \geq \frac{\mathrm{d}s}{\mathrm{d}t}\,\left[\eta(u_-) - \eta(u_+)\right] \tag{10.93}$$

for every entropy pair; and for a strictly convex flux that is in turn equivalent to $u_- \geq u_+$, hence to Equation (10.91).

Rests on Definition 10.101 and Theorem 10.96.

Proof. *Derives Proposition 10.102.*

Off the curve u is a classical solution, so there $\partial_t \eta(u) + \partial_x q(u) = \eta'(u)\,[\partial_t u + F'(u)\partial_x u] = 0$. Repeating the computation of Theorem 10.96 with $(\eta(u), q(u))$ in place of $(u, F(u))$ therefore reduces the left-hand side of Equation (10.92) to $\int \{q(u_-) - q(u_+) - \dot{s}\,[\eta(u_-) - \eta(u_+)]\}\,\varphi\,\mathrm{d}t$, and requiring that to be non-negative for every non-negative φ is Equation (10.93).

For the second equivalence write $\sigma = \mathrm{d}s/\mathrm{d}t$ and

$$G(v) = F(v) - F(u_-) - \sigma\,(v - u_-)\ , \tag{10.94}$$

the difference between the flux and the chord joining the two states. It is convex and vanishes at $v = u_-$ and, by Equation (10.86), at $v = u_+$, so $G \leq 0$ between them. Since $q' = \eta' F'$ one has $\mathrm{d}\big[q(v) - \sigma\eta(v)\big]/\mathrm{d}v = \eta'(v)\,G'(v)$, and integrating that by parts between the two states, the boundary term vanishing with G,

$$q(u_-) - q(u_+) - \sigma\,[\eta(u_-) - \eta(u_+)] = \int_{u_-}^{u_+} \eta''(v)\,G(v)\,\mathrm{d}v\,. \tag{10.95}$$

With $\eta'' \geq 0$ and $G \leq 0$ the integrand is non-positive on the interval between the two states, so the integral in Equation (10.95), whose limits run backwards precisely when $u_- > u_+$, is

non-negative exactly in that case; and for strictly convex F one has $G < 0$ strictly between the states, so a strictly convex η makes the inequality fail whenever $u_- < u_+$. Finally F' is non-decreasing and, by Equation (10.86), σ is a mean value of F' between the two states, so Equation (10.91) is likewise equivalent to $u_- \geq u_+$. □

Theorem 10.103 (Uniqueness in the entropy class)**.** *For a convex flux F and bounded measurable datum u_0, the conservation law Equation (10.81) has exactly one entropy solution in the sense of Definition 10.101, and it depends continuously on u_0 in the mean. Where that solution is C^1 on either side of a C^1 curve of discontinuity, its jumps satisfy Equation (10.91) by Proposition 10.102.*

Rests on Definitions 10.95 and 10.101.

Full derivation: Appendix A.17 (p. 2847).

Derives Theorem 10.103.

The uniqueness half is Kruzhkov's doubling of variables, carried out there in full: the entropy inequality Equation (10.92) is first extended, by approximation from the C^2 family admitted in Definition 10.101, to the entropies $\eta(u) = |u - k|$; each of two solutions is then tested against the other, in two sets of variables at once, and the L^1 contraction is read off. Convexity of F turns out not to be needed for that half. The existence half is the vanishing-viscosity limit described above, whose entropy estimate is derived there and whose two compactness inputs are named. What the appendix does *not* build is the Lebesgue theory the subject is written in — a bounded measurable weak solution is not an object of Chapter 7 — and its section on quoted inputs says so item by item.

Remark 10.104. With Theorem 10.103 the pattern of the chapter closes on itself. A nonlinear equation loses its classical solution in finite time (Proposition 10.94); weak solutions restore existence but cost uniqueness (Example 10.98); and an admissibility criterion drawn from the physics restores uniqueness and with it Hadamard's three conditions (Definition 10.24). Which class of solutions to admit is thus not a technical preference but part of the statement of the problem, and it is settled by asking what the equation is a model of.

Chapter 11

Probability and Statistics

Probability spaces, distributions, and estimators form the mathematical backbone of the theory of measurement error developed in Chapter 2 and of the statistical mechanics of Chapter 118. The source manuscript reserves a part for this material but leaves it unwritten: it fixes only the division of the subject into a discrete and a continuous theory. That division is retained in the first two sections below, whose content — the descriptive statistics of a distribution and of a sample — is authored rather than ported, the source having left both headings empty. So are the remaining four sections: the central limit theorem, which Part I deferred to here, and then the theory of inference built on it — estimation, hypothesis testing, and the correction that a search over a range of an unknown parameter forces on any significance quoted at a point. Those last three exist because the collider search chapters of Part XI test a hypothesis and quote a significance, and a number quoted without the mathematics that defines it is not evidence.

11.1 Discrete statistics

A discrete model is one whose possible outcomes can be listed. Everything in it is a sum, and every identity below is an identity between absolutely convergent series, so nothing is needed here beyond the theory of series of Chapter 7. The continuous case of Section 11.2 replaces those sums by integrals and inherits the algebra unchanged. Together the two supply the vocabulary — mean, variance, standard deviation, moments, median, quantile, covariance, correlation — that the rest of this chapter and the error theory of Chapter 2 are written in.

11.1.1 Definitions

Definition 11.1 (Discrete probability space)**.** A *discrete probability space* is a pair $(\Omega, \Pr)$ in which the *sample space* Ω is a finite or countably infinite set, whose elements are the possible *outcomes*, and $\Pr$ assigns to each $\omega \in \Omega$ a weight $\Pr(\{\omega\}) \geq 0$ with

$$\sum_{\omega \in \Omega} \Pr(\{\omega\}) = 1 \,. \tag{11.1}$$

An *event* is a subset $A \subseteq \Omega$, and its probability is $\Pr(A) = \sum_{\omega \in A} \Pr(\{\omega\})$. A probability is a pure number and carries no SI unit.

Rests on Definition 7.45.

The series in Equation (11.1) has non-negative terms, so it converges to the same value in every order and a sum over an unordered countable set is well defined; the same remark licenses every rearrangement made below. The general setting, in which Ω need not be countable and the events form a σ-algebra, is not needed anywhere in this chapter and is set out in [1894].

Proposition 11.2 (Elementary rules)**.** *Let $A, B \subseteq \Omega$ be events and $A_1, A_2, \ldots$ pairwise disjoint events. Then*

1. $\Pr(\Omega \setminus A) = 1 - \Pr(A)$*, and* $A \subseteq B$ *implies* $\Pr(A) \leq \Pr(B)$*;*
2. $\Pr(\varnothing) = 0$*,* $\Pr(\Omega) = 1$ *and* $0 \leq \Pr(A) \leq 1$*;*
3. $\Pr(A \cup B) = \Pr(A) + \Pr(B) - \Pr(A \cap B)$*;*
4. $\Pr(\bigcup_i A_i) = \sum_i \Pr(A_i)$*.*

Rests on Definition 11.1.

Derivation. *Derives Proposition 11.2.*

Every claim is a statement about a series of non-negative terms indexed by a countable set, and such a series may be split and regrouped at will. (i) Splitting the sum Equation (11.1) over A and its complement gives the first identity; splitting the sum over B over A and $B \setminus A$ gives $\Pr(B) = \Pr(A) + \Pr(B \setminus A) \geq \Pr(A)$. (ii) The empty sum is 0 and the sum over Ω is 1 by Equation (11.1); the bounds then follow from monotonicity, $\Pr(\varnothing) \leq \Pr(A) \leq \Pr(\Omega)$. (iii) Split $A \cup B$ into $A \setminus B$, $B \setminus A$ and $A \cap B$: the left side is the sum of the three, and the right side counts $A \cap B$ twice and subtracts it once. (iv) Each outcome of the union lies in exactly one A_i, so grouping the terms of the sum over the union by the index i reproduces the right-hand side. □

Definition 11.3 (Discrete random variable)**.** A *discrete random variable* is a map $X : \Omega \to \mathbb{R}$ taking at most countably many values. Its *probability mass function* is

$$p_X(x) = \Pr(X = x) = \Pr(\{\omega \in \Omega : X(\omega) = x\}) \,, \tag{11.2}$$

a non-negative function summing to 1 over the values X attains. If the outcome carries a physical quantity — a count, a length in m, an energy in J — then X carries that SI unit and p_X does not.

Rests on Definition 11.1.

Definition 11.4 (Expectation)**.** The *expectation* of a discrete random variable is

$$\langle X \rangle = \sum_{\omega \in \Omega} X(\omega)\, \Pr(\{\omega\}) \,, \tag{11.3}$$

defined whenever $\sum_\omega |X(\omega)| \Pr(\{\omega\}) < \infty$, in which case X is called *integrable*. The expectation carries the SI unit of X.

Rests on Definitions 7.45 and 11.3.

Proposition 11.5 (Transfer, linearity, monotonicity)**.** *Let X and Y be integrable random variables on one discrete probability space and let $a, b, c \in \mathbb{R}$. Then*

1. *(transfer) for every $g : \mathbb{R} \to \mathbb{R}$ with $\sum_x |g(x)|\, p_X(x) < \infty$, $\langle g(X) \rangle = \sum_x g(x)\, p_X(x)$; in particular $\langle X \rangle = \sum_x x\, p_X(x)$;*
2. *(linearity) $aX + bY$ is integrable and $\langle aX + bY \rangle = a \langle X \rangle + b \langle Y \rangle$, and $\langle c \rangle = c$;*
3. *(monotonicity) if $X \leq Y$ at every outcome then $\langle X \rangle \leq \langle Y \rangle$, and $|\langle X \rangle| \leq \langle |X| \rangle$.*

Rests on Definition 11.4 and Proposition 11.2.

Derivation. *Derives Proposition 11.5.*

(i) Group the outcomes according to the value of X: the terms of $\sum_\omega g(X(\omega)) \Pr(\{\omega\})$ with $X(\omega) = x$ contribute $g(x) \sum_{\omega : X(\omega) = x} \Pr(\{\omega\}) = g(x) p_X(x)$, and the regrouping is legitimate because the series converges absolutely by hypothesis. (ii) Termwise, $(aX + bY)(\omega) \Pr(\{\omega\}) = aX(\omega) \Pr(\{\omega\}) + bY(\omega) \Pr(\{\omega\})$; both series on the right converge absolutely, so their sum may be split, and $|aX + bY| \leq |a|\,|X| + |b|\,|Y|$ gives the integrability. For a constant the sum is c times Equation (11.1). (iii) Termwise again, since each weight is non-negative; and $\pm X \leq |X|$ gives $\pm \langle X \rangle \leq \langle |X| \rangle$. □

Those three properties are the whole toolkit. Every identity in the rest of this section is a formal consequence of them, which is why the continuous theory of Section 11.2 can take them over wholesale.

Definition 11.6 (Moments, variance, standard deviation)**.** Let $\langle |X|^n \rangle < \infty$. The *nth raw moment* of X is $\langle X^n \rangle$ and its *nth central moment* is $\mu_n = \langle (X-\mu)^n \rangle$, where $\mu = \langle X \rangle$ is the *mean*. The *variance* and the *standard deviation* are

$$\operatorname{var} X = \mu_2 = \left\langle (X-\mu)^2 \right\rangle , \qquad \sigma = +\sqrt{\operatorname{var} X} , \tag{11.4}$$

and the *skewness* and *excess kurtosis* are $\gamma_1 = \mu_3/\sigma^3$ and $\gamma_2 = \mu_4/\sigma^4 - 3$.

Rests on Proposition 11.5.

If X carries the SI unit u then μ and σ carry u, the variance carries u^2, the nth moment carries u^n, and γ_1 and γ_2 are pure numbers — which is what makes the last two comparable between a length distribution and an energy distribution. A finite second moment implies a finite first one, since $|x| \le \tfrac{1}{2}(1+x^2)$; the same inequality is used again below to make a covariance exist. The subtracted 3 in γ_2 is a convention fixed by Proposition 11.29, which gives every Gaussian $\mu_4 = 3\sigma^4$ and hence $\gamma_2 = 0$.

Proposition 11.7 (Variance identity)**.** *If* $\langle X^2 \rangle < \infty$ *then*

$$\operatorname{var} X = \left\langle X^2 \right\rangle - \langle X \rangle^2 , \tag{11.5}$$

$\operatorname{var}(aX+b) = a^2 \operatorname{var} X$ *for constants* a *and* b*, and* $\operatorname{var} X = 0$ *if and only if* $X = \mu$ *with probability one.*

Rests on Definition 11.6 and Proposition 11.5.

Derivation. *Derives Proposition 11.7.*

Expand the square and use linearity twice: $\langle X^2 - 2\mu X + \mu^2 \rangle = \langle X^2 \rangle - 2\mu \langle X \rangle + \mu^2 = \langle X^2 \rangle - \mu^2$, since $\langle X \rangle = \mu$. For the second claim, $\langle aX+b \rangle = a\mu + b$, so $(aX+b) - \langle aX+b \rangle = a(X-\mu)$ and squaring produces the factor a^2. For the third, $\operatorname{var} X = \sum_\omega (X(\omega)-\mu)^2 \Pr(\{\omega\})$ is a series of non-negative terms, so it vanishes exactly when every term does, that is when $X(\omega) = \mu$ at every outcome of non-zero probability. □

Equation (11.5) is what allows a variance to be accumulated in one pass over the data, keeping only $\sum X_i$ and $\sum X_i^2$. It is also a trap in finite-precision arithmetic: when $\sigma \ll |\mu|$ the two terms on its right are nearly equal and their difference loses most of its significant digits, so a numerical implementation subtracts the mean first and uses Equation (11.4) directly.

Definition 11.8 (Quantiles and median)**.** For $\alpha \in (0,1)$, an *α-quantile* of X is any $q \in \mathbb{R}$ with

$$\Pr(X \le q) \ge \alpha , \qquad \Pr(X \ge q) \ge 1-\alpha . \tag{11.6}$$

A *median* is a $\tfrac{1}{2}$-quantile. A quantile carries the SI unit of X.

Rests on Definition 11.3.

Remark 11.9 (Quantiles exist and need not be unique). Write $F(x) = \Pr(X \le x)$. By countable additivity (Proposition 11.2(iv)) $F(x_n) \to F(q)$ whenever $x_n \downarrow q$ and $F(x_n) \to \Pr(X < q)$ whenever $x_n \uparrow q$; also $F \to 1$ at $+\infty$ and $F \to 0$ at $-\infty$. The set $\{x : F(x) \ge \alpha\}$ is therefore a non-empty half-line $[q, \infty)$ with q finite, and that q satisfies both requirements of Equation (11.6): the first by construction, the second because $F(x) < \alpha$ for $x < q$ forces $\Pr(X < q) \le \alpha$. Uniqueness fails in general: for X taking the values 0 and 1 with probability $\tfrac{1}{2}$ each, every point of $[0,1]$ is a median.

Proposition 11.10 (What the mean and the median minimise)**.** *Let X be integrable and let m be a median of X. Then*

$$\langle |X - m| \rangle \;\le\; \langle |X - c| \rangle \qquad \text{for every } c \in \mathbb{R}\,, \tag{11.7}$$

and if in addition $\langle X^2 \rangle < \infty$ then

$$\left\langle (X-c)^2 \right\rangle = \operatorname{var} X + (\mu - c)^2 \;\ge\; \operatorname{var} X\,, \tag{11.8}$$

with equality exactly at $c = \mu$.

Rests on Definition 11.8 and Proposition 11.7.

Derivation. *Derives Proposition 11.10.*

For Equation (11.8) write $X - c = (X - \mu) + (\mu - c)$ and expand; the cross term is $2(\mu - c)\,\langle X - \mu \rangle = 0$.

For Equation (11.7) take first $c > m$ and put $d = c - m > 0$. Then

$$|x - c| - |x - m| \;\ge\; d\left(1 - 2\,\mathbf{1}_{\{x > m\}}\right) \qquad \text{for every } x \in \mathbb{R}\,. \tag{11.9}$$

Indeed, for $x \le m < c$ both sides equal d, because $|x - c| - |x - m| = (c - x) - (m - x) = d$; and for $x > m$ the right-hand side is $-d$, while the left-hand side is at least $-\,|c - m| = -d$ by the triangle inequality. Put $x = X$ in Equation (11.9) and take expectations, using monotonicity and linearity (Proposition 11.5):

$$\langle |X - c| \rangle - \langle |X - m| \rangle \;\ge\; d\,(1 - 2\Pr(X > m)) \;\ge\; 0\,,$$

since $\Pr(X > m) = 1 - \Pr(X \le m) \le \tfrac{1}{2}$ by Equation (11.6) at $\alpha = \tfrac{1}{2}$. For $c < m$ the same argument with $d = m - c$ and the indicator of $\{x < m\}$ applies, using $\Pr(X < m) = 1 - \Pr(X \ge m) \le \tfrac{1}{2}$. □

So the mean is the least-squares measure of location and the median the least-absolute-deviation one. The difference between them is robustness: a single grossly wrong reading displaces the mean without bound, and displaces the median by at most the gap to the next value in the sample.

Definition 11.11 (Covariance and correlation)**.** For X and Y with finite second moments,

$$\operatorname{cov}(X, Y) = \langle (X - \langle X \rangle)\,(Y - \langle Y \rangle) \rangle\,, \tag{11.10}$$

which exists because $|uv| \le \tfrac{1}{2}\,(u^2 + v^2)$ makes the product integrable. When both variances are non-zero, the *correlation coefficient* is

$$\rho(X, Y) = \frac{\operatorname{cov}(X, Y)}{\sqrt{\operatorname{var} X}\,\sqrt{\operatorname{var} Y}}\,. \tag{11.11}$$

A covariance carries the product of the SI units of X and Y; a correlation coefficient is a pure number.

Rests on Definition 11.6 and Proposition 11.5.

Proposition 11.12 (Bilinearity)**.** *Covariance is symmetric and bilinear:* $\operatorname{cov}(X, X) = \operatorname{var} X$, $\operatorname{cov}(X, c) = 0$ *for a constant* c, $\operatorname{cov}(aX + bY, Z) = a \operatorname{cov}(X, Z) + b \operatorname{cov}(Y, Z)$, *and* $\operatorname{cov}(X, Y) = \langle XY \rangle - \langle X \rangle \langle Y \rangle$. *Consequently, for constants* $a_1, \dots, a_n$,

$$\operatorname{var}\left(\sum_{i=1}^{n} a_i X_i \right) = \sum_{i=1}^{n} a_i^2 \operatorname{var} X_i + 2 \sum_{i<j} a_i a_j \operatorname{cov}(X_i, X_j)\,. \tag{11.12}$$

Rests on Definition 11.11 and Proposition 11.5.

Derivation. *Derives Proposition 11.12.*

The first two claims are Equation (11.4) and the vanishing of $c - \langle c \rangle$. For bilinearity, the centred variable of $aX + bY$ is $a\,(X - \langle X \rangle) + b\,(Y - \langle Y \rangle)$ by linearity of the expectation, and multiplying by $Z - \langle Z \rangle$ and taking expectations splits the result by linearity again; symmetry then gives linearity in the second slot. Expanding Equation (11.10) gives $\langle XY \rangle - \langle X \rangle \langle Y \rangle - \langle Y \rangle \langle X \rangle + \langle X \rangle \langle Y \rangle = \langle XY \rangle - \langle X \rangle \langle Y \rangle$. Finally Equation (11.12) is bilinearity applied to $\operatorname{cov}\left(\sum_i a_i X_i, \sum_j a_j X_j\right)$, the diagonal terms giving the variances and the off-diagonal ones pairing up by symmetry. □

Definition 11.13 (Independence)**.** Discrete random variables $X_1, \ldots, X_n$ are *independent* when

$$\Pr(X_1 = x_1, \ldots, X_n = x_n) = \prod_{i=1}^{n} p_{X_i}(x_i) \tag{11.13}$$

for every choice of values $x_1, \ldots, x_n$. An infinite family is independent when every finite subfamily is.

Rests on Definition 11.3.

Proposition 11.14 (Independence implies zero covariance; the converse fails)**.** *If X and Y are independent with finite second moments then $\langle XY \rangle = \langle X \rangle \langle Y \rangle$ and $\operatorname{cov}(X, Y) = 0$. The converse is false.*

Rests on Definition 11.13 and Proposition 11.12.

Derivation. *Derives Proposition 11.14.*

Grouping the outcomes by the value of the pair (X, Y), exactly as in Proposition 11.5(i), gives $\langle XY \rangle = \sum_{x,y} xy \Pr(X = x, Y = y)$, and the double series converges absolutely because $\sum_{x,y} |x|\,|y|\, p_X(x) p_Y(y) = \langle |X| \rangle \langle |Y| \rangle < \infty$. Absolute convergence permits summing in either order and splitting the product of the two series (Proposition 7.49), so Equation (11.13) gives $\langle XY \rangle = \left(\sum_x x\, p_X(x)\right)\left(\sum_y y\, p_Y(y)\right) = \langle X \rangle \langle Y \rangle$, and Proposition 11.12 makes the covariance vanish. For the converse, let X take the values $-1, 0, 1$ with probability $\frac{1}{3}$ each and put $Y = X^2$. Then $\langle X \rangle = 0$ and $\langle XY \rangle = \langle X^3 \rangle = 0$, so the covariance vanishes; but $\Pr(X = 0, Y = 0) = \frac{1}{3}$ while $p_X(0)\, p_Y(0) = \frac{1}{3} \cdot \frac{1}{3}$, so Equation (11.13) fails and Y is in fact a function of X. □

Zero covariance is a statement about second moments alone, and the example shows how little it excludes. This is exactly why Proposition 11.43(iii) needs full independence rather than mere uncorrelatedness: $\mathrm{e}^{\mathrm{i}tX}$ is a nonlinear function of X.

Corollary 11.15 (Bounds on the correlation coefficient)**.** $|\rho(X, Y)| \le 1$*, with $\rho = \pm 1$ if and only if $Y = aX + b$ with probability one for constants $a \neq 0$ and b; the sign of ρ is then the sign of a.*

Rests on Definition 11.11 and Lemma 11.63.

Derivation. *Derives Corollary 11.15.*

Divide Equation (11.50) by the positive number $\operatorname{var} X \cdot \operatorname{var} Y$ and take square roots. Equality holds exactly under the condition recorded in Lemma 11.63: there are constants $(a_0, c_0) \neq (0, 0)$ with $a_0\,(X - \langle X \rangle) + c_0\,(Y - \langle Y \rangle) = 0$ with probability one. Neither coefficient can vanish here, because $a_0 = 0$ would force $\operatorname{var} Y = 0$ and $c_0 = 0$ would force $\operatorname{var} X = 0$. Hence $Y - \langle Y \rangle = k\,(X - \langle X \rangle)$ with $k = -a_0/c_0 \neq 0$, which is the stated affine relation with $b = \langle Y \rangle - k \langle X \rangle$. For such a Y, Proposition 11.12 gives $\operatorname{cov}(X, Y) = k \operatorname{var} X$ and $\operatorname{var} Y = k^2 \operatorname{var} X$, so $\rho = k/|k| = \operatorname{sgn} k$. □

Lemma 11.63 is stated and proved in Section 11.4.3, where it is needed a second time; its derivation uses nothing from this section, so borrowing it here is not circular.

Definition 11.16 (Sample mean, variance and correlation)**.** Let $X_1, \dots, X_n$ be independent with a common distribution and $n \geq 2$. The *sample mean*, *sample variance* and *sample standard deviation* are

$$\bar{X}_n = \frac{1}{n}\sum_{i=1}^{n} X_i\,, \qquad s_n^2 = \frac{1}{n-1}\sum_{i=1}^{n}\left(X_i - \bar{X}_n\right)^2\,, \qquad s_n = +\sqrt{s_n^2}\,, \tag{11.14}$$

and for pairs (X_i, Y_i) the *sample covariance* and *sample correlation coefficient* are

$$c_n = \frac{1}{n-1}\sum_{i=1}^{n}\left(X_i - \bar{X}_n\right)\left(Y_i - \bar{Y}_n\right)\,, \qquad r_n = \frac{c_n}{s_{X,n}\, s_{Y,n}}\,. \tag{11.15}$$

These are functions of the data alone: they are *statistics*, estimating the μ, σ^2, σ, $\operatorname{cov}(X,Y)$ and ρ of the distribution that produced them.

Rests on Definitions 11.6, 11.11 and 11.13.

Proposition 11.17 (Sampling identities)**.** *With the notation of Equation* (11.14) *and a common mean μ and variance $\sigma^2 < \infty$,*

$$\left\langle \bar{X}_n \right\rangle = \mu\,, \qquad \operatorname{var} \bar{X}_n = \frac{\sigma^2}{n}\,, \qquad \left\langle s_n^2 \right\rangle = \sigma^2\,, \tag{11.16}$$

while $\langle s_n \rangle \leq \sigma$, with equality only if s_n is constant with probability one.

Rests on Definition 11.16 and Propositions 11.12 and 11.14.

Derivation. *Derives Proposition 11.17.*

The first identity is linearity. The second is Equation (11.12) with $a_i = 1/n$: the covariances vanish by Proposition 11.14, leaving $n \cdot n^{-2}\sigma^2$. For the third, write $X_i - \bar{X}_n = (X_i - \mu) - \left(\bar{X}_n - \mu\right)$ and sum the squares; since $\sum_i (X_i - \mu) = n\left(\bar{X}_n - \mu\right)$, the cross term is $-2n\left(\bar{X}_n - \mu\right)^2$ and

$$\sum_{i=1}^{n}\left(X_i - \bar{X}_n\right)^2 = \sum_{i=1}^{n}(X_i - \mu)^2 - n\left(\bar{X}_n - \mu\right)^2\,. \tag{11.17}$$

Taking expectations gives $n\sigma^2 - n \cdot \sigma^2/n = (n-1)\sigma^2$, and dividing by $n-1$ gives $\langle s_n^2 \rangle = \sigma^2$. Finally $0 \leq \operatorname{var} s_n = \langle s_n^2 \rangle - \langle s_n \rangle^2 = \sigma^2 - \langle s_n \rangle^2$ by Equation (11.5), so $\langle s_n \rangle \leq \sigma$, with equality exactly when $\operatorname{var} s_n$ vanishes. □

The divisor $n-1$ is the entire content of the third identity: the deviations in Equation (11.14) are taken from $\bar{X}_n$ rather than from the unknown μ, and $\bar{X}_n$ is itself pulled towards the data, which is what Equation (11.17) measures. The last clause is a warning worth stating plainly: correcting the variance does not correct the standard deviation. Whatever the distribution, s_n underestimates σ on average, and no divisor can fix that for every distribution at once, since the deficit $\sigma - \langle s_n \rangle$ depends on the sampling distribution of s_n itself.

Example 11.18 (Three standard discrete distributions)**.** *Bernoulli*: $X \in \{0,1\}$ with $\Pr(X=1) = p$. Then $\langle X \rangle = p$ and $\langle X^2 \rangle = p$, so $\operatorname{var} X = p(1-p)$ by Equation (11.5), largest at $p = \frac{1}{2}$.

Binomial: $S = \sum_{i=1}^{n} X_i$ with the X_i independent Bernoulli variables, so that $\Pr(S = k) = \binom{n}{k} p^k (1-p)^{n-k}$. Linearity gives $\langle S \rangle = np$ and Equation (11.12) gives $\operatorname{var} S = np(1-p)$, neither calculation touching the mass function.

Poisson: $p(k) = \nu^k \mathrm{e}^{-\nu}/k!$ for $k = 0, 1, 2, \dots$ and $\nu > 0$, which sums to $\mathrm{e}^{-\nu}\mathrm{e}^{\nu} = 1$. Cancelling one factor from $k/k! = 1/(k-1)!$ gives $\langle X \rangle = \nu \sum_{j \geq 0} \nu^j \mathrm{e}^{-\nu}/j! = \nu$, and the same manoeuvre twice gives $\langle X(X-1) \rangle = \nu^2$, so $\langle X^2 \rangle = \nu^2 + \nu$ and $\operatorname{var} X = \nu$. Mean and variance coincide: that is the signature of a counting process, and the reason a count of N events is quoted with an uncertainty $\sqrt{N}$.

Rests on Definition 11.6 and Propositions 11.12 and 11.14.

Example 11.19 (A counting measurement)**.** A detector is read out five times over equal live times $t_{\text{live}} = 60\,\text{s}$ and records 41, 52, 47, 44 and 46 counts. Counts are pure numbers; only the derived rate carries a unit. The sample mean is $\bar{n}_5 = 230/5 = 46.0$, the deviations are $-5, 6, 1, -2, 0$, their squares sum to 66, and Equation (11.14) gives $s_5^2 = 66/4 = 16.5$ and $s_5 = 4.06$. The standard deviation of the mean is $s_5/\sqrt{5} = 1.82$ by Equation (11.16). Sorting the readings as $41, 44, 46, 47, 52$ shows the median to be 46, close to the mean here because nothing is grossly discrepant.

Dividing by the live time turns the estimate into a rate,

$$\hat{\Gamma} = \frac{\bar{n}_5}{t_{\text{live}}} = 0.767/\text{s}\,, \qquad \frac{s_5}{\sqrt{5}\,t_{\text{live}}} = 0.030/\text{s}\,, \tag{11.18}$$

the division by a constant scaling the standard deviation by that same constant, as Proposition 11.7 requires. Had the five readings come from a Poisson law, Example 11.18 would predict $\sigma = \sqrt{\nu} \simeq 6.8$ for a single reading against the $s_5 = 4.06$ observed — a difference that five readings cannot resolve, and exactly the kind of question Section 11.5 is built to answer.

Rests on Definition 11.16, Proposition 11.17, and Example 11.18.

11.2 Continuous statistics

A continuously distributed variable takes each individual value with probability zero, so the mass function of Equation (11.2) is useless and a density takes its place. The sums of Section 11.1 become integrals, and because every identity proved there used only linearity, monotonicity and positivity of the expectation, the algebra survives the change intact. What has to be redone is only what depended on rearranging a series.

11.2.1 Definitions

Definition 11.20 (Density)**.** A real random variable X is *continuously distributed* with *probability density* f when $f \geq 0$ is Riemann integrable on every bounded interval, the improper integral

$$\int_{-\infty}^{\infty} f(x)\,\mathrm{d}x = 1 \tag{11.19}$$

converges, and $\Pr(a \leq X \leq b) = \int_a^b f(x)\,\mathrm{d}x$ for all $a < b$. If X carries the SI unit u, then f carries u^{-1}: only the product $f(x)\,\mathrm{d}x$ is a probability, and only a probability is a pure number.

Rests on Definition 7.39.

Definition 11.21 (Distribution function)**.** The *distribution function* of a real random variable X is $F_X(x) = \Pr(X \leq x)$, whether or not X has a density. When it has one, $F_X(x) = \int_{-\infty}^{x} f(t)\,\mathrm{d}t$. In general F_X is only non-decreasing, and it may jump: for a variable taking the single value c with probability one it steps from 0 to 1 at c. The proposition below is the density case, and continuity is what that case adds.

Rests on Definition 11.20.

Proposition 11.22 (Properties of the distribution function)**.** *If X has a density f, then F_X is non-decreasing and continuous, tends to 0 at $-\infty$ and to 1 at $+\infty$, satisfies $\Pr(a < X \leq b) = F_X(b) - F_X(a)$ and $\Pr(X = x) = 0$ for every x, and has $F_X'(x) = f(x)$ at every point where f is continuous.*

Rests on Definition 11.21 and Theorem 7.42.

Derivation. Derives Proposition 11.22.

Monotonicity and the difference formula follow from additivity of the integral over subintervals together with $f \geq 0$; the two limits are Equation (11.19). A Riemann integrable

function is bounded on each bounded interval, say by M near x, so $|F_X(x+h) - F_X(x)| \le M\,|h|$ and F_X is continuous — indeed locally Lipschitz. Hence $\Pr(X = x) \le F_X(x+\varepsilon) - F_X(x-\varepsilon) \to 0$. The last claim is the first fundamental theorem of calculus (Theorem 7.42), which needs f continuous only at the point in question. □

Definition 11.23 (Expectation, moments and quantiles in the continuous case)**.** For $g : \mathbb{R} \to \mathbb{R}$ with $\int |g(x)|\, f(x)\,\mathrm{d}x$ convergent,

$$\langle g(X) \rangle = \int_{-\infty}^{\infty} g(x)\, f(x)\,\mathrm{d}x\,, \tag{11.20}$$

and the mean, moments, variance, standard deviation, skewness, excess kurtosis, covariance and correlation coefficient are defined by the very formulas of Definitions 11.6 and 11.11, read with this expectation. Quantiles are defined by Equation (11.6); by Proposition 11.22 the two requirements there collapse to $F_X(q) = \alpha$.

Rests on Definitions 11.4 and 11.20.

Proposition 11.24 (The algebra of the discrete case transfers)**.** *The expectation Equation (11.20) is linear and monotone and satisfies $|\langle g(X)\rangle| \le \langle |g(X)|\rangle$. Consequently Propositions 11.7, 11.10, 11.12 and 11.17 and Corollary 11.15 hold verbatim for continuously distributed variables.*

Rests on Definition 11.23 and Proposition 11.5.

Derivation. *Derives Proposition 11.24.*

Linearity and monotonicity of the integral are the elementary properties of the Darboux construction recorded with Definition 7.39, and applying monotonicity to $\pm g f \le |g|\, f$ gives the third property. Reading the proofs of the five results named, each uses the expectation only through those three properties together with pointwise algebraic identities and the pointwise inequality Equation (11.9); none of them rearranges a series. The same holds of Lemma 11.63, whose proof needs only that $\left\langle \left(s\tilde{V} + \tilde{W} \right)^2 \right\rangle \ge 0$, and which is in any case stated for arbitrary random variables of finite variance. One dependence is not of that kind and has to be replaced rather than reread: Proposition 11.17 also uses the vanishing of the covariance of two independent variables, which here is Proposition 11.26 below and not Proposition 11.14. □

What does *not* transfer for free is the product rule for independent variables, since its discrete proof rearranged a double series. It is restated and reproved here.

Definition 11.25 (Joint density and independence)**.** A pair (X, Y) has *joint density* $f_{XY} \ge 0$ when $\Pr(a \le X \le b,\ c \le Y \le d) = \int_a^b \int_c^d f_{XY}(x,y)\,\mathrm{d}y\,\mathrm{d}x$ for all $a < b$ and $c < d$. The two variables are *independent* when $f_{XY}(x,y) = f_X(x) f_Y(y)$ for all x and y.

Rests on Definitions 11.13 and 11.20.

Proposition 11.26 (Product rule)**.** *If X and Y are independent in the sense of Definition 11.25 and both are integrable, then $\langle XY \rangle = \langle X \rangle \langle Y \rangle$ and $\operatorname{cov}(X,Y) = 0$.*

Rests on Definition 11.25 and Proposition 11.24.

Derivation. *Derives Proposition 11.26.*

In the iterated integral $\langle XY \rangle = \int \left(\int xy\, f_X(x) f_Y(y)\,\mathrm{d}y \right) \mathrm{d}x$ the inner integrand is $x f_X(x)$ times a function of y alone, so the inner integral equals $x f_X(x) \int y f_Y(y)\,\mathrm{d}y$ — a constant multiple of $x f_X(x)$, the constant being $\langle Y \rangle$, which is finite by hypothesis. Integrating in x gives $\langle X \rangle \langle Y \rangle$. No interchange of integrations is used: the factorisation is of the integrand, not of the order of integration. Proposition 11.12, which transfers by Proposition 11.24, then makes the covariance vanish. □

Proposition 11.27 (Probability integral transform)**.** *Let $F = F_X$ be strictly increasing on an interval carrying all the probability. Then $U = F(X)$ is uniformly distributed on $[0,1]$, that is $\Pr(U \le \alpha) = \alpha$ for $\alpha \in (0,1)$; conversely, if U is uniformly distributed on $[0,1]$ then $F^{-1}(U)$ has distribution function F.*

Rests on Proposition 11.22 and Definition 11.23.

Derivation. Derives Proposition 11.27.

F is continuous by Proposition 11.22 and strictly increasing by hypothesis, so it has a continuous strictly increasing inverse on $(0,1)$ and $\{F(X) \le \alpha\} = \{X \le F^{-1}(\alpha)\}$. Hence $\Pr(U \le \alpha) = F(F^{-1}(\alpha)) = \alpha$. Conversely $\Pr(F^{-1}(U) \le x) = \Pr(U \le F(x)) = F(x)$. □

The transform is what makes quantiles computable — the α-quantile is $F^{-1}(\alpha)$ — and it is the same statement, read through the survival function instead of the distribution function, as the uniformity of a p-value in Proposition 11.76.

Definition 11.28 (Gaussian distribution)**.** The *Gaussian* (or normal) distribution $\mathcal{N}(\mu, \sigma^2)$ with $\sigma > 0$ has density

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) . \tag{11.21}$$

The case $\mu = 0$, $\sigma = 1$ is the *standard* Gaussian, with density φ and distribution function Φ. Here μ and σ carry the SI unit of X, f carries its reciprocal, and the exponent is a pure number.

Rests on Definition 11.20.

Proposition 11.29 (Gaussian moments)**.** *Equation (11.21) is a density; its mean is μ and its variance σ^2; its central moments are $\mu_{2n+1} = 0$ and $\mu_{2n} = (2n-1)!!\,\sigma^{2n}$; and its skewness and excess kurtosis both vanish.*

Rests on Definitions 11.23 and 11.28.

Derivation. Derives Proposition 11.29.

The substitution $u = (x-\mu)/\sigma$ (Equation (7.27)) reduces every statement to the standard case, with $\mu_n = \sigma^n \langle U^n \rangle$ for U standard. For the normalisation put $I = \int_{-\infty}^{\infty} \mathrm{e}^{-u^2/2}\,\mathrm{d}u$ and evaluate I^2 as a double integral in polar coordinates, whose Jacobian is r:

$$I^2 = \int_0^{2\pi}\int_0^{\infty} \mathrm{e}^{-r^2/2}\, r\,\mathrm{d}r\,\mathrm{d}\theta = 2\pi\,, \tag{11.22}$$

so $I = \sqrt{2\pi}$ and φ integrates to 1. This is the one step of the derivation that uses the change-of-variables formula for a double integral.

The odd moments vanish because $u^{2n+1}\varphi(u)$ is odd and absolutely integrable. For the even ones use $\varphi'(u) = -u\varphi(u)$ and integrate by parts (Equation (7.28)):

$$\left\langle U^{2n} \right\rangle = -\int_{-\infty}^{\infty} u^{2n-1}\varphi'(u)\,\mathrm{d}u = (2n-1)\int_{-\infty}^{\infty} u^{2n-2}\varphi(u)\,\mathrm{d}u = (2n-1)\left\langle U^{2n-2} \right\rangle , \tag{11.23}$$

the boundary term vanishing because $u^{2n-1}\varphi(u) \to 0$ at both ends. With $\langle U^0 \rangle = 1$ this gives $\langle U^{2n} \rangle = (2n-1)!!$, hence $\langle U^2 \rangle = 1$ and $\langle U^4 \rangle = 3$. So the mean is μ, the variance is σ^2, $\gamma_1 = 0$ and $\gamma_2 = 3 - 3 = 0$, which is the convention fixed in Definition 11.6. □

Example 11.30 (Exponential lifetimes)**.** A decay with constant λ, carried in 1/s, has density $f(t) = \lambda \mathrm{e}^{-\lambda t}$ for $t \ge 0$ and $f(t) = 0$ for $t < 0$. It integrates to 1, and integrating by parts n times (Equation (7.28)) gives $\langle T^n \rangle = n!/\lambda^n$. Hence the mean lifetime and the standard deviation are both $\tau = 1/\lambda$, in s, and

$$\operatorname{var} T = \frac{2}{\lambda^2} - \frac{1}{\lambda^2} = \tau^2\,, \qquad \mu_3 = \frac{6}{\lambda^3} - \frac{6}{\lambda^3} + \frac{3}{\lambda^3} - \frac{1}{\lambda^3} = 2\tau^3\,, \qquad \gamma_1 = 2\,. \tag{11.24}$$

The distribution function is $F(t) = 1 - \mathrm{e}^{-\lambda t}$, so by Definition 11.23 the median is the half-life $t_{1/2} = \tau \ln 2 = 0.693\,\tau$, strictly less than the mean — the quantitative form of the positive skewness, and a reminder that for an asymmetric law the two measures of location of Proposition 11.10 answer different questions.

Rests on Definition 11.23 and Propositions 11.10 and 11.24.

Example 11.31 (A length measurement)**.** Six readings of a gauge block on a comparator give, in m, 0.025 001 3, 0.025 000 9, 0.025 001 5, 0.025 001 1, 0.025 001 0 and 0.025 001 4. Working in units of 1×10^{-7} m above 0.025 m, the readings are 13, 9, 15, 11, 10, 14, with sample mean 12 and deviations $1, -3, 3, -1, -2, 2$ whose squares sum to 28. By Equation (11.14),

$$\bar{\ell}_6 = 2.500\,120 \times 10^{-2}\,\mathrm{m}\,, \qquad s_6^2 = 5.6 \times 10^{-14}\,\mathrm{m}^2\,, \qquad s_6 = 2.4 \times 10^{-7}\,\mathrm{m}\,, \tag{11.25}$$

and the standard deviation of the mean is $s_6/\sqrt{6} = 9.7 \times 10^{-8}$ m. The units track the definitions exactly: a variance in m^2, a standard deviation in m, and a skewness or a correlation coefficient that would be a pure number. The ordered readings are $9, 10, 11, 13, 14, 15$, so any point of $[11, 13]$ is a median by Equation (11.6); the customary choice is the midpoint, here 12, which coincides with the mean because this sample happens to be symmetric.

Rests on Definitions 11.8 and 11.16 and Proposition 11.17.

The limit theorems that join the two theories are the subject of the next section. The binomial variable of Example 11.18 is a sum of independent identically distributed Bernoulli variables, so Theorem 11.46 applies to it verbatim: a discrete law, suitably centred and scaled, is described in the limit by the continuous Gaussian density Equation (11.21). That is the passage from the first of these two sections to the second, and it is proved rather than asserted in Section 11.3.2.

Remark 11.32 (Neither case is the general one). A distribution need be neither discrete nor continuous. The asymptotic law of the discovery statistic in Equation (11.86) is a half-and-half mixture of a point mass at zero and a chi-squared density, and is of neither kind: its distribution function jumps at the origin and grows continuously above it. The theory that covers every case at once replaces both the sum Equation (11.3) and the integral Equation (11.20) by an integral against a measure [1894]. Every identity proved in these two sections survives that generalisation unchanged, because each rests only on the linearity, monotonicity and positivity of the expectation — which is also why they could be proved once and transferred once, rather than twice.

11.2.2 Measure spaces, null sets and “almost every”

Both sections above are built on sums and on Riemann integrals, and that is enough for every distribution they treat. It is not enough for one thing the rest of the treatise says repeatedly: that a statement holds *for almost every* point, or that some exceptional set has *zero volume*. That phrase has no meaning until sets are assigned sizes, and the assignment has to survive countable operations or the phrase is useless — the whole force of “almost every” is that countably many exceptions may be discarded at once. The definitions below supply exactly that much and nothing more. They are used in Chapter 24 for the recurrence theorem, in Chapter 32 for the sets on which a Lyapunov exponent is defined, and in Chapter 12 wherever L^2 appears.

Definition 11.33 (Sigma-algebra)**.** A *σ-algebra* on a set Ω is a family $\mathcal{F}$ of subsets of Ω such that

1. $\Omega \in \mathcal{F}$;
2. $A \in \mathcal{F}$ implies $\Omega \setminus A \in \mathcal{F}$;

3. $A_1, A_2, \dots \in \mathcal{F}$ implies $\bigcup_{n\geq 1} A_n \in \mathcal{F}$.

Its members are the *measurable sets*, and $(\Omega, \mathcal{F})$ is a *measurable space*. Complements and countable unions give countable intersections as well, by de Morgan's laws (Proposition 3.37), so $\mathcal{F}$ is closed under every countable Boolean operation. The *Borel* σ-algebra of a topological space is the smallest σ-algebra containing the open sets — smallest because an arbitrary intersection of σ-algebras is one.

Rests on Definitions 6.1 and 11.1.

Definition 11.34 (Measure; measure space)**.** A *measure* on $(\Omega, \mathcal{F})$ is a map $\mu : \mathcal{F} \longrightarrow [0, \infty]$ with $\mu(\varnothing) = 0$ which is *countably additive*: for pairwise disjoint $A_1, A_2, \dots \in \mathcal{F}$,

$$\mu\Big(\bigcup_{n\geq 1} A_n\Big) = \sum_{n\geq 1} \mu(A_n)\,. \tag{11.26}$$

The triple $(\Omega, \mathcal{F}, \mu)$ is a *measure space*, and a *probability space* when $\mu(\Omega) = 1$, in which case μ is written Pr. A measure carries the SI unit of the quantity it measures — m^3 for a volume in space, the product of the units of the phase-space coordinates for the Liouville measure of Chapter 24 — and a probability is a pure number.

Rests on Definitions 11.1 and 11.33.

Definition 11.35 (Null set; almost everywhere)**.** A set $N \in \mathcal{F}$ is *null* (or *of measure zero*) if $\mu(N) = 0$. A statement holds *almost everywhere*, or for *almost every* point, if the set where it fails is contained in a null set. In a probability space one says *almost surely*.

Rests on Definition 11.34.

Proposition 11.36 (Monotonicity, countable subadditivity, and null sets)**.** *Let $(\Omega, \mathcal{F}, \mu)$ be a measure space. Then*

1. *$A \subseteq B$ implies $\mu(A) \leq \mu(B)$;*
2. *$\mu\left(\bigcup_n A_n\right) \leq \sum_n \mu(A_n)$ for any countable family, disjoint or not;*
3. *a countable union of null sets is null;*
4. *consequently, countably many statements each holding almost everywhere hold simultaneously almost everywhere.*

Rests on Definitions 11.34 and 11.35.

Derivation. *Derives Proposition 11.36.*

(i) Write $B = A \cup (B \setminus A)$, a disjoint union of measurable sets; Equation (11.26) with all later terms empty gives $\mu(B) = \mu(A) + \mu(B \setminus A) \geq \mu(A)$, the last step because a measure is non-negative.

(ii) Disjointify: put $B_1 = A_1$ and $B_n = A_n \setminus (A_1 \cup \dots \cup A_{n-1})$, which lie in $\mathcal{F}$ by Definition 11.33, are pairwise disjoint, have the same union as the A_n, and satisfy $B_n \subseteq A_n$. Then $\mu\left(\bigcup_n A_n\right) = \sum_n \mu(B_n) \leq \sum_n \mu(A_n)$ by Equation (11.26) and (i).

(iii) If every $\mu(A_n) = 0$ then the right-hand side of (ii) is a series of zeros, so the union has measure at most zero, hence exactly zero.

(iv) Apply (iii) to the union of the countably many exceptional sets: outside it, every one of the statements holds. □

Remark 11.37 (What is quoted here, and what is not). The definitions above are the whole of what this treatise needs from measure theory, and everything asserted about them is proved in Proposition 11.36. What is *not* proved anywhere here is that interesting measures exist: that there is a measure on the Borel sets of $\mathbb{R}^n$ assigning to a box the product of its edge lengths — Lebesgue measure — is a construction (Carathéodory's extension of a

premeasure from an algebra to the σ-algebra it generates), and it is quoted, from [1894], wherever it is used; so is the Lebesgue integral built on it, which enters this book only through the completeness of L^2 in Theorem 12.12 and through the convergence theorems listed in Remark 12.1. The distinction is worth keeping sharp. A statement of the form "the exceptional set has measure zero" needs only Definition 11.35 and Proposition 11.36 to be meaningful and to be combined with others; it needs the construction only when a particular set is to be shown null by computing something. The recurrence theorem of Chapter 24 is of the first kind, which is why it can be stated honestly here.

11.2.3 Invariant measures and the ergodic theorem

A dynamical system supplies a measure space with a map of it into itself, and the question that then arises — whether a long time average along one trajectory equals an average over the space — is the question every use of statistical mechanics and of Lyapunov exponents in this book turns on. It is a theorem of probability, not of mechanics, and it belongs here.

Definition 11.38 (Measure-preserving map; invariant measure; ergodicity)**.** Let $(\Omega, \mathcal{F}, \mu)$ be a measure space with $\mu(\Omega) < \infty$. A measurable map $T : \Omega \longrightarrow \Omega$ *preserves* μ, equivalently μ is *invariant* under T, if

$$\mu(T^{-1}(A)) = \mu(A)\,, \qquad \forall\, A \in \mathcal{F}\,. \tag{11.27}$$

A set A is *invariant* if $T^{-1}(A) = A$, and the system (T, μ) is *ergodic* if every invariant set is null or has null complement — that is, if the space cannot be split into two parts of positive measure that the motion never mixes. The same definitions apply to a one-parameter family $\{T_t\}_{t\in\mathbb{R}}$, a *measure-preserving flow*, with Equation (11.27) required of every T_t.

Rests on Definitions 11.34 and 11.35.

Theorem 11.39 (Birkhoff's pointwise ergodic theorem)**.** *Let T preserve a finite measure μ on $(\Omega, \mathcal{F})$ and let f be μ-integrable. Then the time average*

$$\bar{f}(\omega) = \lim_{N\to\infty} \frac{1}{N} \sum_{n=0}^{N-1} f(T^n\omega) \tag{11.28}$$

exists for μ-almost every ω, is T-invariant, and satisfies $\int \bar{f}\,\mathrm{d}\mu = \int f\,\mathrm{d}\mu$. If (T, μ) is ergodic then $\bar{f}$ is almost everywhere equal to the constant $\mu(\Omega)^{-1}\int f\,\mathrm{d}\mu$: the time average along almost every trajectory equals the space average. The same statements hold for a measure-preserving flow, with the time average $T^{-1}\int_0^T f(T_t\omega)\,\mathrm{d}t$.

Rests on Definition 11.38 and Proposition 11.36.

Remark 11.40 (What is quoted here). Theorem 11.39 is quoted, not proved. It is Birkhoff's theorem [674], and its proof rests on a maximal inequality for the partial sums together with the dominated convergence theorem of Lebesgue integration — exactly the theory Remark 11.37 declares this treatise does not develop. Von Neumann's mean ergodic theorem [705], proved a little earlier, gives convergence in L^2 rather than pointwise and is a statement about the unitary operator $f \mapsto f \circ T$ on that space; it is the weaker conclusion and the easier proof, and it is not enough for a statement about individual trajectories. Nothing in this chapter is derived from either. The theorem is stated here so that Chapter 32, which reports measured Lyapunov exponents, and Chapter 118, which replaces a time average by an ensemble average, can name the hypothesis they need — ergodicity of a specified invariant measure — instead of leaving it implicit. The multiplicative extension that governs the whole Lyapunov spectrum, rather than a single average, is Oseledets' [1378]; it is stated and used, with the same declaration, where the exponents are defined.

Remark 11.41 (Ergodicity is a hypothesis, not a consequence). Theorem 11.39 says what follows *if* the system is ergodic; it says nothing about whether any given system is. That is a question about the system, and for mechanical systems it is usually open and sometimes answered in the negative: an integrable system is never ergodic on an energy surface, because each invariant torus of Chapter 23 is an invariant set of measure zero whose union of positive-measure families fills the surface, and the surviving tori of the KAM theorem in Chapter 32 do the same for a nearly integrable one. The honest form of the statistical-mechanical postulate is therefore an assumption about the measure, not a theorem about the dynamics.

11.3 Characteristic functions and the central limit theorem

The theory of measurement error in Chapter 2 rests on one theorem: that a quantity assembled from many small independent contributions is Gaussian, whatever the contributions individually look like. That is what licenses quoting a standard uncertainty at all, and it is proved here.

The proof goes through the Fourier transform of a distribution, which turns the convolution that describes a sum of independent variables into a product. Throughout, $\langle \cdot \rangle$ denotes expectation, as in Chapter 2.

11.3.1 Characteristic functions

Definition 11.42 (Characteristic function)**.** The *characteristic function* of a real random variable X is

$$\varphi_X(t) = \left\langle \mathrm{e}^{\mathrm{i}tX} \right\rangle , \qquad t \in \mathbb{R} . \tag{11.29}$$

Unlike the moment generating function $\left\langle \mathrm{e}^{tX} \right\rangle$, this exists for every distribution without exception: $\left|\mathrm{e}^{\mathrm{i}tX}\right| = 1$, so the expectation is an integral of a bounded function and always converges. That unconditional existence is why the argument below needs no assumption beyond a finite variance.

Proposition 11.43 (Elementary properties)**.** *For any random variables X, Y and constants $a, b \in \mathbb{R}$:*

1. $\varphi_X(0) = 1$ *and* $|\varphi_X(t)| \le 1$ *for all* t*;*
2. $\varphi_{aX+b}(t) = \mathrm{e}^{\mathrm{i}bt}\, \varphi_X(at)$*;*
3. *if X and Y are independent, then* $\varphi_{X+Y} = \varphi_X\, \varphi_Y$*.*

Rests on Definition 11.42.

Derivation. *Derives Proposition 11.43.*
(i) $\varphi_X(0) = \langle 1 \rangle = 1$, and $|\varphi_X(t)| = \left|\left\langle \mathrm{e}^{\mathrm{i}tX} \right\rangle\right| \le \left\langle \left|\mathrm{e}^{\mathrm{i}tX}\right| \right\rangle = 1$. (ii) $\left\langle \mathrm{e}^{\mathrm{i}t(aX+b)} \right\rangle = \mathrm{e}^{\mathrm{i}bt} \left\langle \mathrm{e}^{\mathrm{i}(ta)X} \right\rangle$. (iii) $\mathrm{e}^{\mathrm{i}t(X+Y)} = \mathrm{e}^{\mathrm{i}tX}\mathrm{e}^{\mathrm{i}tY}$, and if X and Y are independent then $\langle f(X)g(Y)\rangle = \langle f(X)\rangle\, \langle g(Y)\rangle$ for all bounded measurable f, g — which is what independence means, and is strictly stronger than being uncorrelated: the latter is the case $f = g = \mathrm{id}$ alone and would not suffice here, since $\mathrm{e}^{\mathrm{i}tX}$ is a nonlinear function of X. Both factors are bounded, so both expectations exist. □

Property (iii) is the whole point: addition of independent variables, which is a convolution of distributions, becomes multiplication of characteristic functions — and no density need exist for that to hold.

Lemma 11.44 (Second-order expansion)**.** *If* $\langle X\rangle = 0$ *and* $\langle X^2\rangle = \sigma^2 < \infty$*, then*

$$\varphi_X(t) = 1 - \tfrac{1}{2}\sigma^2 t^2 + o(t^2) \qquad (t \to 0)\,. \tag{11.30}$$

Rests on Definition 11.42.

Derivation. *Derives Lemma 11.44.*

Writing the remainder of $\mathrm{e}^{\mathrm{i}x}$ in integral form by integrating by parts n times gives, for real x,

$$\left|\mathrm{e}^{\mathrm{i}x} - \sum_{k=0}^{n} \frac{(\mathrm{i}x)^k}{k!}\right| \le \min\left(\frac{|x|^{n+1}}{(n+1)!}, \frac{2\,|x|^n}{n!}\right). \tag{11.31}$$

Bounding the integrand of that remainder gives the first estimate; the second follows instead from the triangle inequality applied to the order-$(n-1)$ remainder together with the last term of the series. The minimum matters because only the second branch survives when no moment beyond the nth exists. Taking $n = 2$ and $x = tX$,

$$\left|\mathrm{e}^{\mathrm{i}tX} - 1 - \mathrm{i}tX + \tfrac{1}{2}t^2X^2\right| \le \min\left(\tfrac{1}{6}\,|t|^3\,|X|^3\,,\; t^2X^2\right).$$

Take expectations, and use $|\langle Z\rangle| \le \langle |Z|\rangle$. Since $\langle X\rangle = 0$ the left side becomes $\left|\varphi_X(t) - 1 + \tfrac{1}{2}t^2\sigma^2\right|$, so

$$\frac{\left|\varphi_X(t) - 1 + \tfrac{1}{2}\sigma^2 t^2\right|}{t^2} \le \left\langle \min\left(\tfrac{1}{6}\,|t|\,|X|^3\,,\; X^2\right)\right\rangle.$$

The right-hand side tends to 0 as $t \to 0$. The usual reason given is dominated convergence, which this treatise cannot yet invoke: Chapter 7 develops the Riemann integral only, and the Lebesgue theory the dominated-convergence theorem belongs to is not built anywhere in the book. An elementary truncation does the same work. Fix $K > 0$ and split the expectation at $|X| = K$: where $|X| \le K$ the first branch of the minimum bounds the integrand by $\tfrac{1}{6}\,|t|\,K^3$, and where $|X| > K$ the second branch bounds it by $X^2\mathbf{1}_{\{|X|>K\}}$, so

$$\left\langle \min\left(\tfrac{1}{6}\,|t|\,|X|^3\,,\; X^2\right)\right\rangle \;\le\; \tfrac{1}{6}\,|t|\,K^3 + \left\langle X^2\,\mathbf{1}_{\{|X|>K\}}\right\rangle. \tag{11.32}$$

From Equation (11.31) (take $n = 2$ and $x = tX$, then split the expectation at $|X| = K$ and use one branch of the minimum on each piece).

Given $\varepsilon > 0$, choose K so large that the second term is below $\varepsilon/2$ — possible precisely because $\langle X^2\rangle$ is finite, a finite integral being one whose tail contribution vanishes [1894] — and then take $|t| < 3\varepsilon/K^3$, which puts the first term below $\varepsilon/2$ as well. That is exactly Equation (11.30). □

The lemma is where the finite variance enters, and it is the only place it is needed. Note what it does *not* require: no third moment, no density, no symmetry.

Theorem 11.45 (Lévy's continuity theorem)**.** *Let* $X_1, X_2, \dots$ *be random variables with characteristic functions* φ_n*. If* $\varphi_n(t) \to \varphi(t)$ *for every* $t \in \mathbb{R}$ *and* φ *is continuous at* $t = 0$*, then* φ *is the characteristic function of a random variable* X *and* $X_n \to X$ *in distribution.*

Rests on Definition 11.42.

This is the bridge from pointwise convergence of transforms back to convergence of the distributions themselves, and it is the deepest analytic statement this section rests on: the proof needs Helly's selection theorem, the Fourier inversion formula and a tightness estimate that is where continuity of the limit at the origin does its work [1446, 1894]. It is carried out in full in the appendix, so Theorem 11.45 is derived rather than quoted; what the derivation does assume, and all it assumes, are two theorems of Lebesgue theory, named there.

Full derivation: Appendix A.18 (p. 2856).

Derives Theorem 11.45.

11.3.2 The central limit theorem

Theorem 11.46 (Central limit theorem, Lindeberg–Lévy)**.** *Let $X_1, X_2, \dots$ be independent, identically distributed random variables with finite mean μ and finite variance $\sigma^2 \in (0, \infty)$. Then*

$$Z_n = \frac{1}{\sigma\sqrt{n}} \sum_{i=1}^{n} (X_i - \mu) \xrightarrow[n\to\infty]{\text{in distribution}} \mathcal{N}(0,1)\,, \tag{11.33}$$

that is, $\Pr(Z_n \le z) \to \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{z} \mathrm{e}^{-u^2/2}\,\mathrm{d}u$ *for every* $z \in \mathbb{R}$.

Rests on Proposition 11.43, Lemma 11.44, and Theorem 11.45.

Derivation. *Derives Theorem 11.46.*

Put $Y_i = (X_i - \mu)/\sigma$, so the Y_i are independent and identically distributed with $\langle Y_i \rangle = 0$ and $\langle Y_i^2 \rangle = 1$, and $Z_n = n^{-1/2} \sum_i Y_i$. Write φ for the common characteristic function of the Y_i.

By Proposition 11.43(ii) and (iii), the latter extended to n factors by induction,

$$\varphi_{Z_n}(t) = \left[\varphi\!\left(\frac{t}{\sqrt{n}} \right) \right]^n . \tag{11.34}$$

Fix t. By Lemma 11.44 applied at argument $t/\sqrt{n}$,

$$\varphi\!\left(\frac{t}{\sqrt{n}} \right) = 1 - \frac{t^2}{2n} + r_n(t)\,, \qquad n\, r_n(t) \longrightarrow 0\,. \tag{11.35}$$

From Equation (11.30) (the second-order expansion evaluated at argument $t/\sqrt{n}$).

The remainder $r_n(t)$ is defined by that equation; the convergence is the lemma rescaled. Writing $\varphi(s) = 1 - s^2/2 + R(s)$ with $R(s)/s^2 \to 0$, we have $r_n(t) = R(t/\sqrt{n})$ and hence $n\, r_n(t) = t^2\, R(s)/s^2$ at $s = t/\sqrt{n}$, which tends to 0 for each fixed t because $s \to 0$. Now compare the two products using the elementary inequality

$$\left| \prod_{i=1}^{n} a_i - \prod_{i=1}^{n} b_i \right| \le \sum_{i=1}^{n} |a_i - b_i|\,, \qquad |a_i| \le 1,\ |b_i| \le 1\,, \tag{11.36}$$

which follows by telescoping $\prod a_i - \prod b_i = \sum_i \left(\prod_{j<i} a_j \right) (a_i - b_i) \left(\prod_{j>i} b_j \right)$ and bounding each partial product by 1. Take $a_i = \varphi(t/\sqrt{n})$, whose modulus is at most 1 by Proposition 11.43(i), and $b_i = 1 - t^2/(2n)$, which lies in $[0,1]$ once $n \ge t^2/2$. Then

$$\left| \varphi_{Z_n}(t) - \left(1 - \frac{t^2}{2n} \right)^n \right| \le n\, |r_n(t)| \longrightarrow 0\,.$$

Since $(1 - t^2/(2n))^n \to \mathrm{e}^{-t^2/2}$, it follows that

$$\varphi_{Z_n}(t) \longrightarrow \mathrm{e}^{-t^2/2} \qquad \text{for every } t \in \mathbb{R}\,. \tag{11.37}$$

From Equations (11.34) to (11.36) (compare the two products factor by factor and let n grow).

The limit is the characteristic function of the standard Gaussian. That is quickest to see without contour shifting: writing $g(t) = \int \mathrm{e}^{\mathrm{i}tu} \mathrm{e}^{-u^2/2} \mathrm{d}u/\sqrt{2\pi}$ and differentiating under the integral sign, an integration by parts gives $g'(t) = -t\, g(t)$ with $g(0) = 1$, whence $g(t) = \mathrm{e}^{-t^2/2}$. It is continuous at $t = 0$. Theorem 11.45 therefore gives $Z_n \to \mathcal{N}(0,1)$ in distribution. □

Remark 11.47 (What the theorem does and does not say). Three qualifications matter for the use made of this result in Chapter 2.

First, the convergence is *in distribution* and says nothing about any individual sample. Second, it is a statement about the centre: the approximation is worst in the tails, which is

exactly where a coverage factor $k = 3$ is being asked to do work. Third — and this is the hypothesis that actually fails in practice — a finite variance is required. Errors drawn from a heavy-tailed law need not converge to anything Gaussian: the Cauchy distribution has no finite variance — indeed no finite mean — and the average of n Cauchy samples has the *same* distribution as a single one, so averaging never narrows it at all and Theorem 2.7's $\sigma/\sqrt{N}$ has nothing to describe.

Theorem 11.48 (Lindeberg–Feller)**.** *For each n let $X_{n,1}, \dots, X_{n,k_n}$ be independent with $\langle X_{n,k} \rangle = 0$ and $s_n^2 = \sum_k \operatorname{var} X_{n,k}$. If for every $\varepsilon > 0$*

$$\frac{1}{s_n^2} \sum_{k=1}^{k_n} \left\langle X_{n,k}^2 \, \mathbf{1}_{\{|X_{n,k}| > \varepsilon s_n\}} \right\rangle \longrightarrow 0 \,, \tag{11.38}$$

then $s_n^{-1} \sum_k X_{n,k} \to \mathcal{N}(0,1)$ in distribution.

Theorem 11.46 is the special case of identically distributed summands. The general form is the one the error theory actually needs, because the disturbances that perturb a measurement are *not* identically distributed: they are a thermal drift, a vibration, a quantisation step, a reading error.

Condition Equation (11.38) is *sufficient*, and the implication it does carry is the one wanted here: it forces every individual variance share to vanish. Indeed, splitting the expectation at $|X_{n,k}| = \varepsilon s_n$ gives, for any $\varepsilon > 0$,

$$\frac{\operatorname{var} X_{n,k}}{s_n^2} \le \varepsilon^2 + \frac{1}{s_n^2} \sum_j \left\langle X_{n,j}^2 \, \mathbf{1}_{\{|X_{n,j}| > \varepsilon s_n\}} \right\rangle \qquad \text{for every } \varepsilon > 0 \,, \tag{11.39}$$

so Equation (11.38) implies $\max_k \operatorname{var} X_{n,k}/s_n^2 \to 0$, which is *uniform asymptotic negligibility* — no single source carries a fixed fraction of the total variance. A dominant source therefore violates the condition.

The converse fails, and it is worth being precise about how, because the temptation is to read Equation (11.38) as a characterisation of "many small contributions". It is strictly stronger than negligibility: it constrains tail mass, not merely variance shares. Summands equal to $\pm\sqrt{n}$ with probability $1/(2n)$ each and 0 otherwise have variance share $1/n \to 0$, yet the Lindeberg sum equals 1 for every n and the limit is compound Poisson, not Gaussian. Nor does failure of the condition force a non-Gaussian limit: adjoining one $\mathcal{N}(0,n)$ summand to n independent $\mathcal{N}(0,1)$ summands breaks Equation (11.38) while leaving the normalised sum exactly $\mathcal{N}(0,1)$. Feller's companion theorem closes the loop only within the negligible class: if $\max_k \operatorname{var} X_{n,k}/s_n^2 \to 0$ *and* the normalised sum is asymptotically Gaussian, then Equation (11.38) holds [1446].

Lindeberg introduced the condition in 1922 [493]; the method of that paper — replacing the summands by Gaussians one at a time and controlling the accumulated error — also yields an elementary proof of Theorem 11.46 that avoids characteristic functions altogether. A sufficient condition that is easier to check in practice is Lyapunov's: $s_n^{-(2+\delta)} \sum_k \left\langle |X_{n,k}|^{2+\delta} \right\rangle \to 0$ for some $\delta > 0$ [1446, 1894]; it implies Equation (11.38) in a line, and that line is in the appendix. The characteristic-function argument that establishes Theorem 11.46 generalises to Theorem 11.48, with Lemma 11.44 replaced by an expansion uniform in the summand index and controlled by Equation (11.38); that generalisation is carried out there in full, and Equation (11.39) above is one of its lemmas.

Full derivation: Appendix A.19 (p. 2862).
Derives Theorem 11.48.

Remark 11.49 (How fast). The theorem is a limit, and an uncertainty budget needs a rate. The Berry–Esseen inequality supplies one: if $\rho = \left\langle |X - \mu|^3 \right\rangle < \infty$, then

$$\sup_{z \in \mathbb{R}} \left| \Pr(Z_n \le z) - \Phi(z) \right| \le \frac{C\rho}{\sigma^3 \sqrt{n}} \,, \tag{11.40}$$

with Φ the standard normal distribution function and C an absolute constant, shown finite by Berry [856] and, independently and in the same period, by Esseen. It is proved in the appendix along Esseen's route — a smoothing inequality, a bound on the characteristic function of Z_n over $|t| \lesssim \sqrt{n}\,\sigma^3/\rho$, and an integration — which delivers the explicit admissible value $C = 7.23$ [1446]. Determining the *smallest* admissible constant is a separate literature and is not attempted there; the sharpest published value for identically distributed summands is $C \leq 0.4690$, which is due to Shevtsova alone [2238].

Two things follow, and neither is comfortable. The bound is *uniform in* z: it limits the absolute error of the Gaussian approximation equally at the centre and in the tails, so where the probability being approximated is itself small the *relative* error is large — which is exactly the regime a coverage factor $k = 3$ operates in. And the $n^{-1/2}$ is slow. Since $\rho/\sigma^3 \geq 1$ always, the right-hand side of Equation (11.40) is at least $0.4690/\sqrt{n}$, which for a dozen contributions guarantees only about 0.14 in Kolmogorov distance; several hundred are needed before the inequality itself certifies a few per cent. Actual convergence is usually far better than the worst case the bound protects against — but "usually" is not a quantity an uncertainty budget can carry, and the bound is what can be asserted.

Full derivation: Appendix A.20 (p. 2867).
Derives Equation (11.40).

11.4 Estimation

The central limit theorem says what a sum of many small contributions looks like. Inference runs the other way: given the numbers a measurement actually produced, what can be said about the parameter that produced them, and how well? This section builds the likelihood function, the estimator that maximises it, the exact lower bound on how well *any* estimator can do, and the asymptotic law the maximum-likelihood estimator obeys. The last of these is what the next two sections need, and the profile likelihood constructed at the end of this one is the object a collider search actually evaluates.

Two elementary tools are used repeatedly and the earlier sections of this chapter do not yet supply them, so they are derived here.

Lemma 11.50 (Markov and Chebyshev inequalities)**.** *Let $Y \geq 0$ be a random variable and $a > 0$. Then $\Pr(Y \geq a) \leq \langle Y \rangle / a$. Consequently, if X has finite mean μ and finite variance σ^2, then for every $a > 0$*

$$\Pr(|X - \mu| \geq a) \leq \frac{\sigma^2}{a^2}\,. \tag{11.41}$$

Derivation. *Derives Lemma 11.50.*

Since $Y \geq 0$, $Y \geq Y\,\mathbf{1}_{\{Y \geq a\}} \geq a\,\mathbf{1}_{\{Y \geq a\}}$ pointwise; taking expectations gives $\langle Y \rangle \geq a \Pr(Y \geq a)$. Apply this to $Y = (X - \mu)^2$ with the level a^2: the event $|X - \mu| \geq a$ is the event $Y \geq a^2$, and $\langle Y \rangle = \sigma^2$. □

Corollary 11.51 (Weak law of large numbers)**.** *If $X_1, X_2, \ldots$ are independent and identically distributed with mean μ and finite variance σ^2, then the sample mean $\bar{X}_n = n^{-1}\sum_{i=1}^{n} X_i$ converges to μ in probability: $\Pr(\left|\bar{X}_n - \mu\right| \geq a) \to 0$ for every $a > 0$.*

Rests on Lemma 11.50.

Derivation. *Derives Corollary 11.51.*

$\left\langle \bar{X}_n \right\rangle = \mu$ and, by independence, $\operatorname{var} \bar{X}_n = \sigma^2/n$. Then Equation (11.41) gives $\Pr(\left|\bar{X}_n - \mu\right| \geq a) \leq \sigma^2/(na^2) \to 0$. □

One further result is needed, a statement about modes of convergence rather than about any model here. It is elementary and is derived in full.

Lemma 11.52 (Slutsky)**.** *If $A_n \to A$ in distribution and $B_n \to b$ in probability with b a constant, then $A_n + B_n \to A + b$ and $A_n B_n \to bA$ in distribution. If moreover $b \neq 0$, then $A_n / B_n \to A/b$ in distribution.*

Rests on Definition 11.21.

Derivation of the sum and product clauses. *Derives Lemma 11.52.*

Write F for the distribution function of A and $F_n(y) = \Pr(A_n \le y)$, both in the general sense of Definition 11.21: no density is assumed here, and F may jump — as it does for the constant limits met below — which is exactly why the continuity points have to be watched. Convergence in distribution means $F_n(y) \to F(y)$ at every continuity point y of F. Two remarks are used repeatedly. First, F is non-decreasing, so its discontinuities are at most countable — the open intervals $(F(y^-), F(y^+))$ belonging to distinct jumps are disjoint and each contains a rational — and continuity points are therefore dense. Second, $F(y) \to 1$ as $y \to +\infty$ and $F(y) \to 0$ as $y \to -\infty$.

The sum. Let x be a continuity point of the distribution function of $A + b$, that is, let F be continuous at $x - b$, and let $\varepsilon > 0$. If $A_n + B_n \le x$ and $|B_n - b| \le \varepsilon$ then $A_n \le x - B_n \le x - b + \varepsilon$; conversely, if $A_n \le x - b - \varepsilon$ and $|B_n - b| \le \varepsilon$ then $A_n + B_n \le x$. Passing to probabilities,

$$F_n(x - b - \varepsilon) - \delta_n \;\le\; \Pr(A_n + B_n \le x) \;\le\; F_n(x - b + \varepsilon) + \delta_n \,, \tag{11.42}$$

with $\delta_n = \Pr(|B_n - b| > \varepsilon)$, which tends to 0 because $B_n \to b$ in probability. Restrict ε to the values — all but countably many, by the first remark — for which both $x - b \pm \varepsilon$ are continuity points of F. Taking the lower and upper limits in Equation (11.42) gives

$$F(x - b - \varepsilon) \;\le\; \liminf_n \Pr(A_n + B_n \le x) \;\le\; \limsup_n \Pr(A_n + B_n \le x) \;\le\; F(x - b + \varepsilon) \,,$$

and letting ε decrease to zero through admissible values makes both ends tend to $F(x - b)$, since F is continuous at $x - b$. Hence $\Pr(A_n + B_n \le x) \to F(x - b) = \Pr(A + b \le x)$, which is the claim.

Boundedness in probability. Given $\delta > 0$, choose $K > 0$ with $\pm K$ both continuity points of F, $F(K) > 1 - \delta/2$ and $F(-K) < \delta/2$; the second remark makes this possible and the first makes it possible at continuity points. Since $\Pr(|A_n| > K) \le (1 - F_n(K)) + F_n(-K)$,

$$\limsup_n \Pr(|A_n| > K) \;\le\; 1 - F(K) + F(-K) \;<\; \delta \,. \tag{11.43}$$

The product. Decompose $A_n B_n = b\, A_n + A_n\,(B_n - b)$ and treat the two pieces separately. For the second, fix $\varepsilon > 0$ and $\delta > 0$ and take K as in Equation (11.43). Since $|A_n (B_n - b)| > \varepsilon$ forces either $|A_n| > K$ or $|B_n - b| > \varepsilon / K$,

$$\Pr(|A_n\,(B_n - b)| > \varepsilon) \;\le\; \Pr(|A_n| > K) + \Pr(|B_n - b| > \varepsilon/K) \;,$$

whose second term tends to 0; so the upper limit is at most δ, and δ was arbitrary. Thus $A_n (B_n - b) \to 0$ in probability.

For the first piece, $b\, A_n \to b\, A$ in distribution. This is trivial for $b = 0$, both sides being the constant 0. For $b > 0$ the events $\{bA_n \le x\}$ and $\{A_n \le x/b\}$ coincide, and x is a continuity point of the law of bA exactly when x/b is one of F. For $b < 0$ they are $\{A_n \ge x/b\}$, so $\Pr(bA_n \le x) = 1 - \Pr(A_n < x/b)$; and at a continuity point y of F one has $F_n(y') \le \Pr(A_n < y) \le F_n(y)$ for every continuity point $y' < y$, so the limits squeeze $\Pr(A_n < y)$ between $F(y')$ and $F(y)$, and $F(y') \to F(y)$ as y' increases to y. Hence $\Pr(bA_n \le x) \to 1 - F(x/b) = \Pr(bA \le x)$ at every such x.

Applying the sum clause already proved, with bA_n in place of A_n and the constant 0 in place of b, gives $A_n B_n \to bA$ in distribution. □

The quotient is used below and is not a special case of the other two, so it is worth reducing it to them explicitly rather than leaving the reader to supply the step.

Derivation of the quotient clause from the product clause. *Derives Lemma 11.52.*

Let $b \neq 0$ and $\varepsilon > 0$. The map $y \mapsto 1/y$ is continuous at b, so there is a $\delta \in (0, |b|/2)$ such that $|y - b| < \delta$ implies both $y \neq 0$ and $|1/y - 1/b| < \varepsilon$. Hence

$$\Pr(|1/B_n - 1/b| \geq \varepsilon) \;\leq\; \Pr(|B_n - b| \geq \delta) \;\longrightarrow\; 0\,, \tag{11.44}$$

the same bound also showing that B_n is nonzero with probability tending to one, so the quotient is defined on an event of probability approaching 1. Thus $1/B_n \to 1/b$ in probability — this is the continuous-mapping theorem, in the only case this chapter needs, and its proof is the two lines just given. Applying the product clause to A_n and $1/B_n$ gives $A_n/B_n \to A/b$ in distribution. □

All three clauses are therefore derived here, and Lemma 11.52 joins the list of results this chapter proves rather than imports. Four results that are stated in this chapter are proved not here but in the appendix, because their derivations are long: Theorem 11.45, Theorem 11.48 and the Berry–Esseen inequality Equation (11.40) of Section 11.3, and Rice's formula Theorem 11.102. What remains genuinely imported is smaller and is worth naming exactly: a handful of theorems of Lebesgue theory — dominated convergence, Fubini–Tonelli — which Chapter 7 does not build and which the appendix names at each use; the weak law of large numbers in the form that assumes only integrability of the summand, which Section 11.4.4 needs wherever Corollary 11.51, resting as it does on Chebyshev's inequality, has no finite variance to work with; and, for the multi-parameter form of Theorem 11.88, the Cramér–Wold device and the continuous-mapping theorem in $\mathbb{R}^k$.

11.4.1 The likelihood function

Definition 11.53 (Statistical model)**.** A *statistical model* for data taking values in a set $\mathcal{X}$ is a family $\{f(\,\cdot\,;\theta) : \theta \in \Theta\}$ of probability densities (or, for discrete data, probability mass functions) on $\mathcal{X}$, indexed by a parameter θ ranging over a set $\Theta \subseteq \mathbb{R}^k$.

The parameter is what the experiment is trying to learn; the model is the physics, written as a statement about what data each possible value of the parameter would produce. Nothing in the definition is dimensionful, but every component of θ in a physical application carries an SI dimension — a mass in kg, a rate in 1/s, a cross-section in m^2 — and the estimators below inherit it. What is dimensionless is everything built from a *ratio* of likelihoods: the test statistics of Section 11.5, the p-values and significances read off them, and the trials factor, global p-value and global significance of Section 11.6. The dimensionful quantities in that last section are the scanned range and the resolution that fix the correction, not the correction itself.

The likelihood function, and with it most of the vocabulary of this section — parameter, statistic, likelihood, sufficiency, efficiency, and the information of Definition 11.60 — is Fisher's, introduced in a single paper [487].

Definition 11.54 (Likelihood)**.** Given observed data $x \in \mathcal{X}$, the *likelihood function* is $L(\theta) = f(x;\theta)$, regarded as a function of θ with x held fixed at its observed value. For an independent sample $x = (x_1, \ldots, x_n)$ from a common density,

$$L(\theta) = \prod_{i=1}^{n} f(x_i;\theta)\,, \qquad \ell(\theta) = \ln L(\theta) = \sum_{i=1}^{n} \ln f(x_i;\theta)\,. \tag{11.45}$$

Rests on Definition 11.53.

Remark 11.55 (What a likelihood is not). L is not a probability density in θ. The integral $\int_\Theta L(\theta)\,\mathrm{d}\theta$ is not 1, need not be finite, and changes if θ is reparametrised — it has no meaning. Nor is L determined by the data: multiplying f by any factor that depends on x alone leaves the model unchanged and rescales L. What survives both objections is a *ratio* of likelihoods at two parameter values, and that is why every construction below is built from ratios and never from L on its own.

Definition 11.56 (Maximum-likelihood estimator)**.** A *maximum-likelihood estimator* (MLE) is any $\hat\theta = \hat\theta(x)$ with $L(\hat\theta) = \sup_{\theta\in\Theta} L(\theta)$.
Rests on Definition 11.54.

Proposition 11.57 (Invariance)**.** *Let $g : \Theta \to \Theta^*$ be any map and define the* induced likelihood *of $\tau \in \Theta^*$ by*

$$L^*(\tau) = \sup\{L(\theta) : \theta \in \Theta,\ g(\theta) = \tau\}\ . \tag{11.46}$$

If $\hat\theta$ maximises L, then $g(\hat\theta)$ maximises L^*.
Rests on Definition 11.56.

Derivation. *Derives Proposition 11.57.*
For every τ the supremum in Equation (11.46) is taken over a subset of Θ, so $L^*(\tau) \le \sup_\Theta L = L(\hat\theta)$. On the other hand $\hat\theta$ itself lies in the fibre over $\tau = g(\hat\theta)$, so $L^*(g(\hat\theta)) \ge L(\hat\theta)$. The two inequalities force $L^*(g(\hat\theta)) = L(\hat\theta) = \max_\tau L^*(\tau)$. □

Invariance is the property that makes maximum likelihood usable in physics at all: an experiment that estimates a decay rate has thereby estimated the lifetime, with no separate calculation and no ambiguity about which parametrisation was "the right one". It is also, taken with g a projection, exactly the construction of the profile likelihood in Section 11.4.5.

Example 11.58 (Counting experiment)**.** A detector records n events in a fixed exposure, the events being independent and the expected number $\nu > 0$. Then $f(n;\nu) = \nu^n \mathrm{e}^{-\nu}/n!$, so $\ell(\nu) = n\ln\nu - \nu - \ln n!$ and $\frac{\mathrm{d}\ell}{\mathrm{d}\nu} = n/\nu - 1$, which vanishes at $\hat\nu = n$. The second derivative $-n/\nu^2$ is negative there, so $\hat\nu = n$: the estimate of the expected count is the observed count. By Proposition 11.57 the estimate of $\sqrt{\nu}$ is $\sqrt{n}$, and if the exposure is a live time t_{live} then the estimate of the rate $\Gamma = \nu/t_{\mathrm{live}}$ is n/t_{live}, carried in 1/s.
Rests on Definition 11.56 and Proposition 11.57.

11.4.2 Score and Fisher information

Everything asymptotic below needs the model to be smooth in θ and the data to be informative about it. Those requirements are made explicit once, here, and referred to by name afterwards. Let θ_0 denote the true value.

Definition 11.59 (Regularity conditions)**.** A model satisfies the *regularity conditions* at θ_0 when

(R1) *common support*: the set $\{x : f(x;\theta) > 0\}$ does not depend on θ;

(R2) *identifiability*: distinct parameter values give distinct distributions, $\theta \neq \theta' \Rightarrow f(\,\cdot\,;\theta) \neq f(\,\cdot\,;\theta')$;

(R3) *interior point*: θ_0 lies in the interior of Θ;

(R4) *differentiability under the integral*: $\theta \mapsto f(x;\theta)$ is three times continuously differentiable near θ_0, and the first two derivatives may be taken under $\int \mathrm{d}x$;

(R5) *non-degenerate information*: the quantity $I_1(\theta_0)$ of Definition 11.60 is finite and nonzero, and there are a neighbourhood of θ_0 and an integrable $M(x)$ with $|\partial^3 \ln f(x;\theta)/\partial\theta^3| \le M(x)$ throughout it.

Rests on Definitions 11.53 and 11.60.

Each of the five fails somewhere in physics, and the failures are not pathologies of the mathematics: (R1) fails for a uniform density on $[0,\theta]$, (R2) for a signal mass when the signal strength is zero, (R3) for a rate or a squared mass constrained to be non-negative and tested at zero. The last two are exactly the cases Section 11.5.4 has to treat.

Both objects of the next definition, and the word "information" attached to the second of them, are Fisher's [487].

Definition 11.60 (Score and Fisher information)**.** For a one-parameter model the *score* is

$$U(\theta;x) = \frac{\partial \ln f(x;\theta)}{\partial \theta}\,, \tag{11.47}$$

and the *Fisher information* carried by one observation is $I_1(\theta) = \langle U(\theta;X)^2 \rangle$, the expectation taken under $f(\,\cdot\,;\theta)$. For a k-parameter model the information is the $k \times k$ matrix with entries $[I_1(\theta)]_{ab} = \left\langle \frac{\partial \ln f}{\partial \theta^a} \frac{\partial \ln f}{\partial \theta^b} \right\rangle$.

Rests on Definition 11.53.

Lemma 11.61 (Score identities)**.** *Under (R1) and (R4), $\langle U(\theta;X) \rangle = 0$, so $I_1(\theta) = \operatorname{var} U(\theta;X)$, and*

$$I_1(\theta) = -\left\langle \frac{\partial^2 \ln f(X;\theta)}{\partial \theta^2} \right\rangle . \tag{11.48}$$

For an independent sample of size n the total information is $I_n(\theta) = n\, I_1(\theta)$.

Rests on Definitions 11.59 and 11.60.

Derivation. *Derives Lemma 11.61.*

Because the support does not move with θ, the domain of the integral below is fixed, and (R4) licenses differentiating under it:

$$\langle U \rangle = \int \frac{1}{f}\frac{\partial f}{\partial \theta}\, f \,\mathrm{d}x = \frac{\partial}{\partial \theta}\int f \,\mathrm{d}x = \frac{\partial 1}{\partial \theta} = 0\,.$$

Differentiate that identity once more with respect to θ, again under the integral:

$$0 = \frac{\partial}{\partial \theta}\int \left(\frac{\partial \ln f}{\partial \theta}\right) f \,\mathrm{d}x = \int \left(\frac{\partial^2 \ln f}{\partial \theta^2}\right) f \,\mathrm{d}x + \int \left(\frac{\partial \ln f}{\partial \theta}\right)\left(\frac{\partial f}{\partial \theta}\right) \mathrm{d}x\,.$$

In the second integral write $\partial f/\partial\theta = (\partial \ln f/\partial\theta) f$; it becomes $\langle U^2 \rangle = I_1$. Rearranging gives Equation (11.48). Finally, for an independent sample $\ell = \sum_i \ln f(x_i;\theta)$, so the total score is a sum of n independent copies of U, each of mean zero; variances of independent variables add, giving $I_n = n I_1$. □

Information is additive in the data and that is the whole reason a measurement improves with running time: doubling the exposure doubles I_n and, by the bound of the next subsection, halves the smallest attainable variance.

Example 11.62 (Information in a counting experiment)**.** For the Poisson model of Example 11.58, $U(\nu;n) = n/\nu - 1$ and $\partial^2\ell/\partial\nu^2 = -n/\nu^2$, so Equation (11.48) gives $I(\nu) = \langle n \rangle / \nu^2 = 1/\nu$. The information is therefore largest where the expected count is smallest, but the conclusion to draw from that is the opposite of the obvious one, because

the bound it supplies is a bound on an *absolute* variance. By the Cramér–Rao inequality of the next subsection, Equation (11.53),

$$\operatorname{var}\hat{\nu} \;\geq\; \frac{1}{I(\nu)} = \nu\,, \qquad \text{so} \qquad \frac{\sqrt{\operatorname{var}\hat{\nu}}}{\nu} \;\geq\; \frac{1}{\sqrt{\nu}}\,. \tag{11.49}$$

A rare process is thus measured *well* in absolute terms — the standard deviation $\sqrt{\nu}$ shrinks as the process gets rarer — and *badly* in fractional terms, the fractional uncertainty $\nu^{-1/2}$ growing without bound as $\nu \to 0$. Ten expected events are known to ± 3.2 events, which is about 32 per cent; 1×10^6 expected events are known to $\pm 1 \times 10^3$ events, which is 0.1 per cent. The scale-free comparison is the information about $\ln \nu$, which by the same calculation is $I(\ln \nu) = \nu^2 I(\nu) = \nu$: it is *smallest* for a rare process, and that is the honest statement of why a rare process needs a long exposure.

Rests on Example 11.58, Lemma 11.61, and Theorem 11.64.

11.4.3 The Cramér–Rao bound

The subject of this subsection is the information inequality [870, 882], universally called the Cramér–Rao bound; Remark 11.66 records why that name and the priority disagree. It rests on one algebraic fact about second moments, which the treatise states and proves here rather than importing: Chapter 12, where a reader would look for the Cauchy–Schwarz inequality, reserves its headings and proves nothing, and Chapter 5 likewise leaves the Schwarz inequality a reserved heading with no content.

Lemma 11.63 (Cauchy–Schwarz for random variables)**.** *Let V and W be random variables of finite variance. Then*

$$\operatorname{cov}(V,W)^2 \;\leq\; \operatorname{var} V \cdot \operatorname{var} W\,, \tag{11.50}$$

with equality if and only if there are constants $(a,c) \neq (0,0)$ with $a\,(V - \langle V\rangle) + c\,(W - \langle W\rangle) = 0$ with probability one.

Rests on Definitions 11.6 and 11.11.

Derivation. *Derives Lemma 11.63.*

Write $\tilde{V} = V - \langle V\rangle$ and $\tilde{W} = W - \langle W\rangle$, both of mean zero and finite second moment. Their product is integrable, since $\left|\tilde{V}\tilde{W}\right| \leq \frac{1}{2}(\tilde{V}^2 + \tilde{W}^2)$, so $\operatorname{cov}(V,W) = \left\langle \tilde{V}\tilde{W} \right\rangle$ is a finite number and

$$\phi(s) = \left\langle \left(s\tilde{V} + \tilde{W}\right)^2 \right\rangle = s^2 \operatorname{var} V + 2s \operatorname{cov}(V,W) + \operatorname{var} W \;\geq\; 0 \qquad \text{for every } s \in \mathbb{R}\,. \tag{11.51}$$

If $\operatorname{var} V = 0$ then $\tilde{V} = 0$ almost surely, both sides of Equation (11.50) vanish, and the stated equality condition holds with $(a,c) = (1,0)$. Otherwise ϕ is a genuine quadratic that is nowhere negative, so its discriminant is non-positive: $4\operatorname{cov}(V,W)^2 - 4 \operatorname{var} V \operatorname{var} W \leq 0$, which is Equation (11.50). Equality holds exactly when the discriminant vanishes, i.e. when ϕ has a real root s_0; and $\phi(s_0) = 0$ says that the non-negative variable $\left(s_0\tilde{V} + \tilde{W}\right)^2$ has zero mean, hence vanishes almost surely, which is the stated condition with $(a,c) = (s_0, 1)$. □

Theorem 11.64 (Cramér–Rao inequality)**.** *Let the model satisfy (R1) and (R4), let the information be non-degenerate,*

$$0 < I(\theta) < \infty\,, \tag{11.52}$$

and let $T(X)$ be an estimator with finite variance and mean $\langle T\rangle = \theta + b(\theta)$, where the bias *$b$ is differentiable and $\partial/\partial\theta$ may be taken under $\int T f \,\mathrm{d}x$. Then*

$$\operatorname{var} T \;\geq\; \frac{\left(1 + b'(\theta)\right)^2}{I(\theta)}\,. \tag{11.53}$$

In particular an unbiased estimator has $\operatorname{var} T \geq 1/I(\theta)$*, which for an independent sample of size* n *is* $1/(nI_1(\theta))$*.*
Rests on Definitions 11.59 and 11.60 and Lemmas 11.61 and 11.63.

Both halves of Equation (11.52) are load-bearing and neither is cosmetic: finiteness is what lets the Cauchy–Schwarz step be applied to the score at all, since $\operatorname{var} U = I(\theta)$ must be a number, and non-vanishing is what lets Equation (11.53) divide by it. Where the regularity conditions of Definition 11.59 are in force, Equation (11.52) is the first half of their clause (R5) and nothing new is being assumed; the theorem is stated without (R2), (R3) and (R5) because it needs none of the rest of them.

Derivation. *Derives Theorem 11.64.*
By Lemma 11.61 the score has mean zero, so $\operatorname{cov}(T, U) = \langle TU \rangle - \langle T \rangle \langle U \rangle = \langle TU \rangle$. Evaluate that expectation by the same manoeuvre as before, writing $Uf = \partial f / \partial \theta$:

$$\langle TU \rangle = \int T \, \frac{\partial f}{\partial \theta} \, \mathrm{d}x = \frac{\partial}{\partial \theta} \int T f \, \mathrm{d}x = \frac{\partial}{\partial \theta} \left(\theta + b(\theta) \right) = 1 + b'(\theta) \, . \tag{11.54}$$

Now apply Lemma 11.63 to T and U, whose variances are finite by hypothesis and by Equation (11.52) respectively:

$$\left(1 + b'(\theta) \right)^2 = \operatorname{cov}(T, U)^2 \leq \operatorname{var} T \cdot \operatorname{var} U = \operatorname{var} T \cdot I(\theta) \, ,$$

which is Equation (11.53). □

Corollary 11.65 (When the bound is attained)**.** *Equality holds in Equation (11.53) for a given* θ *if and only if* $U(\theta; x) = c(\theta) \left(T(x) - \langle T \rangle \right)$ *with probability one, for some* $c(\theta)$*. If this holds for all* θ *in an interval then, integrating in* θ*,*

$$\ln f(x; \theta) = A(\theta) \, T(x) + B(\theta) + C(x) \, , \tag{11.55}$$

a one-parameter exponential family with T *as its natural sufficient statistic.*
Rests on Theorem 11.64 and Lemma 11.63.

Derivation. *Derives Corollary 11.65.*
By Lemma 11.63 equality holds exactly when the two centred variables are proportional with probability one; since $\operatorname{var} U = I(\theta) > 0$ the proportionality can be solved for the score, giving $U = c(\theta)(T - \langle T \rangle)$ almost surely. Given that for every θ, integrate $\partial \ln f / \partial \theta = c(\theta)(T(x) - \langle T \rangle_\theta)$ with respect to θ: the x-dependence enters only through the factor $T(x)$ multiplying $\int c \, \mathrm{d}\theta$, and the remaining terms are functions of θ alone plus a constant of integration $C(x)$. □

So the bound is achievable at finite sample size only inside the exponential family; the Poisson model of Example 11.62 is such a case, and indeed $\operatorname{var} \hat{\nu} = \operatorname{var} n = \nu = 1/I(\nu)$, saturating Equation (11.53) exactly. Outside that family the bound is still true and still useful, because Theorem 11.67 shows the MLE attains it asymptotically.

Remark 11.66 (Attribution: the name and the priority disagree)*.* The inequality was obtained independently, within a few years of one another, by Fréchet, Darmois, Rao and Cramér; the name that stuck records only two of the four, and neither of those two was first. The earliest published statement is Fréchet's, in 1943 [870]; Rao's independent derivation, which is the one that introduced the information-geometric reading now standard, appeared in 1945 [882]; Cramér's is later still, in his 1946 textbook. This treatise keeps the customary name "Cramér–Rao" because that is what a reader will meet everywhere else, and cites the two papers it actually has — [870, 882] — rather than the book, for which it carries no bibliography entry at all. A reader tracing the priority should start from Fréchet, not from either of the names in the title. The statement above is in any case derived in full and stands on its derivation.

11.4.4 Consistency and asymptotic normality

Theorem 11.67 (Asymptotics of the MLE)**.** *Let $X_1, \dots, X_n$ be independent and identically distributed with density $f(\,\cdot\,;\theta_0)$, and let the regularity conditions (R1)–(R5) hold at θ_0. Then there is a sequence $\hat\theta_n$ of solutions of the score equation $\ell_n'(\theta) = 0$ such that*

1. *$\hat\theta_n \to \theta_0$ in probability (*consistency*); and*
2. *$\sqrt{n}\left(\hat\theta_n - \theta_0\right) \to \mathcal{N}(0,\, I_1(\theta_0)^{-1})$ in distribution (*asymptotic normality*).*

The same holds in k parameters with $I_1(\theta_0)^{-1}$ the inverse of the information matrix.
Rests on Definitions 11.56 and 11.59, Lemmas 11.52 and 11.61, Theorem 11.46, and Corollary 11.51.

Derivation of (ii), given (i). *Derives Theorem 11.67.*

Write $\ell_n(\theta) = \sum_i \ln f(X_i;\theta)$ and expand its derivative about θ_0 with a Lagrange remainder, which (R4) permits:

$$0 = \ell_n'(\hat\theta_n) = \ell_n'(\theta_0) + \left(\hat\theta_n - \theta_0\right)\ell_n''(\theta_0) + \tfrac{1}{2}\left(\hat\theta_n - \theta_0\right)^2 \ell_n'''(\bar\theta_n)\,, \tag{11.56}$$

with $\bar\theta_n$ between θ_0 and $\hat\theta_n$. Solve for the deviation and multiply by $\sqrt{n}$:

$$\sqrt{n}\left(\hat\theta_n - \theta_0\right) = \frac{n^{-1/2}\,\ell_n'(\theta_0)}{-n^{-1}\ell_n''(\theta_0) - \tfrac{1}{2}n^{-1}\left(\hat\theta_n - \theta_0\right)\ell_n'''(\bar\theta_n)}\,. \tag{11.57}$$

Treat the three pieces separately.

The numerator is $n^{-1/2}\sum_i U(\theta_0;X_i)$, a normalised sum of independent identically distributed variables of mean zero (Lemma 11.61) and variance $I_1(\theta_0)$, finite and nonzero by (R5). Theorem 11.46 therefore gives $n^{-1/2}\ell_n'(\theta_0) \to \mathcal{N}(0, I_1(\theta_0))$ in distribution.

The first term of the denominator is $-n^{-1}\sum_i \partial^2 \ln f(X_i;\theta_0)/\partial\theta^2$, an average of independent identically distributed variables whose common mean is $I_1(\theta_0)$ by Equation (11.48) — an identity that presupposes the summand integrable, and asserts nothing about its second moment. Nothing in (R1)–(R5) bounds that second moment, so Corollary 11.51, which is the Chebyshev form and needs a finite variance, does not apply here; the weak law in the form that needs only integrability [1894] gives convergence to $I_1(\theta_0)$ in probability.

The second term of the denominator is bounded in absolute value by $\tfrac{1}{2}\left|\hat\theta_n - \theta_0\right| \cdot n^{-1}\sum_i M(X_i)$, using the domination in (R5). The average converges in probability to $\langle M\rangle < \infty$, and $\left|\hat\theta_n - \theta_0\right| \to 0$ in probability by (i); the product therefore tends to zero in probability.

The two denominator terms therefore converge in probability, by the sum clause of Lemma 11.52, to the constant $I_1(\theta_0)$, which is nonzero by (R5). Equation (11.57) is a *quotient*, not a sum or a product, so the passage to the limit is the quotient clause of Lemma 11.52 — available exactly because $I_1(\theta_0) \neq 0$, and resting on the convergence $1/B_n \to 1/I_1(\theta_0)$ in probability established at Equation (11.44). The ratio therefore converges in distribution to $\mathcal{N}(0, I_1(\theta_0))/I_1(\theta_0) = \mathcal{N}(0, I_1(\theta_0)^{-1})$, since scaling a Gaussian by $1/I_1$ scales its variance by $1/I_1^2$. □

The variance $1/(nI_1)$ is precisely the Cramér–Rao bound Equation (11.53) for an unbiased estimator: the MLE is *asymptotically efficient* in Fisher's sense [487], wasting none of the information in the data in the limit of many observations. That is the whole case for maximum likelihood, and it is an asymptotic case only — at finite n the MLE can be biased, and Example 11.58 is the exception rather than the rule in being exactly unbiased.

The consistency statement (i) has a short heart and a long technical remainder, and it is worth separating them. The heart is an inequality of Jensen's type, used nowhere else in this treatise and therefore proved here rather than quoted.

Lemma 11.68 (Jensen's inequality for the logarithm)**.** *Let $Y > 0$ almost surely with $\langle Y \rangle < \infty$. Then*

$$\langle \ln Y \rangle \;\le\; \ln \langle Y \rangle \,, \tag{11.58}$$

with equality if and only if $Y = \langle Y \rangle$ with probability one. (The left side may be $-\infty$, in which case the inequality is trivially true.)

Rests on Theorem 7.35.

Derivation. *Derives Lemma 11.68.*

Put $a = \langle Y \rangle$, which is finite and strictly positive because $Y > 0$. The logarithm has second derivative $-1/y^2 < 0$ on $(0, \infty)$, so it is strictly concave there and its graph lies below the tangent at a:

$$\ln y \;\le\; \ln a + \frac{y - a}{a} \qquad \text{for every } y > 0 \,, \tag{11.59}$$

with equality only at $y = a$. To see Equation (11.59) without appealing to a general theory of convexity, apply the mean value theorem (Theorem 7.35) to $h(y) = \ln y - \ln a - (y - a)/a$: $h(a) = 0$ and $h'(y) = 1/y - 1/a$, which is positive for $y < a$ and negative for $y > a$, so h increases up to a and decreases after it, attaining its strict maximum 0 there. Now put $y = Y$ in Equation (11.59) and take expectations, which is legitimate because the right-hand side is integrable:

$$\langle \ln Y \rangle \;\le\; \ln a + \frac{\langle Y \rangle - a}{a} = \ln a = \ln \langle Y \rangle \,.$$

Equality forces the non-positive variable $\ln Y - \ln a - (Y - a)/a$ to have zero mean, hence to vanish almost surely, which by the strictness in Equation (11.59) means $Y = a$ almost surely. □

Apply Lemma 11.68 to the likelihood ratio $Y = f(X;\theta)/f(X;\theta_0)$, which is positive almost surely because (R1) makes the support common to all θ, and whose mean is $\int f(x;\theta)\,\mathrm{d}x = 1$. For any $\theta \neq \theta_0$,

$$\left\langle \ln \frac{f(X;\theta)}{f(X;\theta_0)} \right\rangle \le \ln \left\langle \frac{f(X;\theta)}{f(X;\theta_0)} \right\rangle = \ln \int f(x;\theta)\,\mathrm{d}x = 0 \,, \tag{11.60}$$

with equality only if the ratio is constant — and, its mean being 1, only if that constant is 1, i.e. only if the two distributions coincide, which (R2) excludes. So the expected log-likelihood per observation is strictly maximised at the true value, and by Corollary 11.51 the observed $n^{-1}[\ell_n(\theta) - \ell_n(\theta_0)]$ converges to that negative number for each fixed θ. Passing from "for each fixed θ" to a statement about the *global* maximiser of the likelihood needs that convergence to be uniform on Θ, or a compactness argument in its place; that step is Wald's, under conditions weaker than the ones assumed here [950], and it is not carried out in this treatise.

Clause (i) of Theorem 11.67 claims less than that, and the less is enough for clause (ii): it asserts a consistent sequence of *solutions of the score equation*, which the expansion already in hand delivers.

Derivation of (i). *Derives Theorem 11.67.*

Take $k = 1$; the modification for k parameters is given at the end. Write $I = I_1(\theta_0)$, which is finite and strictly positive by (R5), and let $a_0 > 0$ be small enough that $[\theta_0 - a_0, \theta_0 + a_0]$ lies both inside Θ, which (R3) permits, and inside the neighbourhood on which (R5) supplies the dominating function M. For $0 < a \le a_0$ and $\theta = \theta_0 \pm a$, expand with a Lagrange remainder, as (R4) allows:

$$\frac{\ell_n(\theta) - \ell_n(\theta_0)}{n} = (\theta - \theta_0)\,\frac{\ell_n'(\theta_0)}{n} + \frac{(\theta - \theta_0)^2}{2}\,\frac{\ell_n''(\theta_0)}{n} + \frac{(\theta - \theta_0)^3}{6}\,\frac{\ell_n'''(\bar{\theta})}{n} \,, \tag{11.61}$$

with $\bar\theta$ between θ_0 and θ.

Each of the three coefficients is an average of independent identically distributed terms. The first, $n^{-1}\sum_i U(\theta_0;X_i)$, converges in probability to 0, the score having mean zero by Lemma 11.61; the second converges in probability to $-I$ by Equation (11.48); and the third is bounded in absolute value by $n^{-1}\sum_i M(X_i)$, which converges in probability to $\bar M = \langle M\rangle < \infty$. Corollary 11.51 gives the first of these, the score having variance $I_1(\theta_0)$ by (R5). It gives neither of the other two: (R5) bounds the variance of $\partial^2 \ln f/\partial\theta^2$ no more than it bounds that of M, which it assumes integrable and nothing more, and Equation (11.48) says only that the second derivative has a mean. Both are averages of integrable summands, so for both the weak law in the form that needs only integrability is used instead [1894].

Now shrink the radius, requiring in addition

$$0 < a < \frac{I}{\bar M + 1}\,, \tag{11.62}$$

and let $E_n(a)$ be the event on which all three of

$$\left|\frac{\ell_n'(\theta_0)}{n}\right| < \frac{aI}{16}\,, \qquad \left|\frac{\ell_n''(\theta_0)}{n} + I\right| < \frac{I}{4}\,, \qquad \frac{1}{n}\sum_{i=1}^{n} M(X_i) < \bar M + 1$$

hold. By the previous paragraph $\Pr(E_n(a)) \to 1$. On $E_n(a)$, and for either sign of $\theta - \theta_0 = \pm a$, the three terms of Equation (11.61) are bounded by $a^2 I/16$, by $-a^2 I/2 + a^2 I/8$ and, using Equation (11.62), by $a^3(\bar M + 1)/6 < a^2 I/6$ respectively, so that

$$\frac{\ell_n(\theta_0 \pm a) - \ell_n(\theta_0)}{n} \;<\; a^2 I\left(\frac{1}{16} - \frac{1}{2} + \frac{1}{8} + \frac{1}{6}\right) \;<\; 0\,. \tag{11.63}$$

From Equations (11.61) and (11.62) (bound the three terms on the event $E_n(a)$ and add).

So on $E_n(a)$ the log-likelihood is strictly smaller at both endpoints of $[\theta_0 - a, \theta_0 + a]$ than at its midpoint. It is continuous there, so by the extreme value theorem (Theorem 7.24) it attains a maximum on that interval; the maximum is at neither endpoint, hence at an interior point, where the derivative of a differentiable function vanishes. The score equation $\ell_n'(\theta) = 0$ therefore has a solution in $(\theta_0 - a, \theta_0 + a)$.

Define $\hat\theta_n$ to be a solution of the score equation in $[\theta_0 - a_0, \theta_0 + a_0]$ nearest to θ_0 when one exists — the solution set is closed, being the zero set of a continuous function, so a nearest point is attained — and any fixed point of Θ otherwise. For every a satisfying Equation (11.62), $E_n(a)$ implies $\left|\hat\theta_n - \theta_0\right| < a$, so $\Pr(\left|\hat\theta_n - \theta_0\right| < a) \to 1$; and since the event grows with a, the same holds for every $a > 0$. That is convergence in probability.

In k parameters, replace the interval by the closed ball of radius a about θ_0 and its endpoints by the sphere, expanding along $\theta = \theta_0 + a\boldsymbol{e}$ with $\boldsymbol{e}$ a unit vector. The linear term is bounded by a times the length of $n^{-1}\nabla\ell_n$; the quadratic term is $-\frac{1}{2}a^2\,\boldsymbol{e}^{\mathsf T} I \boldsymbol{e}$ up to the same error; and the cubic term is bounded as before, with M dominating every third partial derivative. Read in k parameters, (R5) makes I positive definite, and $\boldsymbol{e} \mapsto \boldsymbol{e}^{\mathsf T} I \boldsymbol{e}$ is continuous and strictly positive on the unit sphere, which is closed and bounded, so it has a strictly positive minimum λ (Theorem 7.24); putting λ in place of I throughout gives Equation (11.63) at every point of the sphere, and the argument closes as before with the gradient in place of the derivative. □

Remark 11.69 (In what sense the sequence solves the score equation). The sequence just constructed solves $\ell_n'(\hat\theta_n) = 0$ on the event $E_n(a_0)$, whose probability tends to one, and is defined arbitrarily on the complement. That is the standard reading of Theorem 11.67(i), and the arbitrariness is immaterial to both clauses: each is a statement about a limit in probability or in distribution, and neither is affected by altering the sequence on events whose probability tends to zero. What is *not* claimed, here or anywhere in this chapter,

is that the root so chosen is the global maximiser of the likelihood; that is the content of Wald's theorem [950], and a likelihood with several local maxima can have a consistent root far from its highest peak at any finite n.

11.4.5 Nuisance parameters and the profile likelihood

A real measurement almost never has a one-dimensional parameter. A search for a signal must simultaneously determine the size of the background, the detector efficiency and the energy scale, none of which is of interest and all of which are unknown. Write

$$\theta = (\mu, \boldsymbol{\nu}) , \qquad \mu \in \mathbb{R} , \quad \boldsymbol{\nu} \in \mathbb{R}^{m} , \tag{11.64}$$

with μ the *parameter of interest* and $\boldsymbol{\nu}$ the *nuisance parameters*.

Definition 11.70 (Profile likelihood)**.** The *profile likelihood* is

$$L_{\mathrm{p}}(\mu) = L\Big(\mu, \hat{\hat{\boldsymbol{\nu}}}(\mu)\Big) , \qquad \hat{\hat{\boldsymbol{\nu}}}(\mu) = \arg\max_{\boldsymbol{\nu}} L(\mu, \boldsymbol{\nu}) , \tag{11.65}$$

the double hat marking a maximisation carried out at fixed μ. The *profile likelihood ratio* is $\lambda(\mu) = L_{\mathrm{p}}(\mu)/L(\hat{\mu}, \hat{\boldsymbol{\nu}})$, where $(\hat{\mu}, \hat{\boldsymbol{\nu}})$ is the unconstrained MLE.
Rests on Definitions 11.54 and 11.56.

Proposition 11.71 (Elementary properties)**.** $0 < \lambda(\mu) \leq 1$ *for every* μ*, with* $\lambda(\hat{\mu}) = 1$*; and* L_{p} *is maximised at* $\hat{\mu}$*.*
Rests on Definition 11.70 and Proposition 11.57.

Derivation. *Derives Proposition 11.71.*

L_{p} is the induced likelihood Equation (11.46) for the map $g(\mu, \boldsymbol{\nu}) = \mu$, so Proposition 11.57 applies verbatim: g of the unconstrained maximiser, namely $\hat{\mu}$, maximises L_{p}, and the maximum value is $L(\hat{\mu}, \hat{\boldsymbol{\nu}})$. The ratio is therefore at most 1 and equals 1 at $\hat{\mu}$; it is positive because $L_{\mathrm{p}}(\mu) \geq L(\mu, \boldsymbol{\nu}) > 0$ for any admissible $\boldsymbol{\nu}$. □

Proposition 11.72 (Nuisance parameters cost information)**.** *Partition the information matrix of the full model as*

$$I = \begin{pmatrix} I_{\mu\mu} & I_{\mu\nu} \\ I_{\nu\mu} & I_{\nu\nu} \end{pmatrix} , \qquad I_{\nu\mu} = I_{\mu\nu}^{\mathsf{T}} , \tag{11.66}$$

with $I_{\nu\nu}$ *positive definite. Then the asymptotic variance of* $\hat{\mu}$ *is* $(n I_{\mathrm{p}})^{-1}$ *with*

$$I_{\mathrm{p}} = I_{\mu\mu} - I_{\mu\nu} I_{\nu\nu}^{-1} I_{\nu\mu} \;\leq\; I_{\mu\mu} , \tag{11.67}$$

with equality if and only if $I_{\mu\nu} = 0$*.*
Rests on Definition 11.60 and Theorem 11.67.

Derivation. *Derives Proposition 11.72.*

By Theorem 11.67 the asymptotic covariance of $\sqrt{n}(\hat{\theta} - \theta_0)$ is I^{-1}, so the asymptotic variance of $\sqrt{n}(\hat{\mu} - \mu_0)$ is the $\mu\mu$ entry of I^{-1}. To identify it, solve $I\,(x, \boldsymbol{y})^{\mathsf{T}} = (1, \boldsymbol{0})^{\mathsf{T}}$: the lower block gives $I_{\nu\mu} x + I_{\nu\nu} \boldsymbol{y} = \boldsymbol{0}$, hence $\boldsymbol{y} = -I_{\nu\nu}^{-1} I_{\nu\mu} x$, and substituting in the upper block gives $\left(I_{\mu\mu} - I_{\mu\nu} I_{\nu\nu}^{-1} I_{\nu\mu}\right) x = 1$. By construction $x = \left(I^{-1}\right)_{\mu\mu}$, so $\left(I^{-1}\right)_{\mu\mu} = I_{\mathrm{p}}^{-1}$. Finally $I_{\mu\nu} I_{\nu\nu}^{-1} I_{\nu\mu} \geq 0$ because $I_{\nu\nu}^{-1}$ is positive definite, and it vanishes exactly when $I_{\mu\nu} = 0$. □

The content of Equation (11.67) is that not knowing the background costs precision on the signal, and costs nothing only when the two are *information-orthogonal*. Designing an analysis so that $I_{\mu\nu}$ is small — a control region that fixes the background without touching the signal region — is the practical form of that statement.

Remark 11.73 (The profile is not a likelihood). L_{p} is not the likelihood of any probability model for the data: there is generally no density $h(x;\mu)$ with $h(x;\mu) = L_{\mathrm{p}}(\mu)$ for all x, because the maximising $\hat{\boldsymbol{\nu}}(\mu)$ depends on x as well as on μ. The identities of Lemma 11.61 therefore do not hold for it, and its curvature can understate the true uncertainty at finite sample size. What survives is the asymptotic statement proved in Section 11.5.4, which is the only property the search analyses of Part XI use [2172].

11.5 Hypothesis testing

Estimation asks what value a parameter has. Testing asks a coarser and often more consequential question: is a proposed value compatible with the data at all? The apparatus is small — a critical region, its size, its power — and one theorem, due to Neyman and Pearson, says which critical region to use. Everything a modern search does is a corollary of that theorem plus the asymptotic distribution derived in Section 11.5.4.

11.5.1 Tests, size, power and p-values

Definition 11.74 (Hypotheses and tests)**.** A *hypothesis* is a subset $\Theta_0 \subseteq \Theta$; it is *simple* if Θ_0 is a single point and *composite* otherwise. A *test* is a measurable function $\psi : \mathcal{X} \to [0,1]$ giving the probability with which the null hypothesis $H_0 : \theta \in \Theta_0$ is rejected when x is observed; a test is *non-randomised* when ψ is the indicator of a *critical region* $W \subseteq \mathcal{X}$. Its *size* is

$$\alpha = \sup_{\theta \in \Theta_0} \langle \psi \rangle_\theta \,, \tag{11.68}$$

and its *power* against an alternative $\theta \in \Theta_1$ is $\beta(\theta) = \langle \psi \rangle_\theta$.

Rests on Definition 11.53.

Size is the probability of rejecting a true null — the rate of false discovery claims, fixed in advance by the experimenter. Power is the probability of rejecting a false one, and is not free: it is whatever the data and the chosen critical region deliver.

Definition 11.75 (p-value)**.** Let $t(X)$ be a test statistic, large values of which disfavour a simple H_0. The *p-value* of an observation t_{obs} is

$$p = \Pr(t(X) \geq t_{\mathrm{obs}} \mid H_0) \,. \tag{11.69}$$

Rests on Definition 11.74.

Proposition 11.76 (Uniformity)**.** *If $t(X)$ has a continuous, strictly decreasing survival function $G(s) = \Pr(t \geq s \mid H_0)$ on its support, then $p = G(t(X))$ is uniformly distributed on $[0,1]$ under H_0. Consequently the test that rejects when $p \leq \alpha$ has size exactly α.*

Rests on Definitions 11.74 and 11.75.

Derivation. *Derives Proposition 11.76.*

For $\alpha \in (0,1)$, G is invertible on its range, and G is decreasing, so $\{G(t) \leq \alpha\} = \{t \geq G^{-1}(\alpha)\}$. Hence $\Pr(p \leq \alpha \mid H_0) = \Pr(t \geq G^{-1}(\alpha) \mid H_0) = G(G^{-1}(\alpha)) = \alpha$, which is the distribution function of the uniform law on $[0,1]$. □

That uniformity is what makes a p-value comparable across experiments: it is a calibrated quantity, and a threshold on it means the same thing whatever the statistic and whatever the model. It is also the source of the most persistent misreading in the subject, which is worth stating without diplomacy.

Remark 11.77 (A p-value is not the probability that the hypothesis is true). The p-value is a probability computed *assuming H_0 holds*. It is $\Pr(\text{data at least this extreme} \mid H_0)$. It is not $\Pr(H_0 \mid \text{data})$, and the two are different numbers that answer different questions. Nothing in Equation (11.69) even mentions the alternative hypothesis or the plausibility of H_0 before the data arrived, and both enter the second quantity:

$$\Pr(H_0 \mid x) = \frac{f(x;\theta_0)\,\pi_0}{f(x;\theta_0)\,\pi_0 + \int_{\Theta_1} f(x;\theta)\,\pi(\theta)\,\mathrm{d}\theta}\,, \tag{11.70}$$

with π_0 the prior probability of H_0 and π the prior density over the alternative. The gap is not small. Take an observation with $q = 25$, which Section 11.5.5 will show corresponds to $p = 2.87 \times 10^{-7}$ — a "five sigma" result.

The comparison needs the direction of one inequality stated, or it proves nothing. What Equation (11.80) supplies is the *maximised* likelihood ratio $\mathrm{e}^{q/2}$, whereas Equation (11.70) contains the likelihood *averaged* over the prior. Since π is a probability density, integrating to 1,

$$\int_{\Theta_1} f(x;\theta)\,\pi(\theta)\,\mathrm{d}\theta \;\le\; \sup_{\theta\in\Theta_1} f(x;\theta) \;=\; f(x;\hat\theta) \;=\; \mathrm{e}^{q/2} f(x;\theta_0)\,, \tag{11.71}$$

the last two equalities holding whenever the unconstrained maximiser lies in Θ_1, which is the case here because $q > 0$. So replacing the average by the maximum can only *inflate* the odds against H_0: whatever the prior, the posterior odds on the alternative are at most $\mathrm{e}^{q/2}(1-\pi_0)/\pi_0$, and $\Pr(H_0 \mid x)$ is at least $\left[1 + \mathrm{e}^{q/2}(1-\pi_0)/\pi_0\right]^{-1}$.

With $\mathrm{e}^{q/2} = 2.68 \times 10^5$ and prior odds of 1 to 1000 against the alternative, the posterior odds are therefore at most $2.68 \times 10^5 \times 1 \times 10^{-3} = 2.68 \times 10^2$, so $\Pr(H_0 \mid x) \ge 1/(1 + 2.68 \times 10^2) = 3.7 \times 10^{-3}$. The inequality runs the helpful way: the true posterior probability of the null is *at least* four orders of magnitude larger than the p-value — larger by a factor of at least 1.3×10^4 — and using a real prior density in place of its maximum can only widen the gap. The two numbers were never the same quantity.

Two corollaries follow. A small p-value is evidence against H_0 only in the presence of an alternative that predicts the observation better; with no such alternative it is a sign that something in the model is wrong, and the something is at least as likely to be the background estimate as the physics. And a p-value cannot be converted into a probability that a discovery is real without supplying a prior, which is a judgement and must be declared as one.

11.5.2 The Neyman–Pearson lemma

The lemma below is Neyman and Pearson's, from the joint paper of 1933 that created the whole framework of size, power and critical regions used above [725].

Theorem 11.78 (Neyman–Pearson). *Let H_0 and H_1 be simple, with densities f_0 and f_1. Fix $k \ge 0$ and let*

$$\psi^*(x) = \begin{cases} 1 & f_1(x) > k f_0(x)\,, \\ \gamma(x) & f_1(x) = k f_0(x)\,, \\ 0 & f_1(x) < k f_0(x)\,, \end{cases} \tag{11.72}$$

for any γ taking values in $[0,1]$, and write $\alpha = \langle\psi^*\rangle_0$ for its size. Then every test ψ with $\langle\psi\rangle_0 \le \alpha$ satisfies $\langle\psi\rangle_1 \le \langle\psi^*\rangle_1$: no test of size at most α is more powerful.

Rests on Definition 11.74.

Derivation. *Derives Theorem 11.78.*

Consider the function

$$D(x) = \left(\psi^*(x) - \psi(x)\right)\left(f_1(x) - k f_0(x)\right)\,.$$

It is non-negative everywhere. Where $f_1 > k f_0$ the second factor is positive and $\psi^* = 1 \geq \psi$, so the first is non-negative; where $f_1 < k f_0$ the second factor is negative and $\psi^* = 0 \leq \psi$, so the first is non-positive; where $f_1 = k f_0$ the second factor vanishes. Integrating,

$$0 \leq \int D \, \mathrm{d}x = \left(\langle \psi^* \rangle_1 - \langle \psi \rangle_1 \right) - k \left(\langle \psi^* \rangle_0 - \langle \psi \rangle_0 \right) ,$$

so that $\langle \psi^* \rangle_1 - \langle \psi \rangle_1 \geq k \, (\alpha - \langle \psi \rangle_0)$. The right-hand side is non-negative because $k \geq 0$ and $\langle \psi \rangle_0 \leq \alpha$ by hypothesis. □

The lemma answers the design question completely for a simple-versus-simple test: order the sample space by the likelihood ratio f_1/f_0 and reject the largest values. It is the reason every construction that follows is built from a likelihood ratio rather than from anything else. For composite hypotheses no uniformly most powerful test exists in general, and the statistic of Section 11.5.4 — the ratio of maximised likelihoods — is the standard substitute: not optimal by any theorem, but reducing to the Neyman–Pearson statistic when both hypotheses are simple.

Remark 11.79 (Attribution). The lemma is Neyman and Pearson's, from their joint work of the early 1930s, and the reference is [725]. Two traps attend that citation and are recorded here because both have been fallen into. The Pearson is Egon, not his father Karl, and not either of the two other Pearsons this bibliography carries, who work on silicon and on convection cells. And Crossref stores the title with the issue's article number "IX." prefixed to it; that numeral is not part of the title and is dropped in the bibliography entry.

11.5.3 The chi-squared distribution

Definition 11.80 (Chi-squared)**.** Let $Z_1, \ldots, Z_k$ be independent standard Gaussian variables. The distribution of $\sum_{i=1}^{k} Z_i^2$ is the *chi-squared distribution with k degrees of freedom*, written χ^2_k.

Proposition 11.81 (Density, mean and variance)**.** *The χ^2_k distribution has density*

$$f_k(x) = \frac{1}{2^{k/2}\,\Gamma(k/2)} \, x^{k/2-1} \, \mathrm{e}^{-x/2} , \qquad x > 0 , \tag{11.73}$$

mean k and variance $2k$.

Rests on Definitions 11.42 and 11.80 and Proposition 11.43.

Derivation. *Derives Proposition 11.81.*

Work with the Laplace transform $M_k(s) = \left\langle \mathrm{e}^{-sX} \right\rangle$, which for a distribution on $(0, \infty)$ exists for all $s \geq 0$. For one degree of freedom, completing the exponent,

$$M_1(s) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathrm{e}^{-su^2} \mathrm{e}^{-u^2/2} \, \mathrm{d}u = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathrm{e}^{-(1+2s)u^2/2} \, \mathrm{d}u = (1+2s)^{-1/2} , \tag{11.74}$$

using $\int \mathrm{e}^{-au^2/2} \mathrm{d}u = \sqrt{2\pi/a}$. The k squares are independent, so their transforms multiply exactly as characteristic functions do in Proposition 11.43(iii), giving $M_k(s) = (1+2s)^{-k/2}$.

Now transform the claimed density. Substituting $y = (\tfrac{1}{2} + s)x$,

$$\int_0^{\infty} \frac{x^{k/2-1} \mathrm{e}^{-x/2}}{2^{k/2}\Gamma(k/2)} \mathrm{e}^{-sx} \, \mathrm{d}x = \frac{\left(\tfrac{1}{2}+s\right)^{-k/2}}{2^{k/2}\Gamma(k/2)} \int_0^{\infty} y^{k/2-1} \mathrm{e}^{-y} \, \mathrm{d}y = \frac{\left(\tfrac{1}{2}+s\right)^{-k/2}}{2^{k/2}} = (1+2s)^{-k/2} ,$$

the middle integral being $\Gamma(k/2)$ by definition. The two distributions have the same Laplace transform on $s > 0$; since both are supported on $[0, \infty)$ their transforms extend analytically to $\operatorname{Re} s > -\tfrac{1}{2}$ and agree there, in particular on the imaginary axis, where they are the

characteristic functions of Definition 11.42. Uniqueness of the characteristic function [1446, 1894] then forces the distributions to coincide, which is Equation (11.73).

For the moments, differentiate M_k at $s = 0$: $M_k'(s) = -k(1+2s)^{-k/2-1}$ and $M_k''(s) = k(k+2)(1+2s)^{-k/2-2}$, so $\langle X \rangle = -M_k'(0) = k$ and $\langle X^2 \rangle = M_k''(0) = k(k+2)$, whence $\operatorname{var} X = k(k+2) - k^2 = 2k$. □

Corollary 11.82 (The one degree of freedom tail)**.** *For $z \geq 0$,*

$$\Pr\!\left(\chi^2_1 \geq z^2\right) = 2\,(1 - \Phi(z))\ . \tag{11.75}$$

Rests on Definition 11.80.

Derivation. *Derives Corollary 11.82.*

$\chi^2_1 = Z^2$ with Z standard Gaussian, and $Z^2 \geq z^2$ exactly when $|Z| \geq z$, an event of probability $\Pr(Z \geq z) + \Pr(Z \leq -z) = 2(1 - \Phi(z))$ by symmetry. □

That factor of two is small, obvious, and responsible for more misquoted significances than any other step in the subject. It is tracked explicitly in Section 11.5.5.

Lemma 11.83 (Gaussian quadratic forms)**.** *If $\boldsymbol{Y} \in \mathbb{R}^k$ is Gaussian with mean zero and positive-definite covariance Σ, then $\boldsymbol{Y}^{\mathsf{T}}\Sigma^{-1}\boldsymbol{Y} \sim \chi^2_k$. More generally, if $\boldsymbol{V} \in \mathbb{R}^k$ is Gaussian with mean zero and covariance $\mathbb{1}$ and P is the orthogonal projector onto a subspace of dimension r, then $\|P\boldsymbol{V}\|^2 \sim \chi^2_r$.*

Rests on Definition 11.80.

Derivation. *Derives Lemma 11.83.*

By the spectral theorem for real symmetric matrices — diagonalise Σ by an orthogonal matrix and take the positive square roots of its eigenvalues, which are positive because Σ is positive definite — Σ has a symmetric positive-definite square root $\Sigma^{1/2}$. Put $\boldsymbol{V} = \Sigma^{-1/2}\boldsymbol{Y}$; a linear image of a Gaussian vector is Gaussian, with covariance $\Sigma^{-1/2}\Sigma\,\Sigma^{-1/2} = \mathbb{1}$, so the components of $\boldsymbol{V}$ are independent standard Gaussians. Then $\boldsymbol{Y}^{\mathsf{T}}\Sigma^{-1}\boldsymbol{Y} = \boldsymbol{V}^{\mathsf{T}}\boldsymbol{V} = \sum_i V_i^2$, which is χ^2_k by Definition 11.80. For the second statement choose an orthonormal basis $\boldsymbol{u}_1, \dots, \boldsymbol{u}_r$ of the image of P; the components $\boldsymbol{u}_j \cdot \boldsymbol{V}$ are jointly Gaussian with $\langle (\boldsymbol{u}_i \cdot \boldsymbol{V})(\boldsymbol{u}_j \cdot \boldsymbol{V}) \rangle = \boldsymbol{u}_i \cdot \boldsymbol{u}_j = \delta_{ij}$, hence independent standard Gaussians, and $\|P\boldsymbol{V}\|^2 = \sum_{j=1}^{r} (\boldsymbol{u}_j \cdot \boldsymbol{V})^2$. □

The projector form of Lemma 11.83 has one consequence that metrology uses constantly and that is worth having as a labelled statement rather than rederived at each site.

Corollary 11.84 (Residuals about a weighted mean; the Birge ratio)**.** *Let $x_1, \dots, x_n$ be independent Gaussian measurements of one quantity μ, with known standard uncertainties u_i, and let*

$$\hat{x} = \frac{\sum_i x_i/u_i^2}{\sum_i 1/u_i^2} \tag{11.76}$$

be their inverse-variance weighted mean (Theorem 2.10). Then

$$\chi^2 = \sum_{i=1}^{n} \frac{(x_i - \hat{x})^2}{u_i^2} \sim \chi^2_{n-1}\,, \tag{11.77}$$

whatever the value of μ. In particular $\langle \chi^2 \rangle = n - 1$ with variance $2(n-1)$, and the Birge ratio *$R = \sqrt{\chi^2/(n-1)}$ is the factor by which every u_i must be multiplied to make the set internally consistent, in the sense that the χ^2 recomputed with uncertainties Ru_i equals $n-1$ exactly.*

Rests on Lemma 11.83, Proposition 11.81, and Theorem 2.10.

Derivation. *Derives Corollary 11.84.*

Put $V_i = (x_i - \mu)/u_i$, so that $\boldsymbol{V} \in \mathbb{R}^n$ is Gaussian with mean zero and covariance $\mathbb{1}$. Write $S = \sum_k u_k^{-2}$ and let $\boldsymbol{m}$ be the vector with components $m_i = u_i^{-1}/\sqrt{S}$, which is a unit vector because $\sum_i m_i^2 = S^{-1}\sum_i u_i^{-2} = 1$. From Equation (11.76),

$$\hat{x} - \mu = \frac{1}{S}\sum_j \frac{x_j - \mu}{u_j^2} = \frac{1}{S}\sum_j \frac{V_j}{u_j} = \frac{1}{\sqrt{S}}\,\boldsymbol{m}\cdot\boldsymbol{V}\,, \tag{11.78}$$

and therefore

$$\frac{x_i - \hat{x}}{u_i} = V_i - \frac{\hat{x} - \mu}{u_i} = V_i - m_i\,(\boldsymbol{m}\cdot\boldsymbol{V}) = \big(P\boldsymbol{V}\big)_i\,, \tag{11.79}$$

where $P = \mathbb{1} - \boldsymbol{m}\boldsymbol{m}^{\mathsf{T}}$ is the orthogonal projector onto the hyperplane orthogonal to $\boldsymbol{m}$, of dimension $n-1$. Hence $\chi^2 = \|P\boldsymbol{V}\|^2$, which is χ^2_{n-1} by the second statement of Lemma 11.83; μ has cancelled, as Equation (11.79) shows. The mean and variance are Proposition 11.81 with $k = n-1$, and the rescaling claim is immediate because χ^2 is homogeneous of degree -2 in the uncertainties. □

Remark 11.85 (What the ratio does and does not say). A Birge ratio near unity is consistency, not correctness: it says the scatter of the measurements matches the uncertainties they quote, and it is blind to a bias common to all of them. A ratio well above unity says at least one quoted uncertainty is too small, and gives no information about which. Expanding every uncertainty by R is therefore a confession rather than a correction, and it is what the CODATA adjustments do where inputs disagree [2431]; the worked case is the six modern determinations of the gravitational constant in Chapter 33, where $R \approx 4$. The count of degrees of freedom is $n-1$ and not n because one linear combination of the residuals is forced to vanish by the definition of $\hat{x}$ — that is exactly the content of the projector in Equation (11.79).

Remark 11.86 (What the last derivation imports). The finite-dimensional spectral theorem is proved in this treatise for a self-adjoint operator on a *complex* inner-product space (Theorem 5.75 in Section 5.6, whose infinite-dimensional counterpart is Theorem 12.59); what is used above is its real orthogonal form, for a real symmetric matrix, which is a standard corollary and is nowhere separately stated. It is quoted here, in the same explicit way as in Chapter 15, and the reader should treat it as an assumption of this lemma rather than as something established earlier in the book. What is actually needed is weaker than the full theorem: only the existence of *some* invertible A with $\Sigma = AA^{\mathsf{T}}$, since $\boldsymbol{V} = A^{-1}\boldsymbol{Y}$ then has covariance $\mathbb{1}$ and $\boldsymbol{Y}^{\mathsf{T}}\Sigma^{-1}\boldsymbol{Y} = \boldsymbol{V}^{\mathsf{T}}\boldsymbol{V}$; the symmetric square root is one such A, and Gram–Schmidt applied to the inner product defined by Σ^{-1} supplies a triangular one. The same weaker statement is all that Theorem 11.88 uses when it writes $I^{1/2}$.

11.5.4 The likelihood-ratio statistic and Wilks' theorem

Definition 11.87 (Likelihood-ratio test statistic)**.** For a null hypothesis $H_0 : \theta \in \Theta_0$ inside a model with parameter set Θ, the *likelihood-ratio test statistic* is

$$q = -2\ln\frac{\sup_{\theta\in\Theta_0} L(\theta)}{\sup_{\theta\in\Theta} L(\theta)} = -2\left[\ell(\hat{\theta}_0) - \ell(\hat{\theta})\right] \;\geq\; 0\,, \tag{11.80}$$

where $\hat{\theta}_0$ is the constrained and $\hat{\theta}$ the unconstrained maximum-likelihood estimator. For a simple null $\Theta_0 = \{\theta_0\}$ this is $q(\theta_0) = -2\ln\big[L(\theta_0)/L(\hat{\theta})\big]$; for a parameter of interest with nuisance parameters it is $q(\mu) = -2\ln\lambda(\mu)$ with λ the profile likelihood ratio of Definition 11.70.

Rests on Definitions 11.54, 11.56 and 11.70.

Non-negativity is immediate: the constrained supremum is over a subset, so the ratio is at most 1 and its logarithm at most zero. The statistic is also a pure number — the SI dimensions of θ cancel in the ratio — which is what allows a single tabulated distribution to serve every measurement.

The asymptotic law of that statistic is Wilks' theorem [825]; its hypotheses are stated in full below because the two ways they fail are exactly the two corrections a collider search has to apply.

Theorem 11.88 (Wilks)**.** *Let the model satisfy (R1)–(R5) at the true value θ_0, let the sample be independent and identically distributed of size n, let $\Theta \subseteq \mathbb{R}^k$ and let Θ_0 be, near θ_0, a smooth submanifold of dimension $k - r$ — equivalently, let H_0 impose r smooth, functionally independent constraints. If θ_0 lies in Θ_0 and in the interior of Θ, then under H_0*

$$q \;\longrightarrow\; \chi^2_r \qquad \text{in distribution as } n \to \infty\,, \tag{11.81}$$

where r is the number of parameters constrained by the null.

Rests on Definitions 11.59, 11.80 and 11.87, Theorem 11.67, and Lemmas 11.52 and 11.83.

Derivation, one parameter and a simple null. *Derives Theorem 11.88.*

Take $k = r = 1$ and $\Theta_0 = \{\theta_0\}$. Expand ℓ_n about the unconstrained MLE $\hat\theta_n$, where ℓ_n' vanishes:

$$\ell_n(\theta_0) = \ell_n(\hat\theta_n) + \tfrac{1}{2}\ell_n''(\hat\theta_n)\left(\theta_0 - \hat\theta_n\right)^2 + \tfrac{1}{6}\ell_n'''(\bar\theta_n)\left(\theta_0 - \hat\theta_n\right)^3\,, \tag{11.82}$$

with $\bar\theta_n$ between the two. Multiply by -2:

$$q = \left[\sqrt{n}\left(\hat\theta_n - \theta_0\right)\right]^2 \left(\frac{-\ell_n''(\hat\theta_n)}{n}\right) - \frac{1}{3}\ell_n'''(\bar\theta_n)\left(\theta_0 - \hat\theta_n\right)^3\,. \tag{11.83}$$

From Equation (11.82) (multiply by -2 and rescale the deviation by $\sqrt{n}$).

The first bracket converges in distribution to $\mathcal{N}(0, I_1(\theta_0)^{-1})$ by Theorem 11.67, and is therefore bounded in probability. The second factor converges in probability to $I_1(\theta_0)$: it is an average of independent identically distributed terms evaluated at $\hat\theta_n$ rather than at θ_0, and the difference is controlled by the domination in (R5) together with the consistency of $\hat\theta_n$. The last term is bounded in absolute value by $\tfrac{1}{3}\left(n^{-1}\textstyle\sum_i M(X_i)\right) n\left|\hat\theta_n - \theta_0\right|^3$, and $n\left|\hat\theta_n - \theta_0\right|^3 = n^{-1/2}\left[\sqrt{n}\left|\hat\theta_n - \theta_0\right|\right]^3 \to 0$ in probability. By Lemma 11.52,

$$q \;\longrightarrow\; \left[\sqrt{I_1(\theta_0)}\,W\right]^2\,, \qquad W \sim \mathcal{N}\!\left(0, I_1(\theta_0)^{-1}\right)\,,$$

and $\sqrt{I_1}\,W$ is standard Gaussian, so its square is χ^2_1 by Definition 11.80. □

Derivation, k parameters and r constraints. *Derives Theorem 11.88.*

The same expansion in k dimensions gives, for any θ near $\hat\theta_n$,

$$Q(\theta) \equiv -2\left[\ell_n(\theta) - \ell_n(\hat\theta_n)\right] = n\left(\theta - \hat\theta_n\right)^{\mathsf T}\left[I_1(\theta_0) + o_P(1)\right]\left(\theta - \hat\theta_n\right) + o_P(1)\,, \tag{11.84}$$

the Hessian term being handled exactly as above and the cubic remainder again vanishing. Since $\hat\theta_0$ maximises ℓ_n over Θ_0, it minimises Q there, and $q = Q(\hat\theta_0) = \min_{\theta\in\Theta_0} Q(\theta)$. Near θ_0 the submanifold Θ_0 is its tangent space to the accuracy the expansion retains, $\Theta_0 \simeq \theta_0 + E$ with E that tangent space, of dimension $\dim E = k - r$. Writing $\boldsymbol{W} = \sqrt{n}\left(\hat\theta_n - \theta_0\right)$ and $I = I_1(\theta_0)$,

$$q \;\longrightarrow\; \min_{\boldsymbol{e}\in E} (\boldsymbol{W} - \boldsymbol{e})^{\mathsf T}\, I\, (\boldsymbol{W} - \boldsymbol{e})\,. \tag{11.85}$$

Substitute $\boldsymbol{V} = I^{1/2}\boldsymbol{W}$ and $S = I^{1/2}E$; the right side is $\min_{\boldsymbol{s}\in S}\|\boldsymbol{V} - \boldsymbol{s}\|^2 = \|P\boldsymbol{V}\|^2$ with P the orthogonal projector onto $S^\perp$, of dimension r. By Theorem 11.67 $\boldsymbol{W} \to \mathcal{N}(0, I^{-1})$, so $\boldsymbol{V}$ is asymptotically Gaussian with covariance $I^{1/2}I^{-1}I^{1/2} = \mathbb{1}$, and Lemma 11.83 gives $\|P\boldsymbol{V}\|^2 \sim \chi^2_r$. □

Two steps of that derivation are argued here rather than proved: the remainder in the k-dimensional Taylor expansion must be shown uniform on a neighbourhood of the true parameter shrinking at rate $n^{-1/2}$, and both maximum-likelihood estimators must be shown to lie in that neighbourhood with probability tending to one, which is what licenses replacing the constraint surface by its tangent space at Equation (11.85). Both are supplied in the appendix, from the same regularity conditions (R1)–(R5) assumed here.

Full derivation: Appendix A.21 (p. 2873).

Derives Theorem 11.88.

Corollary 11.89 (Degrees of freedom with nuisance parameters)**.** *For a single parameter of interest μ with any number m of nuisance parameters, the profile statistic $q(\mu_0) = -2\ln\lambda(\mu_0)$ of Definition 11.70 is asymptotically χ^2_1 under $H_0 : \mu = \mu_0$, whatever m is.*

Rests on Definition 11.70 and Theorem 11.88.

Derivation. *Derives Corollary 11.89.*

The null constrains one coordinate and leaves the other m free, so Θ_0 is a submanifold of codimension $r = 1$ and Theorem 11.88 applies with $r = 1$. The nuisance parameters affect the *variance* of $\hat\mu$, through the Schur complement Equation (11.67), but not the number of degrees of freedom. □

This is the result a collider search relies on: however many nuisance parameters describe the background and the detector, the significance is read off a one-degree-of-freedom distribution [2172]. It is worth saying exactly when it stops being true.

Remark 11.90 (Failure I: a parameter on the boundary). Condition (R3) requires θ_0 to be interior. A signal strength constrained to $\mu \geq 0$ and tested at $\mu = 0$ violates it, and the distribution changes. In the quadratic regime let $\hat\mu_{\mathrm{u}}$ be the unconstrained maximiser, asymptotically Gaussian with mean zero and variance σ^2 under H_0; the maximiser over $\mu \geq 0$ is $\hat\mu = \max(\hat\mu_{\mathrm{u}}, 0)$, because the quadratic log-likelihood opens downward and, with its vertex at a negative abscissa, is decreasing throughout $[0, \infty)$. Then

$$q = \begin{cases} 0 & \hat\mu_{\mathrm{u}} \leq 0\,, \\ \hat\mu_{\mathrm{u}}^2/\sigma^2 & \hat\mu_{\mathrm{u}} > 0\,, \end{cases} \qquad \text{so} \qquad q \;\longrightarrow\; \tfrac{1}{2}\delta_0 + \tfrac{1}{2}\chi^2_1\,, \tag{11.86}$$

a half-and-half mixture of a point mass at zero and a chi-squared law, since $\hat\mu_{\mathrm{u}} \leq 0$ has asymptotic probability $\frac{1}{2}$ by symmetry. Hence $\Pr(q \geq u) = \frac{1}{2}\Pr(\chi^2_1 \geq u)$ for $u > 0$: using the uncorrected χ^2_1 tail overstates the p-value by exactly a factor of two, and therefore understates the significance. The boundary correction and the half-and-half mixture are Chernoff's [1033]; the same mixture is used deliberately in Section 11.5.5, and the convention a search actually quotes is fixed in [2172].

Rests on Definition 11.59 and Corollary 11.89.

Remark 11.91 (Failure II: a parameter unidentified under the null). Condition (R2) can fail on Θ_0 itself. Consider a model $f(x; \mu, m)$ in which μ is the strength of a signal and m its mass. At $\mu = 0$ the density does not depend on m at all: every value of m gives the same distribution, the parameter is unidentified, the information matrix is singular in the m direction, and the expansion behind Theorem 11.88 has nothing to expand in. The statistic $q(m)$ is then not a single number but a *random field* over the mass range, and the quantity actually reported — $\sup_m q(m)$ — has no chi-squared distribution and is not covered by any theorem above. This is the look-elsewhere problem, and Section 11.6 treats it. The standard analysis of the unidentified-parameter case is R. B. Davies' [1594], extended in his sequel of ten years later [1791]; the two papers share a title and neither supersedes the other. He is not the E. B. Davies of the master-equation literature cited elsewhere in this treatise.

11.5.5 Significance

Definition 11.92 (Significance)**.** The *significance* Z corresponding to a p-value is defined by

$$p = 1 - \Phi(Z)\,, \qquad \text{equivalently} \qquad Z = \Phi^{-1}(1-p)\,, \tag{11.87}$$

with Φ the standard Gaussian distribution function: Z is the number of standard deviations beyond which a *one-sided* Gaussian tail carries probability p.

Rests on Definition 11.75.

Z is a pure number and carries no unit. The thresholds conventionally called evidence and discovery in particle physics are $Z = 3$ and $Z = 5$; the corresponding tail probabilities, computed directly from Equation (11.87), are $p = 1.35 \times 10^{-3}$ and $p = 2.87 \times 10^{-7}$. The statistical practice of the field, these conventions among it, is reviewed in [2427], and the profile-likelihood asymptotics that turn a measured statistic into one of these numbers are collected in [2172].

Proposition 11.93 ($Z = \sqrt{q}$)**.** *Let μ be a signal strength with $H_0 : \mu = 0$, and define the* one-sided discovery statistic

$$\tilde{q}_0 = \begin{cases} -2\ln\left[L(0)/L(\hat{\mu})\right] & \hat{\mu} \geq 0\,, \\ 0 & \hat{\mu} < 0\,, \end{cases} \tag{11.88}$$

which refuses to count a deficit as evidence for a signal. Then under H_0, asymptotically, $\tilde{q}_0 \sim \frac{1}{2}\delta_0 + \frac{1}{2}\chi^2_1$, and for an observed value $q > 0$

$$p = \Pr(\tilde{q}_0 \geq q \mid H_0) = \tfrac{1}{2}\Pr\!\left(\chi^2_1 \geq q\right) = 1 - \Phi(\sqrt{q})\ , \qquad \textit{so} \qquad Z = \sqrt{q}\,. \tag{11.89}$$

Rests on Definition 11.92, Corollaries 11.82 and 11.89, and Equation (11.86)*.*

Derivation. *Derives Proposition 11.93.*

The mixture is the one derived in Equation (11.86): writing $q_0 = \hat{\mu}^2/\sigma^2$ for the two-sided statistic, which is asymptotically χ^2_1 by Corollary 11.89, the event $\tilde{q}_0 \geq q$ with $q > 0$ is the event $\{\hat{\mu} > 0\} \cap \{q_0 \geq q\}$. The sign of $\hat{\mu}$ and the magnitude $|\hat{\mu}|$ are independent for a Gaussian of mean zero, and the sign is positive with probability $\frac{1}{2}$, so $\Pr(\tilde{q}_0 \geq q) = \frac{1}{2}\Pr(\chi^2_1 \geq q)$. Insert Equation (11.75) with $z = \sqrt{q}$: the right-hand side is $\frac{1}{2} \cdot 2\,(1 - \Phi(\sqrt{q})) = 1 - \Phi(\sqrt{q})$. Comparing with Equation (11.87) gives $Z = \sqrt{q}$. □

The identity $Z = \sqrt{q}$ is the reason a collider search can quote a significance without simulating anything, and it is the convention fixed, together with the asymptotic distributions it rests on, in [2172]. The same reference supplies the companion device for the *expected* significance of a planned measurement: a single artificial "Asimov" data set, in which every observable is set to its expectation under the assumed signal, returns the median q of an ensemble of simulated experiments directly, so that the sensitivity of a search can be quoted without generating the ensemble at all. The treatise uses only the observed-data statement above; the Asimov construction is named here because the searches of Part XI quote sensitivities computed with it.

Remark 11.94 (The factor of two). The identity $Z = \sqrt{q}$ is a property of the one-sided convention and of nothing else. Used with the two-sided statistic q_0, which counts a downward fluctuation as evidence against $\mu = 0$ just as readily as an upward one, the correct p-value is $\Pr(\chi^2_1 \geq q) = 2\,(1 - \Phi(\sqrt{q}))$, exactly twice as large, and the significance is $Z = \Phi^{-1}(1 - 2\,(1 - \Phi(\sqrt{q})))$, which is not $\sqrt{q}$. At $q = 25$ the two conventions give $p = 2.87 \times 10^{-7}$ with $Z = 5.00$, and $p = 5.73 \times 10^{-7}$ with $Z = 4.86$. The difference of 0.14 in Z is small enough to look like a rounding disagreement and large enough to move a result across the conventional discovery threshold. State which convention is in force, once, and do not mix them.

Remark 11.95 (Exclusion is the same machinery reversed). An upper limit uses a statistic that is one-sided the other way — large values of μ disfavoured — and the same asymptotic distributions apply [2172]. The additional difficulty there is that a downward background fluctuation can exclude a signal the experiment had no sensitivity to; the standard remedy is to report the ratio of the two tail probabilities rather than the numerator alone [2036]. That construction belongs with the searches that use it and is not developed here.

11.6 The look-elsewhere effect

Everything in Section 11.5 assumes the hypothesis was fixed before the data were examined. A search does not work that way. It scans a range of an unknown parameter — a mass, a lifetime, a frequency — computes a test statistic at every point of the range, and reports the largest value found. The probability that *some* point of a wide range fluctuates upward is far greater than the probability that a nominated point does, and the difference can be one or two units of significance. This section makes the correction quantitative.

11.6.1 Local and global p-values

Definition 11.96 (Local, global, trials factor)**.** Let $M = [m_1, m_2]$ be the scanned range and $\tilde{q}(m)$ the one-sided statistic Equation (11.88) evaluated with the signal parameter fixed at m. Let $u = \max_{m\in M} \tilde{q}(m)$ be the observed maximum. The *local p-value* is the tail probability at a point fixed in advance,

$$p_{\text{loc}} = \Pr(\tilde{q}(m_{\text{fix}}) \geq u \mid H_0) = 1 - \Phi(\sqrt{u}) \,, \tag{11.90}$$

by Equation (11.89); the *global p-value* is

$$p_{\text{glob}} = \Pr\Big(\max_{m\in M} \tilde{q}(m) \geq u \mid H_0\Big) \,, \tag{11.91}$$

and the *trials factor* is $N_{\text{tr}} = p_{\text{glob}}/p_{\text{loc}}$.

Rests on Definition 11.75 and Equations (11.88) *and* (11.89).

Proposition 11.97 (The trials factor is at least one)**.** $p_{\text{glob}} \geq p_{\text{loc}}$*, so* $N_{\text{tr}} \geq 1$.

Rests on Definition 11.96.

Derivation. *Derives Proposition 11.97.*

For any fixed $m_{\text{fix}} \in M$ the event $\{\tilde{q}(m_{\text{fix}}) \geq u\}$ is contained in the event $\{\max_{m\in M} \tilde{q}(m) \geq u\}$; a probability is monotone under inclusion. □

Proposition 11.98 (Union bound and the naive estimate)**.** *Suppose the maximum over M is attained, to the accuracy required, at one of N points $m_1, \dots, m_N$. Then*

$$p_{\text{glob}} \leq \sum_{j=1}^{N} \Pr(\tilde{q}(m_j) \geq u) = N\, p_{\text{loc}} \,, \qquad \text{so} \qquad N_{\text{tr}} \leq N \,. \tag{11.92}$$

If in addition the N tests were independent, then

$$p_{\text{glob}} = 1 - (1 - p_{\text{loc}})^N = N p_{\text{loc}} - \binom{N}{2} p_{\text{loc}}^2 + \cdots \simeq N p_{\text{loc}} \quad \text{when } N p_{\text{loc}} \ll 1 \,. \tag{11.93}$$

Rests on Definition 11.96.

Derivation. *Derives Proposition 11.98.*

Write $A_j = \{\tilde{q}(m_j) \geq u\}$. The first claim is Boole's inequality $\Pr(\bigcup_j A_j) \leq \sum_j \Pr(A_j)$, which follows by induction from $\Pr(A \cup B) = \Pr(A) + \Pr(B) - \Pr(A \cap B) \leq \Pr(A) + \Pr(B)$, together with the fact that each $\Pr(A_j)$ equals p_{loc} because the statistic has the same null distribution at every m. If the A_j are independent then so are their complements, so $\Pr(\bigcap_j A_j^c) = (1 - p_{\mathrm{loc}})^N$; expanding by the binomial theorem gives the series. □

The customary choice is $N \simeq \Delta m / \delta m$, the width of the scanned window divided by the experimental resolution, on the reasoning that two hypotheses separated by much less than the resolution are tested by essentially the same data and are not independent trials.

Remark 11.99 (What is and is not proved here). Equation (11.92) is a theorem and Equation (11.93) is not. The union bound holds unconditionally but is weak, and it becomes vacuous as the grid is refined — nothing stops N from being taken larger, and the bound then exceeds 1. The independence assumption is false by construction: $\tilde{q}(m)$ and $\tilde{q}(m')$ are computed from the same events and are strongly correlated when $|m - m'|$ is of order the resolution. The number N is therefore a judgement about a correlation length, not a quantity the model supplies, and the estimate it gives can err in either direction. The next subsection replaces the judgement by a measurable quantity.

11.6.2 Upcrossings

The honest object is the whole function $m \mapsto \tilde{q}(m)$, a random field on M whose null distribution at each point is known but whose maximum is not. What controls the maximum is how often the field crosses a high level on its way up.

Definition 11.100 (Upcrossings)**.** For a continuous path $\tilde{q}(\,\cdot\,)$ on M and a level u, an *upcrossing* is a point $m \in (m_1, m_2)$ at which the path passes from below u to above it. Write N_u for the number of upcrossings in M, a non-negative integer-valued random variable.

Rests on Definition 11.96.

The bound below is Davies' [1594, 1791]: it is the result that replaces Wilks' theorem when a parameter — here the mass — is present only under the alternative, and it is what the trials-factor practice of a search is built on [2158].

Theorem 11.101 (Davies' bound)**.** *If the paths of $\tilde{q}$ are continuous, then for every level u*

$$\Pr\Big(\max_{m \in M} \tilde{q}(m) \geq u\Big) \leq \Pr(\tilde{q}(m_1) \geq u) + \langle N_u \rangle \,, \tag{11.94}$$

that is, $p_{\mathrm{glob}} \leq p_{\mathrm{loc}} + \langle N_u \rangle$.

Rests on Definition 11.100, Lemma 11.50, and Theorem 7.23.

Derivation. *Derives Theorem 11.101.*

Suppose $\max_{m \in M} \tilde{q}(m) \geq u$ and that the left endpoint is below the level, $\tilde{q}(m_1) < u$. The path is continuous and reaches a value at least u somewhere in M, so by the intermediate value theorem (Theorem 7.23) it attains the value u at some interior point, having come from below; that is an upcrossing, so $N_u \geq 1$. Hence

$$\Big\{\max_{m \in M} \tilde{q}(m) \geq u\Big\} \subseteq \{\tilde{q}(m_1) \geq u\} \cup \{N_u \geq 1\} \,,$$

and subadditivity gives $\Pr(\max \geq u) \leq \Pr(\tilde{q}(m_1) \geq u) + \Pr(N_u \geq 1)$. Finally N_u is non-negative, so Markov's inequality (Lemma 11.50) with $a = 1$ gives $\Pr(N_u \geq 1) \leq \langle N_u \rangle$. □

The bound is exact mathematics and it is also practical, because it replaces an unknown — the distribution of a maximum in the far tail, which no feasible number of simulated experiments can sample — by a mean, which can be estimated at a *low* level where upcrossings are common. What makes that replacement useful is the way $\langle N_u \rangle$ depends on the level.

The level dependence below is Gross and Vitells' [2158], and it descends from Rice's formula for the expected number of level crossings of a smooth Gaussian process. The memoir on random noise is usually cited whole, but the crossing count is specifically section 3.3 of its second instalment [883]; the first [877] carries the shot effect and the power spectra, and not the formula used here. That formula is derived in the appendix — by a Kac counting integral whose expectation factorises, because a field of constant variance is independent of its own derivative at each point — and everything built on it here follows from it.

Theorem 11.102 (Rice's formula)**.** *Let X be a Gaussian process on $M = [m_1, m_2]$ with zero mean, unit variance at every point and continuously differentiable sample paths, and write $\sigma_1(m)^2 = \operatorname{var} X'(m)$, assumed finite and continuous in m. Then the expected number of upcrossings of a level $z \in \mathbb{R}$ by X on M is*

$$\langle N_z(X) \rangle = \frac{\mathrm{e}^{-z^2/2}}{2\pi} \int_{m_1}^{m_2} \sigma_1(m)\, \mathrm{d}m \,. \tag{11.95}$$

Rests on Definitions 11.28 and 11.100.

Two features of Equation (11.95) are worth naming, because they are what the next theorem lives on. Constancy of the variance forces $\operatorname{cov}(X(m), X'(m)) = \frac{1}{2}\,\mathrm{d}\operatorname{var} X(m)/\mathrm{d}m = 0$, so field and derivative are independent at each fixed m; the level therefore enters only through the Gaussian density of $X(m)$ at z, the expected positive part of the derivative, $\langle X'(m)^+ \rangle = \sigma_1(m)/\sqrt{2\pi}$, being the same at every level. That is the whole reason the right-hand side factorises into a function of z times a function of the field. For a stationary field σ_1 is a constant $\sqrt{\lambda_2}$ and Equation (11.95) reduces to Rice's original expression $\langle N_z \rangle = (L/2\pi)\sqrt{\lambda_2}\,\mathrm{e}^{-z^2/2}$, with L the length of M.

The appendix carries the derivation, and states there what it must assume: the smoothness hypotheses above in the sharper form the proof uses, the absence of tangential crossings, and the two Lebesgue-theory statements — Tonelli's theorem and dominated convergence — that license the interchange of the expectation with the counting integral and with the limit. Everything the chapter builds on the formula, including the exponential level dependence and the trials factor, is derived in full.

Full derivation: Appendix A.22 (p. 2879).

Derives Theorem 11.102.

Theorem 11.103 (Level dependence of the mean upcrossing count)**.** *Let the one-sided statistic Equation (11.88) be, asymptotically, $\tilde{q}(m) = X(m)^2\, \mathbf{1}_{\{X(m)>0\}}$ for a Gaussian field X satisfying the hypotheses of Theorem 11.102, indexed by the single scanned parameter m. Then for levels $u, u_0 > 0$ in the range where that asymptotic description holds,*

$$\langle N_u \rangle = \langle N_{u_0} \rangle\, \mathrm{e}^{-(u-u_0)/2} \,. \tag{11.96}$$

Rests on Definition 11.100 and Theorem 11.102.

Derivation. *Derives Theorem 11.103.*

Fix $u > 0$. An upcrossing of the level u by $\tilde{q}$ is exactly an upcrossing of the level $\sqrt{u}$ by X. Where $X \le 0$ the statistic takes the value 0, which is below u, so no crossing of u occurs there; and on the open set where $X > 0$ one has $\tilde{q} = X^2$, a strictly increasing function of X, so $\tilde{q}$ passes from below u to above it precisely where X passes from below $\sqrt{u}$ to above it.

The two counts therefore agree path by path, $N_u = N_{\sqrt{u}}(X)$, and taking expectations and applying Equation (11.95) at $z = \sqrt{u}$,

$$\langle N_u \rangle = \frac{\mathrm{e}^{-u/2}}{2\pi} \int_{m_1}^{m_2} \sigma_1(m)\,\mathrm{d}m\,, \tag{11.97}$$

where the integral does not depend on u. Writing the same identity at u_0 and dividing cancels the integral and leaves Equation (11.96). □

Remark 11.104 (More than one scanned parameter). Gross and Vitells extend the result to a scan over d parameters, where the right-hand side of Equation (11.96) acquires a factor $(u/u_0)^{(d-1)/2}$ [2158]; the upcrossing count is there replaced by the expected Euler characteristic of the set on which the field exceeds the level, of which it is the case $d = 1$. That extension is reported, not derived here, and nothing in this treatise uses it: every application below is a scan over a single mass.

The procedure this licenses is the one searches actually use: simulate a manageable number of background-only experiments, count upcrossings of a *low* threshold u_0 — $u_0 = 1$, i.e. a one-sigma level, is a common choice — average to get $\langle N_{u_0} \rangle$, and extrapolate with Equation (11.96) to the observed level. Nothing has to be simulated at 5×10^{-7} probability.

Corollary 11.105 (Trials factor at high significance)**.** *With $u = Z_{\mathrm{loc}}^2$ and Z_{loc} large,*

$$N_{\mathrm{tr}} \;\le\; 1 + \frac{\langle N_{u_0} \rangle\, \mathrm{e}^{(u_0-u)/2}}{1 - \Phi(\sqrt{u})} \;\simeq\; 1 + \sqrt{2\pi}\,\langle N_{u_0} \rangle\, \mathrm{e}^{u_0/2}\, Z_{\mathrm{loc}}\,, \tag{11.98}$$

so the trials factor grows linearly with the local significance.
Rests on Definition 11.96 and Theorems 11.101 and 11.103.

Derivation. *Derives Corollary 11.105.*

Divide Equation (11.94) by p_{loc} and use Equations (11.90) and (11.96) for the first form. For the second, the Gaussian tail satisfies

$$\frac{z}{z^2+1}\,\frac{\mathrm{e}^{-z^2/2}}{\sqrt{2\pi}} \;\le\; 1 - \Phi(z) \;\le\; \frac{1}{z}\,\frac{\mathrm{e}^{-z^2/2}}{\sqrt{2\pi}}\,, \qquad z > 0\,, \tag{11.99}$$

so that $1 - \Phi(z) = \mathrm{e}^{-z^2/2}\,(1 + O(z^{-2}))\,/\,\big(z\sqrt{2\pi}\big)$. To see Equation (11.99), write $J = \int_z^\infty \mathrm{e}^{-t^2/2}\mathrm{d}t$ and integrate by parts with $\mathrm{e}^{-t^2/2} = t^{-1} \cdot t\,\mathrm{e}^{-t^2/2}$:

$$J = \frac{\mathrm{e}^{-z^2/2}}{z} - \int_z^\infty \frac{\mathrm{e}^{-t^2/2}}{t^2}\,\mathrm{d}t\,.$$

The subtracted integral is positive, giving the upper bound, and is at most $z^{-2}J$, giving $J(1 + z^{-2}) \ge \mathrm{e}^{-z^2/2}/z$ and hence the lower bound. Now put $z = \sqrt{u} = Z_{\mathrm{loc}}$ in the first form of Equation (11.98): the exponentials $\mathrm{e}^{-u/2}$ and $\mathrm{e}^{-z^2/2}$ cancel and what remains is $\langle N_{u_0} \rangle\, \mathrm{e}^{u_0/2}\, Z_{\mathrm{loc}}\sqrt{2\pi}$. □

Remark 11.106 (The factor of two, once more). The same relation appears in the literature with $\sqrt{\pi/2}$ in place of $\sqrt{2\pi}$. Both are right, in their own conventions. There the local p-value is the two-sided tail $\Pr(\chi^2_1 \ge u) = 2\,(1 - \Phi(\sqrt{u}))$ and N_u counts upcrossings of the two-sided statistic $q(m)$, which are twice as numerous because the underlying Gaussian field crosses $+\sqrt{u}$ and $-\sqrt{u}$ with equal frequency. Both the numerator and the denominator of N_{tr} are therefore doubled, and the trials factor — a ratio — is the same number either way, as it must be.

What is fatal is to mix them — but the damage is *not* exactly a factor of two, because the Davies bound Equation (11.94) carries an additive 1 that no convention doubles. Write

$x = \langle N_u \rangle / p_{\mathrm{loc}}$ in the one-sided convention, so that the number a search quotes as its trials factor is $N_{\mathrm{tr}} = 1 + x$, the right-hand side of Equation (11.98). A two-sided upcrossing count divided by a one-sided local p-value doubles x alone and returns

$$1{+}2x = 2\,(1+x){-}1 = 2N_{\mathrm{tr}}{-}1\,, \qquad \text{too large by the factor } \frac{2N_{\mathrm{tr}}-1}{N_{\mathrm{tr}}} = 2{-}\frac{1}{N_{\mathrm{tr}}}\,. \tag{11.100}$$

What the mistake doubles is the *excess* of the trials factor over one, not the trials factor itself. The overstatement is therefore strictly less than a factor of two, and reaches two only asymptotically, for $N_{\mathrm{tr}} \gg 1$. At the $N_{\mathrm{tr}} \simeq 52$ of Example 11.107 the mixed number is about 104, too large by 1.98 — close enough to two that the loose statement passes unnoticed. In the opposite regime it is nearly harmless: a genuine $N_{\mathrm{tr}} = 1.05$ is reported as 1.10, an overstatement of five per cent, not of a factor of two. The mistake is worth avoiding for its own sake; "exactly twice" is the wrong way to describe it.

11.6.3 A worked example: a bump search over a mass window

Example 11.107 (Degrading a local five sigma)**.** A search scans for a narrow resonance in an invariant-mass spectrum over the window

$$m \in \left[110\,\mathrm{GeV}/c^2,\ 150\,\mathrm{GeV}/c^2\right], \qquad \Delta m = 40\,\mathrm{GeV}/c^2 = 7.13\times10^{-26}\,\mathrm{kg}\,, \tag{11.101}$$

with a mass resolution $\delta m = 1.5\,\mathrm{GeV}/c^2 = 2.67\times10^{-27}\,\mathrm{kg}$. The statistic $\tilde{q}(m)$ of Equation (11.88) is evaluated across the window with the background normalisation and shape treated as nuisance parameters, so Corollary 11.89 applies at each fixed m. Its largest value is $u = 25.0$, at some mass inside the window.

Local significance. By Equation (11.89), $Z_{\mathrm{loc}} = \sqrt{u} = 5.00$ and $p_{\mathrm{loc}} = 1 - \Phi(5) = 2.87\times10^{-7}$. This is the significance the excess would have if the mass had been nominated in advance, and it is not the significance of the search.

Naive trials factor. Taking $N = \Delta m/\delta m = 40/1.5 \simeq 27$ resolution elements and treating them as independent, Equation (11.93) gives $p_{\mathrm{glob}} \simeq 27\times2.87\times10^{-7} = 7.7\times10^{-6}$, whence $Z_{\mathrm{glob}} = \Phi^{-1}(1-p_{\mathrm{glob}}) = 4.32$.

Upcrossings. Suppose background-only simulations at the low threshold $u_0 = 1.0$ yield an average of $\langle N_{u_0}\rangle = 2.4$ upcrossings per experiment across the window. Then Equation (11.96) extrapolates to

$$\langle N_{25}\rangle = 2.4\,\mathrm{e}^{-(25-1)/2} = 2.4\,\mathrm{e}^{-12} = 1.47\times10^{-5}\,, \tag{11.102}$$

and Equation (11.94) gives

$$p_{\mathrm{glob}} \le 2.87\times10^{-7} + 1.47\times10^{-5} = 1.50\times10^{-5}\,, \qquad N_{\mathrm{tr}} = 52\,, \qquad Z_{\mathrm{glob}} = 4.17\,. \tag{11.103}$$

The closed form Equation (11.98) gives $1 + \sqrt{2\pi}\times2.4\times\mathrm{e}^{0.5}\times5.00 = 51$, agreeing with the direct evaluation to about three per cent — the difference being the $O(z^{-2})$ term dropped from the Gaussian tail.

Rests on Corollary 11.89, Propositions 11.93 and 11.98, and Theorems 11.101 and 11.103.

Remark 11.108 (Reading the example). Three things in Table 11.1 are worth separating. First, the degradation is real and large in probability — a factor of 52 — and mild in significance, $5.00 \to 4.17$; that compression is the exponential in Equation (11.87) at work and is why an excess that survives the correction at all tends to survive it comfortably. Second, the naive estimate is not conservative: it happened to be optimistic by a factor of about two here, and which way it errs depends on whether the resolution over-counts or under-counts the correlation length of the field. Third, Equation (11.103) is an upper bound on p_{glob}, so $Z_{\mathrm{glob}} = 4.17$ is a *lower* bound on the global significance — the honest direction for a discovery claim.

Table 11.1: The bump search of Example 11.107, a local $q = 25.0$ found somewhere in a mass window $40\,\mathrm{GeV}/c^2$ wide with a $1.5\,\mathrm{GeV}/c^2$ resolution. The trials factor and both p-values are pure numbers; the window and the resolution that generate them are not. The naive estimate is optimistic here by a factor of about two, and understates the correction by 0.15 in significance.

Treatment	N_{tr}	p_{glob}	Z_{glob}
Mass nominated in advance	1	2.87×10^{-7}	5.00
Independent resolution elements, $N = 27$	27	7.7×10^{-6}	4.32
Expected upcrossings, Equation (11.94)	52	1.50×10^{-5}	4.17

Nothing in the arithmetic depends on the mass window being the one chosen here, and nothing in it is specific to any particular resonance. What the example fixes is the discipline: a significance quoted for a search must state the range searched, and a significance quoted without it is a local number wearing a global name.

Chapter 12

Hilbert Spaces

The vector-space machinery of Chapter 5 was developed largely without regard to dimension, but the passage to infinite dimension is not innocent: limits enter, and with them the topological and metric notions of Chapter 6. A Hilbert space is the structure in which the algebra and the topology cooperate — an inner-product space whose associated metric is complete — and it is the arena in which the postulates of quantum mechanics will be formulated in Chapter 77.

The subject grew out of Hilbert's spectral theory of integral equations [388], was axiomatised by von Neumann for exactly that quantum-mechanical purpose [706], and its standard modern exposition is Reed–Simon [1481]; those three are the references of record for this chapter.

Three things are new here, and each is a place where the finite-dimensional intuition of Chapter 5 fails. A subspace need not be closed, so it need not admit an orthogonal complement; an operator need not be defined on the whole space, and if it is symmetric and everywhere defined it is forced to be bounded; and a self-adjoint operator need have no eigenvector at all, so the decomposition of a state into eigenstates has to be replaced by an integral against a projection-valued measure. The chapter is organised around repairing those three failures.

Remark 12.1 (Analytical inputs quoted, not proved). Three classical results are used below and are *not* derived in this treatise; each is flagged where it is used and all three are in [1481]. (i) The convergence theorems of Lebesgue integration — monotone convergence and Fatou's lemma — which enter only through the completeness of L^2 (Theorem 12.12); the treatise develops no measure theory, and Chapter 11 makes the same declaration. (ii) The closed-graph theorem for Banach spaces, used once, in Theorem 12.74; it rests on the Baire category theorem, which is not proved here either. (iii) The Weierstrass approximation theorem, used once, to pin down the functional calculus in Proposition 12.61. Everything else in this chapter is proved from Chapter 5, Chapter 6, Chapter 7 and Chapter 8.

The long derivations this chapter sends to Appendix A quote two further results — the Riesz–Markov representation theorem, in Appendix A.24, and the Hilbert–Schmidt embedding property of a nuclear space, in Appendix A.27 — together with the Radon–Nikodym theorem and the dominated convergence theorem, which belong to the same measure theory as (i). Each is stated as a displayed theorem where it is used, and each of those four appendix sections closes with a remark titled *What is quoted here* naming its imports exactly.

12.1 Definitions

Definition 12.2 (Hilbert space)**.** Consider a pre-Hilbert space $\mathcal{H}$ — a vector space equipped with an inner product — of infinite dimension, together with the norm associated with that

inner product and the metric associated with that norm. We say that $\mathcal{H}$ is a *Hilbert space* if and only if $\mathcal{H}$ is complete, that is, if and only if every Cauchy sequence in $\mathcal{H}$ converges.

Rests on Definitions 5.17 and 6.27 and Equation (5.44).

Nothing in Definition 12.2 is new except the word *complete*. The inner product is the map $\langle\ |\ \rangle$ of Definition 5.17, antilinear in its first slot and linear in its second (Equations (5.34) and (5.36)); the norm is $\|v\| = \sqrt{\langle v|v\rangle}$ of Equation (5.44); the metric is $d(u,v) = \|u - v\|$ of Equation (5.45); and completeness is Definition 6.27 read in that metric. The infinite dimension is not a hypothesis of any theorem below — a finite-dimensional inner-product space is automatically complete — but it is the case of interest, and we shall say *Hilbert space* for any complete inner-product space and note the finite-dimensional degeneracies where they matter.

Notation 12.3 (Scalars and adjoints). Throughout, $\mathcal{H}$ is a complex Hilbert space unless the real case is named; $\mathbb{K} = \mathbb{C}$, and a^* is the complex conjugate of $a \in \mathbb{C}$. Vectors are written x, y, z or, where the quantum-mechanical reading is intended, $|\psi\rangle$. The dagger $A^\dagger$ denotes the adjoint of Theorem 12.38 throughout the treatise, never the transpose, which is written A^{T} (Chapter 5).

Three consequences of the axioms are used on nearly every page below: the Cauchy–Schwarz inequality, the continuity of the inner product that follows from it, and the parallelogram law, which is what completeness will be levered against in Section 12.2.1.

Proposition 12.4 (Cauchy–Schwarz and continuity of the inner product)**.** *Let $\mathcal{H}$ be an inner-product space. Then*

$$|\langle u|v\rangle| \le \|u\|\ \|v\|\ , \qquad \forall\, u, v \in \mathcal{H}\,, \tag{12.1}$$

and the inner product is jointly continuous: if $u_n \to u$ and $v_n \to v$ in norm, then $\langle u_n|v_n\rangle \to \langle u|v\rangle$ in $\mathbb{C}$.

Rests on Proposition 5.19 and Definition 12.2.

Proof. *Derives Proposition 12.4.*

Equation (12.1) is Equation (5.43) with both sides put under a square root through Equation (5.44). That inequality is available here without any further argument: Remark 5.20 records that its proof used only the five axioms of Definition 5.17 — neither a basis, nor finite dimension, nor completeness — so it holds verbatim in the present setting.

For continuity, a convergent sequence is bounded, say $\|v_n\| \le C$ for all n. Then, adding and subtracting $\langle u|v_n\rangle$ and using Equations (5.35) and (5.37),

$$|\langle u_n|v_n\rangle - \langle u|v\rangle| \le |\langle u_n - u|v_n\rangle| + |\langle u|v_n - v\rangle| \le C\ \|u_n - u\| + \|u\|\ \|v_n - v\|\ ,$$

by Equation (12.1) applied to each term, and both summands tend to zero. □

Corollary 12.5 (Continuity of the norm and of orthogonality)**.** *The norm is continuous, $|\|u\| - \|v\|| \le \|u - v\|$; and if $x_n \to x$ with $\langle y|x_n\rangle = 0$ for all n, then $\langle y|x\rangle = 0$. Orthogonality to a fixed vector is therefore a closed condition.*

Rests on Proposition 12.4 and Definition 5.22.

Proof. *Derives Corollary 12.5.*

The first is the triangle inequality Equation (5.42) used twice, $\|u\| \le \|u - v\| + \|v\|$ and symmetrically. The second is Proposition 12.4 with the constant sequence y in the first slot. □

Proposition 12.6 (Parallelogram law and polarization)**.** *For all u, v in an inner-product space,*

$$\|u + v\|^2 + \|u - v\|^2 = 2\,\|u\|^2 + 2\,\|v\|^2\ , \tag{12.2}$$

and the inner product is recovered from the norm alone by

$$\langle u|v\rangle = \frac{1}{4}\sum_{k=0}^{3} \mathrm{i}^{-k}\left\|u+\mathrm{i}^{k}v\right\|^{2}. \tag{12.3}$$

Rests on Definition 5.17 and Equation (5.44).

Proof. *Derives Proposition 12.6.*

Expanding by Equations (5.35) and (5.37) and the scalar rules Equations (5.34) and (5.36), for any $\lambda \in \mathbb{C}$,

$$\|u+\lambda v\|^{2} = \|u\|^{2} + |\lambda|^{2}\|v\|^{2} + \lambda\langle u|v\rangle + \lambda^{*}\langle v|u\rangle . \tag{12.4}$$

Taking $\lambda = +1$ and $\lambda = -1$ and adding cancels the two cross terms and gives Equation (12.2).

For Equation (12.3), put $\lambda = \mathrm{i}^{k}$ in Equation (12.4), multiply by i^{-k} and sum over $k = 0, 1, 2, 3$. The first two terms carry $\sum_k \mathrm{i}^{-k} = 0$ and vanish. The third carries $\sum_k \mathrm{i}^{-k}\mathrm{i}^{k} = 4$ and leaves $4\langle u|v\rangle$. The fourth carries $\sum_k \mathrm{i}^{-k}\mathrm{i}^{-k} = \sum_k (-1)^{k} = 0$ and vanishes. □

Remark 12.7 (Which norms come from an inner product). Equation (12.2) is a genuine test, not a mere identity: a norm satisfies it if and only if it is the norm associated with an inner product, and Equation (12.3) then constructs that inner product from the norm. The supremum norm on continuous functions fails it — take u, v two bumps with disjoint supports and equal heights, so that all four norms in Equation (12.2) equal that height and the identity reads $2 = 4$ — which is why the space of continuous functions with the supremum norm is a Banach space and not a Hilbert space. The whole of the geometry below, orthogonality and projection included, is unavailable there.

Proposition 12.8 (Absolutely convergent series test)**.** *A normed space is complete if and only if every series $\sum_n x_n$ with $\sum_n \|x_n\| < \infty$ converges in it.*

Rests on Definitions 5.18 and 6.27.

Proof. *Derives Proposition 12.8.*

($\Rightarrow$) The partial sums $S_N = \sum_{n\le N} x_n$ satisfy $\|S_M - S_N\| \le \sum_{n=N+1}^{M} \|x_n\|$ for $M > N$, which is a tail of a convergent series of non-negative reals and so tends to zero; (S_N) is Cauchy and converges by completeness.

($\Leftarrow$) Let (y_n) be Cauchy. Choose $n_1 < n_2 < \cdots$ with $\|y_m - y_{n_k}\| < 2^{-k}$ for all $m \ge n_k$. Then $x_1 = y_{n_1}$ and $x_{k+1} = y_{n_{k+1}} - y_{n_k}$ have $\sum_k \|x_k\| \le \|y_{n_1}\| + \sum_k 2^{-k} < \infty$, so by hypothesis the telescoping series converges, that is, $y_{n_k} \to y$ for some y. A Cauchy sequence with a convergent subsequence converges to the same limit, by the triangle inequality. □

Two examples carry the whole subject, and Theorem 12.33 will show that they are one example seen twice.

Example 12.9 (The sequence space ℓ^2)**.** Let

$$\ell^{2} = \left\{ x = (x_1, x_2, \dots) \in \mathbb{C}^{\mathbb{N}} \;\middle|\; \sum_{n=1}^{\infty} |x_n|^{2} < \infty \right\}, \qquad \langle x|y\rangle = \sum_{n=1}^{\infty} x_n^{*} y_n . \tag{12.5}$$

This is a Hilbert space. The series defining $\langle x|y\rangle$ converges absolutely, because $|x_n^{*}y_n| \le \frac{1}{2}(|x_n|^{2} + |y_n|^{2})$; the five axioms of Definition 5.17 are inherited termwise from $\mathbb{C}$; and ℓ^2 is a vector space because the same bound applied to $|x_n + y_n|^{2} \le 2|x_n|^{2} + 2|y_n|^{2}$ keeps the sum finite.

Rests on Definitions 5.17 and 12.2.

Proposition 12.10 (ℓ^2 is complete)**.** *The space Equation (12.5) is complete.*

Rests on Example 12.9 and Axiom 7.1.

Proof. *Derives Proposition 12.10.*

Let $(x^{(m)})_m$ be Cauchy in ℓ^2. For each fixed n, $\left|x_n^{(m)} - x_n^{(p)}\right| \le \left\|x^{(m)} - x^{(p)}\right\|$, so $(x_n^{(m)})_m$ is Cauchy in $\mathbb{C}$ and converges to some x_n by the completeness of $\mathbb{R}$ (Theorem 7.8, applied to real and imaginary parts). Given $\varepsilon > 0$ choose M with $\left\|x^{(m)} - x^{(p)}\right\| < \varepsilon$ for $m, p \ge M$. For every N and every $m, p \ge M$,

$$\sum_{n=1}^{N} \left|x_n^{(m)} - x_n^{(p)}\right|^2 \le \varepsilon^2 ,$$

a finite sum, in which we may let $p \to \infty$ termwise to get $\sum_{n=1}^{N} \left|x_n^{(m)} - x_n\right|^2 \le \varepsilon^2$; since N is arbitrary, $\left\|x^{(m)} - x\right\| \le \varepsilon$. In particular $x = x^{(M)} - (x^{(M)} - x)$ lies in ℓ^2, and $x^{(m)} \to x$. □

Example 12.11 (The function space L^2)**.** Let $\Omega \subseteq \mathbb{R}^N$ be measurable and let $L^2(\Omega)$ be the set of measurable $f : \Omega \longrightarrow \mathbb{C}$ with $\int_\Omega |f|^2 < \infty$, two functions being identified when they agree outside a set of measure zero, with

$$\langle f | g \rangle = \int_\Omega f(x)^* \, g(x) \, \mathrm{d}^N x \, . \tag{12.6}$$

The identification is not a convenience but a necessity: without it $\langle f|f\rangle = 0$ would not force $f = 0$, and Equation (5.31) would fail. An element of L^2 is therefore an equivalence class, and a statement about "the value $f(x_0)$" is meaningless in L^2 — a point that returns in Section 12.6.3, where the delta functional is shown not to be an element of L^2 at all.

Rests on Definitions 5.17 and 12.2.

Theorem 12.12 (Riesz–Fischer)**.** *$L^2(\Omega)$ is complete, and is therefore a Hilbert space.*

Rests on Example 12.11 and Proposition 12.8.

Proof. *Derives Theorem 12.12.*

By Proposition 12.8 it suffices to sum an absolutely convergent series: let $\sum_k \|f_k\| = S < \infty$ and put $g_K = \sum_{k \le K} |f_k|$, an increasing sequence of non-negative measurable functions with $\|g_K\| \le S$ by the triangle inequality. By monotone convergence (Remark 12.1) $g_K \uparrow g$ pointwise with $\int |g|^2 \le S^2$, so g is finite outside a null set. Where g is finite the series $\sum_k f_k(x)$ converges absolutely in $\mathbb{C}$; call its sum $f(x)$, defined almost everywhere, and note $|f| \le g$, so $f \in L^2$. Finally $\left|f - \sum_{k \le K} f_k\right|^2 \le g^2$ pointwise and tends to zero almost everywhere, so Fatou's lemma applied to $g^2 - \left|f - \sum_{k \le K} f_k\right|^2$ gives $\left\|f - \sum_{k \le K} f_k\right\| \longrightarrow 0$. □

The theorem is the joint work of Riesz [336] and Fischer [335], published within weeks of one another in 1907, and it is what made L^2 usable: before it, "convergence in the mean" had no limit to converge to. Theorem 12.33 will show that ℓ^2 and L^2 are not two examples but one, which is the mathematical content of the equivalence of matrix and wave mechanics.

12.2 Orthonormal bases and separability

12.2.1 Orthogonality and projections

In finite dimension every subspace splits off an orthogonal complement, $\mathbb{V} = \mathbb{S} \oplus \mathbb{S}^\perp$ (Corollary 5.27), and the proof simply orthonormalises a basis of $\mathbb{S}$. In infinite dimension that argument stops at the first step, because $\mathbb{S}$ need have no finite basis, and the conclusion itself becomes false for a general subspace: Remark 5.28 flagged the gap and reserved its repair for this section. The repair rests on completeness and on the parallelogram law, and it begins with a purely metric statement about convex sets.

Definition 12.13 (Convex set)**.** A subset C of a vector space is *convex* if $tx + (1-t)y \in C$ whenever $x, y \in C$ and $t \in [0,1]$. Every subspace, and every translate of a subspace, is convex.

Rests on Definition 5.6.

Theorem 12.14 (Closest point in a closed convex set)**.** *Let $C \subseteq \mathcal{H}$ be non-empty, closed and convex, and let $x \in \mathcal{H}$. Then there is exactly one $y \in C$ with*

$$\|x - y\| = d\,, \qquad d = \inf_{z \in C} \|x - z\|\ . \tag{12.7}$$

Rests on Definitions 12.2 and 12.13 and Proposition 12.6.

Proof. *Derives Theorem 12.14.*

Apply Equation (12.2) to the vectors $u = x - z_1$ and $v = x - z_2$, for $z_1, z_2 \in C$. Then $u + v = 2x - (z_1 + z_2)$ and $u - v = z_2 - z_1$, so

$$\|z_1 - z_2\|^2 = 2\,\|x - z_1\|^2 + 2\,\|x - z_2\|^2 - 4\left\|x - \tfrac{1}{2}(z_1 + z_2)\right\|^2\ . \tag{12.8}$$

The midpoint $\frac{1}{2}(z_1 + z_2)$ lies in C by convexity, so the last norm is at least d and

$$\|z_1 - z_2\|^2 \le 2\,\|x - z_1\|^2 + 2\,\|x - z_2\|^2 - 4d^2\,.$$

Take a minimising sequence (z_n) in C with $\|x - z_n\| \to d$: the right-hand side, with $z_1 = z_n$ and $z_2 = z_m$, tends to $2d^2 + 2d^2 - 4d^2 = 0$ as $n, m \to \infty$, so (z_n) is Cauchy and converges, by Definition 12.2, to some y, which lies in C because C is closed. Continuity of the norm (Corollary 12.5) gives $\|x - y\| = d$.

Uniqueness is the same estimate: if y and y' both realise the infimum, then $\|y - y'\|^2 \le 2d^2 + 2d^2 - 4d^2 = 0$. □

Remark 12.15 (Where each hypothesis is used). All three hypotheses are needed and each fails somewhere. Without closedness the infimum need not be attained (take C an open ball). Without convexity the minimiser need not be unique (take C a sphere and x its centre). Without completeness the Cauchy sequence has nowhere to go: on the pre-Hilbert space of continuous functions in $L^2[-1,1]$, the closed convex set of functions with $\int_{-1}^{0} f = \int_{0}^{1} f$ has no closest point to a suitable x. It is completeness that makes Theorem 12.14 a theorem about Hilbert spaces rather than about inner-product spaces, and everything in this section inherits that.

Definition 12.16 (Orthogonal complement)**.** For any subset $S \subseteq \mathcal{H}$,

$$S^{\perp} = \{\, y \in \mathcal{H} \mid \langle x | y \rangle = 0 \ \ \forall\, x \in S \,\}\ . \tag{12.9}$$

Rests on Definition 5.22 and Equation (5.52).

Proposition 12.17 (The complement is always a closed subspace)**.** *For any $S \subseteq \mathcal{H}$, $S^{\perp}$ is a closed subspace, $S \subseteq S^{\perp\perp}$, and $S^{\perp} = \overline{\langle S \rangle}^{\perp}$, where $\overline{\langle S \rangle}$ is the closure of the set of finite linear combinations of elements of S. Moreover $S \cap S^{\perp} \subseteq \{0\}$.*

Rests on Definition 12.16 and Corollary 12.5.

Proof. *Derives Proposition 12.17.*

$S^{\perp}$ is a subspace by linearity of the bracket in its second slot, Equations (5.34) and (5.35), and it is closed as an intersection over $x \in S$ of the sets $\{y \mid \langle x|y\rangle = 0\}$, each closed by Corollary 12.5. If $y \in S^{\perp}$ then y is orthogonal to every finite combination of elements of S, again by linearity, and hence to every limit of such combinations, again by Corollary 12.5; the reverse inclusion is immediate from $S \subseteq \overline{\langle S \rangle}$. That $S \subseteq S^{\perp\perp}$ is a restatement of the definition read the other way round, using hermiticity Equation (5.33). Finally $x \in S \cap S^{\perp}$ gives $\langle x|x\rangle = 0$, so $x = 0$ by Equation (5.31). □

Theorem 12.18 (Projection theorem)**.** *Let $M \subseteq \mathcal{H}$ be a* closed *subspace. Then*

$$\mathcal{H} = M \oplus M^{\perp}\,, \tag{12.10}$$

that is, every $x \in \mathcal{H}$ has a unique decomposition $x = x_{\parallel} + x_{\perp}$ with $x_{\parallel} \in M$ and $x_{\perp} \in M^{\perp}$; moreover $x_{\parallel}$ is the closest point of M to x, and $\|x\|^2 = \left\|x_{\parallel}\right\|^2 + \|x_{\perp}\|^2$.

Rests on Theorem 12.14 and Proposition 12.17.

Proof. *Derives Theorem 12.18.*

A subspace is convex and M is closed and contains 0, so Theorem 12.14 supplies a unique closest point $x_{\parallel} \in M$; put $x_{\perp} = x - x_{\parallel}$.

We claim $x_{\perp} \in M^{\perp}$. Let $m \in M$ with $m \neq 0$ and let $t \in \mathbb{C}$. Since $x_{\parallel} + tm \in M$, minimality gives $\|x_{\perp} - tm\|^2 \geq \|x_{\perp}\|^2$, while Equation (12.4) with $\lambda = -t$ reads

$$\|x_{\perp} - tm\|^2 = \|x_{\perp}\|^2 + |t|^2\,\|m\|^2 - t\,\langle x_{\perp}|m\rangle - t^*\,\langle m|x_{\perp}\rangle\ . \tag{12.11}$$

Choose $t = \langle m|x_{\perp}\rangle\,/\,\|m\|^2$. Using $\langle x_{\perp}|m\rangle = \langle m|x_{\perp}\rangle^*$ (Equation (5.33)), each of the last three terms of Equation (12.11) equals $|\langle m|x_{\perp}\rangle|^2\,/\,\|m\|^2$ with signs $+, -, -$, so

$$\|x_{\perp} - tm\|^2 = \|x_{\perp}\|^2 - \frac{|\langle m|x_{\perp}\rangle|^2}{\|m\|^2}\,.$$

Comparison with the minimality inequality forces $\langle m|x_{\perp}\rangle = 0$, and m was arbitrary.

Uniqueness: if $x = m + w = m' + w'$ with $m, m' \in M$ and $w, w' \in M^{\perp}$, then $m - m' = w' - w$ lies in $M \cap M^{\perp} = \{0\}$ by Proposition 12.17. The norm identity is Equation (12.4) with $\lambda = 1$ and the cross terms vanishing — the Pythagorean theorem. □

Corollary 12.19 (Double complement; the density criterion)**.** *For a closed subspace M, $M^{\perp\perp} = M$. For an arbitrary subset S, $S^{\perp\perp} = \overline{\langle S\rangle}$. In particular a subspace $D \subseteq \mathcal{H}$ is dense if and only if $D^{\perp} = \{0\}$.*

Rests on Theorem 12.18 and Proposition 12.17.

Proof. *Derives Corollary 12.19.*

$M \subseteq M^{\perp\perp}$ always (Proposition 12.17). Conversely let $x \in M^{\perp\perp}$ and split $x = x_{\parallel} + x_{\perp}$ by Theorem 12.18. Then $x_{\perp} = x - x_{\parallel} \in M^{\perp\perp}$, since $M^{\perp\perp}$ is a subspace containing M; but also $x_{\perp} \in M^{\perp}$, and $M^{\perp} \cap M^{\perp\perp} = \{0\}$. Hence $x = x_{\parallel} \in M$.

For general S, apply this to the closed subspace $M = \overline{\langle S\rangle}$ and use $S^{\perp} = M^{\perp}$ from Proposition 12.17. The density criterion is the case $S = D$: D is dense exactly when $\overline{\langle D\rangle} = \mathcal{H}$, i.e. when $D^{\perp\perp} = \mathcal{H}$, i.e. when $D^{\perp} = \{0\}$. □

The density criterion of Corollary 12.19 is used more often below than the projection theorem itself: it converts every question of the form "is this family total?" into the computation of an orthogonal complement, and it is the standard way to test whether a domain is dense (Section 12.5.1).

Definition 12.20 (Orthogonal projection operator)**.** For M a closed subspace, the map $P_M : \mathcal{H} \longrightarrow \mathcal{H}$, $P_M x = x_{\parallel}$, given by Theorem 12.18, is the *orthogonal projection* onto M.

Rests on Theorem 12.18.

Proposition 12.21 (Characterization of orthogonal projections)**.** *$P = P_M$ is linear and satisfies*

$$P^2 = P\,, \qquad \langle Px|y\rangle = \langle x|Py\rangle \quad \forall\, x, y \in \mathcal{H}\,, \tag{12.12}$$

with $\|Px\| \leq \|x\|$, image M and kernel $M^{\perp}$. Conversely, if $P : \mathcal{H} \longrightarrow \mathcal{H}$ is linear and satisfies Equation (12.12), then its image is a closed subspace M and $P = P_M$.

Rests on Definition 12.20 and Theorem 12.18.

Proof. *Derives Proposition 12.21.*

Linearity. If $x = m + w$ and $x' = m' + w'$ are the decompositions of Theorem 12.18, then $ax + bx' = (am + bm') + (aw + bw')$ is a decomposition of $ax + bx'$ of the required kind, and by uniqueness it is the one; so $P(ax + bx') = aPx + bPx'$.

Idempotence and norm. $Px \in M$, and a vector of M is its own closest point, so $P^2 = P$. The norm identity of Theorem 12.18 gives $\|Px\| \le \|x\|$. The image is M and $Px = 0$ exactly when $x = x_\perp \in M^\perp$.

Symmetry. Write $x = Px + (x - Px)$ and $y = Py + (y - Py)$ with the second term of each in $M^\perp$. Then $\langle Px|y\rangle = \langle Px|Py\rangle$ and $\langle x|Py\rangle = \langle Px|Py\rangle$, because in each case the omitted term pairs a vector of M with a vector of $M^\perp$.

Converse. Let $M = \operatorname{im} P$. If $x \in M$, say $x = Pz$, then $Px = P^2 z = Pz = x$, so $M = \{x \mid Px = x\}$. This set is closed, and the argument needs no boundedness of P: if $x_n \in M$ and $x_n \to x$, then for every y the symmetry in Equation (12.12) gives $\langle x_n|Py - y\rangle = \langle Px_n|y\rangle - \langle x_n|y\rangle = 0$, whence $\langle x|Py - y\rangle = 0$ by Proposition 12.4, and reading the symmetry backwards, $\langle Px - x|y\rangle = 0$ for all y, so $Px = x$. For any x and any $m \in M$, $\langle m|x - Px\rangle = \langle Pm|x - Px\rangle = \langle m|Px - P^2 x\rangle = 0$, using Equation (12.12) twice; so $x - Px \in M^\perp$ and Px is the M-component of x. □

Remark 12.22 (Yes–no questions). Equation (12.12) is the whole algebraic content of an orthogonal projection, and it is what makes projections the carriers of propositions in quantum mechanics: $P^2 = P$ says that asking the same question twice adds nothing, and the symmetry says the question has real answers. Two projections commute if and only if the corresponding subspaces decompose compatibly, and non-commuting projections are the formal seat of complementarity. The second identity of Equation (12.12) is exactly self-adjointness, $P^\dagger = P$, once the adjoint is available (Theorem 12.38); it is written out here because the adjoint is defined two sections later and nothing above depends on it. The use made of all this is in Chapter 77 [706].

12.2.2 Gram–Schmidt orthogonalization

Proposition 12.23 (Gram–Schmidt in a Hilbert space). *Let $\{v_1, v_2, \dots\}$ be a finite or countable linearly independent family in an inner-product space. Then there is an orthonormal family $\{e_1, e_2, \dots\}$ with*

$$\langle\{e_1, \dots, e_k\}\rangle = \langle\{v_1, \dots, v_k\}\rangle\,, \qquad k = 1, 2, \dots\,, \tag{12.13}$$

and consequently $\overline{\langle\{e_k\}\rangle} = \overline{\langle\{v_k\}\rangle}$.

Rests on Proposition 5.26 and Definition 5.25.

Proof. *Derives Proposition 12.23.*

The recursion Equation (5.51) is finite at every step, so Proposition 5.26 constructs $e_1, \dots, e_k$ for each k and the construction at step k does not disturb its predecessors; Remark 5.28 already recorded that this much survives to a countable family. Only the last clause is new. By Equation (12.13) the two increasing unions $\bigcup_k \langle\{e_1, \dots, e_k\}\rangle$ and $\bigcup_k \langle\{v_1, \dots, v_k\}\rangle$ coincide, and each is exactly the set of finite linear combinations of the corresponding family; equal sets have equal closures. □

Corollary 12.24 (Separable spaces have countable orthonormal families). *Let $\mathcal{H}$ be an inner-product space containing a countable dense subset. Then there is a finite or countable orthonormal family $\{e_k\}$ with $\overline{\langle\{e_k\}\rangle} = \mathcal{H}$.*

Rests on Proposition 12.23 and Definition 6.27.

Proof. *Derives Corollary 12.24.*

Let $\{w_1, w_2, \dots\}$ be dense. Discard w_n whenever it lies in $\langle\{w_1, \dots, w_{n-1}\}\rangle$; the surviving subfamily $\{v_k\}$ is linearly independent and spans the same set of finite linear combinations, so $\overline{\langle\{v_k\}\rangle} \supseteq \{w_n\} = \mathcal{H}$. Now apply Proposition 12.23. □

Example 12.25 (Orthogonal polynomials)**.** Take $\mathcal{H} = L^2([-1,1])$ and apply Proposition 12.23 to the monomials $v_k(x) = x^{k-1}$, which are linearly independent because a non-trivial polynomial has finitely many roots and so cannot vanish almost everywhere. The output is, up to normalisation, the sequence of Legendre polynomials; running the same recursion in L^2 of a weighted measure $w(x)\,\mathrm{d}x$ produces the Hermite, Laguerre and Chebyshev families according to the weight. That these are the eigenfunctions of the corresponding second-order differential operators is the content of Sturm–Liouville theory (Chapter 9); that the resulting family is *total*, so that the expansion of Section 12.2.3 converges to the function expanded, is a separate fact about each weight and is not supplied by Gram–Schmidt.
Rests on Proposition 12.23 and Example 12.11.

The construction is due to Gram [223], who introduced it for least-squares approximation by series of functions, and to Schmidt [338], who put it in the form used here in the course of his work on integral equations.

12.2.3 Fourier expansion, Bessel and Parseval

Definition 12.26 (Orthonormal system; Fourier coefficients)**.** A finite or countable family $\{e_n\}$ in $\mathcal{H}$ with $\langle e_n | e_m \rangle = \delta_{nm}$ is an *orthonormal system*. For $x \in \mathcal{H}$ the scalars

$$c_n = \langle e_n | x \rangle \tag{12.14}$$

are the *Fourier coefficients* of x in that system.
Rests on Definition 5.25 and Equation (5.49).

Proposition 12.27 (Best approximation and Bessel's inequality)**.** *Let $\{e_n\}$ be an orthonormal system and $x \in \mathcal{H}$. For every N the partial sum $S_N = \sum_{n \le N} c_n e_n$ is the orthogonal projection of x onto $\langle \{e_1, \dots, e_N\} \rangle$, hence the unique closest point of that subspace to x, and*

$$\sum_{n} |\langle e_n | x \rangle|^2 \le \|x\|^2 \,. \tag{12.15}$$

Rests on Definition 12.26 and Theorem 12.18.

Proof. *Derives Proposition 12.27.*
Expanding with Equations (5.35) and (5.37) and using orthonormality,

$$\|x - S_N\|^2 = \|x\|^2 - \sum_{n \le N} |c_n|^2 \,, \tag{12.16}$$

since each of the three quantities $\langle x | S_N \rangle$, $\langle S_N | x \rangle$ and $\|S_N\|^2$ equals $\sum_{n \le N} |c_n|^2$ — for the first, $\langle x | S_N \rangle = \sum_{n \le N} c_n \langle x | e_n \rangle = \sum_{n \le N} c_n c_n^*$ by Equation (5.33), and the other two are the same computation — so that the two cross terms together cancel one copy of $\|S_N\|^2$. The same computation gives $\langle e_m | x - S_N \rangle = 0$ for $m \le N$, so $x - S_N$ is orthogonal to the finite-dimensional — hence closed — subspace $\langle \{e_1, \dots, e_N\} \rangle$, and S_N is its orthogonal projection of x by the uniqueness in Theorem 12.18. The left side of Equation (12.16) is non-negative, so $\sum_{n \le N} |c_n|^2 \le \|x\|^2$ for every N; a bounded increasing sequence of partial sums converges, by Axiom 7.1, and its limit obeys the same bound. □

Bessel's inequality says that the coefficients of any vector are square summable. The converse question — which square-summable coefficient sequences arise — has the best possible answer, and it is completeness that supplies it.

Proposition 12.28 (Convergence criterion for orthogonal series)**.** *Let $\{e_n\}$ be an orthonormal system in a Hilbert space and let $c_n \in \mathbb{C}$. The series $\sum_n c_n e_n$ converges in $\mathcal{H}$ if and only if $\sum_n |c_n|^2 < \infty$, and then $\|\sum_n c_n e_n\|^2 = \sum_n |c_n|^2$ and $\langle e_m | \sum_n c_n e_n \rangle = c_m$.*
Rests on Definitions 12.2 and 12.26.

Proof. *Derives Proposition 12.28.*

By orthonormality and the Pythagorean identity, for $M > N$,

$$\left\| \sum_{n=N+1}^{M} c_n e_n \right\|^2 = \sum_{n=N+1}^{M} |c_n|^2 \,. \tag{12.17}$$

So the partial sums of $\sum_n c_n e_n$ form a Cauchy sequence in $\mathcal{H}$ if and only if the partial sums of $\sum_n |c_n|^2$ form a Cauchy sequence in $\mathbb{R}$. By Definition 12.2 and Theorem 7.8 respectively, each is equivalent to the convergence of the corresponding series. The norm identity follows by letting $N = 0$ and $M \to \infty$ in Equation (12.17) and using Corollary 12.5; the coefficient identity follows from Proposition 12.4, which allows $\langle e_m | \cdot \rangle$ to be taken through the limit. □

Definition 12.29 (Orthonormal basis)**.** An orthonormal system $\{e_n\}$ in $\mathcal{H}$ is an *orthonormal basis*, or a *complete* orthonormal system, if it is maximal: the only vector orthogonal to every e_n is 0.

Rests on Definitions 12.16 and 12.26.

Theorem 12.30 (Completeness, expansion, Parseval)**.** *Let $\{e_n\}$ be an orthonormal system in a Hilbert space $\mathcal{H}$. The following are equivalent.*

1. *$\{e_n\}$ is maximal, i.e. an orthonormal basis (Definition 12.29);*
2. *the finite linear combinations of the e_n are dense in $\mathcal{H}$;*
3. *every $x \in \mathcal{H}$ is the sum of its Fourier series,*

$$x = \sum_n \langle e_n | x \rangle \; e_n \,, \tag{12.18}$$

   the series converging in the norm of $\mathcal{H}$;

4. *Parseval's identity holds for every $x \in \mathcal{H}$,*

$$\|x\|^2 = \sum_n |\langle e_n | x \rangle|^2 \,. \tag{12.19}$$

Any of these implies the polarized form

$$\langle x | y \rangle = \sum_n \langle x | e_n \rangle \, \langle e_n | y \rangle \,, \qquad \forall\, x, y \in \mathcal{H} \,. \tag{12.20}$$

Rests on Propositions 12.27 and 12.28 and Corollary 12.19.

Proof. *Derives Theorem 12.30.*

(1) ⇒ (3). By Equation (12.15) the coefficients $c_n = \langle e_n | x \rangle$ are square summable, so by Proposition 12.28 the series $\sum_n c_n e_n$ converges to some $y \in \mathcal{H}$ with $\langle e_m | y \rangle = c_m = \langle e_m | x \rangle$ for every m. Then $x - y$ is orthogonal to every e_m, hence $x = y$ by maximality.

(3) ⇒ (2). The partial sums of Equation (12.18) are finite linear combinations converging to x.

(2) ⇒ (1). If x is orthogonal to every e_n then $x \in \{e_n\}^\perp = \overline{\langle \{e_n\} \rangle}^{\perp} = \mathcal{H}^\perp = \{0\}$, by Proposition 12.17 and density.

(3) ⇒ (4). Take norms in Equation (12.18) using the norm identity of Proposition 12.28.

(4) ⇒ (1). If $x \perp e_n$ for every n, then Equation (12.19) gives $\|x\|^2 = 0$.

Finally Equation (12.20) follows from Equation (12.19) by polarization: apply Equation (12.3) to both sides, each of the four terms of which is an instance of Equation (12.19). Alternatively, substitute Equation (12.18) for y and take $\langle x | \cdot \rangle$ through the sum by Proposition 12.4. □

Remark 12.31 (What "basis" has come to mean). An orthonormal basis in the sense of Definition 12.29 is *not* a basis in the algebraic sense of Definition 5.14: the expansion Equation (12.18) is an infinite sum, a limit in the topology, and not a finite linear combination. The two notions coincide only in finite dimension. An infinite-dimensional Hilbert space does have algebraic bases, but they are uncountable and useless; the topological notion is the one physics means, and Chapter 5 said as much when it reserved this section. The identity Equation (12.20), written in Dirac notation as $\sum_n |e_n\rangle\langle e_n| = \mathbb{1}$, is the completeness relation used constantly from Chapter 77 onwards.

Definition 12.32 (Separable Hilbert space)**.** $\mathcal{H}$ is *separable* if it contains a countable dense subset.

Rests on Definitions 6.27 and 12.2.

Theorem 12.33 (Every separable Hilbert space is ℓ^2)**.** *Let $\mathcal{H}$ be a separable Hilbert space of infinite dimension. Then there is a linear bijection $U : \mathcal{H} \longrightarrow \ell^2$ preserving the inner product, $\langle Ux|Uy\rangle_{\ell^2} = \langle x|y\rangle$. Any two separable infinite-dimensional Hilbert spaces are therefore isomorphic; up to isomorphism there is only one.*

Rests on Corollary 12.24, Theorem 12.30, and Proposition 12.10.

Proof. *Derives Theorem 12.33.*

By Corollary 12.24 there is a countable orthonormal family $\{e_n\}$ whose finite combinations are dense, which is condition (2) of Theorem 12.30; the family is infinite because $\mathcal{H}$ is. Define $Ux = (\langle e_n|x\rangle)_n$. It lands in ℓ^2 by Equation (12.15), is linear because the bracket is linear in its second slot, and is isometric by Equation (12.19); an isometric linear map is injective. It is surjective because a sequence $(c_n) \in \ell^2$ is, by Proposition 12.28, the coefficient sequence of the convergent sum $\sum_n c_n e_n$. Preservation of the inner product is Equation (12.20), or equivalently isometry plus Equation (12.3). Composing the map for one space with the inverse of the map for another gives the last claim. □

Remark 12.34 (Why wave mechanics and matrix mechanics agree). Theorem 12.33 is a mathematical triviality with a large physical consequence. Heisenberg's mechanics is written on ℓ^2 — infinite matrices acting on square-summable coefficient sequences — and Schrödinger's on L^2, and the two were presented as rival theories. They are formulations on the same space: L^2 is separable, so Theorem 12.33 produces a bracket-preserving bijection with ℓ^2, and the map is explicitly the assignment of Fourier coefficients in any orthonormal basis, Equation (12.14). This is the observation von Neumann made the organising principle of his treatise [706], and it is why Chapter 77 may state the postulates on an abstract $\mathcal{H}$ without choosing a representation. The name attached to Equation (12.19) is Parseval's [51], who wrote the identity for trigonometric series more than a century before there was a space to write it on; the general form is inseparable from the Riesz–Fischer theorem [335, 336], of which it is the abstract shadow, and the trigonometric case is worked out in Chapter 17.

12.3 Bounded operators and duality

12.3.1 Bounded operators and their adjoints

In finite dimension every linear map is continuous, so Chapter 5 never had to distinguish the algebra of linear transformations from the analysis of continuous ones. Here they part company, and the first order of business is to show that for linear maps the two words mean the same thing.

Definition 12.35 (Bounded operator; operator norm)**.** A linear map $A : \mathcal{H}_1 \longrightarrow \mathcal{H}_2$ is *bounded* if there is $C \geq 0$ with $\|Ax\| \leq C\,\|x\|$ for all x. The least such C,

$$\|A\| = \sup_{x \neq 0} \frac{\|Ax\|}{\|x\|} = \sup_{\|x\|=1} \|Ax\| \,, \tag{12.21}$$

is the *operator norm*. The bounded operators from $\mathcal{H}$ to itself form a set written $\mathcal{B}(\mathcal{H})$.
Rests on Definitions 5.18 and 5.35.

Proposition 12.36 (Boundedness is continuity)**.** *For a linear $A : \mathcal{H}_1 \longrightarrow \mathcal{H}_2$ the following are equivalent: (i) A is continuous at 0; (ii) A is continuous everywhere; (iii) A is bounded.*
Rests on Definition 12.35 and Proposition 6.28.

Proof. *Derives Proposition 12.36.*

(iii) $\Rightarrow$ (ii): $\|Ax - Ax_0\| = \|A(x - x_0)\| \leq \|A\| \, \|x - x_0\|$, so $\delta = \varepsilon/(1 + \|A\|)$ serves in Equation (6.11). (ii) $\Rightarrow$ (i) is a special case. (i) $\Rightarrow$ (iii): continuity at 0 with $\varepsilon = 1$ gives a $\delta > 0$ with $\|Ax\| \leq 1$ whenever $\|x\| \leq \delta$. For $x \neq 0$ apply this to $\delta x / \|x\|$, which has norm δ: $\|Ax\| \leq \|x\| / \delta$, so A is bounded with $\|A\| \leq 1/\delta$. □

Proposition 12.37 ($\mathcal{B}(\mathcal{H})$ is a Banach algebra)**.** *Equation (12.21) is a norm on $\mathcal{B}(\mathcal{H})$; it is submultiplicative,*

$$\|AB\| \leq \|A\| \, \|B\| \,, \tag{12.22}$$

the identity $\mathbb{1}$ has norm 1, and $\mathcal{B}(\mathcal{H})$ is complete.
Rests on Definition 12.35 and Proposition 12.8.

Proof. *Derives Proposition 12.37.*

The norm axioms Equations (5.40) to (5.42) follow pointwise from those of $\mathcal{H}$ and the definition of a supremum; Equation (12.22) from $\|ABx\| \leq \|A\| \, \|Bx\| \leq \|A\| \, \|B\| \, \|x\|$.

For completeness let (A_n) be Cauchy in $\mathcal{B}(\mathcal{H})$. For each x, $\|A_n x - A_m x\| \leq \|A_n - A_m\| \, \|x\|$, so $(A_n x)$ is Cauchy in $\mathcal{H}$ and converges; call the limit Ax. The map A is linear, being a pointwise limit of linear maps (Proposition 12.4 is not even needed: addition and scalar multiplication are continuous). Given $\varepsilon > 0$ pick N with $\|A_n - A_m\| \leq \varepsilon$ for $n, m \geq N$; then $\|A_n x - A_m x\| \leq \varepsilon \, \|x\|$, and letting $m \to \infty$ with x fixed gives $\|A_n x - Ax\| \leq \varepsilon \, \|x\|$. Hence $A - A_N$ is bounded, so A is, and $\|A_n - A\| \leq \varepsilon$ for $n \geq N$. □

Theorem 12.38 (Existence and uniqueness of the adjoint)**.** *For every $A \in \mathcal{B}(\mathcal{H})$ there is exactly one $A^\dagger \in \mathcal{B}(\mathcal{H})$ with*

$$\left\langle A^\dagger x \middle| y \right\rangle = \langle x | Ay \rangle \,, \qquad \forall \, x, y \in \mathcal{H} \,, \tag{12.23}$$

and $\left\| A^\dagger \right\| = \|A\|$.
Rests on Definition 5.39, Theorem 12.46, and Proposition 12.37.

Proof. *Derives Theorem 12.38.*

Fix x. The map $y \longmapsto \langle x | Ay \rangle$ is linear, by Equations (5.34) and (5.35) and linearity of A, and bounded, $|\langle x | Ay \rangle| \leq \|x\| \, \|A\| \, \|y\|$ by Equation (12.1). By the Riesz representation theorem (Theorem 12.46) there is a unique vector, call it $A^\dagger x$, with $\left\langle A^\dagger x \middle| y \right\rangle = \langle x | Ay \rangle$ for all y. No circularity is involved: Theorem 12.46 is proved in Section 12.3.2 from Theorem 12.18 alone and uses nothing from the present subsection. Uniqueness of $A^\dagger x$ is uniqueness in Riesz's theorem; linearity of $x \longmapsto A^\dagger x$ follows because $\left\langle A^\dagger(ax_1 + bx_2) - aA^\dagger x_1 - bA^\dagger x_2 \middle| y \right\rangle = 0$ for every y, using Equations (5.36) and (5.37), so the vector in the first slot is 0 by Equation (5.31).

For the norm, Equation (12.23) with $y = A^\dagger x$ gives

$$\left\| A^\dagger x \right\|^2 = \left\langle A^\dagger x \middle| A^\dagger x \right\rangle = \left\langle x \middle| AA^\dagger x \right\rangle \leq \|x\| \, \|A\| \, \left\| A^\dagger x \right\| \,,$$

whence $\left\| A^\dagger x \right\| \leq \|A\| \, \|x\|$ and $\left\| A^\dagger \right\| \leq \|A\|$. Reading Equation (12.23) backwards shows $(A^\dagger)^\dagger = A$, and the same estimate then gives the reverse inequality. □

Equation (12.23) is Equation (5.69) verbatim; what has changed is the proof. In finite dimension Proposition 5.40 built $A^\dagger$ from an orthonormal basis and read off the conjugate transpose. Here there is no finite basis to write a matrix in, and the existence of $A^\dagger$ is a theorem of analysis, resting on completeness through the projection theorem.

Proposition 12.39 (Algebra of the adjoint; the C^* identity)**.** *For $A, B \in \mathcal{B}(\mathcal{H})$ and $a \in \mathbb{C}$:*

$$(A+B)^\dagger = A^\dagger + B^\dagger\,, \quad (aA)^\dagger = a^* A^\dagger\,, \quad (AB)^\dagger = B^\dagger A^\dagger\,, \quad (A^\dagger)^\dagger = A\,, \tag{12.24}$$

and

$$\left\| A^\dagger A \right\| = \|A\|^2\,. \tag{12.25}$$

Moreover $\ker A^\dagger = (\operatorname{im} A)^\perp$.

Rests on Theorem 12.38 and Proposition 12.37.

Proof. *Derives Proposition 12.39.*

Each identity in Equation (12.24) is verified by checking that both sides satisfy Equation (12.23) for the operator in question and invoking uniqueness; for the product, $\left\langle B^\dagger A^\dagger x \middle| y \right\rangle = \left\langle A^\dagger x \middle| By \right\rangle = \langle x | ABy \rangle$.

For Equation (12.25), one inequality is Equation (12.22) together with $\left\|A^\dagger\right\| = \|A\|$. For the other, for any x with $\|x\| = 1$,

$$\|Ax\|^2 = \langle Ax | Ax \rangle = \left\langle A^\dagger A x \middle| x \right\rangle \le \left\| A^\dagger A x \right\| \, \|x\| \le \left\| A^\dagger A \right\|\,,$$

using Equation (12.23) and Equation (12.1); taking the supremum over such x gives $\|A\|^2 \le \left\|A^\dagger A\right\|$.

Finally $x \in \ker A^\dagger$ means $\left\langle A^\dagger x \middle| y \right\rangle = 0$ for all y, that is, $\langle x | Ay \rangle = 0$ for all y, that is, $x \in (\operatorname{im} A)^\perp$. □

Remark 12.40 (Why $\mathcal{B}(\mathcal{H})$ is the model C^*-algebra). A Banach algebra with an involution obeying Equation (12.24) and the norm identity Equation (12.25) is called a C^*-algebra, and Propositions 12.37 and 12.39 say that $\mathcal{B}(\mathcal{H})$ is one. The identity is far stronger than the inequality $\left\|A^\dagger A\right\| \le \|A\| \left\|A^\dagger\right\|$ that any Banach $*$-algebra has: it ties the norm to the algebra so tightly that a C^*-algebra admits exactly one norm making it one, so the analytic structure is determined by the algebraic. That rigidity is what the algebraic formulations of quantum theory (Chapter 109) trade on. This treatise does not develop C^*-algebras; Equation (12.25) is proved here because it is used directly — it is what makes $\|A^2\| = \|A\|^2$ for self-adjoint A, and hence what controls the functional calculus of Section 12.4.2.

Definition 12.41 (The operator classes)**.** Let $A \in \mathcal{B}(\mathcal{H})$. It is

1. *self-adjoint* (or hermitian) if $A^\dagger = A$;
2. *unitary* if $A^\dagger A = A A^\dagger = \mathbb{1}$;
3. *normal* if $A^\dagger A = A A^\dagger$;
4. *positive*, written $A \ge 0$, if $\langle x | Ax \rangle \ge 0$ for every x;
5. a *projection* if $A^2 = A = A^\dagger$ (Proposition 12.21);
6. *compact* if the image under A of the unit ball $\{x \mid \|x\| \le 1\}$ has compact closure (Definition 6.9).

Rests on Theorem 12.38, Definition 6.9, and Proposition 12.21.

Proposition 12.42 (Elementary consequences)**.** *(i) Self-adjoint and unitary operators are normal, and a projection is self-adjoint and positive. (ii) A unitary U preserves the inner product, $\langle Ux|Uy\rangle = \langle x|y\rangle$, and $\|U\| = 1$ when $\mathcal{H} \neq \{0\}$. (iii) On a complex Hilbert space, A is self-adjoint if and only if $\langle x|Ax\rangle \in \mathbb{R}$ for every x; in particular a positive operator is self-adjoint. (iv) $A^\dagger A$ is positive for every A.*

Rests on Definition 12.41 and Proposition 12.39.

Proof. *Derives Proposition 12.42.*

(i) and (iv) are immediate from the definitions, (iv) because $\left\langle x\middle|A^\dagger Ax\right\rangle = \|Ax\|^2 \geq 0$. (ii) $\langle Ux|Uy\rangle = \left\langle U^\dagger Ux\middle|y\right\rangle = \langle x|y\rangle$, and $y = x$ gives $\|Ux\| = \|x\|$.

(iii) If $A^\dagger = A$ then $\langle x|Ax\rangle = \langle Ax|x\rangle = \langle x|Ax\rangle^*$ by Equation (5.33), so the number is real. Conversely suppose $\langle x|Ax\rangle$ is real for every x, and put $B = A - A^\dagger$, so that $\langle x|Bx\rangle = \langle x|Ax\rangle - \langle Ax|x\rangle = 0$ for every x. Replacing x by $x + y$ and by $x + \mathrm{i}y$ and expanding as in Equation (12.4) gives $\langle x|By\rangle + \langle y|Bx\rangle = 0$ and $\langle x|By\rangle - \langle y|Bx\rangle = 0$, whence $\langle x|By\rangle = 0$ for all x, y and $B = 0$. (The complex field is essential: on a real Hilbert space a rotation by a quarter turn in a plane has $\langle x|Ax\rangle = 0$ identically and is not self-adjoint.) □

Proposition 12.43 (Norm of a self-adjoint operator)**.** *If $A \in \mathcal{B}(\mathcal{H})$ is self-adjoint then*

$$\|A\| = \sup_{\|x\|=1} |\langle x|Ax\rangle| \,. \tag{12.26}$$

In particular a self-adjoint operator with $\langle x|Ax\rangle = 0$ for all x is 0.

Rests on Propositions 12.39 and 12.42.

Proof. *Derives Proposition 12.43.*

Write M for the supremum. That $M \leq \|A\|$ is Equation (12.1). For the converse, note first that $|\langle z|Az\rangle| \leq M\|z\|^2$ for every z, by homogeneity. Since A is self-adjoint, $\langle y|Ax\rangle = \langle Ay|x\rangle = \langle x|Ay\rangle^*$, so

$$\langle x+y|A(x+y)\rangle - \langle x-y|A(x-y)\rangle = 2\langle x|Ay\rangle + 2\langle y|Ax\rangle = 4\,\mathrm{Re}\,\langle x|Ay\rangle \,.$$

Bounding each term on the left and using Equation (12.2),

$$4\,|\mathrm{Re}\,\langle x|Ay\rangle| \leq M\left(\|x+y\|^2 + \|x-y\|^2\right) = 2M\left(\|x\|^2 + \|y\|^2\right) .$$

Take $\|x\| = \|y\| = 1$, so $|\mathrm{Re}\,\langle x|Ay\rangle| \leq M$; replacing x by $\mathrm{e}^{\mathrm{i}\theta}x$ for a suitable θ makes $\langle x|Ay\rangle$ real and non-negative, giving $|\langle x|Ay\rangle| \leq M$. Now take the supremum over unit x: if $Ay \neq 0$ the choice $x = Ay/\|Ay\|$ gives $|\langle x|Ay\rangle| = \|Ay\|$, so $\|Ay\| \leq M$, and if $Ay = 0$ that bound is trivial. Hence $\|Ay\| \leq M$ for every unit y, i.e. $\|A\| \leq M$. □

Theorem 12.44 (Hilbert–Schmidt: compact self-adjoint operators)**.** *Let $A \in \mathcal{B}(\mathcal{H})$ be compact and self-adjoint on a Hilbert space $\mathcal{H} \neq \{0\}$. Then $\mathcal{H}$ has an orthonormal basis of eigenvectors of A: there are real $\lambda_1, \lambda_2, \ldots$ with $\lambda_n \to 0$ and an orthonormal system $\{e_n\}$ with*

$$Ax = \sum_n \lambda_n \langle e_n|x\rangle\, e_n \,, \qquad \forall\, x \in \mathcal{H} \,, \tag{12.27}$$

the series converging in norm. Every non-zero eigenvalue has finite-dimensional eigenspace, and $\|A\| = \max_n |\lambda_n|$.

Rests on Definition 12.41, Proposition 12.43, and Theorem 12.30.

The derivation is carried out in Appendix A.23. The route is: the supremum in the numerical-radius formula Equation (12.26) is attained on a compact operator, which produces a first eigenvector; its orthogonal complement is invariant, and the argument recurses; the eigenvalues tend to zero because an orthonormal sequence of eigenvectors with eigenvalues

bounded away from 0 has an image with no convergent subsequence. The attainment step is the one that needs compactness, and the appendix carries it out without the weak topology, which the standard treatment [1481] uses: self-adjointness alone forces a maximising sequence to satisfy $Ax_n - \lambda x_n \to 0$ in norm, after which the sequential form of compactness delivers a genuine eigenvector.

Full derivation: Appendix A.23 (p. 2885).

Derives Theorem 12.44.

Equation (12.27) is the exact infinite-dimensional analogue of the finite-dimensional spectral theorem Equation (5.105), and it is the only case in which the analogy is that close — the eigenvectors really do form a basis. It is also the historical starting point: this is the theorem Hilbert proved for the symmetric integral kernels of his spectral theory [388] and that Schmidt recast in the language used here [338]. The kernels concerned,

$$(Kf)(x) = \int_\Omega K(x,y)\, f(y)\, \mathrm{d}^N y\,, \qquad \int_\Omega \int_\Omega |K(x,y)|^2 \, \mathrm{d}^N x\, \mathrm{d}^N y < \infty\,, \tag{12.28}$$

define compact operators on $L^2(\Omega)$, and K is self-adjoint exactly when $K(y,x) = K(x,y)^*$. The Green functions of Chapter 10 are of this form, which is why a boundary-value problem has a discrete spectrum of modes while the free operators of Section 12.4.1 need not.

12.3.2 The Riesz representation theorem

Definition 12.45 (Continuous linear functional; the dual)**.** A *continuous linear functional* on $\mathcal{H}$ is a bounded linear map $f : \mathcal{H} \longrightarrow \mathbb{C}$. The set of them is the *topological dual* $\mathcal{H}^*$, normed by Equation (12.21).

Rests on Definitions 5.44 and 12.35.

Theorem 12.46 (Riesz representation)**.** *For every $f \in \mathcal{H}^*$ there is exactly one $z \in \mathcal{H}$ with*

$$f(x) = \langle z | x \rangle\,, \qquad \forall\, x \in \mathcal{H}\,, \tag{12.29}$$

and $\|f\| = \|z\|$.

Rests on Theorem 12.18 and Definition 12.45.

Proof. *Derives Theorem 12.46.*

If $f = 0$ take $z = 0$; uniqueness is proved below. Otherwise let $N = \ker f$, a subspace, closed because f is continuous and $N = f^{-1}(\{0\})$ is the preimage of a closed set (Definition 6.6), and proper because $f \neq 0$. By Theorem 12.18 applied to N, and by $N^\perp \neq \{0\}$ — which holds because otherwise $\mathcal{H} = N \oplus \{0\} = N$ — we may choose $u \in N^\perp$ with $\|u\| = 1$; note $f(u) \neq 0$, since $u \notin N$.

For arbitrary x, the vector $f(x)\,u - f(u)\,x$ is annihilated by f, by linearity, so it lies in N and is orthogonal to u:

$$0 = \langle u | f(x)u - f(u)x \rangle = f(x)\,\langle u|u\rangle - f(u)\,\langle u|x\rangle = f(x) - f(u)\,\langle u|x\rangle\,.$$

Hence $f(x) = f(u)\,\langle u|x\rangle = \langle f(u)^* u | x\rangle$ by Equation (5.36), and $z = f(u)^* u$ represents f.

Uniqueness. If $\langle z|x\rangle = \langle z'|x\rangle$ for all x, take $x = z - z'$ and use Equation (5.31). *Norm.* $|f(x)| \le \|z\|\,\|x\|$ by Equation (12.1), so $\|f\| \le \|z\|$; and $f(z) = \|z\|^2$ gives $\|f\| \ge \|z\|$. □

Corollary 12.47 ($\mathcal{H}$ is its own dual, antilinearly)**.** *The map $J : \mathcal{H} \longrightarrow \mathcal{H}^*$, $Jz = \langle z|\cdot\rangle$, is a bijection, is isometric, and is* antilinear*: $J(az_1 + bz_2) = a^* Jz_1 + b^* Jz_2$.*

Rests on Theorem 12.46 and Definition 12.45.

Proof. *Derives Corollary 12.47.*

Surjectivity and injectivity are the existence and uniqueness in Theorem 12.46, isometry is its last clause, and antilinearity is Equation (5.36). □

Remark 12.48 (What the bra–ket notation is). Corollary 12.47 is the whole content of Dirac's notation [1140]. The edition cited is the fourth, and deliberately so: the bra–ket split is not in the first edition of the *Principles* of 1930 [646], which is the source of the delta-function calculus used later in this chapter and of nothing else here. Dirac introduced the split in a note of 1939 [832], and brought it into the book at the third edition of 1947. Writing the vector z as $|z\rangle$ and the functional Jz as $\langle z|$, the value of the functional on a vector is $\langle z|x\rangle$ — the bracket split into a bra and a ket, which is where the words come from. The antilinearity of J is the rule that scalars are conjugated on passing the vertical bar, $\langle az| = a^* \langle z|$, and it is not a convention but a theorem: it is forced by Equation (5.36). In finite dimension the same identification was made in Proposition 5.59, where it needed only a basis; the point of Theorem 12.46 is that it survives without one.

The identification is special to Hilbert spaces and is exactly what fails elsewhere. The dual of a Banach space is in general a different space, and even for a pre-Hilbert space that is not complete the theorem is false — completeness enters through Theorem 12.18. It fails again, in the opposite direction, when one insists on writing $|x\rangle$ and $|p\rangle$ for position and momentum "eigenstates": those are functionals on a smaller space than $\mathcal{H}$ and correspond to no vector of $\mathcal{H}$ at all. That is the subject of Section 12.6.3, and it is the one place in this treatise where the bra–ket notation has to be read with care.

12.4 Self-adjointness and the spectral theorem

12.4.1 Spectrum and resolvent

Definition 12.49 (Resolvent set; spectrum)**.** Let $A \in \mathcal{B}(\mathcal{H})$. The *resolvent set* is

$$\rho(A) = \{\lambda \in \mathbb{C} \mid A - \lambda \mathbb{1} \text{ has an inverse in } \mathcal{B}(\mathcal{H})\} \,, \tag{12.30}$$

the map $R(\lambda) = (A - \lambda\mathbb{1})^{-1}$ on $\rho(A)$ is the *resolvent*, and the *spectrum* is $\sigma(A) = \mathbb{C} \setminus \rho(A)$.
Rests on Definitions 5.45 and 12.35.

Definition 12.50 (Point, continuous and residual spectrum)**.** For $\lambda \in \sigma(A)$ write $T = A - \lambda\mathbb{1}$. Then λ belongs to

1. the *point spectrum* $\sigma_p(A)$ if T is not injective; λ is then an *eigenvalue* and $\ker T$ the eigenspace;
2. the *continuous spectrum* $\sigma_c(A)$ if T is injective, $\operatorname{im} T$ is dense, and the inverse map T^{-1}, defined on $\operatorname{im} T$, is unbounded;
3. the *residual spectrum* $\sigma_r(A)$ if T is injective and $\operatorname{im} T$ is not dense.

Rests on Definition 12.49 and Corollary 12.19.

Proposition 12.51 (The three cases are exclusive and exhaustive)**.** *$\sigma(A)$ is the disjoint union of $\sigma_p(A)$, $\sigma_c(A)$ and $\sigma_r(A)$.*
Rests on Definitions 12.2 and 12.50.

Proof. *Derives Proposition 12.51.*

Exclusivity is clear from the statements. For exhaustiveness, suppose λ belongs to none of the three: then T is injective, $\operatorname{im} T$ is dense, and T^{-1} is bounded on $\operatorname{im} T$, say $\|T^{-1}y\| \le c\,\|y\|$. Then $\operatorname{im} T$ is closed: if $Tx_n \to y$, the sequence (Tx_n) is Cauchy, so $\|x_n - x_m\| \le c\,\|Tx_n - Tx_m\|$ shows (x_n) is Cauchy, and $x_n \to x$ for some x by Definition 12.2, with $Tx = y$ because T is continuous. A dense closed subspace is the whole space, so $\operatorname{im} T = \mathcal{H}$ and $T^{-1} \in \mathcal{B}(\mathcal{H})$, i.e. $\lambda \in \rho(A)$. □

In finite dimension injectivity and surjectivity coincide (Proposition 5.47) and only σ_p survives; Remark 5.48 already recorded that this is the identity that infinite dimension destroys.

Proposition 12.52 (Neumann series; the spectrum is bounded)**.** *If $|\lambda| > \|A\|$ then $\lambda \in \rho(A)$ and*

$$R(\lambda) = -\sum_{n=0}^{\infty} \frac{A^n}{\lambda^{n+1}}\,, \qquad \|R(\lambda)\| \le \frac{1}{|\lambda| - \|A\|}\,. \tag{12.31}$$

Hence $\sigma(A)$ is contained in the closed disc of radius $\|A\|$ about the origin, and $\|R(\lambda)\| \to 0$ as $|\lambda| \to \infty$.

Rests on Proposition 12.37 and Definition 12.49.

Proof. *Derives Proposition 12.52.*

By Equation (12.22), $\|A^n/\lambda^{n+1}\| \le \|A\|^n / |\lambda|^{n+1}$, a geometric series of ratio $\|A\| / |\lambda| < 1$ (Proposition 7.46), so the series converges absolutely and hence in $\mathcal{B}(\mathcal{H})$, by Propositions 12.8 and 12.37; its sum S obeys the stated norm bound. Multiplying the partial sums by $A - \lambda\mathbb{1}$ telescopes to $-\mathbb{1} + A^{N+1}/\lambda^{N+1}$, whose second term tends to 0; by continuity of multiplication in a Banach algebra, $(A - \lambda\mathbb{1})S = S(A - \lambda\mathbb{1}) = -\mathbb{1}$. Hence $A - \lambda\mathbb{1}$ is invertible with $R(\lambda) = (A - \lambda\mathbb{1})^{-1} = -S$, which is Equation (12.31), and $\|R(\lambda)\| = \|S\|$ obeys the bound already established. □

Proposition 12.53 (The resolvent set is open, the resolvent analytic)**.** *$\rho(A)$ is open, and for $x, y \in \mathcal{H}$ the scalar function $\lambda \longmapsto \langle x|R(\lambda)y\rangle$ is holomorphic on $\rho(A)$.*

Rests on Proposition 12.52 and Definition 8.5.

Proof. *Derives Proposition 12.53.*

Let $\lambda_0 \in \rho(A)$ and write $A - \lambda\mathbb{1} = (A - \lambda_0\mathbb{1})\big[\mathbb{1} - (\lambda - \lambda_0)R(\lambda_0)\big]$. For $|\lambda - \lambda_0| < 1/\|R(\lambda_0)\|$ the bracket is invertible by the same geometric-series argument as in Proposition 12.52, so $\lambda \in \rho(A)$ and

$$R(\lambda) = \sum_{n=0}^{\infty} (\lambda - \lambda_0)^n R(\lambda_0)^{n+1}\,. \tag{12.32}$$

Pairing Equation (12.32) with x and y and using Proposition 12.4 to take the bracket through the sum exhibits $\langle x|R(\lambda)y\rangle$ as a convergent power series about λ_0, hence holomorphic there (Theorem 7.50, and Chapter 8 for the complex statement). □

Theorem 12.54 (The spectrum is compact and non-empty)**.** *For $A \in \mathcal{B}(\mathcal{H})$ with $\mathcal{H} \neq \{0\}$, the set $\sigma(A)$ is compact and non-empty.*

Rests on Propositions 12.52 and 12.53 and Theorem 8.18.

Proof. *Derives Theorem 12.54.*

$\sigma(A)$ is closed because $\rho(A)$ is open (Proposition 12.53) and bounded by Proposition 12.52; a closed bounded subset of $\mathbb{C}$, identified with $\mathbb{R}^2$ as a metric space, is compact by the Heine–Borel theorem in $\mathbb{R}^N$ (Section 6.1.3, where the one-dimensional case Theorem 6.11 is proved and the N-dimensional one is recorded as owed).

Suppose $\sigma(A) = \varnothing$. Then for every x, y the function $g(\lambda) = \langle x|R(\lambda)y\rangle$ is entire, by Proposition 12.53, and by the norm bound in Equation (12.31) together with Equation (12.1) it satisfies $|g(\lambda)| \le \|x\|\,\|y\| / (|\lambda| - \|A\|)$ for $|\lambda| > \|A\|$, so g is bounded on $\mathbb{C}$ and tends to 0 at infinity. By Liouville's theorem (Theorem 8.18) g is constant, and the constant is 0. Since x and y were arbitrary, $R(\lambda) = 0$ for every λ — impossible, because $R(\lambda)(A - \lambda\mathbb{1}) = \mathbb{1} \neq 0$ on $\mathcal{H} \neq \{0\}$. □

Theorem 12.55 (The spectrum of a self-adjoint operator is real)**.** *Let $A \in \mathcal{B}(\mathcal{H})$ be self-adjoint. Then $\sigma(A) \subseteq \mathbb{R}$, the residual spectrum is empty, eigenvalues are real, and eigenvectors belonging to distinct eigenvalues are orthogonal.*

Rests on Definition 12.41, Theorem 12.54, and Corollary 12.19.

Proof. *Derives Theorem 12.55.*

Let $\lambda = a + \mathrm{i}b$ with $a, b \in \mathbb{R}$ and $b \neq 0$, and put $B = A - a\mathbb{1}$, which is self-adjoint. Since $\langle x|Bx\rangle$ is real (Proposition 12.42), expanding as in Equation (12.4) with $\lambda = -\mathrm{i}b$ makes the two cross terms $-\mathrm{i}b\,\langle Bx|x\rangle$ and $+\mathrm{i}b\,\langle x|Bx\rangle$ cancel, leaving

$$\|(A - \lambda\mathbb{1})x\|^2 = \|Bx\|^2 + b^2\,\|x\|^2 \geq b^2\,\|x\|^2 \,. \tag{12.33}$$

So $A - \lambda\mathbb{1}$ is injective with $\|(A - \lambda\mathbb{1})^{-1}\| \leq 1/|b|$ on its image, and that image is dense: by Equation (12.24) the adjoint of $A - \lambda\mathbb{1}$ is $A - \lambda^*\mathbb{1}$, so

$$\big(\mathrm{im}(A - \lambda\mathbb{1})\big)^{\perp} = \ker(A - \lambda^*\mathbb{1}) = \{0\} \,,$$

by Proposition 12.39 and by Equation (12.33) applied to λ^*, which has the same $|b|$; density then follows from Corollary 12.19. So $A - \lambda\mathbb{1}$ is injective with dense image and bounded inverse on it, which by the argument of Proposition 12.51 puts λ in $\rho(A)$. Hence $\sigma(A) \subseteq \mathbb{R}$.

The same computation for real λ shows $\big(\mathrm{im}(A - \lambda\mathbb{1})\big)^{\perp} = \ker(A - \lambda\mathbb{1})$, so if $A - \lambda\mathbb{1}$ is injective its image is dense: the residual spectrum is empty. If $Ax = \lambda x$ with $x \neq 0$ then $\lambda\,\|x\|^2 = \langle x|Ax\rangle$ is real; and if $Ax = \lambda x$, $Ay = \mu y$ with $\lambda \neq \mu$ real, then $\lambda\,\langle x|y\rangle = \langle Ax|y\rangle = \langle x|Ay\rangle = \mu\,\langle x|y\rangle$, forcing $\langle x|y\rangle = 0$. □

Example 12.56 (Multiplication by the coordinate: spectrum without eigenvectors)**.** On $\mathcal{H} = L^2([0,1])$ define

$$(Qf)(t) = t\,f(t) \,. \tag{12.34}$$

Then Q is bounded and self-adjoint with $\|Q\| = 1$, and

$$\sigma(Q) = \sigma_c(Q) = [0,1] \,, \qquad \sigma_p(Q) = \varnothing \,. \tag{12.35}$$

The operator has a full interval of spectrum and not one eigenvector.

Rests on Definition 12.50, Theorem 12.55, and Example 12.11.

Proof. *Derives Example 12.56.*

Bounded and self-adjoint. $|tf(t)| \leq |f(t)|$ on $[0,1]$ gives $\|Qf\| \leq \|f\|$; and since t is real, $\langle f|Qg\rangle = \int_0^1 f(t)^* t\,g(t)\,\mathrm{d}t = \langle Qf|g\rangle$, which is Equation (12.23).

No eigenvectors. If $Qf = \lambda f$ then $(t - \lambda)f(t) = 0$ for almost every t, so f vanishes almost everywhere on $[0,1] \setminus \{\lambda\}$, a set whose complement in $[0,1]$ has measure zero; hence $f = 0$ as an element of L^2 (Example 12.11). This is exactly where the identification of functions agreeing almost everywhere does its work.

$\sigma(Q) \subseteq [0,1]$. For $\lambda \notin [0,1]$ the function $t \longmapsto (t - \lambda)^{-1}$ is continuous on the compact set $[0,1]$, hence bounded there by Theorem 7.24, so multiplication by it is a bounded operator and is a two-sided inverse of $Q - \lambda\mathbb{1}$.

$[0,1] \subseteq \sigma(Q)$. Fix $\lambda \in [0,1]$ and let I_n be the intersection of $[0,1]$ with the interval of half-width $1/n$ about λ, of length $\ell_n \geq 1/n$. Put $f_n = \ell_n^{-1/2}$ on I_n and 0 elsewhere, so $\|f_n\| = 1$ while

$$\|(Q - \lambda\mathbb{1})f_n\|^2 = \frac{1}{\ell_n}\int_{I_n} |t - \lambda|^2\,\mathrm{d}t \leq \frac{1}{n^2} \,.$$

If $Q - \lambda\mathbb{1}$ had a bounded inverse R we would get $1 = \|f_n\| \leq \|R\|\,\|(Q - \lambda)f_n\| \leq \|R\|/n$ for every n, which is false. Hence $\lambda \in \sigma(Q)$, and $\|Q\| = 1$ follows from Proposition 12.52 and $1 \in \sigma(Q)$. By Theorem 12.55 the residual spectrum is empty and by the previous paragraph the point spectrum is, so all of $[0,1]$ is continuous spectrum. □

Remark 12.57 (What the example costs). Example 12.56 is the operator Remark 5.79 promised, and it settles the shape of the rest of the chapter. Every statement of Theorem 5.75 that mentions eigenvectors is simply false for Q: there is no orthonormal basis of eigenvectors,

no diagonal matrix Equation (5.105), no decomposition of $\mathcal{H}$ into eigenspaces. What survives is the *real spectrum*, and what replaces the eigenbasis is an integral over that spectrum against a projection-valued measure — for Q itself, the measure that assigns to a Borel set $\Omega \subseteq [0,1]$ the projection "multiply by the indicator of Ω". Physically, the difference is the difference between a bound state, which is a genuine eigenvector with a normalisable wavefunction, and a scattering state, which is not; the two coexist in the hydrogen spectrum of Chapter 81 and are the whole subject of Chapter 86. It is also why a position "eigenstate" $|x_0\rangle$ cannot be a vector of L^2 — Section 12.6.3 says what it is instead.

12.4.2 The spectral theorem

Definition 12.58 (Projection-valued measure)**.** A *projection-valued measure* on $\mathbb{R}$, acting on $\mathcal{H}$, is a map E assigning to every Borel set $\Omega \subseteq \mathbb{R}$ a projection $E(\Omega) \in \mathcal{B}(\mathcal{H})$ (Definition 12.41) such that

1. $E(\varnothing) = 0$ and $E(\mathbb{R}) = \mathbb{1}$;
2. $E(\Omega_1 \cap \Omega_2) = E(\Omega_1)E(\Omega_2)$;
3. for pairwise disjoint $\Omega_1, \Omega_2, \ldots$ and every $x \in \mathcal{H}$,

$$E\Big(\bigcup_n \Omega_n\Big)x = \sum_n E(\Omega_n)\,x\,, \tag{12.36}$$

the series converging in the norm of $\mathcal{H}$.

For $x, y \in \mathcal{H}$ the complex measure $\Omega \longmapsto \langle x|E(\Omega)y\rangle$ is written $\langle x|\mathrm{d}E(\lambda)y\rangle$; taking $y = x$ gives a positive measure of total mass $\|x\|^2$.

Rests on Definition 12.41 and Proposition 12.21.

The last remark is the reason the definition is shaped this way: for a unit vector x, $\Omega \longmapsto \langle x|E(\Omega)x\rangle = \|E(\Omega)x\|^2$ is a probability measure on $\mathbb{R}$. That is already the Born rule in embryo, before any physics has been assumed (Chapter 77).

Theorem 12.59 (Spectral theorem for a bounded self-adjoint operator)**.** *Let $A \in \mathcal{B}(\mathcal{H})$ be self-adjoint. Then there is exactly one projection-valued measure E on $\mathbb{R}$, supported on $\sigma(A)$, such that*

$$\langle x|Ay\rangle = \int_{\sigma(A)} \lambda\, \langle x|\mathrm{d}E(\lambda)y\rangle\,, \qquad \forall\, x, y \in \mathcal{H}\,, \tag{12.37}$$

written $A = \int_{\sigma(A)} \lambda\,\mathrm{d}E(\lambda)$. Every bounded operator commuting with A commutes with every $E(\Omega)$.

Equivalently, in the multiplication form: if $\mathcal{H}$ is separable there is a measure space (M,μ) with $\mu(M) < \infty$, a bounded real measurable function a on M, and a unitary $U : \mathcal{H} \longrightarrow L^2(M,\mu)$ with

$$\big(UAU^{-1}f\big)(m) = a(m)\,f(m)\,, \qquad \forall\, f \in L^2(M,\mu)\,. \tag{12.38}$$

Every bounded self-adjoint operator is a multiplication operator in disguise.

Rests on Definition 12.58, Theorem 12.55, and Proposition 12.43.

Both halves are derived in Appendix A.24. The route is the standard one: the continuous functional calculus is built first, from the fact that for a self-adjoint operator the norm of a polynomial in it equals the supremum of that polynomial on the spectrum; a complex measure is then obtained for each pair of vectors by the Riesz–Markov representation theorem; the calculus is extended to bounded Borel functions, and the projections $E(\Omega)$ are the values it takes on indicator functions. The multiplication form follows by decomposing $\mathcal{H}$ into cyclic subspaces, on each of which the calculus itself provides the unitary. Two

classical theorems are used there and are not proved in this treatise — Riesz–Markov, which is measure theory, and Stone–Weierstrass, of which only the Weierstrass approximation theorem already quoted in Remark 12.1 is needed; the appendix states each precisely where it is used and collects both in a remark, and nothing else is assumed. The original is von Neumann's memoir [664]; the modern account followed there is [1481], chapters VII and VIII.
Full derivation: Appendix A.24 (p. 2889).

Derives Theorem 12.59.

The uniqueness of the functional calculus is worth isolating from that argument, and it costs only a paragraph, so it is proved here: it is what makes "the" functions of an observable well defined — without it the expression $f(A)$ would depend on how it was constructed.

Definition 12.60 (Functional calculus)**.** Given E as in Theorem 12.59 and a bounded Borel function $f : \sigma(A) \longrightarrow \mathbb{C}$, the operator $f(A)$ is defined by

$$\langle x | f(A)\, y \rangle = \int_{\sigma(A)} f(\lambda)\ \langle x | \mathrm{d}E(\lambda) y \rangle\ . \tag{12.39}$$

Rests on Theorem 12.59 and Definition 12.58.

Proposition 12.61 (Uniqueness of the continuous functional calculus)**.** *Let $A \in \mathcal{B}(\mathcal{H})$ be self-adjoint and let Φ_1, Φ_2 be maps from the continuous functions on $\sigma(A)$ to $\mathcal{B}(\mathcal{H})$ such that each is linear and multiplicative, sends the constant function 1 to $\mathbb{1}$ and the function $\lambda \longmapsto \lambda$ to A, and is continuous for the supremum norm on the domain and the operator norm on the target. Then $\Phi_1 = \Phi_2$.*

Rests on Definition 12.60 and Proposition 12.37.

Proof. *Derives Proposition 12.61.*

Linearity and multiplicativity, together with the two normalisations, force $\Phi_i(p) = p(A)$ for every polynomial p, where $p(A)$ is the algebraic expression: the monomial λ^n goes to A^n by multiplicativity and induction, and linear combinations follow. So Φ_1 and Φ_2 agree on polynomials. By the Weierstrass approximation theorem (Remark 12.1) the polynomials are dense, in the supremum norm, in the continuous functions on the compact set $\sigma(A)$ (Theorem 12.54). Two continuous maps agreeing on a dense subset of a metric space agree everywhere. □

Remark 12.62 (The finite-dimensional case is the whole picture)*.* In finite dimension Theorem 12.59 is Theorem 5.75, already proved, and the translation is worth carrying out once because it fixes the meaning of every symbol above. Let $\dim \mathcal{H} = n < \infty$ and let A be self-adjoint, with distinct eigenvalues $\lambda_1, \dots, \lambda_r$ and P_i the orthogonal projection onto the eigenspace of λ_i. Then Theorem 5.75 says

$$A = \sum_{i=1}^{r} \lambda_i P_i\,, \qquad \sum_{i=1}^{r} P_i = \mathbb{1}\,, \qquad P_i P_j = \delta_{ij} P_i\,, \tag{12.40}$$

and the projection-valued measure is $E(\Omega) = \sum_{\lambda_i \in \Omega} P_i$, which manifestly satisfies the three conditions of Definition 12.58; the integral Equation (12.37) is then a finite sum and reproduces Equation (12.40). The functional calculus Equation (12.39) becomes $f(A) = \sum_i f(\lambda_i) P_i$, which is the familiar rule that a function of a diagonalizable operator acts by that function on each eigenvalue. What the general theorem does is exactly to replace the finite sum over eigenvalues by an integral over the spectrum — nothing more, and nothing less. Example 12.56 shows why nothing less will do.

Remark 12.63 (Reading the spectral theorem physically)*.* Three of the quantum postulates of Chapter 77 are statements about Theorem 12.59. That an observable is represented by a self-adjoint operator is the demand that the theorem apply at all; that the possible values

of a measurement are the points of $\sigma(A)$ is the support statement; and that the probability of finding a value in Ω is $\|E(\Omega)\psi\|^2$ is the positive measure of Definition 12.58, whose total mass is 1 for a normalised state. The expectation value is $\langle\psi|A\psi\rangle$, which is Equation (12.37) read as the mean of that probability measure. Functions of observables — $\mathcal{H}^2$, $\mathrm{e}^{-\mathrm{i}\mathcal{H}t/\hbar}$, the projectors of a filtering measurement — are Equation (12.39), and Proposition 12.61 is what allows the treatise to speak of *the* function of an operator. This is the content von Neumann extracted from the formalism [664, 706], and it is the reason the postulates can be stated without approximation or interpretation of the mathematics.

12.4.3 Stone's theorem

Definition 12.64 (Strongly continuous one-parameter unitary group)**.** A family $\{U(t)\}_{t\in\mathbb{R}}$ of unitary operators on $\mathcal{H}$ is a *strongly continuous one-parameter unitary group* if

$$U(t+s) = U(t)\,U(s)\,, \qquad U(0) = \mathbb{1}\,, \tag{12.41}$$

and for every $x \in \mathcal{H}$ the map $t \longmapsto U(t)x$ is continuous from $\mathbb{R}$ to $\mathcal{H}$. The parameter t carries the SI unit s throughout this section.

Rests on Definitions 6.6 and 12.41.

Continuity is demanded of $t \longmapsto U(t)x$ for each fixed x (*strong* continuity), not of $t \longmapsto U(t)$ in the operator norm, which would be a much stronger and, for the groups physics needs, a false requirement — norm continuity forces the generator to be bounded, and Theorem 12.75 will show that the generators of interest are not.

Proposition 12.65 (Exponential of a bounded self-adjoint operator)**.** *Let $H \in \mathcal{B}(\mathcal{H})$ be self-adjoint, with the SI dimension of energy,* J*. Then the series*

$$U(t) = \exp\left(-\frac{\mathrm{i}Ht}{\hbar}\right) = \sum_{n=0}^{\infty} \frac{1}{n!}\left(-\frac{\mathrm{i}t}{\hbar}\right)^n H^n \tag{12.42}$$

converges in $\mathcal{B}(\mathcal{H})$ for every t and defines a strongly continuous one-parameter unitary group with

$$\mathrm{i}\hbar\,\frac{\mathrm{d}}{\mathrm{d}t}U(t)\,x = H\,U(t)\,x\,, \qquad \forall\, x \in \mathcal{H}\,, \tag{12.43}$$

the derivative existing in the norm of $\mathcal{H}$.

Rests on Propositions 12.37 and 12.39 and Definition 12.64.

Proof. *Derives Proposition 12.65.*

Since $\hbar$ has the SI unit J s, the combination $Ht/\hbar$ is dimensionless and Equation (12.42) is a sum of operators, as it must be. By Equation (12.22) the nth term has norm at most $(|t|\,\|H\|/\hbar)^n/n!$, so the series converges absolutely and hence in $\mathcal{B}(\mathcal{H})$, by Propositions 12.8 and 12.37.

The group law Equation (12.41) follows from the Cauchy product of the two absolutely convergent series (Proposition 7.49) and the binomial theorem, which is legitimate because the two exponents commute, both being polynomials in the single operator H. Taking adjoints term by term — legitimate by Equation (12.24) and continuity of the adjoint, which is isometric — and using $H^\dagger = H$ gives $U(t)^\dagger = \exp(+\mathrm{i}Ht/\hbar) = U(-t)$, which by the group law is $U(t)^{-1}$; so each $U(t)$ is unitary.

For Equation (12.43), the difference quotient

$$\frac{U(t+s)-U(t)}{s} + \frac{\mathrm{i}}{\hbar}H\,U(t) = \left[\frac{U(s)-\mathbb{1}}{s} + \frac{\mathrm{i}}{\hbar}H\right]U(t)$$

has norm at most $\|(U(s)-\mathbb{1})/s + \mathrm{i}H/\hbar\|$, and the bracket is the tail of Equation (12.42) divided by s, of norm at most $|s|\,\|H\|^2\,\hbar^{-2}\exp(|s|\,\|H\|/\hbar)$, which tends to 0. Multiplying by $\mathrm{i}\hbar$ gives Equation (12.43), in the operator norm and hence also strongly. □

Theorem 12.66 (Stone)**.** *The map $H \longmapsto U(t) = \exp(-\mathrm{i}Ht/\hbar)$ is a bijection between the self-adjoint operators on $\mathcal{H}$ — bounded or not, in the sense of Section 12.5.2 — and the strongly continuous one-parameter unitary groups on $\mathcal{H}$. Given the group, the operator is recovered as*

$$H\,x = \mathrm{i}\hbar \lim_{t\to 0} \frac{U(t)\,x - x}{t}\,, \tag{12.44}$$

on the domain $D(H)$ of vectors for which the limit exists, and $D(H)$ is dense with H self-adjoint on it.

Rests on Definition 12.64, Proposition 12.65, and Theorem 12.59.

Half of Theorem 12.66 was proved in Proposition 12.65 for bounded H, and one further piece — everything that does not require the unbounded functional calculus — is proved next; the remainder is derived in Appendix A.25.

Proposition 12.67 (The generator is symmetric, and generates the motion)**.** *Let U be a strongly continuous one-parameter unitary group and let $D(H)$ and H be as in Equation (12.44). Then $D(H)$ is a subspace, $U(t)D(H) = D(H)$ for every t, and*

$$\langle x|Hy\rangle = \langle Hx|y\rangle\,, \qquad \forall\, x, y \in D(H)\,. \tag{12.45}$$

Moreover, for $x \in D(H)$ the curve $t \longmapsto U(t)x$ is differentiable and

$$\mathrm{i}\hbar\,\frac{\mathrm{d}}{\mathrm{d}t}\big(U(t)x\big) = H\,U(t)\,x\,. \tag{12.46}$$

Rests on Definition 12.64 and Theorem 12.66.

Proof. *Derives Proposition 12.67.*

$D(H)$ is a subspace because the limit in Equation (12.44) is linear in x where it exists. If $x \in D(H)$ then, by Equation (12.41), $\big(U(t)U(s)x - U(t)x\big)/s = U(t)\big(U(s)x - x\big)/s$, and $U(t)$ is isometric, so the limit as $s \to 0$ exists and equals $-\mathrm{i}\hbar^{-1}U(t)Hx$; thus $U(t)x \in D(H)$ with $HU(t)x = U(t)Hx$, which is Equation (12.46), and applying the same with $-t$ gives $U(t)D(H) = D(H)$.

For Equation (12.45), let $x, y \in D(H)$ and let $t \neq 0$. Since $U(t)^\dagger = U(-t)$, and writing $s = -t$,

$$\left\langle x \middle| \frac{U(t)y - y}{t} \right\rangle = \left\langle \frac{U(-t)x - x}{t} \middle| y \right\rangle = -\left\langle \frac{U(s)x - x}{s} \middle| y \right\rangle . \tag{12.47}$$

Now $s \to 0$ exactly when $t \to 0$, and by Equation (12.44) both difference quotients converge: $\big(U(t)y - y\big)/t \to -\mathrm{i}Hy/\hbar$ and $\big(U(s)x - x\big)/s \to -\mathrm{i}Hx/\hbar$. Taking the limit in Equation (12.47), with the bracket carried through the limit by Proposition 12.4 and the antilinearity Equation (5.36) applied on the right,

$$-\frac{\mathrm{i}}{\hbar}\,\langle x|Hy\rangle = -\left(-\frac{\mathrm{i}}{\hbar}\right)^{*}\langle Hx|y\rangle = -\frac{\mathrm{i}}{\hbar}\,\langle Hx|y\rangle\,,$$

which is Equation (12.45). □

The two hard halves — that the domain defined by the limit in Equation (12.44) is dense, and that the operator on it is self-adjoint rather than merely symmetric; and the converse, that every self-adjoint operator, bounded or not, exponentiates to a group — are derived in Appendix A.25. The first uses a vector-valued integral to produce enough vectors in the domain by smoothing, and then an elementary differential-equation argument to kill both deficiency subspaces; the second needs the spectral theorem for *unbounded* self-adjoint operators, which the appendix obtains from Theorem 12.59 through the Cayley transform rather than quoting. Stone's paper [707] and [1481], chapter VIII, carry both.

Full derivation: Appendix A.25 (p. 2897).

Derives Theorem 12.66.

Remark 12.68 (Time evolution, and why $\hbar$ is written). Equation (12.46) is the Schrödinger equation before any Hamiltonian has been chosen: written for a state vector it is

$$\mathrm{i}\hbar\,\frac{\mathrm{d}}{\mathrm{d}t}\,|\psi(t)\rangle = \mathcal{H}\,|\psi(t)\rangle\ , \qquad |\psi(t)\rangle = \exp\left(-\frac{\mathrm{i}\mathcal{H}t}{\hbar}\right)|\psi(0)\rangle\ , \tag{12.48}$$

and Chapter 77 adopts it as a postulate. Stone's theorem [707] is what makes the two halves of Equation (12.48) equivalent, and it explains the otherwise unmotivated demand that the Hamiltonian be self-adjoint and not merely symmetric: symmetry alone gives neither a unitary group nor a conserved norm, so probability would not be conserved. That is not a technicality — Section 12.5.2 exhibits a symmetric momentum operator with no self-adjoint extension at all.

The factor $\hbar$ is carried explicitly here and everywhere in this treatise (CLAUDE.md rule 3). Its role is dimensional and is worth stating once: $\mathcal{H}$ has the unit J and t the unit s, so $\mathcal{H}t$ has the unit J s, which is the unit of $\hbar$; the argument of the exponential is therefore a pure number, as the series Equation (12.42) requires. The generator of the group is thus not the Hamiltonian but $\mathcal{H}/\hbar$, an angular frequency in 1/s — which is the mathematical form of the Planck–Einstein relation, and the reason a stationary state of energy E oscillates at angular frequency $E/\hbar$. The convention $\hbar = 1$, common in the literature, sets a unit of action to 1 and is not used here.

12.5 Unbounded operators and domains

12.5.1 Closed operators and domains

Definition 12.69 (Operator with a domain)**.** An *operator* on $\mathcal{H}$ is a pair $(A, D(A))$ with $D(A) \subseteq \mathcal{H}$ a subspace, the *domain*, and $A : D(A) \longrightarrow \mathcal{H}$ linear. It is *densely defined* if $D(A)$ is dense. Two operators are equal only if their domains agree; $A \subseteq B$ means $D(A) \subseteq D(B)$ and $Bx = Ax$ on $D(A)$, and B is then an *extension* of A.

Rests on Definition 5.35 and Corollary 12.19.

The insistence that the domain be part of the operator is not bookkeeping. Section 12.5.2 exhibits one differential expression, on one interval, that is several different operators according to the domain chosen, with different spectra and different physics; and Theorem 12.75 shows that the operators of quantum mechanics have no choice in the matter.

Definition 12.70 (Graph; closed and closable operators)**.** The *graph* of $(A, D(A))$ is

$$\Gamma(A) = \{(x, Ax) \mid x \in D(A)\} \subseteq \mathcal{H} \oplus \mathcal{H}\,, \tag{12.49}$$

where $\mathcal{H} \oplus \mathcal{H}$ carries the inner product $\langle (x_1, y_1)|(x_2, y_2)\rangle = \langle x_1|x_2\rangle + \langle y_1|y_2\rangle$. The operator is *closed* if $\Gamma(A)$ is a closed subspace, and *closable* if the closure of $\Gamma(A)$ is itself the graph of an operator, called the *closure* $\overline{A}$.

Rests on Definitions 6.3 and 12.69.

Unwinding Equation (12.49): A is closed if and only if, whenever $x_n \in D(A)$ with $x_n \to x$ *and* $Ax_n \to y$, it follows that $x \in D(A)$ and $Ax = y$. This is strictly weaker than continuity, which would require the second hypothesis to follow from the first. The closure of the graph fails to be a graph exactly when it contains some $(0, y)$ with $y \neq 0$, which is the obstruction to closability.

Definition 12.71 (Adjoint of a densely defined operator)**.** Let $(A, D(A))$ be densely defined. Put

$$D(A^\dagger) = \{y \in \mathcal{H} \mid \exists\, z \in \mathcal{H} : \langle z|x\rangle = \langle y|Ax\rangle \quad \forall\, x \in D(A)\}\ , \tag{12.50}$$

and $A^\dagger y = z$ on it. The vector z is unique because $D(A)$ is dense: if $\langle z - z'|x\rangle = 0$ for every x in a dense set then $z = z'$, by Corollary 12.19.

Rests on Definition 12.69, Theorem 12.38, and Corollary 12.19.

Definition 12.72 (Symmetric; self-adjoint)**.** A densely defined $(A, D(A))$ is *symmetric* if $\langle x|Ay\rangle = \langle Ax|y\rangle$ for all $x, y \in D(A)$, equivalently $A \subseteq A^\dagger$; it is *self-adjoint* if $A = A^\dagger$, that is, if in addition $D(A^\dagger) = D(A)$.

Rests on Definitions 12.69 and 12.71.

Proposition 12.73 (The adjoint is always closed)**.** *For densely defined A, the operator $A^\dagger$ is closed. A self-adjoint operator is therefore closed, and a symmetric operator is closable, with $\overline{A} \subseteq A^\dagger$.*

Rests on Definitions 12.70 and 12.71.

Proof. *Derives Proposition 12.73.*

Let $y_n \in D(A^\dagger)$ with $y_n \to y$ and $A^\dagger y_n \to z$. For every $x \in D(A)$, $\left\langle A^\dagger y_n \middle| x \right\rangle = \langle y_n|Ax\rangle$; letting $n \to \infty$ and using Proposition 12.4 on both sides gives $\langle z|x\rangle = \langle y|Ax\rangle$. By Equation (12.50) this says $y \in D(A^\dagger)$ with $A^\dagger y = z$, which is closedness. If A is symmetric then $A \subseteq A^\dagger$ with $A^\dagger$ closed, so the closure of $\Gamma(A)$ lies inside $\Gamma(A^\dagger)$ and is therefore a graph. □

Theorem 12.74 (Hellinger–Toeplitz)**.** *Let A be defined on all of $\mathcal{H}$ and symmetric, that is $\langle x|Ay\rangle = \langle Ax|y\rangle$ for all $x, y \in \mathcal{H}$. Then A is bounded.*

Rests on Definition 12.72, Proposition 12.36, and Remark 12.1.

Proof. *Derives Theorem 12.74.*

First, A is closed. Let $x_n \to x$ and $Ax_n \to y$. For every $z \in \mathcal{H}$,

$$\langle z|y\rangle = \lim_n \langle z|Ax_n\rangle = \lim_n \langle Az|x_n\rangle = \langle Az|x\rangle = \langle z|Ax\rangle \ ,$$

using symmetry twice and Proposition 12.4 for the limits. Hence $\langle z|y - Ax\rangle = 0$ for all z, so $y = Ax$ by Equation (5.31): the graph is closed. Since A is everywhere defined and closed between Banach spaces, the closed-graph theorem (Remark 12.1) makes it bounded. □

Theorem 12.75 (The canonical commutation relation admits no bounded solution)**.** *Let $\mathcal{H} \neq \{0\}$ and let $Q, P \in \mathcal{B}(\mathcal{H})$. Then*

$$[Q, P] = QP - PQ = \mathrm{i}\hbar\, \mathbb{1} \tag{12.51}$$

is impossible.

Rests on Proposition 12.37 and Definition 12.35.

Proof. *Derives Theorem 12.75.*

Assume Equation (12.51). By induction,

$$QP^n - P^n Q = \mathrm{i}\hbar\, n\, P^{n-1} \,, \qquad n \geq 1 \,, \tag{12.52}$$

the step being $QP^n - P^n Q = (QP - PQ)\, P^{n-1} + P\,(QP^{n-1} - P^{n-1}Q)$, which by the inductive hypothesis is $\mathrm{i}\hbar P^{n-1} + \mathrm{i}\hbar(n-1)P^{n-1}$.

No power of P vanishes. For suppose $m \geq 1$ is least with $P^m = 0$. Then Equation (12.52) at $n = m$ reads $0 = \mathrm{i}\hbar\, m\, P^{m-1}$, so $P^{m-1} = 0$; minimality forces $m - 1 = 0$, i.e. $P^0 = \mathbb{1} = 0$, which is false on $\mathcal{H} \neq \{0\}$.

So $\|P^{n-1}\| > 0$ for every n, and taking norms in Equation (12.52) with Equation (12.22),

$$\hbar\, n \left\|P^{n-1}\right\| = \|QP^n - P^n Q\| \leq 2\,\|Q\|\,\|P^n\| \leq 2\,\|Q\|\,\|P\|\,\left\|P^{n-1}\right\| \,,$$

whence $\hbar\, n \leq 2\,\|Q\|\,\|P\|$ for every $n \in \mathbb{N}$ — absurd. □

Corollary 12.76 (Position and momentum are unbounded, and cannot be everywhere defined)**.** *Any pair of operators satisfying Equation (12.51) on a dense domain must be unbounded, and if they are symmetric they cannot be defined on all of $\mathcal{H}$.*

Rests on Theorems 12.74 and 12.75.

Proof. *Derives Corollary 12.76.*

Unboundedness is Theorem 12.75. If such an operator were symmetric and defined on all of $\mathcal{H}$ it would be bounded by Theorem 12.74, a contradiction. □

Remark 12.77 (Why quantum mechanics needs domains). Corollary 12.76 is the reason this section exists. The canonical relation Equation (12.51) is not optional — it is the content of canonical quantisation (Chapter 99) and the source of the uncertainty relation — and it forbids position and momentum from being tame operators. They are unbounded, hence discontinuous, hence not defined on every state; every statement about them carries a domain, and Chapter 77 must say on which vectors an observable acts. The point was von Neumann's, and it is the technical core of the axiomatisation [664, 706].

A second consequence is that a domain is a piece of *physics*, not a technicality to be suppressed. For a differential operator the domain encodes the boundary conditions, so choosing it is choosing the physical situation — a particle in a box, on a ring, or on a half-line — and the eigenvalue problem that results is the Sturm–Liouville problem of Chapter 9, whose "self-adjoint boundary conditions" are exactly the choices that make the operator self-adjoint in the sense of Definition 12.72. The next subsection works one such family out completely.

12.5.2 Symmetric versus self-adjoint: deficiency indices

Definition 12.78 (Essential self-adjointness)**.** A symmetric operator A is *essentially self-adjoint* if its closure $\overline{A}$ (Proposition 12.73) is self-adjoint; equivalently, if A has exactly one self-adjoint extension. A *core* for a self-adjoint B is a subspace $D \subseteq D(B)$ on which B is essentially self-adjoint.

Rests on Definition 12.72 and Proposition 12.73.

The three notions — symmetric, essentially self-adjoint, self-adjoint — are genuinely distinct, and the distinction is measured by two integers.

Definition 12.79 (Deficiency subspaces and indices)**.** Let A be a closed symmetric operator and let $\mu > 0$ be a fixed number carrying the same SI dimension as A, so that $A \mp \mathrm{i}\mu$ is dimensionally consistent. The *deficiency subspaces* are

$$K_{\pm} = \ker\left(A^{\dagger} \mp \mathrm{i}\mu\right) = \left(\mathrm{im}(A \pm \mathrm{i}\mu)\right)^{\perp}, \tag{12.53}$$

and the *deficiency indices* are $n_{\pm} = \dim K_{\pm}$. They do not depend on the choice of μ.

Rests on Definition 12.71, Proposition 12.39, and Corollary 12.19.

The second equality in Equation (12.53) is Proposition 12.39 carried over to the unbounded case, where it reads $\ker A^{\dagger} = (\mathrm{im}\, A)^{\perp}$ with the same one-line proof; the independence of μ is part of von Neumann's analysis. Writing μ rather than 1 is not pedantry: for a momentum operator μ is a momentum in $\mathrm{kg\,m/s}$, and $A^{\dagger} \mp \mathrm{i}$ would be the difference of a momentum and a pure number.

Theorem 12.80 (von Neumann's criterion)**.** *Let A be a closed symmetric operator with deficiency indices (n_+, n_-).*

1. *A is self-adjoint if and only if $n_+ = n_- = 0$;*
2. *A has self-adjoint extensions if and only if $n_+ = n_-$, and they are then in bijective correspondence with the unitary maps $K_+ \longrightarrow K_-$ — a family parametrised by the group $\mathrm{U}(n)$ when $n_+ = n_- = n < \infty$;*
3. *if $n_+ \neq n_-$, A has no self-adjoint extension at all.*

Rests on Definitions 12.72, 12.78 and 12.79.

The criterion is proved in Appendix A.26. The proof passes to the Cayley transform, which converts a closed symmetric operator into an isometry between the orthogonal complements of the deficiency subspaces and a self-adjoint operator into a unitary; the self-adjoint extensions of the operator then correspond to the unitary extensions of that isometry, which exist exactly when the two deficiency subspaces have the same dimension. The appendix also derives the explicit description of each extension, and the independence of the indices from μ asserted in Definition 12.79. Von Neumann's memoir of 1930 [664] is the original.

Full derivation: Appendix A.26 (p. 2904).

Derives Theorem 12.80.

The deficiency-index theory and von Neumann's extension theorem are in the second Reed–Simon volume [1559], chapter X; the first volume [1481], which is what the rest of this chapter cites, does not carry them. The two examples that follow are the ones the criterion was made for, and they differ only in the interval.

Example 12.81 (Momentum on a finite interval: a circle of self-adjoint momenta)**.** Let $L > 0$ be a length and $\mathcal{H} = L^2([0, L])$, and let

$$P = -\mathrm{i}\hbar \, \frac{\mathrm{d}}{\mathrm{d}x} \, , \tag{12.54}$$

with the initial domain D_0 of continuously differentiable functions vanishing at both endpoints, which is dense. Then P is symmetric on D_0 but not self-adjoint; its deficiency indices are $(n_+, n_-) = (1, 1)$; and it has a one-parameter family of self-adjoint extensions P_θ, $\theta \in [0, 2\pi)$, with domains

$$D_\theta = \left\{ \psi \;\middle|\; \psi \text{ absolutely continuous},\ \psi' \in \mathcal{H},\ \psi(L) = \mathrm{e}^{\mathrm{i}\theta}\psi(0) \right\} , \tag{12.55}$$

whose spectra are the discrete sets

$$\sigma(P_\theta) = \left\{ p_n = \frac{\hbar\,(\theta + 2\pi n)}{L} \;\middle|\; n \in \mathbb{Z} \right\} , \tag{12.56}$$

with normalised eigenfunctions $\psi_n(x) = L^{-1/2}\mathrm{e}^{\mathrm{i}p_n x/\hbar}$.

Rests on Definition 12.79, Theorem 12.80, and Example 12.11.

Proof. *Derives Example 12.81.*

Symmetry. For $\varphi, \psi \in D_0$, integration by parts (Theorem 7.43) gives

$$\langle \varphi | P\psi \rangle - \langle P\varphi | \psi \rangle = -\mathrm{i}\hbar \Big[\varphi(x)^* \psi(x) \Big]_0^L = -\mathrm{i}\hbar \left(\varphi(L)^*\psi(L) - \varphi(0)^*\psi(0) \right) , \tag{12.57}$$

which vanishes because both functions vanish at both endpoints.

The adjoint. A computation with Equation (12.50), using the du Bois-Reymond lemma to identify the weak derivative, shows that $P^\dagger$ is the same differential expression on the *maximal* domain — absolutely continuous ψ with $\psi' \in \mathcal{H}$ and *no* boundary condition [1481]. That is already the failure of self-adjointness: $D(P^\dagger)$ is far larger than D_0.

Deficiency indices. Solve $P^\dagger\psi = \pm\mathrm{i}\mu\psi$ with $\mu > 0$ a momentum. The equation $-\mathrm{i}\hbar\psi' = \mathrm{i}\mu\psi$ gives $\psi(x) = C\mathrm{e}^{-\mu x/\hbar}$, and $-\mathrm{i}\hbar\psi' = -\mathrm{i}\mu\psi$ gives $\psi(x) = C\mathrm{e}^{+\mu x/\hbar}$. Both are continuous on the compact interval $[0, L]$, hence bounded, hence in $L^2([0, L])$; each solution space is one-dimensional, so $n_+ = n_- = 1$ and Theorem 12.80 predicts a family of extensions parametrised by $\mathrm{U}(1)$ — a circle.

The extensions. On D_θ the boundary term Equation (12.57) vanishes, since $\varphi(L)^*\psi(L) = \mathrm{e}^{-\mathrm{i}\theta}\mathrm{e}^{\mathrm{i}\theta}\varphi(0)^*\psi(0) = \varphi(0)^*\psi(0)$, so each P_θ is symmetric. That each is exactly self-adjoint,

rather than merely symmetric, and that the D_θ exhaust the possibilities — a boundary condition making Equation (12.57) vanish for all φ, ψ in the domain must relate $\psi(L)$ to $\psi(0)$ by a phase — are proved in Corollary A.274, which also computes which unitary map of Theorem 12.80 carries which value of θ.

Spectrum. $P_\theta\psi = p\psi$ has the solutions $\psi(x) = C\mathrm{e}^{\mathrm{i}px/\hbar}$, which lie in D_θ exactly when $\mathrm{e}^{\mathrm{i}pL/\hbar} = \mathrm{e}^{\mathrm{i}\theta}$, that is, when $pL/\hbar = \theta + 2\pi n$ for an integer n — which is Equation (12.56). These eigenfunctions are orthonormal after the stated normalisation and, being the trigonometric system of Chapter 17 up to the phase θ, form an orthonormal basis; so the spectrum is pure point. □

Example 12.82 (Momentum on the half-line: no self-adjoint extension)**.** Let $\mathcal{H} = L^2([0,\infty))$ and let P be Equation (12.54) on the dense domain of continuously differentiable functions of compact support in $(0,\infty)$. Then P is symmetric, its deficiency indices are $(n_+, n_-) = (1, 0)$, and by Theorem 12.80 it has *no* self-adjoint extension. There is no momentum observable for a particle confined to a half-line.

Rests on Example 12.81, Theorem 12.80, and Definition 12.79.

Proof. *Derives Example 12.82.*

Symmetry is Equation (12.57) again, with both boundary terms zero because the functions have compact support in the open half-line. The adjoint is once more the maximal operator, with no boundary condition [1481]. Solving $P^\dagger\psi = \mathrm{i}\mu\psi$ gives $\psi(x) = C\mathrm{e}^{-\mu x/\hbar}$, which is square integrable on $[0,\infty)$ with $\|\psi\|^2 = |C|^2\,\hbar/(2\mu)$, so $n_+ = 1$. Solving $P^\dagger\psi = -\mathrm{i}\mu\psi$ gives $\psi(x) = C\mathrm{e}^{+\mu x/\hbar}$, whose square integral diverges unless $C = 0$, so $n_- = 0$. The indices differ, and case (3) of Theorem 12.80 applies. □

Remark 12.83 (Three intervals, three fates)*.* The same expression Equation (12.54) behaves in three different ways according to the interval, and nothing but the domain distinguishes the cases.

- On the whole line, P on the smooth rapidly decreasing functions is essentially self-adjoint, with purely continuous spectrum $\mathbb{R}$ and no eigenvectors — the Fourier transform of Chapter 17 turns it into multiplication by $\hbar k$, which is Example 12.56 on an unbounded interval.

- On a finite interval it is not self-adjoint but has a circle of self-adjoint extensions, each with a discrete spectrum Equation (12.56). The parameter θ is physical: $\theta = 0$ is the particle on a ring, and a non-zero θ is the ring threaded by a magnetic flux, the phase being the Aharonov–Bohm phase. The mathematics does not choose; the physical situation does.

- On the half-line it has no self-adjoint extension. The reason is visible in the proof: the translations generated by P push probability off the end of the half-line and back on again, which no unitary group can do. By Theorem 12.66, no self-adjoint generator, no unitary group; and no unitary group, no conservation of probability.

The corresponding question for the *Hamiltonian* — whether $-\hbar^2\nabla^2/(2m) + V$ is essentially self-adjoint on the smooth compactly supported functions — is the question of whether the Schrödinger equation has a unique unitary dynamics, and it is answered, potential by potential, in Chapters 81 and 82 [1335, 1559].

12.6 Direct sums, tensor products and rigged spaces

12.6.1 Direct sums and orthogonal decompositions

Definition 12.84 (External direct sum)**.** Let $\mathcal{H}_1, \mathcal{H}_2, \dots$ be Hilbert spaces. Their *direct sum* is

$$\bigoplus_n \mathcal{H}_n = \left\{ (x_1, x_2, \dots) \;\middle|\; x_n \in \mathcal{H}_n,\ \sum_n \|x_n\|^2 < \infty \right\}, \tag{12.58}$$

with componentwise operations and $\langle x|y\rangle = \sum_n \langle x_n|y_n\rangle$.

Rests on Definition 5.97 and Example 12.9.

Proposition 12.85 (The direct sum is a Hilbert space)**.** *Equation (12.58) is a Hilbert space, and the maps $J_n : \mathcal{H}_n \longrightarrow \bigoplus_m \mathcal{H}_m$ placing a vector in the nth slot are isometric with mutually orthogonal images.*

Rests on Definition 12.84 and Proposition 12.10.

Proof. *Derives Proposition 12.85.*

The inner product is well defined and the space is a vector space by the same two estimates as in Example 12.9, applied to the numbers $\|x_n\|$; the axioms of Definition 5.17 hold slotwise. Completeness is the argument of Proposition 12.10 verbatim, with the modulus $|x_n|$ replaced by the norm $\|x_n\|$ and the completeness of $\mathbb{C}$ replaced by that of $\mathcal{H}_n$: each slot converges, the finite truncations give a uniform bound, and the limit lies in the sum. The last claim is immediate, distinct slots pairing to zero. Note that ℓ^2 is the special case $\mathcal{H}_n = \mathbb{C}$ for every n. □

Definition 12.86 (Internal orthogonal decomposition)**.** Closed subspaces $M_1, M_2, \dots$ of $\mathcal{H}$ are said to *decompose* $\mathcal{H}$, written $\mathcal{H} = \bigoplus_n M_n$, if they are pairwise orthogonal and the only vector orthogonal to all of them is 0.

Rests on Definitions 12.16 and 12.29.

Proposition 12.87 (Expansion in an orthogonal decomposition)**.** *If $\mathcal{H} = \bigoplus_n M_n$ with orthogonal projections $P_n = P_{M_n}$, then $P_n P_m = \delta_{nm} P_n$ and, for every $x \in \mathcal{H}$,*

$$x = \sum_n P_n x\,, \qquad \|x\|^2 = \sum_n \|P_n x\|^2\,, \tag{12.59}$$

the series converging in norm. The map $x \longmapsto (P_1 x, P_2 x, \dots)$ is an inner-product-preserving bijection onto $\bigoplus_n M_n$ in the sense of Definition 12.84.

Rests on Definition 12.86, Theorem 12.30, and Proposition 12.85.

Proof. *Derives Proposition 12.87.*

Orthogonality of the subspaces gives $\operatorname{im} P_m \subseteq M_m \subseteq M_n^{\perp} = \ker P_n$ for $m \neq n$, which is $P_n P_m = 0$; and $P_n^2 = P_n$ is Proposition 12.21.

Choose an orthonormal basis of each M_n — possible in the separable case by Corollary 12.24, and in general by the same argument applied to a maximal orthonormal family — and let $\{e_k\}$ be the union of all of them, which is orthonormal because the M_n are pairwise orthogonal. This family is maximal: a vector orthogonal to every e_k is orthogonal to every M_n, hence 0 by Definition 12.86. So Theorem 12.30 applies, and grouping the terms of Equation (12.18) by the subspace they belong to — legitimate because the partial sums converge absolutely in the sense of Proposition 12.28, whose criterion is insensitive to order — gives Equation (12.59), the group of index n summing to $P_n x$ by Proposition 12.27. The norm identity is Equation (12.19) grouped the same way, and it says precisely that the displayed map lands in Equation (12.58) and is isometric; surjectivity follows from Proposition 12.28 applied slotwise. □

Definition 12.88 (Reducing subspace)**.** A closed subspace M *reduces* $A \in \mathcal{B}(\mathcal{H})$ if $A(M) \subseteq M$ and $A(M^{\perp}) \subseteq M^{\perp}$.
Rests on Definitions 12.20 and 12.35.

Proposition 12.89 (Reduction is commutation)**.** *A closed subspace M reduces $A \in \mathcal{B}(\mathcal{H})$ if and only if $P_M A = A P_M$.*
Rests on Definition 12.88 and Proposition 12.21.

Proof. *Derives Proposition 12.89.*
Write $P = P_M$. ($\Leftarrow$) If $x \in M$ then $Ax = APx = PAx \in M$; if $x \in M^{\perp}$ then $Px = 0$, so $PAx = APx = 0$ and $Ax \in M^{\perp}$ by Proposition 12.21.
($\Rightarrow$) For arbitrary x split $x = Px + (\mathbb{1} - P)x$. The first term lies in M, so $APx \in M$ and $PAPx = APx$; the second lies in $M^{\perp}$, so $A(\mathbb{1} - P)x \in M^{\perp}$ and $PA(\mathbb{1} - P)x = 0$. Adding, $PAx = PAPx + PA(\mathbb{1} - P)x = APx$. □

The extreme case — no proper reducing subspace at all — is what representation theory calls irreducibility, and Proposition 12.89 converts it into a statement about commuting operators that can actually be used.

Definition 12.90 (Self-adjoint family; commutant; irreducibility)**.** A set $\mathcal{S} \subseteq \mathcal{B}(\mathcal{H})$ is *self-adjoint* if $A \in \mathcal{S}$ implies $A^{\dagger} \in \mathcal{S}$. Its *commutant* is

$$\mathcal{S}' = \{B \in \mathcal{B}(\mathcal{H}) \;\mid\; BA = AB \;\; \forall\, A \in \mathcal{S}\}\,, \tag{12.60}$$

and $\mathcal{S}$ *acts irreducibly* on $\mathcal{H}$ if the only closed subspaces reducing every member of $\mathcal{S}$ are $\{0\}$ and $\mathcal{H}$.
Rests on Definitions 12.41 and 12.88.

Theorem 12.91 (Schur's lemma, commutant form)**.** *Let $\mathcal{S} \subseteq \mathcal{B}(\mathcal{H})$ be self-adjoint. Then $\mathcal{S}$ acts irreducibly if and only if $\mathcal{S}' = \mathbb{C}\,\mathbb{1}$: every bounded operator commuting with every member of an irreducible self-adjoint family is a multiple of the identity, and conversely.*
Rests on Definition 12.90, Proposition 12.89, and Theorem 12.59.

Proof. *Derives Theorem 12.91.*
($\Rightarrow$) Let $B \in \mathcal{S}'$. Taking adjoints in $BA = AB$ and using Equation (12.24) gives $A^{\dagger}B^{\dagger} = B^{\dagger}A^{\dagger}$ for every $A \in \mathcal{S}$; since $\mathcal{S}$ is self-adjoint this says $B^{\dagger} \in \mathcal{S}'$, and hence the self-adjoint operators $\frac{1}{2}(B + B^{\dagger})$ and $\frac{1}{2\mathrm{i}}(B - B^{\dagger})$ lie in $\mathcal{S}'$ too. As B is their combination $B_1 + \mathrm{i}B_2$, it is enough to treat a self-adjoint $B \in \mathcal{S}'$.

Let E be the projection-valued measure of B (Theorem 12.59). Every $A \in \mathcal{S}$ is a bounded operator commuting with B, so by the last clause of that theorem it commutes with every $E(\Omega)$; by Proposition 12.89 the range of $E(\Omega)$ therefore reduces every member of $\mathcal{S}$, and irreducibility forces $E(\Omega) \in \{0, \mathbb{1}\}$ for every Borel Ω.

The spectrum $\sigma(B)$ is compact and non-empty (Theorem 12.54) and E is supported on it, so $\lambda \longmapsto E((-\infty, \lambda])$ passes from 0 to $\mathbb{1}$ within a bounded range and $c = \inf\{\lambda \in \mathbb{R} \mid E((-\infty, \lambda]) = \mathbb{1}\}$ is finite. The sets $(-\infty, c - 1/n]$ increase to $(-\infty, c)$ and each carries $E = 0$; the sets $(c + 1/n, \infty)$ increase to (c, ∞) and each carries $E = \mathbb{1} - E((-\infty, c + 1/n]) = 0$. Writing an increasing union as the disjoint union of its successive differences and applying Equation (12.36) gives $E((-\infty, c)) = 0$ and $E((c, \infty)) = 0$, whence $E(\{c\}) = \mathbb{1}$. Then Equation (12.37) reads $\langle x|By\rangle = c\,\langle x|y\rangle$ for all x, y, that is $B = c\,\mathbb{1}$, with c real because B is self-adjoint.

($\Leftarrow$) If a closed subspace M reduces every member of $\mathcal{S}$ then $P_M \in \mathcal{S}'$ by Proposition 12.89, so $P_M = c\,\mathbb{1}$; squaring, $c^2 = c$, so $c \in \{0, 1\}$ and M is $\{0\}$ or $\mathcal{H}$. □

Remark 12.92 (The finite-dimensional lemma, and the unbounded case). Theorem 12.91 is the Hilbert-space form of Theorem 5.155, the second lemma of Schur for finite-dimensional group representations; the hypothesis that has to be added in infinite dimension is that $\mathcal{S}$

be closed under adjoints, without which the argument above cannot pass to the self-adjoint parts of B and the conclusion is false. The self-adjointness costs nothing in practice, because the families that arise are families of unitaries or of self-adjoint operators. That matters for the way the lemma is used on canonical pairs: position and momentum are unbounded (Corollary 12.76) and so are not members of $\mathcal{B}(\mathcal{H})$ at all, but the unitary groups they generate are, and it is to those that Theorem 12.91 is applied in Section 12.7.

Remark 12.93 (Where decompositions come from)*.* Three sources of orthogonal decompositions matter later, and all three are Proposition 12.87 with a different supply of subspaces. The spectral projections $E(\Omega)$ of Theorem 12.59 decompose $\mathcal{H}$ over any Borel partition of the spectrum, and by Proposition 12.89 every such piece reduces the operator — the abstract form of "diagonalise, then work block by block". The eigenspaces of the total angular momentum decompose the state space of a rotationally invariant system, which is how Chapter 79 reduces a problem to one value of ℓ at a time, and the same decomposition organises the hydrogen spectrum of Chapter 81. And a superselection rule is the statement that a decomposition is respected by *every* observable, so that no superposition across the summands is ever prepared or detected; Chapter 85 takes that up.

12.6.2 Tensor products

The direct sum adds dimensions; the tensor product multiplies them (Remark 5.102), and it is the tensor product that describes a composite system. The algebraic construction and its universal property are those of Chapter 5; what is new here is the inner product and the completion.

Definition 12.94 (Tensor product of Hilbert spaces)**.** Let $\mathcal{H}_1, \mathcal{H}_2$ be Hilbert spaces and let $\mathcal{H}_1 \odot \mathcal{H}_2$ be their algebraic tensor product, the space of finite sums $\sum_i u_i \otimes v_i$ characterised by the universal property that every bilinear map out of $\mathcal{H}_1 \times \mathcal{H}_2$ factors uniquely through it. On it define

$$\langle u_1 \otimes v_1 | u_2 \otimes v_2 \rangle = \langle u_1 | u_2 \rangle \, \langle v_1 | v_2 \rangle \, , \tag{12.61}$$

extended to finite sums by sesquilinearity. The *tensor product* $\mathcal{H}_1 \otimes \mathcal{H}_2$ is the completion of $\mathcal{H}_1 \odot \mathcal{H}_2$ in the associated norm.

Rests on Definitions 5.17, 5.106 and 12.2.

Proposition 12.95 (The tensor inner product is well defined and positive definite)**.** *Equation* (12.61) *extends to a genuine inner product on $\mathcal{H}_1 \odot \mathcal{H}_2$, and if $\{e_i\}$ and $\{f_j\}$ are orthonormal bases of $\mathcal{H}_1$ and $\mathcal{H}_2$ then $\{e_i \otimes f_j\}$ is an orthonormal basis of $\mathcal{H}_1 \otimes \mathcal{H}_2$.*

Rests on Definition 12.94, Theorem 12.30, and Proposition 12.23.

Proof. *Derives Proposition 12.95.*

Well defined. The right-hand side of Equation (12.61) is bilinear in (u_2, v_2) and antibilinear in (u_1, v_1), so by the universal property it factors through the algebraic tensor product in each argument separately; the resulting form on $\mathcal{H}_1 \odot \mathcal{H}_2$ does not depend on the representation of an element as a finite sum.

Positive definite. Let $w = \sum_{i=1}^{r} u_i \otimes v_i$ be non-zero. Applying Proposition 12.23 to the v_i and re-expanding, we may assume the v_i orthonormal, in which case Equation (12.61) gives $\langle w | w \rangle = \sum_i \|u_i\|^2 \geq 0$, with equality only if every $u_i = 0$, i.e. only if $w = 0$. The remaining axioms of Definition 5.17 are inherited from the two factors.

Basis. The family $\{e_i \otimes f_j\}$ is orthonormal by Equation (12.61). It is maximal: its closed span contains every $u \otimes v$, because expanding u and v by Equation (12.18) and using continuity of Equation (12.61) in each slot gives $u \otimes v = \sum_{i,j} \langle e_i | u \rangle \, \langle f_j | v \rangle \, e_i \otimes f_j$; hence it contains $\mathcal{H}_1 \odot \mathcal{H}_2$, which is dense in the completion. Now apply criterion (2) of Theorem 12.30. □

Proposition 12.96 (Operators on a tensor product)**.** *For $A_1 \in \mathcal{B}(\mathcal{H}_1)$ and $A_2 \in \mathcal{B}(\mathcal{H}_2)$ there is a unique $A_1 \otimes A_2 \in \mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$ with $(A_1 \otimes A_2)(u \otimes v) = A_1 u \otimes A_2 v$, and*

$$\|A_1 \otimes A_2\| = \|A_1\|\,\|A_2\|\,, \qquad (A_1 \otimes A_2)^\dagger = A_1^\dagger \otimes A_2^\dagger\,. \tag{12.62}$$

Rests on Propositions 12.39 and 12.95.

Proof. *Derives Proposition 12.96.*

Uniqueness is density of $\mathcal{H}_1 \odot \mathcal{H}_2$ and continuity. For existence and the norm, factor $A_1 \otimes A_2 = (A_1 \otimes \mathbb{1})(\mathbb{1} \otimes A_2)$ and bound each factor separately. Expanding $w = \sum_j u_j \otimes f_j$ in the orthonormal basis $\{f_j\}$ of $\mathcal{H}_2$ — possible by Proposition 12.95 — gives $\|w\|^2 = \sum_j \|u_j\|^2$ and

$$\|(A_1 \otimes \mathbb{1})w\|^2 = \sum_j \|A_1 u_j\|^2 \le \|A_1\|^2 \sum_j \|u_j\|^2 = \|A_1\|^2\,\|w\|^2\,,$$

so $\|A_1 \otimes \mathbb{1}\| \le \|A_1\|$, and symmetrically for the other factor; hence $\|A_1 \otimes A_2\| \le \|A_1\|\,\|A_2\|$, which also shows the map is bounded on the dense subspace and so extends. The reverse inequality follows by testing on product vectors, $\|A_1 u \otimes A_2 v\| = \|A_1 u\|\,\|A_2 v\|$, and taking suprema. The adjoint identity is Equation (12.61) checked on product vectors, together with uniqueness in Theorem 12.38. □

Remark 12.97 (The universal property does not survive completion)*.* It is worth stating what Definition 12.94 does and does not claim. The universal property — every bilinear map factors uniquely — belongs to the *algebraic* tensor product $\mathcal{H}_1 \odot \mathcal{H}_2$, and it is what makes Equation (12.61) well defined. The completion $\mathcal{H}_1 \otimes \mathcal{H}_2$ does *not* inherit it for arbitrary bounded bilinear maps: a bilinear B with $\|B(u,v)\| \le C\,\|u\|\,\|v\|$ need not extend continuously to the completion, because the Hilbert norm on $\mathcal{H}_1 \odot \mathcal{H}_2$ is not the largest such norm. The Hilbert tensor product is one of several completions of the same algebraic object, singled out by Equation (12.61) and by nothing else, and it is singled out for a physical reason: it is the one whose orthonormal basis is the set of products of basis vectors (Proposition 12.95), which is the statement that a joint state is specified by an amplitude for each pair of outcomes.

Example 12.98 (Two particles in three-dimensional space)**.** For a single particle in ordinary space the state space is $L^2(\mathbb{R}^3)$, and for two distinguishable particles it is

$$L^2(\mathbb{R}^3) \otimes L^2(\mathbb{R}^3) \cong L^2(\mathbb{R}^6)\,, \tag{12.63}$$

the isomorphism carrying $f \otimes g$ to the function $(x_1, x_2) \longmapsto f(x_1)\,g(x_2)$. It is an isomorphism because the products $f(x_1)g(x_2)$ span a dense subspace of $L^2(\mathbb{R}^6)$ and because Equation (12.61) matches the Fubini factorisation of the integral over $\mathbb{R}^6$ [1481]. Note that the configuration space of the pair is $\mathbb{R}^6$, not $\mathbb{R}^3$: a two-particle wavefunction is a function of six coordinates and is not a field on space. That is a statement about the formalism with observable consequences, and it is where the non-classical correlations begin.

Rests on Definition 12.94 and Example 12.11.

Definition 12.99 (Product and entangled vectors)**.** A vector $w \in \mathcal{H}_1 \otimes \mathcal{H}_2$ is a *product vector* if $w = u \otimes v$ for some u, v, and is *entangled* otherwise.

Rests on Definition 12.94.

Example 12.100 (Entangled vectors exist)**.** Let $\mathcal{H}_1 = \mathcal{H}_2 = \mathbb{C}^2$ with orthonormal bases $\{e_0, e_1\}$ and $\{f_0, f_1\}$. The unit vector

$$w = \frac{1}{\sqrt{2}}\,(e_0 \otimes f_0 + e_1 \otimes f_1) \tag{12.64}$$

is entangled.

Rests on Definition 12.99 and Proposition 12.95.

Proof. *Derives Example 12.100.*

Suppose $w = (ae_0 + be_1) \otimes (cf_0 + df_1)$. Expanding in the basis $\{e_i \otimes f_j\}$, which is a basis by Proposition 12.95, and comparing coefficients with Equation (12.64) gives

$$ac = bd = \frac{1}{\sqrt{2}}\,, \qquad ad = bc = 0\,.$$

From $ad = 0$ either $a = 0$, contradicting $ac = 1/\sqrt{2}$, or $d = 0$, contradicting $bd = 1/\sqrt{2}$. □

Remark 12.101 (Composite systems). Definition 12.94 is the mathematics behind the composition postulate: the state space of a system assembled from two others is the tensor product of their state spaces, an assumption already explicit in von Neumann [706] and stated as a postulate in Chapter 77. Example 12.100 is then not a curiosity but a forced consequence: the tensor product contains vectors that are not products, so a composite system has states in which neither part has a state of its own. Whether nature actually realises them is a question for experiment, and it has been settled affirmatively; the argument that turns Equation (12.64) into a testable inequality is Chapter 84, and the measurements are in Chapter 89. For identical rather than merely distinguishable particles the state space is not the whole tensor product but a symmetric or antisymmetric subspace of it, which is a reducing subspace in the sense of Definition 12.88; Chapter 83 takes that up.

12.6.3 Rigged Hilbert spaces

Two objects used constantly in quantum mechanics are not elements of $\mathcal{H}$: the plane wave, which is not square integrable, and the delta "function", which is not a function. Neither is an approximation to be apologised for; both are legitimate objects, and the structure they live in is a triple of spaces rather than a single one.

Proposition 12.102 (Neither plane waves nor deltas are in L^2)**.** *(i) The function $x \longmapsto \mathrm{e}^{\mathrm{i}px/\hbar}$ is not in $L^2(\mathbb{R})$ for any real p. (ii) There is no $g \in L^2(\mathbb{R})$ with $\langle g|\varphi\rangle = \varphi(0)$ for every continuous, compactly supported φ.*

Rests on Example 12.11 and Proposition 12.4.

Proof. *Derives Proposition 12.102.*

(i) The integrand $\left|\mathrm{e}^{\mathrm{i}px/\hbar}\right|^2 = 1$, so the integral over $\mathbb{R}$ diverges.

(ii) Suppose such a g existed. Let φ_n be the continuous function equal to 1 at 0, vanishing outside $[-1/n, 1/n]$, and linear in between, so $\varphi_n(0) = 1$ while $\|\varphi_n\|^2 = \int |\varphi_n|^2 \le 2/n$. Then Equation (12.1) gives $1 = |\langle g|\varphi_n\rangle| \le \|g\|\,\sqrt{2/n}$ for every n, which is false for large n. □

Definition 12.103 (Gelfand triple)**.** A *Gelfand triple*, or *rigged Hilbert space*, is a chain

$$\Phi \subseteq \mathcal{H} \subseteq \Phi'\,, \tag{12.65}$$

in which Φ is a dense subspace of $\mathcal{H}$ carrying its own, strictly finer, topology under which it is a nuclear space, and Φ' is the space of continuous *linear* functionals on Φ for that topology. The middle inclusion is the Riesz identification of Corollary 12.47: each $x \in \mathcal{H}$ acts on Φ by $\varphi \longmapsto \langle x|\varphi\rangle$, which is linear in φ by Equation (5.34) and therefore is an element of Φ', and that action determines x because Φ is dense. The identification $x \longmapsto \langle x|\cdot\rangle$ is itself antilinear in x, exactly as Corollary 12.47 says; it is the functionals, not the embedding, that are linear.

Rests on Corollaries 12.19 and 12.47 and Definition 12.45.

Example 12.104 (The Schwartz triple)**.** The standard triple of quantum mechanics on the line is

$$\mathcal{S}(\mathbb{R}) \subseteq L^2(\mathbb{R}) \subseteq \mathcal{S}'(\mathbb{R})\,, \tag{12.66}$$

where $\mathcal{S}(\mathbb{R})$ is the Schwartz space of smooth functions all of whose derivatives decay faster than any power, and $\mathcal{S}'(\mathbb{R})$ is the space of tempered distributions [971]. Both objects of Proposition 12.102 live in the third space: the delta is the functional $\varphi \longmapsto \varphi(0)$, which is continuous for the topology of $\mathcal{S}$ though not for the L^2 norm, and the plane wave is the functional

$$F_p(\varphi) = \frac{1}{\sqrt{2\pi\hbar}} \int_{\mathbb{R}} \mathrm{e}^{-\mathrm{i}px/\hbar}\, \varphi(x)\, \mathrm{d}x\,, \tag{12.67}$$

which is the Fourier transform of Chapter 17 evaluated at the wavenumber $p/\hbar$.

Rests on Definition 12.103, Proposition 12.102, and Example 12.11.

Definition 12.105 (Generalized eigenvector)**.** Let A map Φ into Φ continuously. A functional $F \in \Phi'$ is a *generalized eigenvector* of A with eigenvalue λ if

$$F(A\varphi) = \lambda\, F(\varphi)\,, \qquad \forall\, \varphi \in \Phi\,. \tag{12.68}$$

Rests on Definitions 12.50 and 12.103.

Proposition 12.106 (The plane wave is a generalized momentum eigenvector)**.** *On the triple Equation (12.66), with $P = -\mathrm{i}\hbar\,\mathrm{d}/\mathrm{d}x$ mapping $\mathcal{S}(\mathbb{R})$ into itself, the functional Equation (12.67) satisfies $F_p(P\varphi) = p\,F_p(\varphi)$ for every $\varphi \in \mathcal{S}(\mathbb{R})$, and p ranges over all of $\mathbb{R}$.*

Rests on Definition 12.105, Example 12.104, and Equation (12.54).

Proof. *Derives Proposition 12.106.*

Integrate by parts in Equation (12.67); the boundary terms vanish because φ and all its derivatives decay faster than any power. Writing $C = (2\pi\hbar)^{-1/2}$,

$$F_p(P\varphi) = C \int_{\mathbb{R}} \mathrm{e}^{-\mathrm{i}px/\hbar}\, \bigl(-\mathrm{i}\hbar\varphi'(x)\bigr)\, \mathrm{d}x = C \int_{\mathbb{R}} \mathrm{i}\hbar\, \frac{\mathrm{d}}{\mathrm{d}x}\Bigl(\mathrm{e}^{-\mathrm{i}px/\hbar}\Bigr)\, \varphi(x)\, \mathrm{d}x\,,$$

and $\mathrm{i}\hbar\,\mathrm{d}(\mathrm{e}^{-\mathrm{i}px/\hbar})/\mathrm{d}x = \mathrm{i}\hbar\,(-\mathrm{i}p/\hbar)\,\mathrm{e}^{-\mathrm{i}px/\hbar} = p\,\mathrm{e}^{-\mathrm{i}px/\hbar}$, which gives $p\,F_p(\varphi)$. □

Theorem 12.107 (Nuclear spectral theorem)**.** *Let $\Phi \subseteq \mathcal{H} \subseteq \Phi'$ be a Gelfand triple with Φ nuclear, and let A be a self-adjoint operator on $\mathcal{H}$ mapping Φ continuously into itself. Then A possesses a* complete *set of generalized eigenvectors: there is a measure μ on $\sigma(A)$ and a family $\{F_\lambda\}$ in Φ', with F_λ a generalized eigenvector of eigenvalue λ for μ-almost every λ, such that*

$$\langle \varphi | \psi \rangle = \int_{\sigma(A)} F_\lambda(\varphi)^*\, F_\lambda(\psi)\, \mathrm{d}\mu(\lambda)\,, \qquad \forall\, \varphi, \psi \in \Phi\,. \tag{12.69}$$

Rests on Definitions 12.103 and 12.105 and Theorem 12.59.

The proof is in Appendix A.27: it builds the direct-integral decomposition supplied by the spectral theorem Theorem 12.59, and then uses nuclearity of the test space to realise the fibre maps as continuous functionals, so that almost every fibre furnishes a generalized eigenvector. This is the one long derivation of the chapter that rests on a theory this treatise does not develop — the theory of nuclear spaces, for which Gelfand and Vilenkin, volume 4, is the reference of record [1276]. The appendix isolates exactly what is assumed, in one displayed statement: that a nuclear test space embeds in $\mathcal{H}$ through some Hilbert–Schmidt map. Everything else is derived, and two things the statement above suppresses are made explicit there: $\mathcal{H}$ and Φ are assumed separable, and when the spectrum of A has multiplicity greater than one the integrand of Equation (12.69) carries a sum over a multiplicity index — the display as written is the simple-spectrum case, which is the case of Proposition 12.106 and of every use made of the theorem in this treatise.

Full derivation: Appendix A.27 (p. 2910).

Derives Theorem 12.107.

Remark 12.108 (The working rule). Equation (12.69) is the completeness relation that physics writes as $\int |\lambda\rangle\langle\lambda| \, \mathrm{d}\mu(\lambda) = \mathbb{1}$, and Theorem 12.107 is what licenses it. The rule this treatise follows is therefore precise, and it is worth stating once for all the later chapters that use it.

- A ket $|\lambda\rangle$ belonging to a point of continuous spectrum denotes an element of Φ', not of $\mathcal{H}$. It is not a state, it cannot be normalised, and $\langle\lambda|\lambda\rangle$ is meaningless. Proposition 12.102 is the proof that no other reading is available.
- An expression $\langle\lambda|\varphi\rangle$ is legitimate whenever $\varphi \in \Phi$ — it is the value $F_\lambda(\varphi)$ — and the "normalisation" $\langle\lambda|\lambda'\rangle = \delta(\lambda - \lambda')$ is shorthand for Equation (12.69), an identity between functionals and never between numbers.
- A physical state is always a vector of $\mathcal{H}$. A wave packet built by superposing generalized eigenvectors against a square-integrable amplitude is such a vector; a single plane wave is not, which is why every scattering calculation in Chapter 86 that is done with plane waves must be read as a statement about packets.

The triple also explains, retrospectively, why Dirac's formalism worked before it had a foundation [646]: he was computing in Φ' with functionals that the nuclear spectral theorem later showed to exist. The rigorous setting is due to Gelfand and his collaborators [1276], built on Schwartz's theory of distributions [971]. It is a completion of the formalism, not a correction to it, and no result of this chapter is disturbed by it: the spectral theorem Theorem 12.59 remains the statement that carries the physics, and Equation (12.69) is a convenient way of writing its conclusion in the notation physicists actually use.

12.7 The canonical commutation relations in Weyl form

Theorem 12.75 shows that no pair of bounded operators satisfies $[\hat{q}, \hat{p}] = \mathrm{i}\hbar\mathbb{1}$, so any realisation of that relation involves unbounded operators, each with a domain that is not the whole space (Corollary 12.76). This is not a technicality to be waved through. Two pairs can satisfy the relation on every vector where both sides are defined and still be inequivalent, because the relation says nothing about what happens off the common domain: momentum on a half-line has no self-adjoint realisation at all (Example 12.82), and momentum on an interval has a whole circle of them (Example 12.81), and in neither case does the formal commutator notice. The repair is to exponentiate, replacing the unbounded generators by the unitary groups they generate — which by Theorem 12.66 carry exactly the same information — and to impose the commutation relation on those.

Definition 12.109 (Weyl system)**.** A *Weyl system* of one degree of freedom on $\mathcal{H}$ is a pair of strongly continuous one-parameter unitary groups (Definition 12.64)

$$U(\alpha) = \exp\left(\frac{\mathrm{i}\alpha Q}{\hbar}\right), \qquad V(\beta) = \exp\left(-\frac{\mathrm{i}\beta P}{\hbar}\right), \tag{12.70}$$

with Q and P the self-adjoint generators supplied by Theorem 12.66, satisfying the *Weyl relation*

$$U(\alpha)\,V(\beta) = \mathrm{e}^{\mathrm{i}\alpha\beta/\hbar}\,V(\beta)\,U(\alpha), \qquad \forall\,\alpha,\beta \in \mathbb{R}. \tag{12.71}$$

Here Q carries the SI unit m and P the unit kg m/s, so that the parameters carry kg m/s and m respectively and both $\alpha Q/\hbar$ and $\alpha\beta/\hbar$ are pure numbers. For f degrees of freedom the parameters become vectors $\boldsymbol{\alpha}, \boldsymbol{\beta} \in \mathbb{R}^f$, the exponents become $\boldsymbol{\alpha}\cdot\boldsymbol{Q}$ and $\boldsymbol{\beta}\cdot\boldsymbol{P}$, the phase in Equation (12.71) becomes $\mathrm{e}^{\mathrm{i}\boldsymbol{\alpha}\cdot\boldsymbol{\beta}/\hbar}$, and the groups belonging to different degrees of freedom are required to commute.

Rests on Definition 12.64 and Theorems 12.66 and 12.75.

Example 12.110 (The Schrödinger system)**.** On $\mathcal{H} = L^2(\mathbb{R})$ put

$$\big(U(\alpha)\psi\big)(x) = \mathrm{e}^{\mathrm{i}\alpha x/\hbar}\,\psi(x)\,, \qquad \big(V(\beta)\psi\big)(x) = \psi(x-\beta)\,. \tag{12.72}$$

Both are unitary, both are groups, and both are strongly continuous — the first by dominated convergence, the second because translation is continuous in the mean. Their generators are multiplication by x and $-\mathrm{i}\hbar\,\mathrm{d}/\mathrm{d}x$, on the domains where the corresponding limits Equation (12.44) exist. Applying the two definitions in the two orders, $(U(\alpha)V(\beta)\psi)(x) = \mathrm{e}^{\mathrm{i}\alpha x/\hbar}\psi(x-\beta)$ while $(V(\beta)U(\alpha)\psi)(x) = \mathrm{e}^{\mathrm{i}\alpha(x-\beta)/\hbar}\psi(x-\beta)$, so Equation (12.71) holds. This system is also irreducible in the sense of Definition 12.90 — a fact taken here from [1481], theorem VIII.14 and its preamble, not proved: the step that does the work is that a bounded operator commuting with multiplication by every bounded measurable function is itself such a multiplication, which is the maximal abelian property of $L^\infty(\mathbb{R})$ acting on $L^2(\mathbb{R})$, and only then does commuting with every translation force the multiplier to be constant.

Rests on Definition 12.109 and Example 12.11.

Proposition 12.111 (The Weyl relation is a covariance statement)**.** *In any Weyl system,*

$$V(\beta)^\dagger\, Q\, V(\beta) = Q + \beta\,\mathbb{1}\,, \qquad U(\alpha)^\dagger\, P\, U(\alpha) = P - \alpha\,\mathbb{1}\,, \tag{12.73}$$

the domains being $V(-\beta)D(Q)$ and $U(-\alpha)D(P)$ respectively. Conversely either identity in Equation (12.73) implies Equation (12.71).

Rests on Definition 12.109, Theorem 12.66, and Proposition 12.67.

Proof. *Derives Proposition 12.111.*

Multiply Equation (12.71) on the left by $V(\beta)^\dagger = V(-\beta)$:

$$V(\beta)^\dagger\, U(\alpha)\, V(\beta) = \mathrm{e}^{\mathrm{i}\alpha\beta/\hbar}\, U(\alpha)\,. \tag{12.74}$$

For fixed β the left-hand side is, as a function of α, a strongly continuous one-parameter unitary group: the group law and the continuity are inherited from U because conjugation by a fixed unitary is multiplicative and isometric. Its generator is $V(\beta)^\dagger Q V(\beta)$ on the domain $V(-\beta)D(Q)$, because

$$\frac{V(\beta)^\dagger U(\alpha) V(\beta)x - x}{\alpha} = V(\beta)^\dagger\,\frac{U(\alpha)\big(V(\beta)x\big) - V(\beta)x}{\alpha}\,, \tag{12.75}$$

and $V(\beta)^\dagger$ is isometric, so the limit on the left exists exactly when the limit Equation (12.44) defining Q exists at the vector $V(\beta)x$, and is then its image under $V(\beta)^\dagger$. The right-hand side of Equation (12.74) is likewise such a group, and its generator is $Q + \beta\mathbb{1}$ on $D(Q)$: the summand $\beta\mathbb{1}$ is bounded and self-adjoint, and by Proposition 12.65 it contributes exactly the constant phase $\mathrm{e}^{\mathrm{i}\alpha\beta/\hbar}$. Two groups that are equal have equal generators, by the bijection of Theorem 12.66; that is the first identity of Equation (12.73), and the second follows in the same way from Equation (12.71) rewritten as $U(\alpha)^\dagger V(\beta) U(\alpha) = \mathrm{e}^{-\mathrm{i}\alpha\beta/\hbar} V(\beta)$. Conversely, exponentiating either identity of Equation (12.73) through the bijection of Theorem 12.66 returns Equation (12.74), hence Equation (12.71). □

Corollary 12.112 (Commutator of the momentum with a function of the position)**.** *Let (U, V) be a Weyl system and let*

$$g(\lambda) = \int_{\mathbb{R}} m(\alpha)\,\mathrm{e}^{\mathrm{i}\alpha\lambda/\hbar}\,\mathrm{d}\alpha\,, \qquad \int_{\mathbb{R}} (1+|\alpha|)\,|m(\alpha)|\,\mathrm{d}\alpha < \infty\,, \tag{12.76}$$

and set $g(Q) = \int_{\mathbb{R}} m(\alpha)\,U(\alpha)\,\mathrm{d}\alpha$, a bounded operator defined by the convergent vector-valued integral. Then for every $x \in D(P)$ one has $g(Q)x \in D(P)$ and

$$[P, g(Q)]\; x = -\mathrm{i}\hbar\, g'(Q)\, x\,, \tag{12.77}$$

where $g'(Q) = \int_{\mathbb{R}} (\mathrm{i}\alpha/\hbar)\, m(\alpha)\, U(\alpha)\,\mathrm{d}\alpha$ is the operator built the same way from g'.

Rests on Proposition 12.111, Theorem 12.66, and Definition 12.109.

Proof. *Derives Corollary 12.112.*

By Equation (12.74) and linearity of the integral,

$$V(\beta)^{\dagger}\, g(Q)\, V(\beta) = \int_{\mathbb{R}} m(\alpha)\, \mathrm{e}^{\mathrm{i}\alpha\beta/\hbar}\, U(\alpha)\, \mathrm{d}\alpha\,, \tag{12.78}$$

which is the operator built the same way from the translate $\lambda \longmapsto g(\lambda+\beta)$. Subtracting $g(Q)$, dividing by β and comparing with $g'(Q)$, the operator norm of the difference is at most

$$\int_{\mathbb{R}} |m(\alpha)| \left| \frac{\mathrm{e}^{\mathrm{i}\alpha\beta/\hbar}-1}{\beta} - \frac{\mathrm{i}\alpha}{\hbar} \right| \mathrm{d}\alpha\,, \tag{12.79}$$

because every $U(\alpha)$ has norm 1. The integrand tends to zero pointwise as $\beta \to 0$ and is bounded by $2\,|\alpha|\,|m(\alpha)|/\hbar$, using $\left|\mathrm{e}^{\mathrm{i}\theta}-1\right| \le |\theta|$; that bound is integrable by the hypothesis in Equation (12.76), so dominated convergence (Remark 12.1) sends Equation (12.79) to zero. The right-hand side of Equation (12.78) is therefore differentiable in β at $\beta = 0$ in the operator norm, with derivative $g'(Q)$.

Now fix $x \in D(P)$ and write, for $\beta \neq 0$,

$$\frac{V(-\beta)\, g(Q)\, V(\beta)x - g(Q)x}{\beta} = V(-\beta)\, g(Q)\, \frac{V(\beta)x - x}{\beta} + \frac{V(-\beta)\, g(Q)x - g(Q)x}{\beta}\,. \tag{12.80}$$

The left-hand side converges to $g'(Q)x$ by the previous paragraph. In the first term on the right, $(V(\beta)x - x)/\beta \to -\mathrm{i}Px/\hbar$ because $x \in D(P)$ and V has generator P (Equation (12.44)), $g(Q)$ is bounded, and $V(-\beta) \to \mathbb{1}$ strongly, so that term converges to $-\mathrm{i}g(Q)Px/\hbar$. The second term therefore converges as well, and by Equation (12.44) applied to the group $V(-\cdot)$ its convergence *is* the statement that $g(Q)x \in D(P)$, the limit being $+\mathrm{i}P\, g(Q)x/\hbar$. Collecting,

$$g'(Q)x = \frac{\mathrm{i}}{\hbar}\Big(P\, g(Q) - g(Q)\, P\Big)x = \frac{\mathrm{i}}{\hbar}\,[P, g(Q)]\, x\,,$$

which is Equation (12.77). □

Remark 12.113 (Scope of the commutator identity). Equation (12.77) is the identity every derivation of Ehrenfest's theorem uses, and the reason for proving it in the class Equation (12.76) rather than for a general function is that this class needs nothing but the Weyl relation: the operator $g(Q)$ is built from the group itself, so no functional calculus for the unbounded Q has to be invoked and no question of domains arises beyond the one settled in the proof. The class contains every bounded potential whose Fourier transform decays fast enough — a Gaussian well, a smoothly screened Coulomb potential, any C^2 function of compact support — and for a polynomial the identity is elementary and is obtained directly from $[P, Q] = -\mathrm{i}\hbar$ by induction. For a general bounded Borel g the identity still holds, with $g(Q)$ read through the functional calculus of Definition 12.60 extended to unbounded operators in Appendix A.25; that extension is not carried out here, and where a chapter needs it the fact is flagged.

Theorem 12.114 (Stone–von Neumann)**.** *Let f be finite and let (U, V) be a Weyl system of f degrees of freedom, in the sense of Definition 12.109, on a separable Hilbert space $\mathcal{H}$, acting irreducibly (Definition 12.90). Then there is a unitary $T : \mathcal{H} \longrightarrow L^2(\mathbb{R}^f)$ carrying it to the Schrödinger system Equation (12.72), and T is unique up to a phase. Without the irreducibility assumption, every such Weyl system on a separable space is a direct sum (Definition 12.84) of copies of the Schrödinger system.*

Rests on Definitions 12.90 and 12.109 and Theorem 12.91.

Remark 12.115 (What is quoted here). Theorem 12.114 is quoted, not proved. The argument builds from the Weyl operators a weighted average $\Pi = \iint w(\alpha,\beta)\, U(\alpha)V(\beta)\, \mathrm{d}\alpha\, \mathrm{d}\beta$ with

a Gaussian weight w chosen so that the phase Equation (12.71) reproduces itself on multiplication, shows by that relation alone that $\Pi^2 = \Pi = \Pi^\dagger$ and that Π is not zero, deduces from irreducibility and Theorem 12.91 that its range is one-dimensional, and then shows that the Weyl operators applied to a unit vector of that range generate $\mathcal{H}$ and reproduce the Schrödinger action — whence the unitary. It is functional analysis about the Weyl algebra, and the treatise takes the statement from [1481], theorem VIII.14, where the proof is given in full; the uniqueness question was von Neumann's, raised by Weyl's formulation of the commutation relations in exponentiated form. What is proved here is everything Equation (12.71) yields directly — the covariance Equation (12.73), the commutator Equation (12.77), and the Schur step Theorem 12.91 on which the quoted argument turns — so exactly one thing is owed, and it is named.

Remark 12.116 (Why the theorem is stated for finitely many degrees of freedom)*.* The hypothesis that f be finite is essential and its failure is physics rather than pathology. A field has infinitely many degrees of freedom, the theorem then fails, and inequivalent irreducible representations of the commutation relations exist in profusion; the choice among them becomes a physical question, and it is the origin of superselection sectors, of inequivalent vacua, and of the theorems of Chapter 109. Within its hypotheses the theorem is what makes "the" Schrödinger representation a legitimate phrase: the quantum kinematics of a system with finitely many canonical pairs is fixed, up to unitary equivalence, by the commutation relations alone, which is the statement Chapter 25 needs when it asks what a quantization can and cannot be.

Chapter 13

Differentiable Manifolds, Tensors, and Curvature

The differential geometry of curves and surfaces, and its generalisation to differentiable manifolds of arbitrary dimension, provides the language in which modern physics describes configuration spaces, spacetimes, and gauge fields. This chapter builds that language in the order in which the source manuscript develops it: tensors under orthogonal transformations in Euclidean space; the classical theory of curves and surfaces in $\mathbb{R}^3$, where the metric, the Christoffel symbols, and the Riemann symbols first appear in concrete form; the definition of a differentiable manifold through charts and atlases; tensor analysis on manifolds and under general coordinate transformations; differential forms; the metric tensor; the covariant derivative and affine connections; and the curvature tensors. The chapters on general relativity build directly on this material [1509, 1746].

Notation 13.1. Repeated indices are summed. In the sections on Cartesian tensors and on curve and surface theory all indices are written as subscripts and summation runs over repeated subscripts, as is customary for Cartesian tensors; from the section on differentiable manifolds onwards, coordinate indices are written as superscripts (x^i) and the summation convention pairs one upper with one lower index. Throughout this chapter, the *type* of a tensor is written (r, s) (r contravariant and s covariant slots); the pair (p, q) is reserved for the signature of a metric, with $D = p + q$ the dimension. Where a derivation manipulates both sides of an equation, the operation applied is displayed after the equation being manipulated, e.g. $A = B, \quad \boldsymbol{x}_l \cdot (\ )$ means "take the scalar product of both sides with $\boldsymbol{x}_l$"; this compact notation is inherited from the source manuscript.

13.1 Index conventions and the symmetry ladder

This chapter, and every chapter that builds on it, works in general dimension $D = p + q$ with metric signature (p, q) (project rule, Chapter 1); the observed case is the instantiation $p + q = 3 + 1$ of Parts IV and V. Two families of transformations act on everything we construct: *diffeomorphisms* (general coordinate transformations of the manifold) and *local frame transformations* (rotations of the orthonormal frames introduced in Section 13.8). Moreover, the maximally symmetric geometries of Section 13.13 are most transparently described by embedding the $(p+q)$-dimensional space in flat spaces of one and two dimensions more. We therefore fix, once and for all, the covariant index notation for tensors and connections defined in $(p + q)$-, $(p + q + 1)$- and $(p + q + 2)$-dimensional spaces. The following types of letters are used for indices of (pseudo-)tensors and connections under

diffeomorphisms:

$$\mu, \nu, \ldots = 1, \ldots, p+q\,,$$
$$m, n, \ldots = 1, \ldots, p+q+1\,,$$
$$M, N, \ldots = 1, \ldots, p+q+2\,,$$

while for the indices of (pseudo-)tensors and connections under *local Lorentz, (anti-)de Sitter and conformal transformations* we use

$$a, b, \ldots = 1, \ldots, p+q\,,$$
$$A, B, \ldots = 1, \ldots, p+q+1\,,$$
$$I, J, \ldots = 1, \ldots, p+q+2\,,$$

respectively.

The groups these indices transform under form a ladder that recurs throughout the treatise; we fix its names and symbols in Table 13.1.

Name	Symbol	Group
Poincaré	P_{p+q}	$\mathrm{ISO}(p,q)$
Lorentz	L_{p+q}	$\mathrm{SO}(p,q)$
translations	T_{p+q}	$\mathrm{T}(p,q)$ (abelian)
anti-de Sitter	AdS_{p+q}	$\mathrm{SO}(p,q+1)$
de Sitter	dS_{p+q}	$\mathrm{SO}(p+1,q)$
Conformal	C_{p+q}	$\mathrm{SO}(p+1,q+1)$

Table 13.1: The symmetry ladder of signature (p,q): the groups acting on flat space (Poincaré and its Lorentz and translation subgroups), on the two maximally symmetric curved spaces (anti-de Sitter and de Sitter, realized linearly in $p+q+1$ dimensions), and on the conformal structure of flat space (realized linearly in $p+q+2$ dimensions). See Section 13.13 for the constructions and Chapter 14 for the group theory.

The frame metric of signature (p,q) is fixed as

$$\eta_{ab} = \mathrm{diag}(\underbrace{+1, \ldots, +1}_{p}, \underbrace{-1, \ldots, -1}_{q})\,, \tag{13.1}$$

and likewise η_{AB} and η_{IJ} denote the flat metrics of the signatures indicated by the corresponding group in Table 13.1 — $(p,q+1)$ for AdS_{p+q}, $(p+1,q)$ for dS_{p+q}, and $(p+1,q+1)$ for C_{p+q}. In the relativistic chapters of the physical parts, where $p+q=3+1$ and the signature convention is $(-,+,+,+)$ (Part IV), the dictionary is $(p,q)=(3,1)$ with the roles of the signs read from context; nothing in this chapter depends on the overall sign choice.

13.2 Tensors under orthogonal transformations

Before tensors are defined on a general manifold, it is instructive to meet them in their simplest habitat: Euclidean space referred to orthogonal coordinate systems, where all indices can be written as subscripts and the transformation matrices are constant.

13.2.1 Orthogonal coordinate transformations

Linear transformations

Definition 13.2 (Linear coordinate transformation)**.** We say that a general coordinate transformation is *linear* if and only if it can be written as

$$x'_i = \Lambda_{ij} x_j\,, \tag{13.2}$$

with Λ_{ij} the *transformation matrix*, with constant coefficients.

Differentiating Equation (13.2) we see that

$$\Lambda_{ij} = \frac{\partial x'_i}{\partial x_j} \,. \tag{13.3}$$

From Equations (13.2) and (13.3) we have

$$\begin{aligned} x'_i &= \Lambda_{ij} x_j \\ &= \frac{\partial x'_i}{\partial x_j} x_j \,, \qquad \frac{\partial x_k}{\partial x'_i}(\ ) \\ x'_i \frac{\partial x_k}{\partial x'_i} &= \delta_{jk} x_j = x_k \,. \end{aligned}$$

Renaming indices, we obtain the inverse transformation of the coordinates,

$$x_j = \frac{\partial x_j}{\partial x'_i} x'_i \,. \tag{13.4}$$

We denote

$$\left(\Lambda^{-1}\right)_{ij} = \frac{\partial x_j}{\partial x'_i} \,, \tag{13.5}$$

which is justified because

$$\begin{aligned} \left(\Lambda^{-1}\right)_{ik} \Lambda_{ij} &= \frac{\partial x_k}{\partial x'_i} \frac{\partial x'_i}{\partial x_j} \\ &= \delta_{jk} \,, \end{aligned}$$

where $\left(\Lambda^{-1}\right)_{ik}$ is the *inverse transformation matrix*, with constant coefficients. Therefore, from Equation (13.4),

$$x_j = \left(\Lambda^{-1}\right)_{ij} x'_i \,. \tag{13.6}$$

Orthogonal coordinate systems

Definition 13.3 (Orthogonal coordinate system)**.** Consider an n-dimensional vector space generated by the basis $\{\hat{e}_i\}_{i=1}^n$. We say that the given basis forms an *orthogonal coordinate system* if and only if

$$\hat{e}_i \cdot \hat{e}_j = \delta_{ij} \,. \tag{13.7}$$

We denote the orthogonal coordinate system by K.

Definition 13.4 (Orthogonal coordinate transformation)**.** Consider two orthogonal coordinate systems K and K' with respective bases $\{\hat{e}_i\}_{i=1}^n$ and $\{\hat{e}'_i\}_{i=1}^n$. We call *orthogonal coordinate transformation* the coordinate transformation between the two systems,

$$x'_i = a_{ij} x_j \,, \tag{13.8}$$

where a_{ij} is the *transformation matrix*, with constant coefficients.

Rests on Definition 13.3.

Owing to Equation (13.8), the unit vectors of the new basis are related to the old ones by

$$\hat{e}'_i = a_{ij} \hat{e}_j \,, \tag{13.9}$$

and since the new coordinate system is also orthogonal,

$$\hat{e}'_i \cdot \hat{e}'_j = \delta_{ij} \,. \tag{13.10}$$

Geometric interpretation of the transformation matrix

From Equations (13.7) and (13.9) we see that

$$\begin{aligned}\hat{e}'_i \cdot \hat{e}_j &= (a_{ik}\hat{e}_k) \cdot \hat{e}_j \\ &= a_{ik}\,(\hat{e}_k \cdot \hat{e}_j) \\ &= a_{ik}\delta_{jk} \\ &= a_{ij}\,. \end{aligned} \tag{13.11}$$

On the other hand, let θ_{ij} be the angles between the unit vectors $\hat{e}_j$ and $\hat{e}'_i$. Then

$$\begin{aligned}\hat{e}'_i \cdot \hat{e}_j &= |\hat{e}'_i|\,|\hat{e}_j| \cos\theta_{ij} \\ &= \cos\theta_{ij}\,, \end{aligned}$$

so that, by Equation (13.11),

$$a_{ij} = \cos\theta_{ij}\,. \tag{13.12}$$

The transformation matrix therefore contains the cosines of the angles formed between the unit vectors $\hat{e}_j$ and $\hat{e}'_i$.

Orthogonality condition

Consider two orthogonal coordinate systems K and K' related by an orthogonal transformation of the form Equation (13.8). Since K' is orthogonal, from Equations (13.7), (13.9) and (13.10),

$$\begin{aligned}\delta_{ij} &= \hat{e}'_i \cdot \hat{e}'_j \\ &= a_{il}\hat{e}_l \cdot a_{jm}\hat{e}_m \\ &= a_{il}a_{jm}\delta_{lm}\,. \end{aligned}$$

Hence the *orthogonality condition* reads

$$\delta_{ij} = a_{il}a_{jl}\,. \tag{13.13}$$

In matrix notation this corresponds to

$$AA^{\mathsf{T}} = I\,. \tag{13.14}$$

Taking the determinant of both sides,

$$\begin{aligned}\det(A)\det(A^{\mathsf{T}}) &= 1 \\ (\det(A))^2 &= 1 \\ \det(A) &= \pm 1\,. \end{aligned} \tag{13.15}$$

Since $\det(A) \neq 0$, the inverse A^{-1} exists, with

$$AA^{-1} = I\,. \tag{13.16}$$

Comparing Equation (13.14) with Equation (13.16) we see that for orthogonal transformations

$$A^{\mathsf{T}} = A^{-1}\,. \tag{13.17}$$

Since Equation (13.16) may equally be written $A^{-1}A = I$, from Equation (13.17) we also have $A^{\mathsf{T}}A = I$; in index notation the orthogonality condition can therefore also be written

$$\delta_{ij} = a_{li}a_{lj}\,. \tag{13.18}$$

Inverse orthogonal transformation

From Equations (13.8) and (13.18),

$$\begin{aligned} x'_i &= a_{ik}x_k\,, \qquad a_{ij}(\ ) \\ a_{ij}x'_i &= \delta_{jk}x_k = x_j\,. \end{aligned}$$

Thus the *inverse orthogonal coordinate transformation* is given by

$$x_j = a_{ij}x'_i\,. \tag{13.19}$$

Finally, differentiating Equation (13.8) with respect to x_j and Equation (13.19) with respect to x'_i, we see that

$$a_{ij} = \frac{\partial x'_i}{\partial x_j} = \frac{\partial x_j}{\partial x'_i}\,. \tag{13.20}$$

Cartesian tensors

Definition 13.5 (Tensor under orthogonal transformations)**.** We say that the n^r quantities $T_{i_1\cdots i_r}$ are the components of a *tensor of rank r* if and only if under an orthogonal coordinate transformation their components satisfy

$$T'_{i_1\cdots i_r} = a_{i_1j_1}\cdots a_{i_rj_r}T_{j_1\cdots j_r}\,. \tag{13.21}$$

Rests on Definition 13.4.

In particular, for $r = 2$,

$$T'_{ij} = a_{il}a_{jk}T_{lk}\,. \tag{13.22}$$

To find the inverse relation, note from Equations (13.18) and (13.21) that

$$\begin{aligned} T'_{i_1\cdots i_r} &= a_{i_1k_1}\cdots a_{i_rk_r}T_{k_1\cdots k_r}\,, \qquad a_{i_1j_1}\cdots a_{i_rj_r}(\ ) \\ a_{i_1j_1}\cdots a_{i_rj_r}T'_{i_1\cdots i_r} &= \delta_{j_1k_1}\cdots\delta_{j_rk_r}T_{k_1\cdots k_r}\,, \end{aligned}$$

so that

$$T_{j_1\cdots j_r} = a_{i_1j_1}\cdots a_{i_rj_r}T'_{i_1\cdots i_r}\,. \tag{13.23}$$

Notable Cartesian tensors

We call *vector* a tensor of rank 1.

From the orthogonality condition Equation (13.13) we may write

$$\delta_{ij} = a_{il}a_{jk}\delta_{lk}\,.$$

Moreover, by its definition the Kronecker delta takes the same values in every orthogonal coordinate system, so we may write

$$\delta'_{ij} = a_{il}a_{jk}\delta_{lk}\,. \tag{13.24}$$

Comparing with Equation (13.22), the Kronecker delta satisfies the transformation law of a rank-2 tensor. Therefore *the Kronecker delta is an invariant tensor under orthogonal transformations.*

13.2.2 Algebra of Cartesian tensors

Addition

Consider the quantities $A_{i_1\cdots i_r}$ and $B_{i_1\cdots i_r}$, components of tensors under orthogonal transformations, both of rank r. Define the quantities

$$C_{i_1\cdots i_r} = A_{i_1\cdots i_r} + B_{i_1\cdots i_r} .$$

Then, by Equation (13.21),

$$\begin{aligned} C'_{i_1\cdots i_r} &= A'_{i_1\cdots i_r} + B'_{i_1\cdots i_r} \\ &= a_{i_1 j_1}\cdots a_{i_r j_r} A_{j_1\cdots j_r} + a_{i_1 j_1}\cdots a_{i_r j_r} B_{j_1\cdots j_r} \\ &= a_{i_1 j_1}\cdots a_{i_r j_r} \left(A_{j_1\cdots j_r} + B_{j_1\cdots j_r}\right) \\ &= a_{i_1 j_1}\cdots a_{i_r j_r} C_{j_1\cdots j_r} . \end{aligned}$$

Therefore the addition of tensors forms the components of a new tensor under orthogonal transformations.

Multiplication by a scalar

Consider the quantities $A_{i_1\cdots i_r}$, components of a rank-r tensor under orthogonal transformations, and a scalar λ. Define

$$C_{i_1\cdots i_r} = \lambda A_{i_1\cdots i_r} .$$

Then

$$\begin{aligned} C'_{i_1\cdots i_r} &= \lambda A'_{i_1\cdots i_r} \\ &= \lambda\, a_{i_1 j_1}\cdots a_{i_r j_r} A_{j_1\cdots j_r} \\ &= a_{i_1 j_1}\cdots a_{i_r j_r} \lambda A_{j_1\cdots j_r} \\ &= a_{i_1 j_1}\cdots a_{i_r j_r} C_{j_1\cdots j_r} . \end{aligned}$$

Therefore the multiplication of a tensor by a scalar forms the components of a new tensor under orthogonal transformations.

Product

Consider the quantities $A_{i_1\cdots i_r}$ and $B_{i_1\cdots i_s}$, components of tensors under orthogonal transformations, of ranks r and s respectively. Define

$$C_{i_1\cdots i_{r+s}} = A_{i_1\cdots i_r} B_{i_{r+1}\cdots i_{r+s}} . \tag{13.25}$$

Then, by Equation (13.21),

$$\begin{aligned} C'_{i_1\cdots i_{r+s}} &= A'_{i_1\cdots i_r} B'_{i_{r+1}\cdots i_{r+s}} \\ &= \left(a_{i_1 j_1}\cdots a_{i_r j_r} A_{j_1\cdots j_r}\right)\left(a_{i_{r+1} j_{r+1}}\cdots a_{i_{r+s} j_{r+s}} B_{j_{r+1}\cdots j_{r+s}}\right) \\ &= a_{i_1 j_1}\cdots a_{i_{r+s} j_{r+s}} A_{j_1\cdots j_r} B_{j_{r+1}\cdots j_{r+s}} \\ &= a_{i_1 j_1}\cdots a_{i_{r+s} j_{r+s}} C_{j_1\cdots j_{r+s}} . \end{aligned}$$

Therefore the product of tensors forms the components of a new tensor under orthogonal transformations.

Permutation of indices

Consider the quantities $A_{i_1\cdots i_r}$, components of a rank-r tensor under orthogonal transformations. Define the symbol

$$C_{i_1\cdots i_{s-1}i_s i_{s+1}\cdots i_{t-1}i_t i_{t+1}\cdots i_r} = A_{i_1\cdots i_{s-1}i_t i_{s+1}\cdots i_{t-1}i_s i_{t+1}\cdots i_r}\,, \tag{13.26}$$

in which the s-th and t-th indices of $A_{i_1\cdots i_r}$ are permuted. Then, by Equation (13.21) and reordering the constant factors a_{ij},

$$\begin{aligned} C'_{i_1\cdots i_s\cdots i_t\cdots i_r} &= A'_{i_1\cdots i_t\cdots i_s\cdots i_r} \\ &= a_{i_1 j_1}\cdots a_{i_t j_t}\cdots a_{i_s j_s}\cdots a_{i_r j_r} A_{j_1\cdots j_t\cdots j_s\cdots j_r} \\ &= a_{i_1 j_1}\cdots a_{i_s j_s}\cdots a_{i_t j_t}\cdots a_{i_r j_r} C_{j_1\cdots j_s\cdots j_t\cdots j_r}\,. \end{aligned}$$

Thus the permutation of indices of a tensor defines a new tensor under orthogonal transformations.

Contraction of indices

Consider the quantities $A_{i_1\cdots i_r}$, components of a rank-r tensor under orthogonal transformations. Define the n^{r-2} quantities

$$C_{i_1\cdots i_{r-2}} = A_{i_1\cdots i\cdots i\cdots i_{r-2}}\,. \tag{13.27}$$

Then, by Equations (13.18) and (13.21),

$$\begin{aligned} C'_{i_1\cdots i_{r-2}} &= A'_{i_1\cdots i\cdots i\cdots i_{r-2}} \\ &= a_{i_1 j_1}\cdots a_{ij}\cdots a_{il}\cdots a_{i_{r-2}j_{r-2}} A_{j_1\cdots j\cdots l\cdots j_{r-2}} \\ &= a_{i_1 j_1}\cdots a_{i_{r-2}j_{r-2}}\,\delta_{jl} A_{j_1\cdots j\cdots l\cdots j_{r-2}} \\ &= a_{i_1 j_1}\cdots a_{i_{r-2}j_{r-2}} A_{j_1\cdots j\cdots j\cdots j_{r-2}} \\ &= a_{i_1 j_1}\cdots a_{i_{r-2}j_{r-2}} C_{j_1\cdots j_{r-2}}\,. \end{aligned}$$

Thus the contraction of two indices of a tensor defines a new tensor, of rank $r-2$, under orthogonal transformations.

Quotient law

Consider the quantities $A_{i_1\cdots i_s j_1\cdots j_r}$, and consider further the quantities $B_{j_1\cdots j_r}$, components of a rank-r tensor under orthogonal transformations. Let $C_{i_1\cdots i_s}$ be given by

$$A_{i_1\cdots i_s j_1\cdots j_r} B_{j_1\cdots j_r} = C_{i_1\cdots i_s}\,. \tag{13.28}$$

With respect to another orthogonal coordinate system,

$$A'_{i_1\cdots i_s j_1\cdots j_r} B'_{j_1\cdots j_r} = C'_{i_1\cdots i_s}\,.$$

Supposing that the $C_{i_1\cdots i_s}$ are the components of a rank-s tensor under orthogonal transformations, from Equation (13.21) we have

$$\begin{aligned} A'_{i_1\cdots i_s j_1\cdots j_r}\, a_{j_1 k_1}\cdots a_{j_r k_r} B_{k_1\cdots k_r} &= a_{i_1 l_1}\cdots a_{i_s l_s} C_{l_1\cdots l_s} \\ \text{[Equation (13.28)]} \quad &= a_{i_1 l_1}\cdots a_{i_s l_s} A_{l_1\cdots l_s m_1\cdots m_r} B_{m_1\cdots m_r} \\ &= a_{i_1 l_1}\cdots a_{i_s l_s} A_{l_1\cdots l_s k_1\cdots k_r} B_{k_1\cdots k_r}\,. \end{aligned}$$

Since the $B_{k_1\cdots k_r}$ are arbitrary, applying $a_{m_1 k_1}\cdots a_{m_r k_r}$ to both sides of the resulting relation and using Equation (13.13),

$$\begin{aligned} \delta_{j_1 m_1}\cdots\delta_{j_r m_r} A'_{i_1\cdots i_s j_1\cdots j_r} &= a_{i_1 l_1}\cdots a_{i_s l_s} a_{m_1 k_1}\cdots a_{m_r k_r} A_{l_1\cdots l_s k_1\cdots k_r} \\ A'_{i_1\cdots i_s m_1\cdots m_r} &= a_{i_1 l_1}\cdots a_{i_s l_s} a_{m_1 k_1}\cdots a_{m_r k_r} A_{l_1\cdots l_s k_1\cdots k_r}\,. \end{aligned}$$

Hence the quantities $A_{i_1\cdots i_s j_1\cdots j_r}$ satisfying Equation (13.28) are the components of a tensor under orthogonal transformations. This result is called the *quotient law*.

The Levi-Civita symbol

Beside the Kronecker delta, three dimensions carry a second array with the same components in every frame. Define ε_{ijk}, with $i,j,k \in \{1,2,3\}$, to be totally antisymmetric with $\varepsilon_{123} = +1$; equivalently $\varepsilon_{ijk} = \operatorname{sgn}\sigma$ when $(i,j,k) = (\sigma(1),\sigma(2),\sigma(3))$ for a permutation σ, and zero when two indices coincide. (The general n-index symbol reappears in Section 13.5.3 as a density of weight -1 under arbitrary coordinate changes; under *orthogonal* changes the weight factor is $\det a = \pm 1$, which is the content of Equation (13.31) below.)

Proposition 13.6 (Levi-Civita identities in three dimensions)**.** *For $n = 3$, with ε_{ijk} as just defined,*

$$\varepsilon_{ijk}\varepsilon_{ilm} = \delta_{jl}\delta_{km} - \delta_{jm}\delta_{kl}\,, \tag{13.29}$$

$$\varepsilon_{ijk}\varepsilon_{ijm} = 2\,\delta_{km}\,, \qquad \varepsilon_{ijk}\varepsilon_{ijk} = 6\,, \tag{13.30}$$

and, for any 3×3 array a_{ij},

$$\varepsilon_{ijk}\,a_{il}a_{jm}a_{kn} = \varepsilon_{lmn}\,\det a\,. \tag{13.31}$$

In particular ε_{ijk} is an isotropic tensor under proper orthogonal transformations, and changes sign under improper ones.

Rests on Definition 13.5 and Equation (5.19).

Derivation. *Derives Proposition 13.6.*

Equation (13.29). Both sides vanish when $j = k$ or when $l = m$: on the left ε_{ijk} or ε_{ilm} is then zero, and on the right, putting $j = k$, the two products coincide and cancel (similarly for $l = m$). So let $j \neq k$ and $l \neq m$. A nonzero ε_{ijk} forces $\{i,j,k\} = \{1,2,3\}$, hence fixes i; the same for ε_{ilm}. The sum on the left is therefore nonzero only if the two constraints select the same i, i.e. only if $\{l,m\} = \{j,k\}$, and then exactly one term survives. If $(l,m) = (j,k)$ that term is $\varepsilon_{ijk}^2 = 1$, while the right side is $1 - \delta_{jk}\delta_{kj} = 1$; if $(l,m) = (k,j)$ it is $\varepsilon_{ijk}\varepsilon_{ikj} = -1$, and the right side is $\delta_{jk}\delta_{kj} - 1 = -1$. In every remaining case $\{l,m\} \neq \{j,k\}$ and both sides are zero.

Equation (13.30). Contract Equation (13.29) with δ_{jl}: the right side gives $\delta_{jj}\delta_{km} - \delta_{jm}\delta_{kj} = 3\delta_{km} - \delta_{km} = 2\delta_{km}$. Contracting once more with δ_{km} gives $2\delta_{kk} = 6$.

Equation (13.31). The left side is totally antisymmetric in (l,m,n): exchanging two of them exchanges two of the factors a, which may be undone by exchanging the corresponding two summation indices of ε_{ijk}, at the cost of one sign. A totally antisymmetric array of three three-valued indices is a multiple of ε_{lmn}, the multiple being its value at $(l,m,n) = (1,2,3)$. That value is $\varepsilon_{ijk}a_{i1}a_{j2}a_{k3}$, which is the Leibniz expansion Equation (5.19) of $\det a$ read by columns: the nonzero terms are indexed by the permutations σ with $(i,j,k) = (\sigma(1),\sigma(2),\sigma(3))$, and $\varepsilon_{\sigma(1)\sigma(2)\sigma(3)} = \operatorname{sgn}\sigma$.

The last sentence. Equation (13.31) holds for every 3×3 array, so it may be applied to the transpose of a, giving $a_{li}a_{mj}a_{nk}\varepsilon_{ijk} = \varepsilon_{lmn}\det a^{\mathsf{T}} = \varepsilon_{lmn}\det a$ by Equation (13.14). The left side is the rank-3 transformation law Equation (13.21) applied to ε; the right side is ε itself when $\det a = +1$ and its negative when $\det a = -1$, the two cases of Equation (13.15). □

Isotropic tensors

The algebra above says how tensors combine. The question left open is which tensors are singled out by the group itself — those whose components are the same in every frame. That question is invariant theory for the rotation group rather than tensor algebra, and it is settled once and for all in Theorem 5.128. In *three* dimensions — and the dimension is essential, as Remark 13.7 records — a Cartesian tensor (Definition 13.5) whose components

are unchanged by every proper rotation vanishes at rank one, is a multiple of δ_{ij} at rank two, a multiple of ε_{ijk} at rank three, and a combination

$$T_{ijkl} = a\,\delta_{ij}\delta_{kl} + b\,\delta_{ik}\delta_{jl} + c\,\delta_{il}\delta_{jk} \tag{13.32}$$

of the three products of Kronecker deltas at rank four — three free numbers in place of $3^4 = 81$. The invariance of δ_{ij} and of ε_{ijk} under proper rotations, which is what makes the converse half true, is Equations (13.24) and (13.31) of this section.

Remark 13.7 (What the classification is used for). A linear constitutive law between two rank-2 Cartesian tensors, $\sigma_{ij} = A_{ijkl}\,e_{kl}$, has 81 coefficients in three dimensions. If the medium is isotropic — no direction distinguished — then A_{ijkl} is an isotropic tensor, and Equation (13.32) reduces the 81 to three, or to two once e_{kl} is symmetric, since then only the combination $b+c$ acts. That single step is what makes linear elasticity a two-constant theory (Lemma 30.26) and the Newtonian stress of a fluid a two-viscosity one. The classification is a statement about SO(3) specifically and does not survive a change of dimension: it is not only the rank-3 case that is three-dimensional. In two dimensions ε_{ij} is SO(2)-invariant, so an isotropic rank-2 tensor is $a\,\delta_{ij} + b\,\varepsilon_{ij}$ rather than a multiple of δ_{ij}; in four, ε_{ijkl} is SO(4)-invariant and is not a combination of Kronecker products, so a rank-4 isotropic tensor carries a fourth independent coefficient. Every step of the proof in Chapter 5 uses $n = 3$ — the parity argument needs $\det \operatorname{diag}(1,-1,-1) = +1$, and the relabelling argument needs a 3-cycle to be even.

Rests on Theorem 5.128 and Definition 13.5.

13.3 The theory of curves and surfaces in $\mathbb{R}^3$

13.3.1 Theory of curves

Curves in $\mathbb{R}^3$

Definition 13.8 (Curve)**.** A *curve* is a differentiable map

$$\begin{aligned} \boldsymbol{x} : I_\lambda \subset \mathbb{R} &\longrightarrow E \subset \mathbb{R}^3 \\ \lambda &\longmapsto \boldsymbol{x}(\lambda)\,, \end{aligned}$$

with I_λ an open interval (so as to guarantee differentiability). The variable λ parametrises, or labels, the curve.

Definition 13.9 (Tangent vector to a curve)**.** The *tangent vector to the curve*, with parameter t, is defined as

$$\boldsymbol{T} = \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\,. \tag{13.33}$$

Rests on Definition 13.8.

Definition 13.10 (Admissible change of parameter)**.** An *admissible change of parameter* is a function α such that

$$t = \alpha(\theta)\,, \quad \theta \in I_\theta\,, \quad \text{with} \quad \alpha \in C^1(I_\theta) \ \wedge\ \alpha'(\theta) \neq 0 \quad \forall\,\theta \in I_\theta\,. \tag{13.34}$$

Definition 13.11 (Arc length)**.** The *arc length of the curve from t_0 to t* is given by

$$s(t) = \int_{t_0}^{t} \left|\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\right| \mathrm{d}t\,. \tag{13.35}$$

Rests on Definitions 13.8 and 13.9.

From this we see that the inverse function of s is an admissible change of parameter for t. Moreover, differentiating both sides of Equation (13.35) with respect to t,

$$\frac{\mathrm{d}s}{\mathrm{d}t} = \left|\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\right| , \tag{13.36}$$

and therefore, from Equation (13.33),

$$\begin{aligned} \boldsymbol{T} &= \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t} \\ &= \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}t} \\ &= \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}s}\left|\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\right| \\ \implies \quad \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}s} &= \frac{\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}}{\left|\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\right|} . \end{aligned} \tag{13.37}$$

Definition 13.12 (Unit tangent vector)**.** We define the *unit tangent vector* as

$$\hat{T} = \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}s} . \tag{13.38}$$

Rests on Definitions 13.9 and 13.11.

From Equation (13.37) we see that $\hat{T}$ is indeed a unit vector.

Definition 13.13 (Normal curvature vector of a curve)**.** We define the *normal curvature vector of the curve* as

$$\boldsymbol{k} = \frac{\mathrm{d}^2\boldsymbol{x}}{\mathrm{d}s^2} = \frac{\mathrm{d}\hat{T}}{\mathrm{d}s} . \tag{13.39}$$

Rests on Definition 13.12.

The derivative of any unit vector $\hat{e}$ lies in the plane orthogonal to $\hat{e}$, for

$$\begin{aligned} & |\hat{e}| = 1 \\ \iff \quad & \hat{e}\cdot\hat{e} = 1 , \qquad \frac{\mathrm{d}}{\mathrm{d}s}(\,) \\ \implies \quad & \frac{\mathrm{d}\hat{e}}{\mathrm{d}s}\cdot\hat{e} = 0 \\ \implies \quad & \frac{\mathrm{d}\hat{e}}{\mathrm{d}s} \perp \hat{e} , \end{aligned} \tag{13.40}$$

and therefore the vector $\boldsymbol{k}$ lies in the plane orthogonal to $\hat{T}$.

We define the *curvature function* κ as

$$\kappa(s) = |\boldsymbol{k}| . \tag{13.41}$$

Definition 13.14 (Principal unit normal vector)**.** We define the *principal unit normal vector* as

$$\hat{N} = \frac{\boldsymbol{k}}{\kappa} . \tag{13.42}$$

Rests on Definition 13.13.

We thus find a relation between the derivative of the unit tangent vector and the unit normal,

$$\frac{\mathrm{d}\hat{T}}{\mathrm{d}s} = \kappa\hat{N} . \tag{13.43}$$

Definition 13.15 (Unit binormal vector)**.** We define the *unit binormal vector* as

$$\hat{B} = \hat{T} \times \hat{N} \,. \tag{13.44}$$

Rests on Definitions 13.12 and 13.14.

We thereby obtain a system of three orthonormal vectors called the *moving trihedron* (the Frenet frame).

Torsion

Differentiating Equation (13.44) with respect to s,

$$\frac{\mathrm{d}\hat{B}}{\mathrm{d}s} = \frac{\mathrm{d}\hat{T}}{\mathrm{d}s} \times \hat{N} + \hat{T} \times \frac{\mathrm{d}\hat{N}}{\mathrm{d}s} \,. \tag{13.45}$$

From Equation (13.43) the first term of this expression vanishes. From Equation (13.40) the vector $\frac{\mathrm{d}\hat{N}}{\mathrm{d}s}$ lies in the plane spanned by $\hat{T}$ and $\hat{B}$, so we may write $\frac{\mathrm{d}\hat{N}}{\mathrm{d}s}$ as a linear combination of $\hat{T}$ and $\hat{B}$. Thus

$$\begin{aligned} \frac{\mathrm{d}\hat{B}}{\mathrm{d}s} &= \hat{T} \times \left(\alpha(s)\hat{T} + \tau(s)\hat{B}\right) \\ &= \tau\, \hat{T} \times \hat{B} \\ \\ \implies \qquad \frac{\mathrm{d}\hat{B}}{\mathrm{d}s} &= -\tau \hat{N} \,, \end{aligned} \tag{13.46}$$

where the function τ is called the *torsion of the curve.*

From Equation (13.44) we see that

$$\begin{aligned} \hat{N} &= \hat{B} \times \hat{T} \,, \qquad \frac{\mathrm{d}}{\mathrm{d}s}(\,) \\ \frac{\mathrm{d}\hat{N}}{\mathrm{d}s} &= \frac{\mathrm{d}\hat{B}}{\mathrm{d}s} \times \hat{T} + \hat{B} \times \frac{\mathrm{d}\hat{T}}{\mathrm{d}s} \,, \end{aligned}$$

and by Equations (13.43) and (13.46),

$$\begin{aligned} \frac{\mathrm{d}\hat{N}}{\mathrm{d}s} &= -\tau \hat{N} \times \hat{T} + \kappa \hat{B} \times \hat{N} \\ \\ \implies \qquad \frac{\mathrm{d}\hat{N}}{\mathrm{d}s} &= \tau \hat{B} - \kappa \hat{T} \,. \end{aligned} \tag{13.47}$$

The Frenet–Serret equations

Equations Equations (13.43), (13.46) and (13.47) are the *Frenet–Serret equations*, which relate the vectors of the moving trihedron to their derivatives:

$$\begin{aligned} \frac{\mathrm{d}\hat{T}}{\mathrm{d}s} &= \kappa \hat{N} \\ \frac{\mathrm{d}\hat{N}}{\mathrm{d}s} &= \tau \hat{B} - \kappa \hat{T} \\ \frac{\mathrm{d}\hat{B}}{\mathrm{d}s} &= -\tau \hat{N} \,, \end{aligned}$$

or, in matrix form,

$$\frac{\mathrm{d}}{\mathrm{d}s} \begin{pmatrix} \hat{T} \\ \hat{N} \\ \hat{B} \end{pmatrix} = \begin{pmatrix} 0 & \kappa & 0 \\ -\kappa & 0 & \tau \\ 0 & -\tau & 0 \end{pmatrix} \begin{pmatrix} \hat{T} \\ \hat{N} \\ \hat{B} \end{pmatrix} \,. \tag{13.48}$$

The fundamental theorem of the theory of curves

The Frenet–Serret system determines the moving trihedron from the two functions κ and τ, and the trihedron determines the curve. The precise statement is the following.

Theorem 13.16 (Fundamental theorem of the theory of curves)**.** *Let $I =]a, b[\subset \mathbb{R}$ and let $\kappa, \tau : I \longrightarrow \mathbb{R}$ be continuous with $\kappa(s) > 0$ for every $s \in I$. Then there exists a curve $\boldsymbol{x} : I \longrightarrow \mathbb{R}^3$, parametrised by arc length, whose curvature function is κ and whose torsion is τ. It is unique up to a rigid motion of $\mathbb{R}^3$: any two such curves are related by $\boldsymbol{x} \longmapsto A\boldsymbol{x} + \boldsymbol{c}$ with $A \in \mathrm{SO}(3)$ and $\boldsymbol{c} \in \mathbb{R}^3$ constant.*

Rests on Equations (13.43)*,* (13.46) *and* (13.47)*.*

Proof. *Derives Theorem 13.16.*

Existence. Read the Frenet–Serret equations as a linear system of ordinary differential equations for the nine components of the triple $(\hat{T}, \hat{N}, \hat{B})$,

$$\frac{\mathrm{d}}{\mathrm{d}s}\begin{pmatrix}\hat{T}\\ \hat{N}\\ \hat{B}\end{pmatrix} = \Omega(s)\begin{pmatrix}\hat{T}\\ \hat{N}\\ \hat{B}\end{pmatrix}, \qquad \Omega = \begin{pmatrix}0 & \kappa & 0\\ -\kappa & 0 & \tau\\ 0 & -\tau & 0\end{pmatrix}. \tag{13.49}$$

The coefficients are continuous on I, so by the existence and uniqueness theorem for linear systems (Chapter 9) the system has exactly one solution on the whole of I for each choice of initial data at some $s_0 \in I$. Choose as initial data any positively oriented orthonormal triple $(\hat{T}_0, \hat{N}_0, \hat{B}_0)$.

The solution remains orthonormal. Write $e_1 = \hat{T}$, $e_2 = \hat{N}$, $e_3 = \hat{B}$ and consider the Gram matrix $G_{AB} = e_A \cdot e_B$. From Equation (13.49),

$$\frac{\mathrm{d}G_{AB}}{\mathrm{d}s} = \Omega_{AC}G_{CB} + \Omega_{BC}G_{AC}\,, \tag{13.50}$$

a linear system for G. Because Ω is antisymmetric, the constant matrix $G_{AB} = \delta_{AB}$ solves Equation (13.50); it agrees with the initial data at s_0, and by uniqueness of solutions it is *the* solution. Hence the triple is orthonormal for every $s \in I$, and $\det(e_1, e_2, e_3)$, a continuous function taking values in $\{+1, -1\}$ on the interval I, stays equal to its initial value $+1$: the triple stays positively oriented.

Now define

$$\boldsymbol{x}(s) = \boldsymbol{x}_0 + \int_{s_0}^{s} \hat{T}(\sigma)\,\mathrm{d}\sigma\,. \tag{13.51}$$

Then $\mathrm{d}\boldsymbol{x}/\mathrm{d}s = \hat{T}$ is a unit vector, so s is the arc-length parameter of $\boldsymbol{x}$ by Equation (13.36); the first row of Equation (13.49) gives $\mathrm{d}\hat{T}/\mathrm{d}s = \kappa\hat{N}$ with $\hat{N}$ a unit vector and $\kappa > 0$, so the curvature function of $\boldsymbol{x}$ is κ and its principal unit normal is $\hat{N}$ (Equations (13.39) and (13.42)); orthonormality and orientation give $\hat{B} = \hat{T} \times \hat{N}$, so $\hat{B}$ is the binormal Equation (13.44); and the third row gives $\mathrm{d}\hat{B}/\mathrm{d}s = -\tau\hat{N}$, so the torsion of $\boldsymbol{x}$ is τ by Equation (13.46).

Uniqueness. A rigid motion $\boldsymbol{x} \longmapsto A\boldsymbol{x} + \boldsymbol{c}$ with $A \in \mathrm{SO}(3)$ preserves arc length, scalar products and cross products, hence carries the trihedron of a curve to the trihedron of the image curve and leaves κ and τ unchanged. Conversely, let $\boldsymbol{x}$ and $\tilde{\boldsymbol{x}}$ both realize the given κ and τ. Their trihedra at s_0 are two positively oriented orthonormal bases of $\mathbb{R}^3$, so there is a unique $A \in \mathrm{SO}(3)$ carrying the second to the first; let $\boldsymbol{c} = \boldsymbol{x}(s_0) - A\tilde{\boldsymbol{x}}(s_0)$. The curve $A\tilde{\boldsymbol{x}} + \boldsymbol{c}$ then has the same κ and τ as $\boldsymbol{x}$ and the same trihedron at s_0; since both trihedra solve Equation (13.49) with the same coefficients and the same data at s_0, they coincide on all of I. In particular the two unit tangents coincide, and the two curves, having the same value at s_0, coincide by Equation (13.51). □

Remark 13.17. The hypothesis $\kappa > 0$ cannot be dropped: where κ vanishes the principal normal Equation (13.42) is undefined, the trihedron is not determined by the curve, and a straight segment may be joined smoothly to curved pieces in inequivalent ways. The theorem is the geometric statement that κ and τ are a *complete* set of invariants of a curve in $\mathbb{R}^3$ under the group of rigid motions — the pattern that recurs throughout this chapter, where a geometric object is classified by the scalars that survive a group of transformations.

13.3.2 Theory of surfaces

Surfaces in $\mathbb{R}^3$

Definition 13.18 (Surface)**.** A *surface* is a differentiable map

$$\begin{aligned} \boldsymbol{x} : I_{u_1} \times I_{u_2} = A \subset \mathbb{R}^2 &\longrightarrow E \subset \mathbb{R}^3 \\ (u_1, u_2) &\longmapsto \boldsymbol{x}(u_1, u_2)\,, \end{aligned}$$

with I_{u_1}, I_{u_2}, and A open sets.

Definition 13.19 (Parameter curves)**.** We call *curve of parameter* u_1 and *curve of parameter* u_2 the curves

$$\boldsymbol{x} = \boldsymbol{x}(u_1, a)\,, \qquad \boldsymbol{x} = \boldsymbol{x}(b, u_2)\,, \tag{13.52}$$

respectively, with a and b constants.

Rests on Definitions 13.8 and 13.18.

From the definition we see that these curves lie on the surface.

The *tangent vectors* to the curves of parameter u_1 and u_2 are given by

$$\frac{\partial \boldsymbol{x}}{\partial u_1} \overset{\text{not.}}{=} \boldsymbol{x}_1\,, \qquad \frac{\partial \boldsymbol{x}}{\partial u_2} \overset{\text{not.}}{=} \boldsymbol{x}_2\,, \tag{13.53}$$

respectively. These vectors lie in the tangent plane of the surface.

Definition 13.20 (Unit normal vector of a surface)**.** We define the *unit normal vector of the surface* as

$$\hat{n} = \frac{\boldsymbol{x}_1 \times \boldsymbol{x}_2}{|\boldsymbol{x}_1 \times \boldsymbol{x}_2|}\,. \tag{13.54}$$

Rests on Definition 13.19.

First fundamental form

Consider the differential

$$\mathrm{d}\boldsymbol{x} = \boldsymbol{x}_i \mathrm{d}u_i = \boldsymbol{x}_1 \mathrm{d}u_1 + \boldsymbol{x}_2 \mathrm{d}u_2\,. \tag{13.55}$$

This differential is written as a linear combination of the vectors $\boldsymbol{x}_1$ and $\boldsymbol{x}_2$, and therefore also lies in the tangent plane of the surface. Consider a curve on the surface, given by

$$\begin{aligned} \boldsymbol{x} &= \boldsymbol{x}\left(u_1(s), u_2(s)\right) \\ &= \boldsymbol{x}(s)\,, \end{aligned} \tag{13.56}$$

where s is the arc-length parameter of the curve. From Equation (13.36) we have

$$\mathrm{d}s = |\mathrm{d}\boldsymbol{x}|\,, \tag{13.57}$$

where $\mathrm{d}s$ is called the *arc element*. Thus

$$\mathrm{d}s^2 = \mathrm{d}\boldsymbol{x} \cdot \mathrm{d}\boldsymbol{x}\,. \tag{13.58}$$

Definition 13.21 (First fundamental form)**.** We call *first fundamental form* the square of the arc element of the curve given by Equation (13.56), that is, the quantity $\mathrm{d}s^2$.

Rests on Definitions 13.11 and 13.18.

From Equations (13.55) and (13.58) we see that

$$\mathrm{d}s^2 = \boldsymbol{x}_i \cdot \boldsymbol{x}_j \, \mathrm{d}u_i \mathrm{d}u_j \,. \tag{13.59}$$

Definition 13.22 (First fundamental coefficients)**.** We define the *first fundamental coefficients* as

$$g_{ij} = \boldsymbol{x}_i \cdot \boldsymbol{x}_j \,. \tag{13.60}$$

Rests on Definitions 13.19 and 13.21.

The first fundamental form is therefore given by

$$\mathrm{d}s^2 = g_{ij} \, \mathrm{d}u_i \mathrm{d}u_j \,. \tag{13.61}$$

From the definition we see that the g_{ij} are the components of a symmetric tensor of rank 2, which is called the *metric tensor*, or simply the *metric*. The *determinant of the metric tensor* is given by

$$g = g_{11} g_{22} - g_{12}^2 \,. \tag{13.62}$$

Definition 13.23 (Inverse metric tensor)**.** We define the *inverse metric tensor* g^{ij} as the quantities that satisfy

$$g_{li} \, g^{ij} = \delta_l{}^j \,. \tag{13.63}$$

Rests on Definition 13.22.

We can compute these quantities using matrix notation: writing

$$[g_{li}][g^{ij}] = I \tag{13.64}$$

with

$$[g_{li}] = \begin{pmatrix} g_{11} & g_{12} \\ g_{12} & g_{22} \end{pmatrix} , \qquad [g^{ij}] = \begin{pmatrix} g^{11} & g^{12} \\ g^{12} & g^{22} \end{pmatrix} , \tag{13.65}$$

we see from Equation (13.64) that $[g^{ij}] = [g_{li}]^{-1}$, and therefore, from the algebra of matrices,

$$\begin{pmatrix} g^{11} & g^{12} \\ g^{12} & g^{22} \end{pmatrix} = \begin{pmatrix} \dfrac{g_{22}}{g} & -\dfrac{g_{12}}{g} \\ -\dfrac{g_{12}}{g} & \dfrac{g_{11}}{g} \end{pmatrix} . \tag{13.66}$$

Length of a curve and area of a surface

Consider the curve on a surface $\boldsymbol{x}$ given by Equation (13.56). Since the surface carries a first fundamental form, we can compute the *length of the whole curve* in terms of the first fundamental coefficients. As $s = \int \mathrm{d}s$, the length of the whole curve is given by

$$L = \int_{I_s} \sqrt{g_{ij} \, \mathrm{d}u_i \mathrm{d}u_j} \,. \tag{13.67}$$

Now define an angle γ between the vectors $\boldsymbol{x}_1$ and $\boldsymbol{x}_2$. Since

$$\boldsymbol{x}_1 \cdot \boldsymbol{x}_2 = |\boldsymbol{x}_1| \, |\boldsymbol{x}_2| \cos\gamma \,, \tag{13.68}$$

from Equation (13.60) we have

$$\cos\gamma = \frac{g_{12}}{\sqrt{g_{11} g_{22}}} \,. \tag{13.69}$$

On the other hand, the area of an infinitesimal parallelogram of the surface is given by

$$\begin{aligned} \mathrm{d}S &= |\boldsymbol{x}_1 \times \boldsymbol{x}_2| \, \mathrm{d}u_1 \mathrm{d}u_2 \\ &= |\boldsymbol{x}_1| \, |\boldsymbol{x}_2| \sin\gamma \, \mathrm{d}u_1 \mathrm{d}u_2 \\ &= \sqrt{g_{11} g_{22}} \, \sin\gamma \, \mathrm{d}u_1 \mathrm{d}u_2 \,, \end{aligned}$$

and from Equation (13.69),

$$\sin\gamma = \sqrt{1 - \frac{g_{12}^2}{g_{11} g_{22}}} \,. \tag{13.70}$$

Thus we see that

$$\mathrm{d}S = \sqrt{g} \, \mathrm{d}u_1 \mathrm{d}u_2 \,. \tag{13.71}$$

Integrating, the *area of a surface* is

$$S = \int_{I_{u_1}} \int_{I_{u_2}} \sqrt{g} \, \mathrm{d}u_1 \mathrm{d}u_2 \,. \tag{13.72}$$

Second fundamental form

The differential of any unit vector $\hat{e}$ lies in the plane orthogonal to $\hat{e}$, for

$$\begin{aligned} & |\hat{e}| = 1 \\ \iff \quad & \hat{e} \cdot \hat{e} = 1 \,, \qquad \mathrm{d}(\,) \\ \implies \quad & \mathrm{d}\hat{e} \cdot \hat{e} = 0 \\ \implies \quad & \mathrm{d}\hat{e} \perp \hat{e} \,, \end{aligned} \tag{13.73}$$

so the vector $\mathrm{d}\hat{n}$ lies in the plane orthogonal to $\hat{n}$. By the chain rule, the differential $\mathrm{d}\hat{n}$ is given by

$$\mathrm{d}\hat{n} = \frac{\partial \hat{n}}{\partial u_i} \mathrm{d}u_i \overset{\text{not.}}{=} \hat{n}_i \, \mathrm{d}u_i \,. \tag{13.74}$$

Definition 13.24 (Second fundamental form)**.** We define the *second fundamental form* as the quantity

$$\mathrm{I\!I} = -\mathrm{d}\boldsymbol{x} \cdot \mathrm{d}\hat{n} \,. \tag{13.75}$$

Rests on Definition 13.20.

From Equations (13.55) and (13.74) we see that

$$\mathrm{I\!I} = -\boldsymbol{x}_i \cdot \hat{n}_j \, \mathrm{d}u_i \mathrm{d}u_j \,. \tag{13.76}$$

Definition 13.25 (Second fundamental coefficients)**.** We define the *second fundamental coefficients* as

$$b_{ij} = -\boldsymbol{x}_i \cdot \hat{n}_j \,. \tag{13.77}$$

Rests on Definitions 13.20 and 13.24.

Thus the second fundamental form is given by

$$\mathrm{I\!I} = b_{ij} \, \mathrm{d}u_i \mathrm{d}u_j \,. \tag{13.78}$$

From their definition, the second fundamental coefficients are the components of a symmetric tensor of rank 2. The *determinant of the matrix formed by the second fundamental coefficients* is given by

$$b = b_{11} b_{22} - b_{12}^2 \,. \tag{13.79}$$

Alternative expression. Note that the unit normal $\hat{n}$ is orthogonal to each of the partial tangent vectors, $\hat{n} \cdot \boldsymbol{x}_i = 0$. Hence

$$\begin{aligned} \hat{n} \cdot \boldsymbol{x}_i &= 0\,, \qquad \frac{\partial}{\partial u_j}(\,) \\ \hat{n}_j \cdot \boldsymbol{x}_i + \hat{n} \cdot \boldsymbol{x}_{ij} &= 0 \\ \text{[Equation (13.77)]} \quad b_{ij} &= \hat{n} \cdot \frac{\partial^2 \boldsymbol{x}}{\partial u_j \partial u_i}\,, \end{aligned} \tag{13.80}$$

and therefore, from Equation (13.78), the second fundamental form is given by

$$\mathrm{I\!I} = \hat{n} \cdot \mathrm{d}^2 \boldsymbol{x}\,. \tag{13.81}$$

Geometric interpretation. Recall from linear algebra that the projection $\boldsymbol{P}$ of a vector $\boldsymbol{A}$ onto another vector $\boldsymbol{B}$ is given by

$$\boldsymbol{P} = \frac{\boldsymbol{A} \cdot \boldsymbol{B}}{|\boldsymbol{B}|^2}\,\boldsymbol{B}\,. \tag{13.82}$$

Consider now the vector that, with respect to a tangent plane of the surface, indicates the small advance of the surface in a neighbourhood of the point of tangency. This vector is $\boldsymbol{x}(u_1 + \mathrm{d}u_1, u_2 + \mathrm{d}u_2) - \boldsymbol{x}(u_1, u_2)$; thus the distance d from the surface to its tangent plane, in a neighbourhood of the point of tangency, equals the projection of this vector onto the unit normal $\hat{n}$. From Equation (13.82),

$$d = [\boldsymbol{x}(u_1 + \mathrm{d}u_1, u_2 + \mathrm{d}u_2) - \boldsymbol{x}(u_1, u_2)] \cdot \hat{n}\,.$$

Making a multivariable Taylor expansion of $\boldsymbol{x}(u_1 + \mathrm{d}u_1, u_2 + \mathrm{d}u_2)$ about (u_1, u_2),

$$\begin{aligned} d &\approx \left[\boldsymbol{x}(u_1, u_2) + \frac{\partial \boldsymbol{x}}{\partial u_i}\mathrm{d}u_i + \frac{1}{2}\frac{\partial^2 \boldsymbol{x}}{\partial u_j \partial u_i}\mathrm{d}u_i \mathrm{d}u_j - \boldsymbol{x}(u_1, u_2)\right] \cdot \hat{n} \\ \text{[Equation (13.54)]} \quad &= \frac{1}{2}\,\mathrm{d}^2 \boldsymbol{x} \cdot \hat{n} \\ &= \frac{1}{2}\,\mathrm{I\!I}\,. \end{aligned}$$

Therefore the second fundamental form is, approximately, *twice the distance from the surface to its tangent plane in a neighbourhood of the point of tangency.*

The Gauss equations and the Christoffel symbols

Since at each point of the surface we have the three linearly independent vectors $\boldsymbol{x}_1$, $\boldsymbol{x}_2$, and $\hat{n}$, we can write any vector of $\mathbb{R}^3$ as a linear combination of them. In particular, we can express the partial derivative of $\boldsymbol{x}_i$ with respect to u_j as

$$\boldsymbol{x}_{ij} = \Gamma_{ij}^{\,k} \boldsymbol{x}_k + \alpha_{ij} \hat{n}\,,$$

where $\Gamma_{ij}^{\,k}$ and α_{ij} are the coefficients of the linear combination. Taking the scalar product with $\hat{n}$ and using Equation (13.80),

$$b_{ij} = \alpha_{ij}\,.$$

Thus we obtain the *Gauss equations*,

$$\boldsymbol{x}_{ij} = \Gamma_{ij}^{\,k} \boldsymbol{x}_k + b_{ij} \hat{n}\,. \tag{13.83}$$

From Equation (13.83), taking the scalar product with $\boldsymbol{x}_l$ and using Equations (13.54) and (13.60),

$$\boldsymbol{x}_{ij} \cdot \boldsymbol{x}_l = \Gamma_{ij}^{\,k} g_{kl}\,.$$

Definition 13.26 (Christoffel symbols)**.** We define the *Christoffel symbol of the first kind* as the quantities

$$\Gamma_{ijk} = \boldsymbol{x}_{ij} \cdot \boldsymbol{x}_k \,, \tag{13.84}$$

and the *Christoffel symbol of the second kind* as the quantities

$$\Gamma_{ij}^{\ k} = \Gamma_{ijl}\, g^{lk} \,. \tag{13.85}$$

Rests on Equation (13.83) *and Definition 13.23.*

Note from their definition that the Christoffel symbols are symmetric in their first two indices: considering that $\boldsymbol{x}$ is a map of class C^2, by Schwarz's theorem

$$\boldsymbol{x}_{ij} = \boldsymbol{x}_{ji} \,. \tag{13.86}$$

Alternative expression for the Christoffel symbols. From the definition of the first fundamental coefficients, Equation (13.60),

$$\begin{aligned} \frac{\partial g_{ij}}{\partial u_k} &\overset{\text{not.}}{=} \partial_k g_{ij} = \boldsymbol{x}_{ik} \cdot \boldsymbol{x}_j + \boldsymbol{x}_{jk} \cdot \boldsymbol{x}_i \\ \text{[Equation (13.84)]} \quad &= \Gamma_{ikj} + \Gamma_{jki} \,. \end{aligned}$$

In the same way,

$$\begin{aligned} \partial_i g_{jk} &= \Gamma_{jik} + \Gamma_{kij} \,, \\ \partial_j g_{ki} &= \Gamma_{kji} + \Gamma_{ijk} \,. \end{aligned}$$

Then, since the Christoffel symbols are symmetric in their first two indices,

$$\partial_i g_{jk} + \partial_j g_{ki} - \partial_k g_{ij} = 2\Gamma_{ijk} \,,$$

and therefore

$$\Gamma_{ijk} = \frac{1}{2} \left(\partial_i g_{jk} + \partial_j g_{ki} - \partial_k g_{ij} \right) . \tag{13.87}$$

From Equation (13.86), multiplying Equation (13.87) by g^{kl} and renaming indices,

$$\Gamma_{ij}^{\ k} = \frac{1}{2} g^{kl} \left(\partial_i g_{jl} + \partial_j g_{li} - \partial_l g_{ij} \right) . \tag{13.88}$$

Note from Equation (13.88) that setting $j = k$ gives

$$\begin{aligned} \Gamma_{ij}^{\ j} &= \frac{1}{2} g^{jl} \left(\partial_i g_{jl} + \partial_j g_{li} - \partial_l g_{ij} \right) \\ &= \frac{1}{2} g^{jl} \partial_i g_{jl} + \frac{1}{2} \left(g^{jl} \partial_j g_{li} - g^{jl} \partial_l g_{ij} \right) \\ &= \frac{1}{2} g^{jl} \partial_i g_{jl} + \frac{1}{2} \left(g^{lj} \partial_l g_{ji} - g^{jl} \partial_l g_{ij} \right) , \end{aligned}$$

where the last two terms cancel after renaming the summed indices; therefore

$$\Gamma_{ij}^{\ j} = \frac{1}{2} g^{jl} \partial_i g_{jl} \,. \tag{13.89}$$

The Weingarten equations

By the same justification as for the Gauss equations, we can write the partial derivative of $\hat{n}$ with respect to u_i as a linear combination of the vectors $\boldsymbol{x}_1$, $\boldsymbol{x}_2$, and $\hat{n}$. Moreover, in analogy with Equations (13.40) and (13.73), the partial derivative of any unit vector $\hat{e}$ with respect to u_i lies in the plane orthogonal to $\hat{e}$:

$$\begin{aligned} & |\hat{e}| = 1 \\ \iff \quad & \hat{e} \cdot \hat{e} = 1\,, \qquad \partial_i(\,) \\ \implies \quad & \hat{e}_i \cdot \hat{e} = 0 \\ \implies \quad & \hat{e}_i \perp \hat{e}\,. \end{aligned} \tag{13.90}$$

Then $\hat{n}_i$ lies in the plane orthogonal to $\hat{n}$, so we may write

$$\hat{n}_i = \beta_i{}^j \boldsymbol{x}_j\,,$$

where the quantities $\beta_i{}^j$ are the factors of the linear combination. To compute them, take the scalar product with $\boldsymbol{x}_k$ and use Equations (13.60) and (13.77):

$$\begin{aligned} -b_{ik} &= \beta_i{}^j g_{jk} \\ b_{ik} &= -\beta_{ik} \\ b_i{}^k &= -\beta_i{}^k\,. \end{aligned}$$

Finally, we obtain the *Weingarten equations*,

$$\hat{n}_i = -b_i{}^j \boldsymbol{x}_j\,. \tag{13.91}$$

The Gauss–Codazzi equations

Starting from the Gauss equations,

$$\begin{aligned} \boldsymbol{x}_{ij} &= \Gamma_{ij}^{\ l} \boldsymbol{x}_l + b_{ij}\hat{n}\,, \qquad \partial_k(\,) \\ \boldsymbol{x}_{ijk} &= \partial_k\left(\Gamma_{ij}^{\ l}\right)\boldsymbol{x}_l + \Gamma_{ij}^{\ l}\boldsymbol{x}_{lk} + \partial_k\left(b_{ij}\right)\hat{n} + b_{ij}\hat{n}_k \\ \text{[Equations (13.83) and (13.91)]} \quad &= \partial_k\left(\Gamma_{ij}^{\ l}\right)\boldsymbol{x}_l + \Gamma_{ij}^{\ l}\Gamma_{lk}^{\ m}\boldsymbol{x}_m + \Gamma_{ij}^{\ l} b_{lk}\hat{n} + \partial_k\left(b_{ij}\right)\hat{n} - b_{ij}b_k{}^l\boldsymbol{x}_l \\ &= \left[\partial_k\left(\Gamma_{ij}^{\ l}\right) + \Gamma_{ij}^{\ m}\Gamma_{mk}^{\ l} - b_{ij}b_k{}^l\right]\boldsymbol{x}_l + \left[\Gamma_{ij}^{\ l}b_{lk} + \partial_k\left(b_{ij}\right)\right]\hat{n}\,. \end{aligned}$$

Renaming indices, we have

$$\begin{aligned} \boldsymbol{x}_{ijk} &= \left[\partial_k\left(\Gamma_{ij}^{\ l}\right) + \Gamma_{ij}^{\ m}\Gamma_{mk}^{\ l} - b_{ij}b_k{}^l\right]\boldsymbol{x}_l + \left[\Gamma_{ij}^{\ l}b_{lk} + \partial_k\left(b_{ij}\right)\right]\hat{n}\,, \\ \boldsymbol{x}_{ikj} &= \left[\partial_j\left(\Gamma_{ik}^{\ l}\right) + \Gamma_{ik}^{\ m}\Gamma_{mj}^{\ l} - b_{ik}b_j{}^l\right]\boldsymbol{x}_l + \left[\Gamma_{ik}^{\ l}b_{lj} + \partial_j\left(b_{ik}\right)\right]\hat{n}\,. \end{aligned}$$

By the compatibility conditions, $\boldsymbol{x}_{ijk} - \boldsymbol{x}_{ikj} = \boldsymbol{0}$; subtracting the previous equations,

$$\begin{aligned} \Big[\partial_k\left(\Gamma_{ij}^{\ l}\right) + \Gamma_{ij}^{\ m}\Gamma_{mk}^{\ l} - b_{ij}b_k{}^l - \partial_j\left(\Gamma_{ik}^{\ l}\right) - \Gamma_{ik}^{\ m}\Gamma_{mj}^{\ l} + b_{ik}b_j{}^l\Big]\boldsymbol{x}_l \\ + \left[\Gamma_{ij}^{\ l}b_{lk} + \partial_k\left(b_{ij}\right) - \Gamma_{ik}^{\ l}b_{lj} - \partial_j\left(b_{ik}\right)\right]\hat{n} = \boldsymbol{0}\,. \end{aligned}$$

Since $\boldsymbol{x}_l$ and $\hat{n}$ are linearly independent, their factors vanish separately. From this we see that

$$b_{ik}b_j{}^l - b_{ij}b_k{}^l = \partial_j\left(\Gamma_{ik}^{\ l}\right) - \partial_k\left(\Gamma_{ij}^{\ l}\right) + \Gamma_{ik}^{\ m}\Gamma_{mj}^{\ l} - \Gamma_{ij}^{\ m}\Gamma_{mk}^{\ l}\,, \tag{13.92}$$

$$\partial_j\left(b_{ik}\right) - \partial_k\left(b_{ij}\right) = \Gamma_{ij}^{\ l}b_{lk} - \Gamma_{ik}^{\ l}b_{lj}\,, \tag{13.93}$$

which are the *Gauss–Codazzi equations*. These equations relate the metric to the second fundamental coefficients.

The Riemann symbols

Definition 13.27 (Riemann symbols)**.** We define the *Riemann symbol of the first kind* as the quantities

$$R^l{}_{ijk} = b_{ik} b_j{}^l - b_{ij} b_k{}^l \,. \tag{13.94}$$

From Equation (13.92) we see that

$$R^l{}_{ijk} = \partial_j \left(\Gamma_{ik}{}^l\right) - \partial_k \left(\Gamma_{ij}{}^l\right) + \Gamma_{ik}{}^m \Gamma_{mj}{}^l - \Gamma_{ij}{}^m \Gamma_{mk}{}^l \,. \tag{13.95}$$

We define the *Riemann symbol of the second kind* as the quantities

$$R_{lijk} = R^m_{ijk}\, g_{ml} = b_{ik} b_{jl} - b_{ij} b_{kl} \,. \tag{13.96}$$

Rests on Definitions 13.25 and 13.26 and Equation (13.92).

13.3.3 Curvatures of a surface

Normal curvature

Let $\boldsymbol{x} = \boldsymbol{x}(u_1(t), u_2(t))$ be a curve whose points lie on the surface $\boldsymbol{x} = \boldsymbol{x}(u_1, u_2)$, and consider the normal curvature vector $\boldsymbol{k}$ of that curve (see Equation (13.39)).

Definition 13.28 (Normal curvature vector of a surface)**.** We define the *normal curvature vector of the surface* as the projection (see Equation (13.82)) of the curve's normal curvature vector $\boldsymbol{k}$ onto the unit normal $\hat{n}$, that is,

$$\boldsymbol{k}_n = (\boldsymbol{k} \cdot \hat{n})\, \hat{n} \,. \tag{13.97}$$

Rests on Definitions 13.13 and 13.20.

We call *normal curvature* the quantity

$$|\boldsymbol{k}_n| = k_n = \boldsymbol{k} \cdot \hat{n} \,. \tag{13.98}$$

Let us derive an alternative expression for the normal curvature. We have, using Equations (13.37) and (13.39),

$$\begin{aligned} k_n &= \boldsymbol{k} \cdot \hat{n} \\ &= \frac{\frac{\mathrm{d}\hat{T}}{\mathrm{d}t} \cdot \hat{n}}{\left|\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\right|} \,. \end{aligned} \tag{13.99}$$

Since the tangent vector $\hat{T}$ of the curve is orthogonal to the surface normal $\hat{n}$,

$$\hat{T} \cdot \hat{n} = 0 \,, \qquad \frac{\mathrm{d}}{\mathrm{d}t}(\,)$$

$$\frac{\mathrm{d}\hat{T}}{\mathrm{d}t} \cdot \hat{n} + \hat{T} \cdot \frac{\mathrm{d}\hat{n}}{\mathrm{d}t} = 0 \,.$$

Therefore Equation (13.99) becomes, using Equations (13.37) and (13.38),

$$\begin{aligned} k_n &= -\frac{\hat{T} \cdot \frac{\mathrm{d}\hat{n}}{\mathrm{d}t}}{\left|\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}\right|} \\ &= -\frac{\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t} \cdot \frac{\mathrm{d}\hat{n}}{\mathrm{d}t}}{\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t} \cdot \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}} \\ &= -\frac{\mathrm{d}\boldsymbol{x} \cdot \mathrm{d}\hat{n}}{\mathrm{d}\boldsymbol{x} \cdot \mathrm{d}\boldsymbol{x}} \,. \end{aligned}$$

Finally, we arrive at

$$k_n = \frac{b_{ij}\, \mathrm{d}u_i \mathrm{d}u_j}{g_{ij}\, \mathrm{d}u_i \mathrm{d}u_j} \,. \tag{13.100}$$

Principal curvatures and Gaussian curvature

From Equation (13.100) we see that

$$k_n = \frac{b_{11}\mathrm{d}u_1^2 + 2b_{12}\mathrm{d}u_1\mathrm{d}u_2 + b_{22}\mathrm{d}u_2^2}{g_{11}\mathrm{d}u_1^2 + 2g_{12}\mathrm{d}u_1\mathrm{d}u_2 + g_{22}\mathrm{d}u_2^2}\,. \tag{13.101}$$

Introducing the auxiliary variable

$$\lambda = \frac{\mathrm{d}u_2}{\mathrm{d}u_1}\,, \tag{13.102}$$

we have

$$k_n = \frac{b_{11} + 2b_{12}\lambda + b_{22}\lambda^2}{g_{11} + 2g_{12}\lambda + g_{22}\lambda^2}\,. \tag{13.103}$$

We now seek an extremal value of k_n, denoted k_{np}, which we call a *principal curvature*. That is,

$$\begin{aligned} &\frac{\mathrm{d}k_n}{\mathrm{d}\lambda} \stackrel{!}{=} 0 \\ \Longrightarrow \quad &(b_{12} + b_{22}\lambda)\left(g_{11} + 2g_{12}\lambda + g_{22}\lambda^2\right) = (g_{12} + g_{22}\lambda)\left(b_{11} + 2b_{12}\lambda + b_{22}\lambda^2\right)\,. \end{aligned} \tag{13.104}$$

This relation holds for a value of λ that makes k_n extremal. Substituting it back into Equation (13.103),

$$k_{np} = \frac{b_{12} + b_{22}\lambda}{g_{12} + g_{22}\lambda}\,. \tag{13.105}$$

Note that Equation (13.104) can be rewritten in the form

$$\begin{aligned} (b_{12} + b_{22}\lambda)\,(g_{11} + g_{12}\lambda + (g_{12} + g_{22}\lambda)\,\lambda) &= (g_{12} + g_{22}\lambda)\,(b_{11} + b_{12}\lambda + (b_{12} + b_{22}\lambda)\,\lambda) \\ \frac{g_{11} + g_{12}\lambda}{g_{12} + g_{22}\lambda} &= \frac{b_{11} + b_{12}\lambda}{b_{12} + b_{22}\lambda}\,, \end{aligned}$$

and substituting this result into Equation (13.105) yields a second expression for the principal curvature,

$$k_{np} = \frac{b_{11} + b_{12}\lambda}{g_{11} + g_{12}\lambda}\,. \tag{13.106}$$

Returning to the original variables, Equations (13.105) and (13.106) give the system of equations

$$\begin{aligned} (b_{12} - g_{12}k_{np})\,\mathrm{d}u_1 + (b_{22} - g_{22}k_{np})\,\mathrm{d}u_2 &= 0\,, \\ (b_{11} - g_{11}k_{np})\,\mathrm{d}u_1 + (b_{12} - g_{12}k_{np})\,\mathrm{d}u_2 &= 0\,. \end{aligned}$$

Being a homogeneous system of two equations in the two variables $\mathrm{d}u_1$ and $\mathrm{d}u_2$, it has a non-trivial solution if and only if the determinant of the system vanishes:

$$\begin{aligned} (b_{12} - g_{12}k_{np})^2 - (b_{11} - g_{11}k_{np})\,(b_{22} - g_{22}k_{np}) &= 0 \\ g\,k_{np}^2 - (g_{11}b_{22} + g_{22}b_{11} - 2g_{12}b_{12})\,k_{np} + b &= 0\,. \end{aligned}$$

We thus obtain a quadratic equation for k_{np} in terms of the first and second fundamental coefficients. Recall from the algebra of polynomials that for a quadratic equation $ax^2+bx+c = 0$ the product of its roots x_1 and x_2 is $x_1x_2 = c/a$.

Definition 13.29 (Gaussian curvature)**.** We define the *Gaussian curvature* as the product of the two principal curvatures,

$$K = k_{np,1}\,k_{np,2} = \frac{b}{g}\,. \tag{13.107}$$

Rests on Definitions 13.22, 13.25 and 13.28.

Geometric interpretation of the Gaussian curvature

The sign of K classifies the local shape of the surface at a point: where $K > 0$ the two principal curvatures share a sign and the surface curves away from its tangent plane on every side (elliptic point, as on a sphere or an ellipsoid); where $K < 0$ they have opposite signs and the surface crosses its tangent plane (a saddle, as on a hyperboloid or the inner rim of a torus); where $K = 0$ at least one principal curvature vanishes (a cylinder, a cone, or a plane). Figure 13.1 illustrates the flat and cylindrical cases, both with $K = 0$.

Theorema Egregium

The definition $K = b/g$ (Equation (13.107)) is built from *both* fundamental forms: g_{ij}, intrinsic to the surface, and b_{ij}, which records how the surface bends inside the ambient space. Gauss's celebrated theorem is that the second form is, in the end, dispensable.

Theorem 13.30 (Theorema Egregium; Gauss, 1827)**.** *The Gaussian curvature K of a surface is determined by its first fundamental form g_{ij} and derivatives of g_{ij} alone; it does not depend on the second fundamental form b_{ij}, i.e. not on how the surface is embedded in $\mathbb{R}^3$.*

Rests on Definitions 13.27 and 13.29 and Equations (13.88) and (13.95).

Proof. *Derives Theorem 13.30.*

Specializing the Riemann symbol of the second kind (Definition 13.27) to $D = 2$ at $(l, i, j, k) = (1, 2, 1, 2)$, and using $b_{21} = b_{12}$,

$$R_{1212} = b_{22}b_{11} - b_{21}b_{12} = b_{11}b_{22} - b_{12}^2 = \det b_{ij} = b\,, \tag{13.108}$$

so that $K = b/g = R_{1212}/g$. Now trace the definition of R_{1212} backwards through what has already been established: by Equation (13.95), $R^l{}_{ijk}$ — and hence, lowering with g_{lm}, R_{lijk} — is built entirely from the Christoffel symbols $\Gamma_{ij}^{\,k}$ and their first derivatives; and by Equation (13.88), $\Gamma_{ij}^{\,k}$ is itself built entirely from g_{ij} and its first derivatives. No occurrence of b_{ij} survives this substitution: R_{1212}, and therefore

$$K = \frac{R_{1212}}{g}\,, \tag{13.109}$$

is a function of g_{ij} and its derivatives up to second order alone. This proves the theorem; K is an *intrinsic* invariant of the surface. □

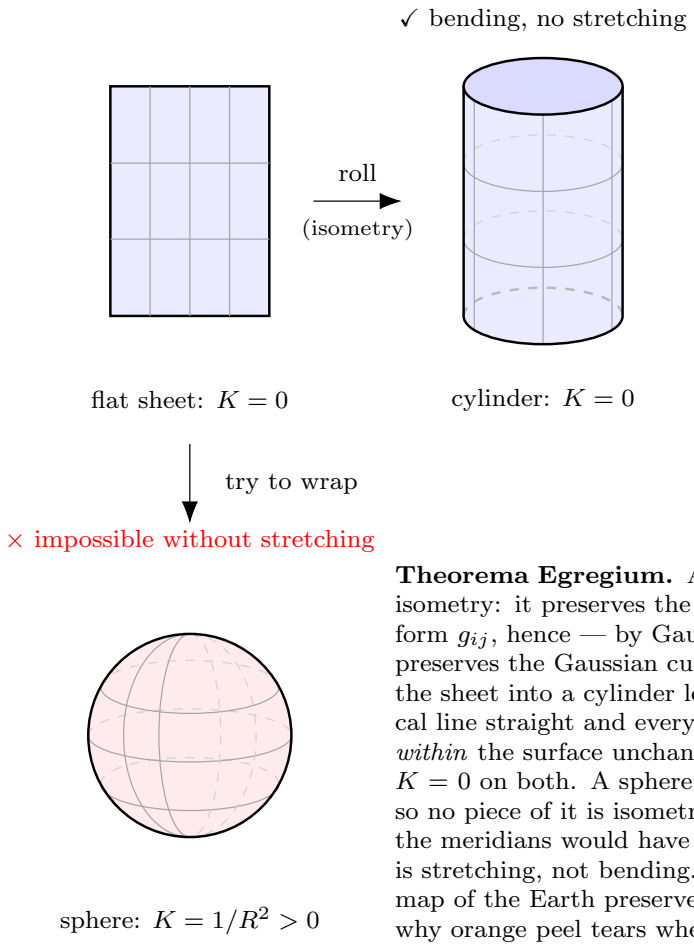
Corollary 13.31 (Bending invariance)**.** *If $f : S \longrightarrow S'$ is a local isometry between two surfaces (Definition 13.120 specialized to $D = 2$), then $K_{S'}(f(P)) = K_S(P)$ for every $P \in S$.*

Rests on Theorem 13.30 and Definition 13.120.

Proof. *Derives Corollary 13.31.*

An isometry pulls back the metric to itself, $f^*g_{S'} = g_S$ (Equation (13.262)). Since K is, by Theorem 13.30, a fixed differential expression in the metric components alone, $K_S(P) = K_{S'}(f(P))$ follows by evaluating that same expression on both sides of the pullback. □

A flat sheet of paper bent, without stretching or tearing, into a cylinder realizes exactly this corollary: the bending is a local isometry (distances measured *along* the surface do not change), and indeed both surfaces have $K = 0$ (Figure 13.1). The same sheet cannot be bent into any piece of a sphere of radius R, whose curvature $K = 1/R^2 \neq 0$ (Example 13.33 below) can never match the flat sheet's $K = 0$ — this is the everyday fact that maps of the round Earth cannot be flat without distortion, and the reason orange peel tears when flattened.



Theorema Egregium. A bending is a local isometry: it preserves the first fundamental form g_{ij}, hence — by Gauss's theorem — it preserves the Gaussian curvature K. Rolling the sheet into a cylinder leaves every vertical line straight and every distance measured *within* the surface unchanged, and indeed $K = 0$ on both. A sphere has $K = 1/R^2 \neq 0$, so no piece of it is isometric to a flat sheet: the meridians would have to converge, which is stretching, not bending. This is why no flat map of the Earth preserves all distances, and why orange peel tears when flattened.

Figure 13.1: Isometric bending preserves K (flat sheet to cylinder, both $K = 0$); no bending of a flat sheet reaches the sphere, whose $K = 1/R^2 > 0$ obstructs it by Theorem 13.30.

Remark 13.32 (Restatement via the Cartan formalism). The proof above reuses the nineteenth-century route already built into Equations (13.88) and (13.95). The Cartan formalism of Section 13.12, developed later in this chapter, makes the same content more transparent and supplies, as a byproduct, an explicit formula for K.

Fix any local orthogonal coordinates (u_1, u_2) on the surface, so that $g_{11} = E(u_1, u_2)$, $g_{22} = G(u_1, u_2)$, $g_{12} = 0$ (such coordinates always exist locally — e.g. the curvature lines of Equation (13.104) away from umbilic points). An orthonormal coframe is then $e^1 = \sqrt{E}\,\mathrm{d}u_1$, $e^2 = \sqrt{G}\,\mathrm{d}u_2$, and the torsion-free structure equation Equation (13.311) in $D = 2$ reads $\mathrm{d}e^1 = -\omega^1{}_2 \wedge e^2$, $\mathrm{d}e^2 = \omega^1{}_2 \wedge e^1$, a linear system for the single connection one-form $\omega^1{}_2$ that involves *only* $\mathrm{d}e^1, \mathrm{d}e^2$, hence only E, G. Solving,

$$\omega^1{}_2 = \frac{\partial_2 E}{2\sqrt{EG}}\,\mathrm{d}u_1 - \frac{\partial_1 G}{2\sqrt{EG}}\,\mathrm{d}u_2\,, \tag{13.110}$$

which is verified by substitution: with $\mathrm{d}e^1 = -\dfrac{\partial_2 E}{2\sqrt{E}}\,\mathrm{d}u_1 \wedge \mathrm{d}u_2$ and $\mathrm{d}e^2 = \dfrac{\partial_1 G}{2\sqrt{G}}\,\mathrm{d}u_1 \wedge \mathrm{d}u_2$, one checks $-\omega^1{}_2 \wedge e^2 = \mathrm{d}e^1$ and $\omega^1{}_2 \wedge e^1 = \mathrm{d}e^2$ directly. In $D = 2$ the Lorentz algebra $\mathfrak{so}(2)$ is abelian, so the quadratic term of Equation (13.312) vanishes identically and $R^1{}_2 = \mathrm{d}\omega^1{}_2$; defining K through $R^1{}_2 = K\, e^1 \wedge e^2$ (consistent with Equation (13.107), checked below) and differentiating Equation (13.110) gives the classical *Liouville formula*,

$$K = -\frac{1}{2\sqrt{EG}}\left[\partial_1\!\left(\frac{\partial_1 G}{\sqrt{EG}}\right) + \partial_2\!\left(\frac{\partial_2 E}{\sqrt{EG}}\right)\right], \tag{13.111}$$

manifestly a functional of E, G and their derivatives alone [1575]. Not one component of $\omega^1{}_2$, hence not one term of Equation (13.111), involves the embedding: the Cartan route makes the Theorema Egregium visible *by construction* rather than by cancellation, since b_{ij} never entered the computation.

Example 13.33 (Sphere of radius R)**.** In spherical coordinates $(u_1, u_2) = (\theta, \phi)$, $E = R^2$, $G = R^2 \sin^2\theta$, so $\partial_2 E = 0$ and $\partial_1 G = 2R^2 \sin\theta\cos\theta$. Then $\partial_1 G/\sqrt{EG} = 2\cos\theta$, whose θ-derivative is $-2\sin\theta$, and Equation (13.111) gives

$$K = -\frac{1}{2R^2\sin\theta}\,(-2\sin\theta) = \frac{1}{R^2}\,,$$

confirming $K = 1/R^2$ used above and matching the direct computation $K = k_{np,1}k_{np,2} = (1/R)(1/R)$ from Definition 13.29, since $b_{ij} = \pm g_{ij}/R$ gives $b = \det b_{ij} = g/R^2$ regardless of the sign convention for the normal.

Remark 13.34 (Consistency of the two computations of $D = 2$ curvature). Definition 13.153 already recorded, for a general torsion-free connection, that $R = 2K$ in $D = 2$ (with R the Ricci scalar). The identity $\Omega = \epsilon_{12}R^{12} + \epsilon_{21}R^{21} = 2R^1{}_2 = 2K\, e^1 \wedge e^2 = 2K\sqrt{g}\,\mathrm{d}u_1 \wedge \mathrm{d}u_2 = R\sqrt{g}\,\mathrm{d}u_1 \wedge \mathrm{d}u_2$ (using $R = 2K$ in the last step), i.e. $\epsilon_{ab}R^{ab} = R\sqrt{g}\,\mathrm{d}^2u$ with *no* extra numerical factor, is exactly the $D = 2$ special case ($(D-2)! = 0! = 1$) of the Einstein–Hilbert equivalence proven in Appendix A.8 — an independent check of the general-D combinatorial factor derived there.

Geodesic curvature

Definition 13.35 (Projection curve)**.** We define the *projection curve* as the curve projected onto the tangent plane at some point of a surface.

Definition 13.36 (Geodesic curvature vector)**.** Under the same conditions used to define the normal curvature (see Equation (13.97)), we define the *geodesic curvature vector* as the normal curvature vector of the projection curve.

Rests on Definitions 13.13, 13.28 and 13.35.

We may take the curve to pass through the origin of an orthogonal system; the curve projected onto the tangent plane, called $\boldsymbol{x}_g$, is then given by

$$\boldsymbol{x}_g = \left(\boldsymbol{x}\cdot\hat{T}'\right)\hat{T}' + \left(\boldsymbol{x}\cdot\hat{N}'\right)\hat{N}', \tag{13.112}$$

where $\hat{T}'$ and $\hat{N}'$ span the tangent plane at the point of tangency. Differentiating with respect to the arc-length parameter of the curve on the surface,

$$\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s} = \left(\hat{T}\cdot\hat{T}'\right)\hat{T}' + \left(\hat{T}\cdot\hat{N}'\right)\hat{N}', \tag{13.113}$$

$$\frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2} = \left(\boldsymbol{k}\cdot\hat{T}'\right)\hat{T}' + \left(\boldsymbol{k}\cdot\hat{N}'\right)\hat{N}'. \tag{13.114}$$

On the other hand, from Equation (13.39), the normal curvature vector of the projected curve is given by

$$\boldsymbol{k}_g = \frac{\mathrm{d}\hat{T}_g}{\mathrm{d}s_g},$$

where $\hat{T}_g$ is the unit tangent vector defined in Equation (13.38) and s_g is the arc-length parameter defined in Equation (13.35), both for the projection curve. By the chain rule we may write

$$\boldsymbol{k}_g = \frac{\mathrm{d}\hat{T}_g}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}s_g}.$$

From Equation (13.37) we see that

$$\frac{\mathrm{d}s_g}{\mathrm{d}s} = \left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right|,$$

so that

$$\boldsymbol{k}_g = \frac{\frac{\mathrm{d}\hat{T}_g}{\mathrm{d}s}}{\left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right|}. \tag{13.115}$$

Furthermore, from the definition of the unit tangent vector (Equation (13.38)),

$$\begin{aligned}\hat{T}_g &= \frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s_g}\\ &= \frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}s_g}.\end{aligned} \tag{13.116}$$

Again by Equation (13.37), substituting in Equation (13.116) and differentiating,

$$\begin{aligned}\hat{T}_g &= \frac{\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}}{\left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right|}, \qquad \frac{\mathrm{d}}{\mathrm{d}s}(\,)\\ \frac{\mathrm{d}\hat{T}_g}{\mathrm{d}s} &= \frac{\frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2}\left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right| - \frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\left(\frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2}\cdot\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right)}{\left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right|^2}\\ \text{[Equation (13.115)]}\quad \boldsymbol{k}_g &= \frac{\frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2}\left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right| - \frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\left(\frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2}\cdot\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right)}{\left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right|^3}.\end{aligned} \tag{13.117}$$

Finally, since in this case we are considering that at the point of tangency $\hat{T} = \hat{T}'$, from Equations (13.113) and (13.114),

$$\begin{aligned}\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s} &= \hat{T}' + \left(\hat{T}'\cdot\hat{N}'\right)\hat{N}',\\ \frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2} &= \left(\boldsymbol{k}\cdot\hat{T}\right)\hat{T} + \left(\boldsymbol{k}\cdot\hat{N}'\right)\hat{N}',\end{aligned}$$

and from Equations (13.40) and (13.42),

$$\begin{aligned} \frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s} &= \hat{T}' \,, \\ \frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2} &= \left(\boldsymbol{k}\cdot\hat{N}'\right)\hat{N}' \\ \implies \quad \left|\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s}\right| &= 1 \,, \\ \implies \quad \frac{\mathrm{d}^2\boldsymbol{x}_g}{\mathrm{d}s^2}\cdot\frac{\mathrm{d}\boldsymbol{x}_g}{\mathrm{d}s} &= 0 \,. \end{aligned}$$

Hence Equation (13.117) reduces to

$$\boldsymbol{k}_g = \left(\boldsymbol{k}\cdot\hat{N}'\right)\hat{N}' \,. \tag{13.118}$$

Considering Equation (13.97), we see that

$$\boldsymbol{k} = \boldsymbol{k}_g + \boldsymbol{k}_n \,. \tag{13.119}$$

Alternative expression for the geodesic curvature vector. Consider a curve on a surface $\boldsymbol{x}$ parametrised by arc length (see Equation (13.56)). From the definition of the normal curvature vector of the curve (Equation (13.39)),

$$\begin{aligned} \boldsymbol{k} &= \frac{\mathrm{d}}{\mathrm{d}s}\left(\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}s}\right) \\ &= \frac{\mathrm{d}}{\mathrm{d}s}\left(\boldsymbol{x}_i\frac{\mathrm{d}u_i}{\mathrm{d}s}\right) \\ &= \boldsymbol{x}_{ij}\frac{\mathrm{d}u_i\mathrm{d}u_j}{\mathrm{d}s^2} + \boldsymbol{x}_i\frac{\mathrm{d}^2u_i}{\mathrm{d}s^2} \\ \text{[Equation (13.83)]} \quad &= \Gamma_{ij}{}^k\frac{\mathrm{d}u_i\mathrm{d}u_j}{\mathrm{d}s^2}\boldsymbol{x}_k + \frac{b_{ij}\mathrm{d}u_i\mathrm{d}u_j}{\mathrm{d}s^2}\hat{n} + \boldsymbol{x}_k\frac{\mathrm{d}^2u_k}{\mathrm{d}s^2} \\ \text{[Equation (13.100)]} \quad &= \left(\Gamma_{ij}{}^k\frac{\mathrm{d}u_i\mathrm{d}u_j}{\mathrm{d}s^2} + \frac{\mathrm{d}^2u_k}{\mathrm{d}s^2}\right)\boldsymbol{x}_k + \boldsymbol{k}_n \,. \end{aligned}$$

Comparing with Equation (13.119), we see that

$$\boldsymbol{k}_g = \left(\Gamma_{ij}{}^k\frac{\mathrm{d}u_i\mathrm{d}u_j}{\mathrm{d}s^2} + \frac{\mathrm{d}^2u_k}{\mathrm{d}s^2}\right)\boldsymbol{x}_k \,. \tag{13.120}$$

Geodesic lines

Consider two points on a surface, and a curve on the surface containing them. Among all curves satisfying this, there must be one of least arc length, as given by Equation (13.67). Intuitively, such a curve possesses a projection curve with vanishing geodesic curvature.

Definition 13.37 (Geodesic lines)**.** We define the *geodesic lines* as the curves whose projection curve has vanishing geodesic curvature, that is, the curves satisfying

$$\Gamma_{ij}{}^k\frac{\mathrm{d}u_i\mathrm{d}u_j}{\mathrm{d}s^2} + \frac{\mathrm{d}^2u_k}{\mathrm{d}s^2} = 0 \,, \tag{13.121}$$

with the initial conditions

$$u_i(s=0) = u_i^0 \quad \wedge \quad \frac{\mathrm{d}u_i}{\mathrm{d}s}(s=0) = \dot{u}_i^0 \,. \tag{13.122}$$

Rests on Definitions 13.26 and 13.36 and Equation (13.120).

By the calculus of variations it can be proved that Equation (13.121) results from extremising the arc length given by Equation (13.67), as the following proposition shows.

Proposition 13.38 (Geodesics as stationary curves of the arc length)**.** *Let $u_i(s)$ be a regular curve on a surface, parametrised by arc length. It is a stationary point of the arc-length functional Equation (13.67) among curves with the same endpoints if and only if it satisfies the geodesic equation Equation (13.121).*

Rests on Equations (13.67), (13.87) and (13.121).

Proof. *Derives Proposition 13.38.*

Write the functional Equation (13.67) for a curve $u_i(t)$ joining two fixed points as

$$L[u] = \int_{t_0}^{t_1} F(u, \dot{u})\, \mathrm{d}t\,, \qquad F(u, \dot{u}) = \sqrt{g_{ij}(u)\, \dot{u}_i \dot{u}_j}\,, \qquad \dot{u}_i = \frac{\mathrm{d}u_i}{\mathrm{d}t}\,. \tag{13.123}$$

For a regular curve $F > 0$, so F is differentiable in its arguments and the Euler–Lagrange equations of Chapter 16,

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial F}{\partial \dot{u}_k}\right) - \frac{\partial F}{\partial u_k} = 0\,, \tag{13.124}$$

are the condition for stationarity under variations vanishing at the endpoints. The functional is invariant under reparametrisation (Definition 13.10), so its stationary points come in reparametrisation classes and we may work with the representative parametrised by arc length, for which $F \equiv 1$ and $t = s$. With

$$\frac{\partial F}{\partial \dot{u}_k} = \frac{g_{kj}\dot{u}_j}{F}\,, \qquad \frac{\partial F}{\partial u_k} = \frac{1}{2F}\, \partial_k g_{ij}\, \dot{u}_i \dot{u}_j\,,$$

setting $F = 1$ turns Equation (13.124) into

$$\begin{aligned} 0 &= \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{kj}\dot{u}_j\right) - \frac{1}{2}\, \partial_k g_{ij}\, \dot{u}_i \dot{u}_j \\ &= g_{kj}\ddot{u}_j + \partial_i g_{kj}\, \dot{u}_i \dot{u}_j - \frac{1}{2}\, \partial_k g_{ij}\, \dot{u}_i \dot{u}_j\,. \end{aligned}$$

The product $\dot{u}_i \dot{u}_j$ is symmetric in i and j, so only the symmetric part of $\partial_i g_{kj}$ in those indices contributes and we may replace it by $\frac{1}{2}(\partial_i g_{kj} + \partial_j g_{ki})$, giving

$$g_{kj}\ddot{u}_j + \frac{1}{2}\left(\partial_i g_{jk} + \partial_j g_{ki} - \partial_k g_{ij}\right) \dot{u}_i \dot{u}_j = 0\,, \tag{13.125}$$

where the symmetry $g_{kj} = g_{jk}$ was used. The bracket is exactly the Christoffel symbol of the first kind Equation (13.87), Γ_{ijk}, so Equation (13.125) reads $g_{kj}\ddot{u}_j + \Gamma_{ijk}\dot{u}_i\dot{u}_j = 0$. Contracting with the inverse metric g^{kl} and using $\Gamma_{ij}^{\ \ l} = \Gamma_{ijk}g^{kl}$ (Definition 13.26) gives

$$\frac{\mathrm{d}^2 u_l}{\mathrm{d}s^2} + \Gamma_{ij}^{\ \ l}\, \frac{\mathrm{d}u_i \mathrm{d}u_j}{\mathrm{d}s^2} = 0\,,$$

which is Equation (13.121). Every step is an equivalence, so the converse holds as well. □

Remark 13.39. Stationarity is necessary but not sufficient for minimality. On the sphere the geodesics are the great circles, and the longer of the two arcs joining two non-antipodal points satisfies Equation (13.121) while plainly failing to minimise the length. What is true is local: a sufficiently short piece of a geodesic is the shortest curve between its endpoints. On a pseudo-Riemannian manifold Equation (13.121) becomes the autoparallel equation Equation (13.297) of the Levi-Civita connection, but the minimising statement does *not* carry over verbatim. The line element changes sign there, so the functional has to be

written $\int \sqrt{|\mathrm{d}s^2|}$ (Remark 13.151), and the conclusion then depends on the causal character of the curve: a short enough spacelike geodesic still minimises the arc length, whereas a short enough timelike geodesic *maximises* the proper time between its endpoints — the twin-paradox inequality of Part IV — and on a null curve the functional vanishes identically, so every null curve is stationary for trivial reasons and the null geodesics are singled out by Equation (13.297) rather than by any extremal property of the length. See Remark 13.151, where the distinction between the shortest and the straightest curve is what torsion measures.

Geodesic parallelism

Consider a curve $\boldsymbol{x} = \boldsymbol{x}(u_1(t), u_2(t))$ on the surface $\boldsymbol{x} = \boldsymbol{x}(u_1, u_2)$. Assign to the curve a vector field $\boldsymbol{A}$ of the form

$$\boldsymbol{A}(t) = v_i(t)\, \boldsymbol{x}_i \,. \tag{13.126}$$

At each point of the curve, $\boldsymbol{A}$ is written as a linear combination of the partial tangent vectors of the surface, and therefore lies in the tangent plane. From vector analysis, the vectors $\boldsymbol{A}$ are parallel for every value of t if and only if

$$\boldsymbol{A}(t) \parallel \boldsymbol{A}(t + \mathrm{d}t) \quad \Longleftrightarrow \quad \frac{\mathrm{d}\boldsymbol{A}}{\mathrm{d}t} = \boldsymbol{0} \quad \forall\, t \,. \tag{13.127}$$

Analogously, we say that the vectors $\boldsymbol{A}$ are *geodesically parallel* for every value of t if and only if

$$\boldsymbol{A}(t) \parallel_g \boldsymbol{A}(t + \mathrm{d}t) \quad \Longleftrightarrow \quad \boldsymbol{x}_l \cdot \frac{\mathrm{d}\boldsymbol{A}}{\mathrm{d}t} = 0 \quad \forall\, t \ \wedge\ \forall\, l \,. \tag{13.128}$$

From Equation (13.126),

$$\begin{aligned}
\frac{\mathrm{d}\boldsymbol{A}}{\mathrm{d}t} &= \frac{\mathrm{d}v_i}{\mathrm{d}t}\boldsymbol{x}_i + v_i \boldsymbol{x}_{ij}\frac{\mathrm{d}u_j}{\mathrm{d}t} \\
\text{[Equation (13.83)]} \quad &= \frac{\mathrm{d}v_i}{\mathrm{d}t}\boldsymbol{x}_i + v_i \left(\Gamma_{ij}^{\ k}\boldsymbol{x}_k + b_{ij}\hat{n}\right)\frac{\mathrm{d}u_j}{\mathrm{d}t} \\
&= \frac{\mathrm{d}v_i}{\mathrm{d}t}\boldsymbol{x}_i + \Gamma_{ij}^{\ k} v_i \frac{\mathrm{d}u_j}{\mathrm{d}t}\boldsymbol{x}_k + b_{ij} v_i \frac{\mathrm{d}u_j}{\mathrm{d}t}\hat{n} \,, \qquad \boldsymbol{x}_l \cdot (\ ) \\
\text{[Equations (13.54) and (13.60)]} \quad \boldsymbol{x}_l \cdot \frac{\mathrm{d}\boldsymbol{A}}{\mathrm{d}t} &= \frac{\mathrm{d}v_i}{\mathrm{d}t} g_{il} + \Gamma_{ij}^{\ k} g_{kl} v_i \frac{\mathrm{d}u_j}{\mathrm{d}t} \\
&= \frac{\mathrm{d}v_l}{\mathrm{d}t} + \Gamma_{ijl}\, v_i \frac{\mathrm{d}u_j}{\mathrm{d}t} \,.
\end{aligned}$$

Therefore the field $\boldsymbol{A}$ is geodesically parallel if and only if

$$\frac{\mathrm{d}v_l}{\mathrm{d}t} + \Gamma_{ijl}\, v_i \frac{\mathrm{d}u_j}{\mathrm{d}t} = 0 \,, \qquad g^{lk}(\ )$$

whence the condition of geodesic parallelism is

$$\frac{\mathrm{d}v^k}{\mathrm{d}t} + \Gamma_{ij}^{\ k} \frac{\mathrm{d}u_j}{\mathrm{d}t} v_i = 0 \,. \tag{13.129}$$

Holonomy and the local Gauss–Bonnet theorem

Transport a vector geodesically parallel all the way around a closed curve on a surface and it comes back to the point it started from — but not, in general, to the vector it started as. The failure is the *holonomy* of the curve, and the theorem of this subsection identifies it: it is the total Gaussian curvature enclosed. That is the local form of the Gauss–Bonnet theorem, and it is what makes curvature an observable rather than a bookkeeping device, since the angle it predicts can be measured by carrying a gyroscope, or a swinging pendulum, around a circuit.

Proposition 13.40 (Parallel transport is an isometry of the tangent plane)**.** *If $\boldsymbol{A}$ and $\boldsymbol{B}$ are geodesically parallel along a curve on a surface, then $\boldsymbol{A}\cdot\boldsymbol{B}$ is constant along it. In particular lengths and angles are preserved, so transport around a closed curve acts on the tangent plane as a rotation.*

Rests on Equations (13.126) *and* (13.129) *and Definition 13.21.*

Derivation. Derives Proposition 13.40.

Both fields are tangent to the surface, and geodesic parallelism says that $\mathrm{d}\boldsymbol{A}/\mathrm{d}t$ has vanishing tangential part, i.e. $\boldsymbol{x}_l\cdot\mathrm{d}\boldsymbol{A}/\mathrm{d}t=0$ for every l; since $\boldsymbol{B}=v_i\boldsymbol{x}_i$ is a combination of the $\boldsymbol{x}_l$, $\boldsymbol{B}\cdot\mathrm{d}\boldsymbol{A}/\mathrm{d}t=0$, and likewise with the roles exchanged. Hence $\frac{\mathrm{d}}{\mathrm{d}t}(\boldsymbol{A}\cdot\boldsymbol{B})=\boldsymbol{B}\cdot\frac{\mathrm{d}\boldsymbol{A}}{\mathrm{d}t}+\boldsymbol{A}\cdot\frac{\mathrm{d}\boldsymbol{B}}{\mathrm{d}t}=0$. A linear map of a two-dimensional Euclidean plane preserving the inner product is a rotation or a reflection, and transport is a rotation because it is reached continuously from the identity at $t=0$. □

Theorem 13.41 (Holonomy equals the enclosed curvature; local Gauss–Bonnet)**.** *Let (u_1,u_2) be orthogonal coordinates on a surface, with $g_{11}=E>0$, $g_{22}=G>0$, $g_{12}=0$, and let γ be a piecewise smooth simple closed curve, positively oriented in the (u_1,u_2) plane, bounding a region D whose closure lies in the coordinate patch. Write ϑ for the angle a geodesically parallel field makes with the orthonormal frame*

$$\hat{e}_1=\frac{\boldsymbol{x}_1}{\sqrt{E}}\,,\qquad \hat{e}_2=\frac{\boldsymbol{x}_2}{\sqrt{G}}\,. \tag{13.130}$$

Then the holonomy of γ — the total change of ϑ on one circuit — is

$$\Delta\vartheta=\int_D K\,\mathrm{d}A\,,\qquad \mathrm{d}A=\sqrt{EG}\,\mathrm{d}u_1\mathrm{d}u_2\,, \tag{13.131}$$

with K the Gaussian curvature Equation (13.107)*. Reversing the orientation of γ reverses the sign.*

Rests on Proposition 13.40, Equation (13.111)*, and Theorem 7.99.*

Proof. Derives Theorem 13.41.

The angle obeys a first-order equation. By Proposition 13.40 a parallel field has constant length, so we may write $\boldsymbol{A}=|\boldsymbol{A}|\,(\cos\vartheta\,\hat{e}_1+\sin\vartheta\,\hat{e}_2)$. Put $\hat{e}_\perp=-\sin\vartheta\,\hat{e}_1+\cos\vartheta\,\hat{e}_2$, a unit tangent vector orthogonal to $\boldsymbol{A}$. Since $\hat{e}_1\cdot\hat{e}_1=1$ the tangential part of $\mathrm{d}\hat{e}_1/\mathrm{d}t$ is a multiple of $\hat{e}_2$; call the coefficient $\varpi=\hat{e}_2\cdot\mathrm{d}\hat{e}_1/\mathrm{d}t$, and then $\hat{e}_1\cdot\mathrm{d}\hat{e}_2/\mathrm{d}t=-\varpi$ because $\hat{e}_1\cdot\hat{e}_2=0$. Taking the scalar product of $\mathrm{d}\boldsymbol{A}/\mathrm{d}t$ with $\hat{e}_\perp$ and dividing by $|\boldsymbol{A}|$,

$$\frac{\hat{e}_\perp}{|\boldsymbol{A}|}\cdot\frac{\mathrm{d}\boldsymbol{A}}{\mathrm{d}t}=\frac{\mathrm{d}\vartheta}{\mathrm{d}t}+\cos\vartheta\left(\hat{e}_\perp\cdot\frac{\mathrm{d}\hat{e}_1}{\mathrm{d}t}\right)+\sin\vartheta\left(\hat{e}_\perp\cdot\frac{\mathrm{d}\hat{e}_2}{\mathrm{d}t}\right)=\frac{\mathrm{d}\vartheta}{\mathrm{d}t}+\varpi\,,$$

the last step using $\hat{e}_\perp\cdot\mathrm{d}\hat{e}_1/\mathrm{d}t=\varpi\cos\vartheta$ and $\hat{e}_\perp\cdot\mathrm{d}\hat{e}_2/\mathrm{d}t=\varpi\sin\vartheta$ together with $\cos^2+\sin^2=1$. The left-hand side vanishes for a parallel field, because $\hat{e}_\perp$ is tangent, so

$$\frac{\mathrm{d}\vartheta}{\mathrm{d}t}=-\varpi\,. \tag{13.132}$$

ϖ is a one-form built from E and G alone. Using $\boldsymbol{x}_1\cdot\boldsymbol{x}_1=E$, $\boldsymbol{x}_2\cdot\boldsymbol{x}_2=G$, $\boldsymbol{x}_1\cdot\boldsymbol{x}_2=0$,

$$\boldsymbol{x}_2\cdot\boldsymbol{x}_{11}=\partial_1(\boldsymbol{x}_2\cdot\boldsymbol{x}_1)-\boldsymbol{x}_{12}\cdot\boldsymbol{x}_1=-\tfrac{1}{2}\partial_2E\,,\qquad \boldsymbol{x}_2\cdot\boldsymbol{x}_{12}=\tfrac{1}{2}\partial_1G\,,$$

so that, since the term coming from differentiating $E^{-1/2}$ is proportional to $\boldsymbol{x}_1$ and dies against $\hat{e}_2$,

$$\varpi\,\mathrm{d}t=\omega_1\mathrm{d}u_1+\omega_2\mathrm{d}u_2\,,\qquad \omega_1=-\frac{\partial_2E}{2\sqrt{EG}}\,,\qquad \omega_2=\frac{\partial_1G}{2\sqrt{EG}}\,. \tag{13.133}$$

This is minus the connection one-form $\omega^1{}_2$ of Equation (13.110), computed here again directly so that nothing is owed to the later Cartan formalism.

Green's theorem. Integrating Equation (13.132) once around γ and applying Theorem 7.99 in the (u_1, u_2) plane,

$$\Delta\vartheta = -\oint_\gamma (\omega_1 \mathrm{d}u_1 + \omega_2 \mathrm{d}u_2) = -\int_D (\partial_1\omega_2 - \partial_2\omega_1)\,\mathrm{d}u_1\mathrm{d}u_2\,.$$

By Equation (13.133),

$$\partial_1\omega_2 - \partial_2\omega_1 = \frac{1}{2}\left[\partial_1\left(\frac{\partial_1 G}{\sqrt{EG}}\right) + \partial_2\left(\frac{\partial_2 E}{\sqrt{EG}}\right)\right] = -K\sqrt{EG}\,,$$

the last step being the Liouville formula Equation (13.111). Substituting gives Equation (13.131). Reversing the orientation of γ reverses the sign of the line integral and hence of $\Delta\vartheta$. □

Example 13.42 (The sphere, the solid angle, and the pole)**.** On the sphere of radius R in the coordinates $(u_1, u_2) = (\theta, \phi)$ of Example 13.33, $E = R^2$ and $G = R^2\sin^2\theta$, so $\partial_2 E = 0$, $\partial_1 G = 2R^2\sin\theta\cos\theta$ and $\sqrt{EG} = R^2\sin\theta$. Equation (13.133) then gives the strikingly simple

$$\omega_1 \mathrm{d}\theta + \omega_2 \mathrm{d}\phi = \cos\theta\,\mathrm{d}\phi\,, \tag{13.134}$$

so a parallel field carried once round the latitude circle $\theta = \theta_0$, in the direction of increasing ϕ, turns relative to the frame Equation (13.130) by

$$\Delta\vartheta\,(\theta_0) = -\oint \cos\theta_0\,\mathrm{d}\phi = -2\pi\cos\theta_0\,. \tag{13.135}$$

The theorem itself is checked on a curve that does satisfy its hypotheses — the boundary of the coordinate rectangle $\theta \in [\theta_1, \theta_2]$, $\phi \in [\phi_1, \phi_2]$, whose closure lies in the patch. Only the two edges of constant θ contribute to $\oint \cos\theta\,\mathrm{d}\phi$, and with the positive orientation they give $(\phi_2 - \phi_1)(\cos\theta_2 - \cos\theta_1)$, so $\Delta\vartheta = (\phi_2 - \phi_1)(\cos\theta_1 - \cos\theta_2)$; and since $K = 1/R^2$ with $\mathrm{d}A = R^2\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi$, the right-hand side of Equation (13.131) is $(\phi_2 - \phi_1)\int_{\theta_1}^{\theta_2}\sin\theta\,\mathrm{d}\theta$, the same number.

Comparing Equation (13.135) at θ_0 and at a small ε gives, by the same direct computation,

$$\Delta\vartheta\,(\theta_0) - \Delta\vartheta\,(\varepsilon) = 2\pi\,(\cos\varepsilon - \cos\theta_0) = \int_{\varepsilon\le\theta\le\theta_0} K\,\mathrm{d}A\,,$$

the total curvature of the annulus between the two latitudes.

The cap $\theta \le \theta_0$ itself is *not* covered by this chart: the pole $\theta = 0$ is a coordinate singularity, where the frame Equation (13.130) is undefined, and the hypothesis of the theorem fails. The bookkeeping is exact and worth stating, because it is the whole content of the Foucault deficit. Letting $\varepsilon \to 0$ above, the total curvature of the cap is

$$\int_{\mathrm{cap}} K\,\mathrm{d}A = 2\pi\,(1 - \cos\theta_0)\,, \tag{13.136}$$

which is precisely the solid angle the cap subtends at the centre, while Equation (13.135) gives $\Delta\vartheta = -2\pi\cos\theta_0$: the two differ by exactly 2π, the limit of $-\Delta\vartheta(\varepsilon)$, which is the turn the singular frame itself makes on one circuit of the pole. So it is the *deficit from a full turn*, $2\pi - 2\pi\cos\theta_0$, and not the frame-relative rotation, that is the geometric invariant of the region enclosed. Written in terms of the latitude $\lambda = \pi/2 - \theta_0$, that deficit is $2\pi\,(1 - \sin\lambda)$.

Rests on Theorem 13.41 and Example 13.33.

13.4 Differentiable manifolds

The definitions given below serve to introduce the concept of a differentiable manifold, which results from generalising the idea of curves and surfaces. The definition is built up from the concept of a topological space (Chapter 6), which we progressively equip with the pertinent structure so as to obtain an object rich in properties that can be linked with nature. One of the key concepts is that of a coordinate system, which is in intimate correspondence with reference frames: the tool of theoretical physics that lets us fix a point in the Universe with respect to which a physical system is being evaluated.

13.4.1 Charts, atlases, and differentiable structure

Coordinate systems

Consider a topological space. In the context of this chapter we refer to the elements of a topological space as *points*.

Let $M \subset \mathbb{R}^N$ be a topological space and $U \subset \mathbb{R}^n$ with $n \leq N$. Consider a point $P \in M$ and $x = (x^1, \ldots, x^n) \in U$, and consider further the injective map $\phi : x \longmapsto \phi(x) = P$.

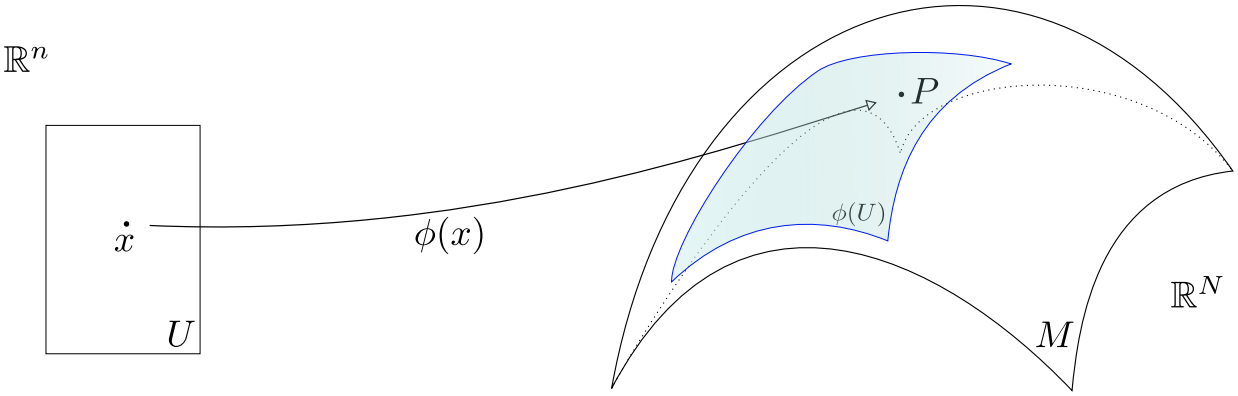


Figure 13.2: A coordinate system: the map ϕ carries a point $x = (x^1, \ldots, x^n)$ of the parameter domain $U \subset \mathbb{R}^n$ to a point $P = \phi(x)$ of the topological space M.

Intuitively, ϕ must respect the topology of M in order to describe its points correctly through coordinates. To this end we must demand that points of M be close if and only if their coordinates are. The idea is to require

$$P_l \longrightarrow P \quad \overset{!}{\Longleftrightarrow} \quad x_l \longrightarrow x\,,$$

where x_l is a sequence of points in U and $P_l = \phi(x_l)$ a sequence of points in M. Demanding "$\Leftarrow$" we meet the continuity of ϕ, and demanding "$\Rightarrow$" we meet the continuity of ϕ^{-1}. We further wish a one-to-one relation between the points of U and (at least some of, since in general more than one set like U is needed to describe all the points of M) the points of M, which suggests that ϕ must be bijective. In conclusion, the topology is respected if and only if ϕ is a homeomorphism. By the definition of continuity, demanding "$\Leftarrow$" the set $\phi^{-1}(\phi(U)) = U$ must be open, and demanding "$\Rightarrow$" the set $(\phi^{-1})^{-1}(U) = \phi(U)$ must be open. The geometric interpretation is that (by the definition of an open set) we can place an open ball centred at P and one centred at x,

from which we see that the points neighbouring x should give us information about the points neighbouring P (by the definition of a neighbourhood), which happens if and only if the map ϕ is smooth.

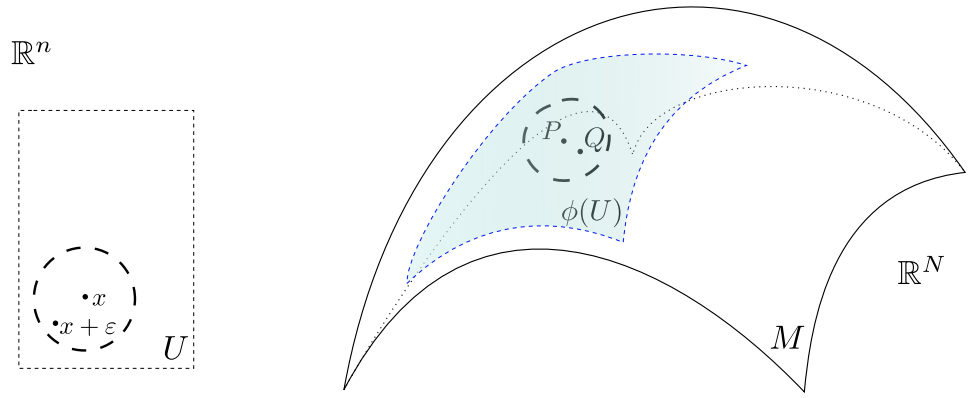

Figure 13.3: Open balls centred at $x \in U$ and at $P = \phi(x) \in M$: the neighbours of x carry information about the neighbours of P precisely when ϕ is a homeomorphism.

Definition 13.43 (Coordinate system)**.** We say that the pair (ϕ, U) is an *n-dimensional coordinate system* (CS), or *local chart*, if and only if

1. the map ϕ is a homeomorphism, which implies that U is open in $\mathbb{R}^n$;
2. the map ϕ is smooth.

Coordinates

As we have seen, given a coordinate system there is a one-to-one relation between the points of U and some points of M. The variables $(x^1, \ldots, x^n)$ corresponding to a point $P \in M$ receive the name of *coordinates* of the point P with respect to the coordinate system (ϕ, U). To symbolise (and not forget) the exact point of M that we wish to describe by means of (ϕ, U), we denote the coordinates of a point $P \in M$ as $(x^1, \ldots, x^n) \overset{\text{not.}}{=} x^i(P)$ with $i = 1, \ldots, n$. Thus, when we want to refer to the point $x \in U$ we write x or $(x^1, \ldots, x^n)$; when we want to refer explicitly to the point P through its coordinates, we write $x^i(P)$; and for the coordinates of arbitrary points of M (within the codomain of ϕ) we use x^i. In summary,

$$\underbrace{x^i(P)}_{\text{coordinates}} = \underbrace{(x^1, \ldots, x^n)}_{\text{point in } U}, \qquad \text{for } P = \phi(x)\,. \tag{13.137}$$

Even though we have insisted on the difference between the quantities in U and the coordinates of the point, numerically they are the same, which is useful in practice; in the theory, however, it is necessary to be rigorous with the notation. It is very important to note that the coordinates of a point depend on the subset U of $\mathbb{R}^n$ we have chosen. Note that $\phi : U \longrightarrow \phi(U)$ is bijective, so this one-to-one relation characterises the points of $\phi(U)$ by their coordinates in $\mathbb{R}^n$. Note also that a correct notation for the point P in terms of its coordinates in U would be $P = \phi(x) = \phi(x^1, \ldots, x^n)$, but not $P = \phi(x^i)$ nor $P = \phi(x^1(P), \ldots, x^n(P))$.

Atlases

Consider a family of n-dimensional coordinate systems $\{(\phi_a, U_a)\}_{a \in I}$ that cover the whole space M, that is,

$$M \subset \bigcup_{a \in I} \phi_a(U_a)\,,$$

such that $U_a \cap U_b \neq \varnothing$ for $a \neq b$. Let the *overlap regions* be

$$\Omega_{ab} = \phi_a(U_a) \cap \phi_b(U_b)\,.$$

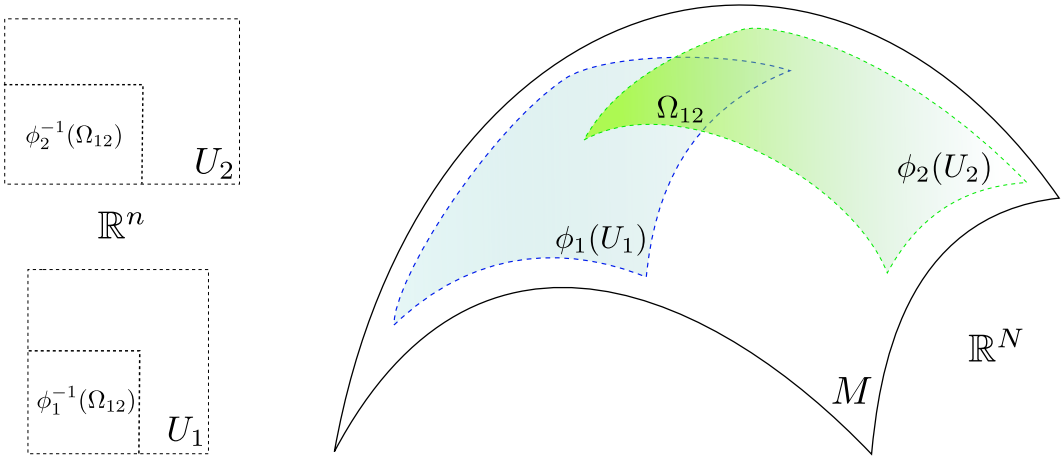

Figure 13.4: Two charts (ϕ_a, U_a) and (ϕ_b, U_b) covering overlapping portions of M; the overlap region is $\Omega_{ab} = \phi_a(U_a) \cap \phi_b(U_b)$.

The sets $\phi_a^{-1}(\Omega_{ab})$ and $\phi_b^{-1}(\Omega_{ab})$ are open because ϕ_a and ϕ_b are homeomorphisms. We further define the *transition maps* as

$$\phi_{ba} = \phi_b^{-1} \circ \phi_a : \phi_a^{-1}(\Omega_{ab}) \longrightarrow \phi_b^{-1}(\Omega_{ab}) \,.$$

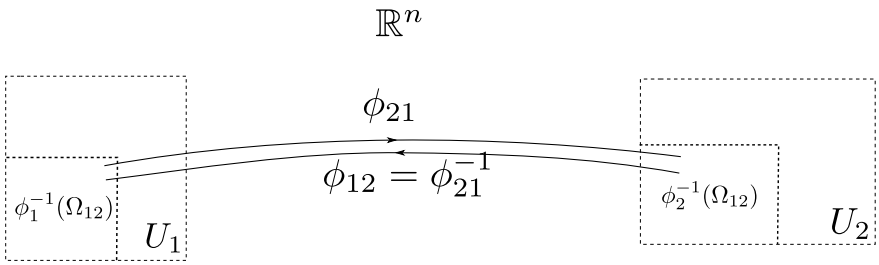

Figure 13.5: The transition map $\phi_{ba} = \phi_b^{-1} \circ \phi_a$ between the coordinate domains of two overlapping charts.

The transition maps are continuous, being compositions of continuous maps, and since the sets $\phi_a^{-1}(\Omega_{ab})$ and $\phi_b^{-1}(\Omega_{ab})$ are open, the transition maps are moreover homeomorphisms. A point P may be described by $P = \phi_a(x_a^1, \ldots, x_a^n)$ or by $P = \phi_b(x_b^1, \ldots, x_b^n)$. This means we can perform a change of coordinate system of the form

$$(x_b^1, \ldots, x_b^n) = \phi_{ba}(x_a^1, \ldots, x_a^n) \,,$$

which respects the topology of M because the ϕ_{ba} are homeomorphisms. For the information about the points neighbouring P to be well defined after changing the coordinate system, we must demand that the transition maps be smooth.

Definition 13.44 (Atlas)**.** We say that a family of coordinate systems $\{(\phi_a, U_a)\}_{a \in I}$ is an *n-dimensional atlas* if and only if

1. the coordinate systems cover the whole space M, that is,

$$M \subset \bigcup_{a \in I} \phi_a(U_a) \,,$$

2. the coordinate systems are smoothly related[1].

Rests on Definition 13.43.

[1]These smoothly related changes of coordinate system are exclusively within the atlas. This concept must not be confused with the general coordinate transformations studied further below.

Differentiable maps on a topological space

Consider now a topological space M equipped with an atlas $\{(\phi_a, U_a)\}_{a\in I}$, and let

$$f : M \longrightarrow \mathbb{R}$$

be a map. A key question is: under what conditions is f differentiable? Since we know the usual definition of differentiability at a point $x \in \mathbb{R}^n$, we wish to extend it to the points of a topological space by virtue of the given atlas. Of course, we know that a map that is not continuous is not differentiable, so at the very least we must demand that f be continuous. Choose the coordinate system (ϕ_a, U_a) and define the map $\bar{f}_a = f \circ \phi_a$.

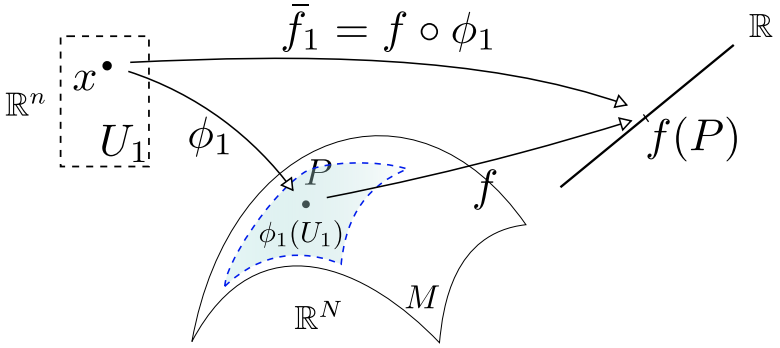

Figure 13.6: A map $f : M \to \mathbb{R}$ read through a chart: the composition $\bar{f}_a = f \circ \phi_a$ is an ordinary map between subsets of $\mathbb{R}^n$ and $\mathbb{R}$, on which differentiability makes sense.

The map $\bar{f}_a$ is continuous, being a composition of continuous maps; moreover, the atlas allows us to define f on a neighbourhood of P, so that ϕ_a is well defined on a neighbourhood of $(x_a^1, \dots, x_a^n)$, since ϕ_a respects the topology (again a consequence of working with an atlas). Thus our map $\bar{f}_a$ is in a position to be differentiable.

Definition 13.45 (Differentiable map on a topological space)**.** We say that f is differentiable at $P = \phi_a(x)$ if and only if

1. f is continuous;
2. $\bar{f}_a = f \circ \phi_a$ is differentiable.

Rests on Definitions 13.43 and 13.44.

But what would happen if we changed to a coordinate system (ϕ_b, U_b) and $\bar{f}_b = f \circ \phi_b$ were not differentiable at P? This does not occur, since

$$\begin{aligned}
\bar{f}_b &= f \circ \phi_b \\
&= f \circ \mathrm{id} \circ \phi_b \\
&= f \circ \left(\phi_a \circ \phi_a^{-1}\right) \circ \phi_b \\
&= (f \circ \phi_a) \circ \left(\phi_a^{-1} \circ \phi_b\right) \\
&= \bar{f}_a \circ \phi_{ab}\,,
\end{aligned}$$

and thus, since ϕ_{ab} is smooth, it is at least of class C^1 and hence differentiable; and since $\bar{f}_a$ is differentiable, $\bar{f}_b$ is differentiable, being a composition of differentiable maps. The atlas has again entered the game: it is the smoothness condition in the atlas that allows us to define a differentiable map on M.

Differentiable structure

Consider a topological space now equipped with the atlases $\{(\phi_a, U_a)\}_{a\in I}$ and $\{(\psi_b, V_b)\}_{b\in J}$. The relation

$$\{(\phi_a, U_a)\} \cup \{(\psi_b, V_b)\} \text{ is an atlas} \iff \{(\phi_a, U_a)\} \wedge \{(\psi_b, V_b)\} \text{ are atlases}$$

is an equivalence relation.

Proposition 13.46 (Compatibility of atlases)**.** *On the set of n-dimensional atlases of a topological space M, the relation*

$$\mathcal{A} \sim \mathcal{B} \quad \iff \quad \mathcal{A} \cup \mathcal{B} \text{ is an atlas} \tag{13.138}$$

is an equivalence relation.

Rests on Definitions 13.43 and 13.44.

Proof. *Derives Proposition 13.46.*

First unpack Equation (13.138). The union of two atlases always satisfies the covering condition of Definition 13.44, since $\mathcal{A}$ alone already covers M; and the transition maps between two charts of $\mathcal{A}$, or between two charts of $\mathcal{B}$, are smooth because each family is an atlas. So $\mathcal{A} \sim \mathcal{B}$ holds if and only if every *crossed* transition map $\psi^{-1} \circ \phi$, between a chart $(\phi, U) \in \mathcal{A}$ and a chart $(\psi, V) \in \mathcal{B}$ with overlapping images, is smooth.

Reflexivity. $\mathcal{A} \cup \mathcal{A} = \mathcal{A}$, which is an atlas by hypothesis.

Symmetry. The union is a symmetric operation, so the condition Equation (13.138) is symmetric as it stands. (Concretely: a crossed transition map in one direction is the inverse of the one in the other, $\psi^{-1} \circ \phi = (\phi^{-1} \circ \psi)^{-1}$, and the atlas condition demands smoothness of both.)

Transitivity. Let $\mathcal{A} \sim \mathcal{B}$ and $\mathcal{B} \sim \mathcal{C}$, and take charts $(\phi, U) \in \mathcal{A}$ and $(\chi, W) \in \mathcal{C}$ whose images overlap. Let $P \in \phi(U) \cap \chi(W)$. Since $\mathcal{B}$ is an atlas it covers M, so there is a chart $(\psi, V) \in \mathcal{B}$ with $P \in \psi(V)$. The set

$$\phi^{-1}\left(\phi(U) \cap \psi(V) \cap \chi(W)\right)$$

is open — it is the preimage under the homeomorphism ϕ of an intersection of three sets open in M — and it contains $\phi^{-1}(P)$. On it,

$$\chi^{-1} \circ \phi = \left(\chi^{-1} \circ \psi\right) \circ \left(\psi^{-1} \circ \phi\right) , \tag{13.139}$$

a composition of two smooth maps by the hypotheses $\mathcal{A} \sim \mathcal{B}$ and $\mathcal{B} \sim \mathcal{C}$, hence smooth. Smoothness is a local property and P was an arbitrary point of the overlap, so $\chi^{-1} \circ \phi$ is smooth on the whole of $\phi^{-1}(\phi(U) \cap \chi(W))$; the same argument with the roles of ϕ and χ exchanged gives the smoothness of $\phi^{-1} \circ \chi$. Every crossed transition map of $\mathcal{A} \cup \mathcal{C}$ is therefore smooth, and $\mathcal{A} \cup \mathcal{C}$ is an atlas, that is $\mathcal{A} \sim \mathcal{C}$.

Note where each hypothesis was used: reflexivity and symmetry are formal, while transitivity rests on the covering property of the intermediate atlas $\mathcal{B}$ — without a chart of $\mathcal{B}$ around P the factorisation Equation (13.139) would not exist. □

Definition 13.47 (Differentiable structure)**.** We say that an equivalence class of atlases is a *differentiable structure*. Two atlases belonging to the same differentiable structure are called *compatible*.

Rests on Definition 13.44.

Note the following: all the coordinate systems of two compatible atlases are smoothly related, because their union is an atlas (and the coordinate systems of an atlas are smoothly related).

Differentiable manifold

Definition 13.48 (Differentiable manifold)**.** We say that a topological space M is an *n-dimensional differentiable manifold* if and only if M is equipped with an (n-dimensional) differentiable structure. When it is necessary to specify the dimension of the manifold, we denote it M_n.

Rests on Definition 13.47.

It is important to discuss the following. The dimension of the manifold refers to the number of coordinates we need to describe completely an arbitrary point of it. The definitions have been constructed in such a way that it is not possible to have an n-dimensional manifold in which some points are described by fewer than n coordinates.

Diffeomorphism

The notion of a differentiable map developed above compares a manifold with $\mathbb{R}$; nothing prevents us from comparing two manifolds with each other.

Definition 13.49 (Smooth map between manifolds)**.** Let M_m and N_n be differentiable manifolds. We say that a map $f : M_m \longrightarrow N_n$ is *smooth* if and only if it is continuous and, for every coordinate system (ϕ_a, U_a) of M_m and every coordinate system (ψ_b, V_b) of N_n, the *coordinate representation*

$$\psi_b^{-1} \circ f \circ \phi_a \,, \tag{13.140}$$

which maps a subset of $\mathbb{R}^m$ into $\mathbb{R}^n$, is smooth wherever it is defined.

Rests on Definitions 13.44, 13.45 and 13.48.

That the condition need be checked in one pair of charts only is the computation already performed for $\bar{f}_a$ and $\bar{f}_b$ above: changing either chart composes Equation (13.140) with a transition map, which is smooth because we are working inside atlases. Definition 13.45 is the special case $N_n = E_1$ read in the Cartesian chart.

Definition 13.50 (Diffeomorphism)**.** A *diffeomorphism* is a smooth homeomorphism $f : M_m \longrightarrow N_n$ whose inverse f^{-1} is also smooth. Two manifolds related by a diffeomorphism are said to be *diffeomorphic*.

Rests on Definitions 6.7 and 13.49.

Remark 13.51. Diffeomorphic manifolds are, for every purpose of this chapter, the same manifold. Applying the chain rule to $f^{-1} \circ f = \mathrm{id}$ shows that the Jacobian of Equation (13.140) is invertible at every point, so $m = n$; and then $(f \circ \phi_a, U_a)$ is a coordinate system of N_n whenever (ϕ_a, U_a) is one of M_n, so f carries atlases to atlases and the differentiable structure of M_n (Definition 13.47) to that of N_n. Every statement expressible through charts, smooth maps and tangent spaces alone therefore transfers. Diffeomorphism is to differential geometry what homeomorphism (Definition 6.7) is to topology.

Smoothness of the inverse must be demanded, for it does not follow: the map $f : \mathbb{R} \longrightarrow \mathbb{R}$ with $f(x) = x^3$ is a smooth homeomorphism, but $f^{-1}(y) = y^{1/3}$ is not differentiable at the origin, so f is not a diffeomorphism — precisely as continuity of a bijection fails to give a homeomorphism (Remark 6.8).

The differential of a smooth map

Definition 13.52 (Differential; pushforward)**.** Let $f : M_m \longrightarrow N_n$ be smooth and let $P \in M_m$. The *differential* of f at P is the map

$$f_{*P} : T_M(P) \longrightarrow T_N(f(P))$$

that assigns to the vector tangent at P to a curve $\lambda \longmapsto x(\lambda)$ (Definition 13.81) the vector tangent at $f(P)$ to the image curve $\lambda \longmapsto f(x(\lambda))$. Writing $y^\alpha = f^\alpha(x^1, \dots, x^m)$ for the coordinate representation Equation (13.140), the chain rule gives, in the coordinate bases $\{\partial/\partial x^i\}$ and $\{\partial/\partial y^\alpha\}$,

$$(f_{*P}V)^\alpha = \left.\frac{\partial f^\alpha}{\partial x^i}\right|_P V^i \,, \tag{13.141}$$

so f_{*P} is linear and is represented by the Jacobian matrix of f at P. It is the pushforward used below in the discussion of pullbacks (Section 13.5.1).

Rests on Definitions 13.49 and 13.81.

Immersion, embedding, and submanifold

Definition 13.53 (Immersion, submersion, embedding)**.** Let $f : M_m \longrightarrow N_n$ be smooth. We say that f is

1. an *immersion* if and only if f_{*P} is injective for every $P \in M_m$, which requires $m \le n$;
2. a *submersion* if and only if f_{*P} is surjective for every $P \in M_m$, which requires $m \ge n$;
3. an *embedding* if and only if it is an injective immersion which is, in addition, a homeomorphism onto its image $f(M_m)$, that image carrying the topology it inherits as a subset of N_n.

Rests on Definitions 6.7 and 13.52.

Definition 13.54 (Embedded submanifold)**.** A subset $S \subseteq N_n$ is an *embedded submanifold of dimension* m if and only if S, equipped with the topology inherited from N_n, admits an m-dimensional differentiable structure for which the inclusion $\iota : S \longrightarrow N_n$ is an embedding. The integer $n - m$ is the *codimension* of S in N_n.

Rests on Definitions 13.48 and 13.53.

The image of an embedding is an embedded submanifold: transporting the differentiable structure of M_m through the homeomorphism $f : M_m \longrightarrow f(M_m)$ produces an atlas on $f(M_m)$ whose charts are the $f \circ \phi_a$, and with respect to it f becomes a diffeomorphism onto its image. The third condition in Definition 13.53 is not implied by the first two, as the following example shows.

Example 13.55 (An injective immersion that is not an embedding)**.** Consider the *figure-eight* curve in E_3,

$$\gamma :]-\pi, \pi[\longrightarrow \mathbb{R}^3 \,, \qquad x^i(\gamma(\lambda)) = (\sin 2\lambda,\ \sin\lambda,\ 0) \,. \tag{13.142}$$

It is an immersion: $\frac{\mathrm{d}x^i}{\mathrm{d}\lambda} = (2\cos 2\lambda, \cos\lambda, 0)$ never vanishes, because $\cos\lambda = 0$ forces $\lambda = \pm\pi/2$ and there $2\cos 2\lambda = -2$. It is injective: let $\lambda_1, \lambda_2 \in]-\pi, \pi[$ have $\gamma(\lambda_1) = \gamma(\lambda_2)$. Equality of the second components, $\sin\lambda_1 = \sin\lambda_2$, leaves besides $\lambda_2 = \lambda_1$ exactly two possibilities inside the interval, $\lambda_2 = \pi - \lambda_1$ (which lies in $]-\pi, \pi[$ only for $\lambda_1 > 0$) and $\lambda_2 = -\pi - \lambda_1$ (only for $\lambda_1 < 0$); both branches must be checked, since the second is the one available on the negative half of the interval. On either of them $\sin 2\lambda_2 = -\sin 2\lambda_1$, because sin has period 2π and $2\lambda_2 = \pm 2\pi - 2\lambda_1$. Equality of the first components then gives $\sin 2\lambda_1 = 0$, that is $\lambda_1 \in \{0, \pm\pi/2\}$; and $\lambda_1 = 0$ sends both branches out of the interval, while $\lambda_1 = \pi/2$ and $\lambda_1 = -\pi/2$ send the available branch back to $\lambda_2 = \lambda_1$. Hence $\lambda_1 = \lambda_2$ in every case.

It is not an embedding. As $\lambda \to \pm\pi$ both components tend to 0, so the image accumulates at $\gamma(0) = (0, 0, 0)$: every neighbourhood of $\gamma(0)$ in the subspace topology of the image contains points $\gamma(\lambda)$ with λ arbitrarily close to $\pm\pi$, whose parameters are *not* close to 0.

Hence γ^{-1} is discontinuous at $\gamma(0)$, and the image, which is a self-touching figure eight, is not an embedded submanifold of E_3: no neighbourhood of the origin in it is homeomorphic to an interval.

Rests on Definitions 13.52 and 13.53.

Product of manifolds

Proposition 13.56 (Product manifold)**.** *Let M_m and N_n be differentiable manifolds with atlases $\{(\phi_a, U_a)\}_{a\in I}$ and $\{(\psi_b, V_b)\}_{b\in J}$. Then the topological product $M_m \times N_n$, carrying the product topology, is a differentiable manifold with the* product atlas

$$\{(\phi_a \times \psi_b,\ U_a \times V_b)\}_{(a,b)\in I\times J}\ , \qquad (\phi_a \times \psi_b)\,(x,y) = (\phi_a(x), \psi_b(y))\ , \tag{13.143}$$

and

$$\dim\,(M_m \times N_n) = \dim M_m + \dim N_n = m + n\,. \tag{13.144}$$

Rests on Definitions 13.43, 13.44 and 13.48.

Proof. *Derives Proposition 13.56.*

Each $U_a \times V_b$ is open in $\mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$, and $\phi_a \times \psi_b$ is a homeomorphism onto its image for the product topology, being a product of homeomorphisms; it is smooth because each factor is, so Definition 13.43 is met and each pair is an $(m+n)$-dimensional coordinate system. The images cover, since $\phi_a(U_a)$ cover M_m and $\psi_b(V_b)$ cover N_n. Finally, the transition map between two such charts is

$$(\phi_{a'} \times \psi_{b'})^{-1} \circ (\phi_a \times \psi_b) = (\phi_{a'a},\ \psi_{b'b})\ ,$$

acting on the two blocks of coordinates separately; it is smooth because the transition maps of the two given atlases are. Both conditions of Definition 13.44 hold, so Equation (13.143) is an atlas, and the number of coordinates needed to locate a point, $(x^1, \ldots, x^m, y^1, \ldots, y^n)$, is $m+n$, which is Equation (13.144). □

Example 13.57 (The cylinder)**.** Take $M = S_1$, the circle of radius R with the two-chart atlas of Section 13.4.3, and $N = \mathbb{R}$ with the single Cartesian chart. The index sets of Equation (13.143) then have two and one element, so the product atlas has $2 \times 1 = 2$ charts, both of the form $(\phi, z) \longmapsto (R\cos\phi, R\sin\phi, z)$ on the corresponding angular range, and it makes $S_1 \times \mathbb{R}$ a two-dimensional manifold, the cylinder of radius R in E_3. Its dimension, $1 + 1 = 2$, is Equation (13.144); it is the surface whose vanishing Gaussian curvature (Section 13.3.3) makes it *locally* isometric to the plane. Globally it is not: a flat strip is simply connected and the cylinder is not, so no isometry of the two exists — the cylinder is a strip with its two edges identified, not a subset of the plane.

Rests on Proposition 13.56.

Hypersurfaces

Definition 13.58 (Hypersurface)**.** A *hypersurface* of N_n is an embedded submanifold of codimension one, that is, of dimension $n - 1$.

Rests on Definition 13.54.

Hypersurfaces are produced in practice by one scalar equation, and the theorem that licenses this is the following.

Theorem 13.59 (Regular value theorem)**.** *Let $F : N_n \longrightarrow \mathbb{R}$ be smooth and let $c \in \mathbb{R}$ be a* regular value *of F: the differential F_{*P} is nonzero at every P with $F(P) = c$, that is, in any chart around such a P at least one of the $\partial F/\partial x^i$ is nonzero there. Then the level set*

$$S = F^{-1}(c) = \{P \in N_n \mid F(P) = c\}\ , \tag{13.145}$$

if non-empty, is a hypersurface of N_n.

Rests on Definitions 13.49, 13.52 and 13.58.

Proof. *Derives Theorem 13.59.*

Let $P \in S$ and choose a chart of N_n around P with coordinates $(x^1, \dots, x^n)$. Relabelling the coordinates we may assume $\partial F/\partial x^n \neq 0$ at P. By the implicit function theorem of multivariable calculus there are then an open set $W \subset \mathbb{R}^{n-1}$ containing $(x^1, \dots, x^{n-1})(P)$, an open interval I containing $x^n(P)$, and a smooth function $h : W \longrightarrow I$ such that, inside $W \times I$,

$$F(x^1, \dots, x^n) = c \quad \Longleftrightarrow \quad x^n = h(x^1, \dots, x^{n-1})\,. \tag{13.146}$$

Thus S meets the coordinate box $W \times I$ in the graph of h, and

$$\chi : W \longrightarrow S\,, \qquad \chi(u^1, \dots, u^{n-1}) = \Big(u^1, \dots, u^{n-1}, h(u)\Big)$$

is smooth and injective; its inverse is the restriction to S of the projection onto the first $n-1$ coordinates, which is continuous, so χ is a homeomorphism onto an open subset of S in the subspace topology. The family of all such χ, one around each point of S, covers S. Two of them are smoothly related, because the transition map is a composition of one such χ with a projection and with a transition map of N_n, all smooth. Hence Definition 13.44 is met and S is an $(n-1)$-dimensional manifold whose inclusion into N_n reads, in these charts, $u \longmapsto (u, h(u))$: an injective immersion — its Jacobian $(\mathbb{1}, \partial h/\partial u)$ has rank $n-1$ — and a homeomorphism onto its image by construction. By Definitions 13.53 and 13.58, S is a hypersurface. □

Remark 13.60. The single input of the proof above is the implicit function theorem. Chapter 7 develops differentiability in several variables but stops short of stating it, so it is stated and proved in the appendix — by an explicit contraction, in the manner of the Picard iteration of Theorem 9.8, so that no fixed-point theorem is imported. The form used here is the scalar one: where $\partial F/\partial x^n \neq 0$, the equation $F = c$ determines x^n as a function of the remaining coordinates, of the same differentiability class as F, which is exactly the assertion Equation (13.146) appealed to above.

Full derivation: Appendix A.28 (p. 2914).
Derives Equation (13.146).

Example 13.61 (The 2-sphere in $\mathbb{R}^3$)**.** Take $N_3 = E_3$ with Cartesian coordinates (x, y, z) and

$$F(x, y, z) = x^2 + y^2 + z^2\,, \qquad c = R^2 > 0\,.$$

On the level set the differential $\partial F/\partial x^i = 2(x, y, z)$ is nonzero, since the origin does not satisfy $F = R^2$; hence R^2 is a regular value and the sphere

$$S_2 = \Big\{(x, y, z) \in \mathbb{R}^3 \mid x^2 + y^2 + z^2 = R^2\Big\} \tag{13.147}$$

is a hypersurface of E_3, of dimension 2 and codimension 1. The charts furnished by Theorem 13.59 are here explicit: the six open hemispheres, on each of which one coordinate is a smooth function of the other two, for instance $z = +\sqrt{R^2 - x^2 - y^2}$ on the northern one. No single chart suffices, by the compactness argument used above for the circle: S_2 is closed and bounded, hence compact (Definition 6.9), while a chart domain must be open in $\mathbb{R}^2$.

The induced metric (Definition 13.119) of S_2 is the first fundamental form of Section 13.3.2; in the spherical parametrisation it is $\mathrm{d}s^2 = R^2\mathrm{d}\theta^2 + R^2 \sin^2\theta\, \mathrm{d}\phi^2$, whose Gaussian curvature was computed to be $K = 1/R^2$ in Example 13.33.

Rests on Theorem 13.59 and Definition 13.58.

Higher codimension and maps of constant rank

Theorem 13.59 cuts out a submanifold with *one* equation. Physics almost never presents one equation: a constraint surface in phase space, the level set of a momentum map, the shell of a conserved four-vector are all defined by several. The extension is not automatic — "at least one partial derivative is nonzero" has to become a rank condition — and the general statement is the following.

Theorem 13.62 (Regular value theorem in codimension k)**.** *Let $F : N_n \longrightarrow \mathbb{R}^k$ be smooth with $1 \le k \le n$, and let $c \in \mathbb{R}^k$ be a* regular value*: at every P with $F(P) = c$ the differential $F_{*P} : T_P N_n \longrightarrow \mathbb{R}^k$ is surjective, equivalently the k differentials $\mathrm{d}F^1, \dots, \mathrm{d}F^k$ are linearly independent at P. Then*

$$S = F^{-1}(c) = \{P \in N_n \mid F(P) = c\} \,, \tag{13.148}$$

if non-empty, is an embedded submanifold of N_n of dimension $n - k$, and at each of its points

$$T_P S = \ker F_{*P} \,. \tag{13.149}$$

For $k = 1$ this is Theorem 13.59.

Rests on Theorem A.286 and Definitions 13.52 and 13.54.

Derivation. Derives Theorem 13.62.

Let $P \in S$ and take a chart around P with coordinates $(x^1, \dots, x^n)$, in which F becomes a smooth map of an open set of $\mathbb{R}^n$ into $\mathbb{R}^k$. Surjectivity of F_{*P} says that the $k \times n$ Jacobian $\partial F^i / \partial x^j$ has rank k at P, so some k of its columns are independent; relabelling the coordinates, take them to be the last k, and split $x = (x', x'')$ with $x' \in \mathbb{R}^{n-k}$ and $x'' \in \mathbb{R}^k$. Then $\det [D_{x''} F(P)] \neq 0$, which is the hypothesis Equation (A.523) of Theorem A.286 for the map $F - c$. That theorem supplies open sets $W \subseteq \mathbb{R}^{n-k}$ and $V \subseteq \mathbb{R}^k$ around the two blocks of P and a smooth $h : W \longrightarrow V$ with

$$\{(x', x'') \in W \times V \mid F(x', x'') = c\} = \{(x', h(x')) \mid x' \in W\} \,. \tag{13.150}$$

From here the argument of Theorem 13.59 runs verbatim with $n - 1$ replaced by $n - k$: S meets the coordinate box $W \times V$ in the graph of h; the map $\chi(u) = (u, h(u))$ is smooth, injective, and a homeomorphism onto its image because its inverse is the restriction of the projection onto the first $n - k$ coordinates; two such charts are smoothly related; and the inclusion has Jacobian $(\mathbb{1}, \partial h / \partial u)$ of rank $n - k$, so it is an injective immersion and a homeomorphism onto its image. By Definitions 13.53 and 13.54, S is an embedded submanifold of dimension $n - k$.

For Equation (13.149): if γ is a curve in S through P then $F \circ \gamma \equiv c$, so $F_{*P} \dot\gamma = 0$ and $T_P S \subseteq \ker F_{*P}$. Both spaces have dimension $n - k$ — the first by the paragraph above, the second by the rank–nullity relation Equation (5.68) applied to the surjection F_{*P} — so they coincide. □

The rank of F_* need not be maximal, and when it is merely *constant* the map still has a normal form. This is the statement that turns "the image of a degenerate Legendre map" or "the set swept out by a family of solutions" into a submanifold with a definite dimension, and it is proved from the same implicit function theorem.

Theorem 13.63 (Constant rank theorem)**.** *Let $U \subseteq \mathbb{R}^N$ be open and let $f : U \longrightarrow \mathbb{R}^{N'}$ be of class C^k, $k \ge 1$, with*

$$\operatorname{rank} Df(x) = \rho \qquad \text{for every } x \in U \,. \tag{13.151}$$

Then about each $p \in U$ and its image $f(p)$ there are C^k changes of coordinates — diffeomorphisms of a neighbourhood of p in $\mathbb{R}^N$ and of a neighbourhood of $f(p)$ in $\mathbb{R}^{N'}$ — in which f reads

$$\left(u^1, \dots, u^N\right) \longmapsto \left(u^1, \dots, u^\rho, 0, \dots, 0\right) . \tag{13.152}$$

Rests on Corollary A.292, Theorem A.286, and Definition 7.66.

Derivation. Derives Theorem 13.63.

Translating source and target we may take $p = 0$ and $f(0) = 0$. Since $Df(0)$ has rank ρ, some $\rho \times \rho$ minor of it is nonsingular; permuting the coordinates of $\mathbb{R}^N$ and of $\mathbb{R}^{N'}$ — themselves linear diffeomorphisms — we may assume it is the leading one. Split $x = (x', x'') \in \mathbb{R}^\rho \times \mathbb{R}^{N-\rho}$ and $y = (y', y'') \in \mathbb{R}^\rho \times \mathbb{R}^{N'-\rho}$, and write $f = (f', f'')$ accordingly, so that $\det [D_{x'} f'(0)] \neq 0$.

Straightening the source. Put

$$\varphi(x', x'') = \left(f'(x', x''),\, x''\right) , \tag{13.153}$$

a C^k map of U into $\mathbb{R}^N$ whose Jacobian at the origin is the block matrix with rows $(D_{x'} f', D_{x''} f')$ and $(0, \mathbb{1})$, of determinant $\det [D_{x'} f'(0)] \neq 0$. By the inverse function theorem (Corollary A.292) φ restricts to a C^k diffeomorphism of a neighbourhood of 0 onto an open set of $\mathbb{R}^N$, inside which we choose a product of open balls $W = W' \times W''$ containing 0; write $\psi = \varphi^{-1}$ on W. By construction the first ρ components of φ are f', so

$$(f \circ \psi)(u', u'') = \left(u',\, g(u', u'')\right) , \qquad (u', u'') \in W , \tag{13.154}$$

with $g = f'' \circ \psi$ of class C^k.

The rank forces g to forget u''. Composing with a diffeomorphism does not change the rank of a differential, by the chain rule Equation (7.52) and the invertibility of $D\psi$; so $D(f \circ \psi)$ has rank ρ throughout W. Its block form, read off Equation (13.154), has rows $(\mathbb{1}, 0)$ and $(D_{u'} g, D_{u''} g)$. The first ρ rows are already independent, so rank ρ forces every row of $D_{u''} g$ to vanish: $D_{u''} g \equiv 0$ on W. Since W'' is a ball, hence connected, $g(u', u'') = g(u')$ depends on u' alone.

Straightening the target. On the open set $W' \times \mathbb{R}^{N'-\rho}$ define

$$\chi(y', y'') = \left(y',\, y'' - g(y')\right) , \tag{13.155}$$

a C^k diffeomorphism onto $W' \times \mathbb{R}^{N'-\rho}$, its inverse being $(z', z'') \mapsto (z', z'' + g(z'))$. It is defined on the image of Equation (13.154), whose first block lies in W', and

$$(\chi \circ f \circ \psi)(u', u'') = \left(u',\, g(u') - g(u')\right) = (u', 0) ,$$

which is Equation (13.152). □

Corollary 13.64 (The image of a constant-rank map, locally)**.** *Under the hypotheses of Theorem 13.63, every $p \in U$ has a neighbourhood U_0 such that $f(U_0)$ is an embedded submanifold of $\mathbb{R}^{N'}$ of dimension ρ, cut out near each of its points by exactly $N' - \rho$ functions with linearly independent differentials.*

Rests on Theorems 13.62 and 13.63 and Definition 13.54.

Derivation. Derives Corollary 13.64.

In the coordinates of Theorem 13.63, take $U_0 = \psi(W)$. Its image is $\{(u', 0) \mid u' \in W'\}$, which is the level set of the last $N' - \rho$ coordinate functions $z^{\rho+1}, \dots, z^{N'}$ at the value 0; those are $N' - \rho$ functions whose differentials $\mathrm{d}z^{\rho+1}, \dots, \mathrm{d}z^{N'}$ are independent everywhere. By Theorem 13.62 the level set is an embedded submanifold of dimension $N' - (N' - \rho) = \rho$, and transporting it back by the target diffeomorphism χ^{-1}, itself a diffeomorphism onto an open set, preserves both statements. □

Remark 13.65 (Two words that mean different things here). In this chapter *rank* names the number of indices of a tensor (Definition 13.5). In Theorems 13.62 and 13.63 it means the rank of a linear map (Definition 5.37), namely the dimension of the image of the differential. The two usages are standard and both are kept; which is meant is fixed by the object carrying the word. Note also that Theorem 13.63 is stated in $\mathbb{R}^N$ because that is where the implicit function theorem lives; it transfers to a smooth map $M_m \longrightarrow N_n$ of constant rank by reading it in charts, since a change of chart is exactly one of the coordinate changes the theorem already allows.

Group actions and quotient manifolds

The other standard way a manifold arises is not by cutting a bigger one with equations but by identifying its points: the configuration space of a rigid body is the set of frames modulo nothing, but the space of *shapes* is a set of configurations modulo rotations, and a reduced phase space is a level set modulo a symmetry group. The question is when the set of orbits is again a manifold, and the answer needs two hypotheses that are easy to state and easy to forget.

Definition 13.66 (Smooth action; free; proper; orbit)**.** Let G be a Lie group (Chapter 14) acting on a manifold M_n by a smooth map $G \times M_n \longrightarrow M_n$, $(g, P) \mapsto g \cdot P$, with $e \cdot P = P$ and $g \cdot (h \cdot P) = (gh) \cdot P$. The *orbit* of P is $G \cdot P = \{g \cdot P \mid g \in G\}$, and the *orbit space* M_n/G is the set of orbits with the quotient topology. The action is

1. *free* iff $g \cdot P = P$ for some P forces $g = e$;
2. *proper* iff the map $G \times M_n \longrightarrow M_n \times M_n$, $(g, P) \mapsto (g \cdot P, P)$, is proper, i.e. the preimage of every compact set is compact.

Rests on Definitions 6.9, 13.48 and 13.49.

Theorem 13.67 (Quotient manifold theorem)**.** *Let a Lie group G of dimension d act smoothly, freely and properly on M_n. Then the orbit space M_n/G carries exactly one smooth structure, of dimension $n - d$, for which the projection*

$$\pi : M_n \longrightarrow M_n/G\,, \qquad \pi(P) = G \cdot P\,, \tag{13.156}$$

is a smooth submersion (Definition 13.53); with it, M_n/G is Hausdorff and second countable. Every orbit is an embedded submanifold of M_n diffeomorphic to G, and

$$\dim\,(M_n/G) = \dim M_n - \dim G = n - d\,. \tag{13.157}$$

A map $f : M_n/G \longrightarrow N$ is smooth if and only if $f \circ \pi$ is.
Rests on Definitions 13.54 and 13.66 and Theorem 13.63.

Full derivation: Appendix A.46 (p. 3032).
Derives Theorem 13.67.

Example 13.68 (Why each hypothesis is there)**.** Let $G = \mathbb{R}$ act on $M = \mathbb{R}^2$ by $t \cdot (x, y) = (x + t,\, y)$. The action is free, and it is proper because $(t, x, y) \mapsto ((x + t, y), (x, y))$ has continuous inverse $((x', y'), (x, y)) \mapsto (x' - x, x, y)$ on its image, so the preimage of a compact set is a closed subset of a compact one. The orbits are the horizontal lines, and Equation (13.157) gives $\dim(M/G) = 2 - 1 = 1$: the orbit space is the y-axis, as it should be.

Freeness is not decoration: let $\mathrm{SO}(2)$ act on $\mathbb{R}^2$ by rotation. The action is proper — the group is compact — but the origin is fixed, so it is not free, and the orbit space is the half-line $[0, \infty[$, which is not a manifold at its endpoint. Properness is not decoration either:

let $\mathbb{R}$ act on the torus $T^2 = \mathbb{R}^2/\mathbb{Z}^2$ by $t \cdot [x, y] = [x + t,\ y + \kappa t]$ with κ irrational. This action is free, but every orbit is dense in T^2, because the successive returns of the line to a fixed meridian occur at the points $\{n\kappa \bmod 1\}$, which are distinct for distinct n and therefore accumulate. Hence the quotient topology on the orbit space is indiscrete: two distinct orbits have no disjoint neighbourhoods and the space is not Hausdorff, hence not a manifold. The failure is exactly the failure of properness, the group $\mathbb{R}$ escaping to infinity while its points stay in a compact set.

Rests on Theorem 13.67 and Definition 13.66.

13.4.2 Euclidean space

The Cartesian coordinate system

Consider the topological space $M = \mathbb{R}^n$. Note that the pair $(\mathrm{id}_{\mathbb{R}^n}, \mathbb{R}^n)$ defines a coordinate system, for $\mathrm{id}_{\mathbb{R}^n}$ is trivially a smooth homeomorphism: it is the bijective map that associates with each point $x \in \mathbb{R}^n$ the point $x \in \mathbb{R}^n$ itself.

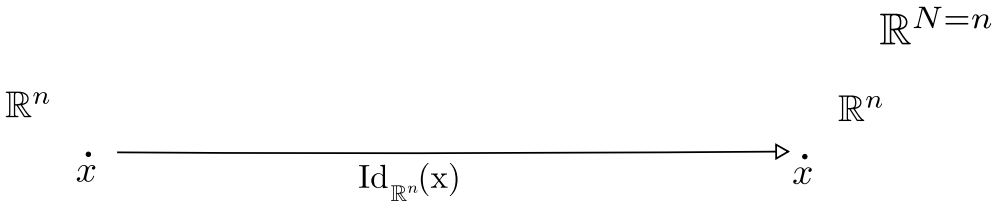

Figure 13.7: The identity chart on $\mathbb{R}^n$: each point is its own coordinate label.

We say that $(\mathrm{id}_{\mathbb{R}^n}, \mathbb{R}^n)$ is a *Cartesian* coordinate system of $\mathbb{R}^n$. In this coordinate system the coordinates of a point $P \in \mathbb{R}^n$ are $x^i(P)$, which are called the *Cartesian coordinates* of the point P (with respect to the coordinate system $(\mathrm{id}_{\mathbb{R}^n}, \mathbb{R}^n)$).

Euclidean space E_n

In the preceding context, a single Cartesian coordinate system suffices to cover all of $\mathbb{R}^n$, so $\{(\mathrm{id}_{\mathbb{R}^n}, \mathbb{R}^n)\}$ defines an n-dimensional atlas and, trivially, a differentiable structure. We conclude that $\mathbb{R}^n$ is an n-dimensional differentiable manifold, which we denote E_n and call *Euclidean space* (or the Euclidean manifold); we also say that spaces of this type possess a *Euclidean geometry*. The fact that a single coordinate system describes the whole Euclidean space leads us to consider describing a manifold, such as a curve or a two-dimensional surface, as a submanifold of E_n.

We say that the *origin* of E_n is the point $O = \mathrm{id}_{\mathbb{R}^n}(0, \ldots, 0)$ (with respect to the coordinate system $(\mathrm{id}_{\mathbb{R}^n}, \mathbb{R}^n)$); therefore $x^i(O) = 0$ for all i.

Pictorial representation

We represent pictorially a Cartesian coordinate system and a point $P = \mathrm{id}_{\mathbb{R}^n}(x) \in E_n$ of coordinates $x^i(P)$ as a diagram of perpendicular axes[2]. For the case $n = 2$ it has been historically common to denote the coordinates of a generic point, x^i, as (x, y):

where E_2 is called *flat two-dimensional space*. For the case $n = 3$ it has been historically common to denote the coordinates of a generic point, x^i, as (x, y, z):

where E_3 receives the name *flat three-dimensional space*.

[2]That the axes are perpendicular has a mathematical background studied further below. This representation is due to René Descartes.

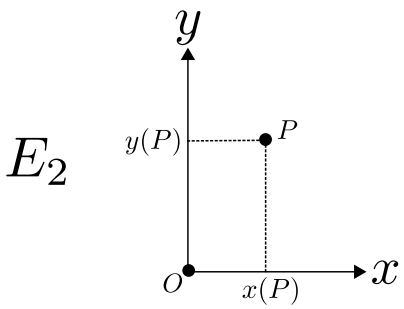

Figure 13.8: The plane E_2 with perpendicular Cartesian axes (x, y).

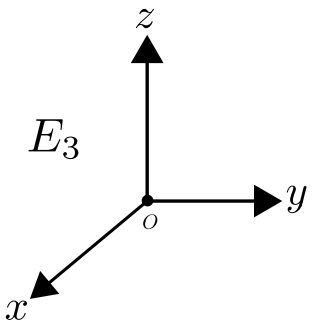

Figure 13.9: The space E_3 with Cartesian axes (x, y, z).

For the case $n = 2$, the Euclidean space E_2 works very well for describing plane geometric figures, for example a square: given a square in the plane, we can specify each of its points by its coordinates. The same occurs with solid geometric figures in the space E_3.

Vectors in E_n

Definition 13.69 (Vector in E_n)**.** Let $P, Q \in E_n$ be two points. We define a *vector* in E_n[3] as a straight-line segment joining P to Q, endowed with the orientation from P towards Q; we symbolise it $\overrightarrow{PQ}$ and represent it pictorially as an arrow pointing from P to Q.

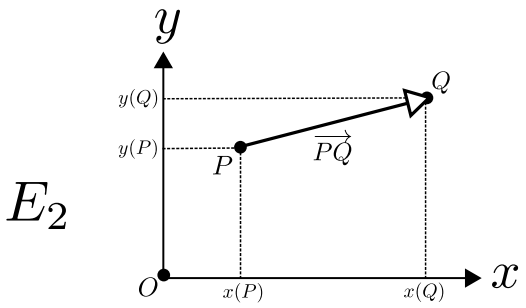

Figure 13.10: A vector in E_n: an oriented straight-line segment $\overrightarrow{PQ}$.

Definition 13.70 (Position vector)**.** We define the *position vector* of a point P with respect to the origin O as the vector $\overrightarrow{OP}$. We introduce the notation $\overrightarrow{OP} \overset{\text{not.}}{=} \boldsymbol{x}_P$.

To refer to the position vector of arbitrary points of E_n we make no reference to the point, denoting it simply $\boldsymbol{x}$. The position vector of the origin is denoted $\mathbf{0}$.

[3] A vector in E_n must not be confused with a vector in the context of vector spaces.

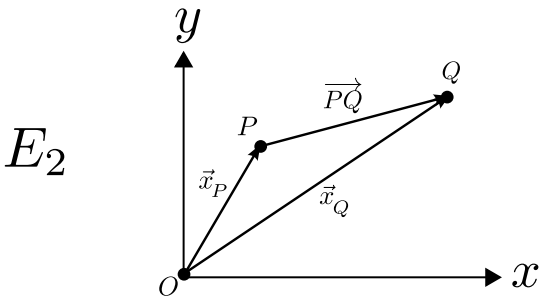

Figure 13.11: The position vector $\boldsymbol{x}_P = \overrightarrow{OP}$ of a point P with respect to the origin O.

Cartesian coordinates as components of the position vector

The fact that a single coordinate system describes the whole Euclidean space provides us with the bijective maps $\boldsymbol{x} : P \longmapsto \boldsymbol{x}_P$ and $x^i : P \longmapsto x^i(P)$; that is, the map assigning to each point of E_n its position vector (with respect to O), and the map assigning to each point of E_n its coordinates. A point of E_n is determined by its position vector or by its Cartesian coordinates, so we may establish a relation between the two concepts.

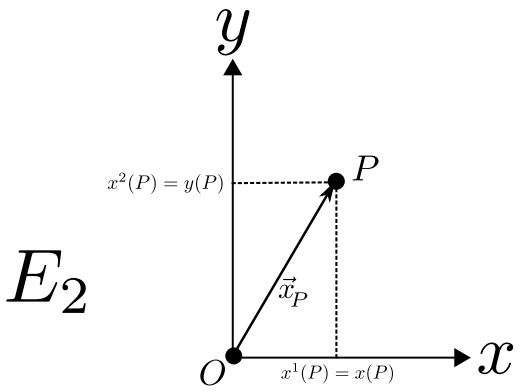

Figure 13.12: The Cartesian coordinates of P are the components of its position vector: $(\boldsymbol{x}_P)^i = x^i(P)$.

We say that the *Cartesian components* of the position vector of a point P with respect to O are the Cartesian coordinates of P (with respect to the coordinate system $(\mathrm{id}_{\mathbb{R}^n}, \mathbb{R}^n)$), which we symbolise as

$$(\boldsymbol{x}_P)^i = x^i(P)\,, \quad i = 1, \ldots, n \tag{13.158}$$

(for a generic point we write $(\boldsymbol{x})^i = x^i$). Note that this relation is one-to-one: given a coordinate system and an origin, the components of the position vector of a point are unique. With respect to the maps just mentioned we have, moreover, $O \longmapsto \mathbf{0}$ and $O \longmapsto (0, \ldots, 0)$ respectively. In this sense, giving a coordinate system amounts to giving an origin (and vice versa) with respect to which we can locate points in E_n.

E_n as a vector space

As we know, the set of all points of $\mathbb{R}^n$ forms an n-dimensional vector space. Moreover, each of these points gives the Cartesian components of the position vector of the corresponding point of Euclidean space E_n. We may therefore picture the vector space $\mathbb{R}^n$ as follows:

Since the relation between the position vector of P (with respect to a given origin) and the coordinates of P (with respect to a given coordinate system) is one-to-one, from now on, given a Cartesian coordinate system (and hence an origin), we refer to the points of E_n by

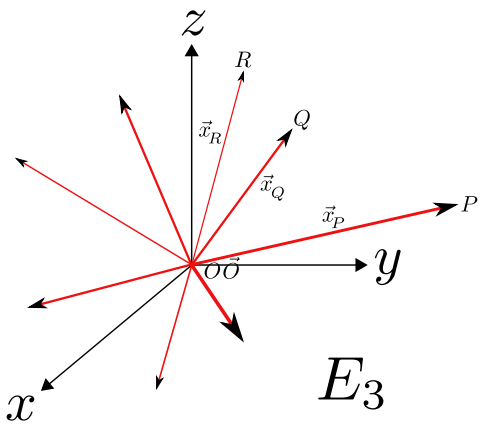

Figure 13.13: $\mathbb{R}^n$ pictured as the space of position vectors of E_n: each point doubles as the arrow from the origin to it.

means of position vectors. This is only a notation to make the equations more transparent. Since we can now conceive the manifold E_n as a vector space — that is, position vectors as vectors of a vector space — we can define the *Euclidean (or standard) inner product* on E_n as

$$\boldsymbol{x}_P \cdot \boldsymbol{x}_Q = \sum_{i=1}^{n} x^i(P)\, x^i(Q)\,, \tag{13.159}$$

which clearly satisfies the axioms of an inner product. We further define the *Euclidean (or standard) norm* of E_n as the norm associated with the Euclidean inner product,

$$|\boldsymbol{x}_P| = \sqrt{\boldsymbol{x}_P \cdot \boldsymbol{x}_P}\,, \tag{13.160}$$

and, lastly, the *Euclidean (or standard) metric* of E_n as the metric associated with the Euclidean norm,

$$d\,(\boldsymbol{x}_P, \boldsymbol{x}_Q) = |\boldsymbol{x}_P - \boldsymbol{x}_Q|\ . \tag{13.161}$$

Displacements

Consider two points P and Q in Euclidean space, with position vectors $\boldsymbol{x}_P$ and $\boldsymbol{x}_Q$ with respect to a given origin. In this context it is common to symbolise the vector $\overrightarrow{PQ}$ as

$$\overrightarrow{PQ} \overset{\text{not.}}{=} \delta\boldsymbol{x}_{PQ}\,, \tag{13.162}$$

or, for two arbitrary points, simply as $\delta\boldsymbol{x}$, which is called the *displacement vector*. It serves to denote the change of position between two points.

In the preceding context, one then analyses the case in which the Euclidean distance between these points is infinitesimally small.

13.4.3 Curves in Euclidean space

Differentiable curves

Definition 13.71 (Differentiable curve)**.** We say that a *differentiable curve*[4] is a one-dimensional differentiable submanifold of E_n, which we denote $\mathcal{C}$.

Rests on Definition 13.48.

[4]More general, topologically founded definitions of a curve exist; they will not be needed in our studies.

We therefore need only one coordinate to describe a curve locally — we say locally because in general more than one coordinate system is needed to describe it globally, though each of them involves a single coordinate. Thus the possible coordinate systems needed to describe the curve are of the form

$$(\gamma,]a,b[\,)\,, \quad \text{where} \quad \begin{array}{rccl} \gamma: &]a,b[& \longrightarrow & \mathcal{C}\subset E_n \\ & \lambda & \longmapsto & P=\gamma(\lambda)\,. \end{array} \tag{13.163}$$

The variable λ is a coordinate associated with the coordinate system $(\gamma,]a,b[\,)$, and $\gamma(\lambda_P)$, with $\lambda_P \in]a,b[$, is a point of the curve. For a generic point of the curve we may identify $\gamma(\lambda)$ with its position vector $\boldsymbol{x}_{\gamma(\lambda)}$. The components of the position vector are therefore the quantities

$$\left(\boldsymbol{x}_{\gamma(\lambda)}\right)^i = x^i(\gamma(\lambda))\,, \tag{13.164}$$

which are the (Cartesian, since the curve lives in E_n) coordinates of the point $\gamma(\lambda) \in \mathcal{C} \subset E_n$. The coordinate λ parametrises the curve: for each value of $\lambda \in \mathbb{R}$ we have a position vector $\boldsymbol{x} = \boldsymbol{x}(\lambda)$ characterising a point of the curve.

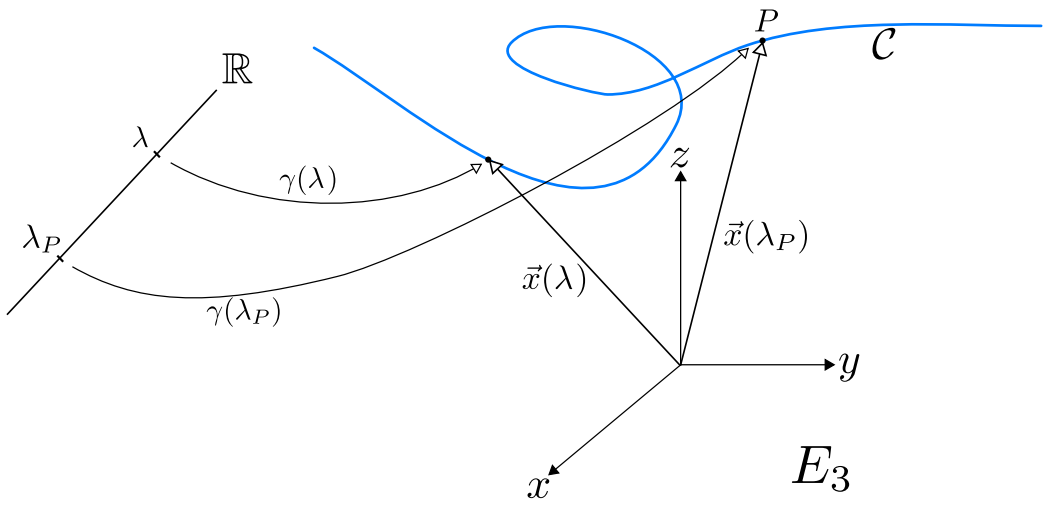

Figure 13.14: A curve in E_n described by a single chart $(\gamma,]a,b[\,)$: the coordinate λ labels the points $\gamma(\lambda)$, whose position vectors are $\boldsymbol{x}(\lambda)$.

It is necessary to clarify the difference between the two statements: λ is the coordinate of the point $\gamma(\lambda) \in \mathcal{C}$, while the $x^i(\gamma(\lambda))$ are the Cartesian coordinates of the point $\gamma(\lambda) \in E_n$. Now, as mentioned before, in general it is not possible to describe a curve completely with a single coordinate system (we need an atlas). The problem of needing more than one coordinate system is not transcendental for calculations (though it does bring topological consequences to be studied in theoretical physics). Let us illustrate with a well-known and much-cited example: the circle of radius R as a hypersurface of E_2, $S_1 = \{(x,y) \in \mathbb{R}^2 \mid x^2+y^2 = R^2\}$. We wish to describe by coordinate systems all points of E_2 satisfying $x^2+y^2=R^2$. A possible candidate is $(\gamma,]0, 2\pi[\,)$, where

$$\begin{array}{rccl} \gamma: &]0,2\pi[& \longrightarrow & \mathcal{C} \\ & \phi & \longmapsto & \gamma(\phi)\,, \end{array}$$

with the Cartesian coordinates of $\gamma(\phi)$ given by

$$x^i(\gamma(\phi)) = (R\cos\phi, R\sin\phi)\ . \tag{13.165}$$

This coordinate system describes almost all of the desired region — almost, because the point $(R,0)$ is not included. If we put the interval $[0,2\pi[$ or $]0,2\pi]$ in the domain of γ we

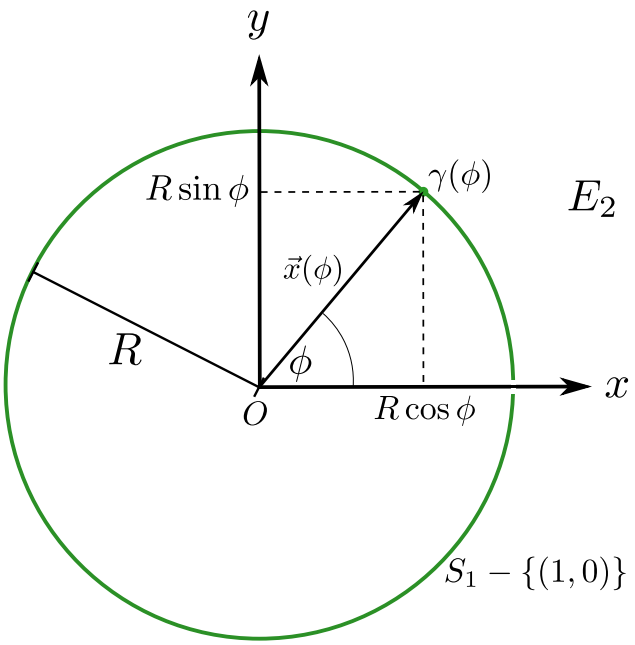

Figure 13.15: The circle $S_1 \subset E_2$ described by the angular chart $\phi \mapsto (R\cos\phi, R\sin\phi)$ on $]0, 2\pi[$; the point $(R, 0)$ escapes this single chart.

would include the point, but in the definition of a differentiable manifold we worked only with open domains, to make sure we respect the topology (the maps of a coordinate system must be homeomorphisms). We could contemplate an interval $]0, 2\pi + \delta[$ so as to include the mentioned point, but then the map γ would no longer be bijective, which as we know is a crucial property of γ as a homeomorphism, meant to preserve the topology. How can we fix this problem? Is there a coordinate system that describes all the points of the circle? The answer is no, and as we shall see this is related to the fact that the circle is a compact subset of E_2. If a single coordinate system (γ, I) described every point of the circle, the homeomorphism $\gamma : I \longrightarrow S_1$ would force I to be compact — a contradiction, since I must necessarily be open.

We define the coordinate systems $(\gamma_1,]-\delta, \pi + \delta[\,)$ and $(\gamma_2,]\pi - \delta, 2\pi + \delta[\,)$ with

$$\begin{array}{rccc} \gamma_1 : &]-\delta, \pi+\delta[& \longrightarrow & E_2 \\ & \phi & \longmapsto & \gamma_1(\phi)\,, \end{array} \qquad \begin{array}{rccc} \gamma_2 : &]\pi-\delta, 2\pi+\delta[& \longrightarrow & E_2 \\ & \phi & \longmapsto & \gamma_2(\phi)\,, \end{array}$$

where $x^i(\gamma_1(\phi)) = (R\cos\phi, R\sin\phi)$ with ϕ varying in $]-\delta, \pi + \delta[$, and $x^i(\gamma_2(\phi)) = (R\cos\phi, R\sin\phi)$ with ϕ varying in $]\pi - \delta, 2\pi + \delta[$. We mention that we have used the same variable ϕ for both coordinate systems because it is a dummy variable and there is no ambiguity (it merely happens that in both coordinate systems the curve behaves locally in the same way). The two coordinate systems cover the whole circle. Thus $\{(\gamma_1,]-\delta, \pi + \delta[\,), (\gamma_2,]\pi - \delta, 2\pi + \delta[\,)\}$ defines an atlas on S_1, which clearly possesses a one-dimensional differentiable structure. This means that S_1 is a hypersurface of E_2.

An example of a non-compact curve that can be described by a single coordinate system is the straight-line segment between two points $P, Q \in E_n$, denoted L_{PQ}. The straight line joining the two points is completely described by the coordinate system $(\gamma,]0, 1[\,)$ with

$$\begin{array}{rccc} \gamma : &]0,1[& \longrightarrow & E_n \\ & \lambda & \longmapsto & \gamma(\lambda)\,, \end{array}$$

where $x^i(\gamma(\lambda)) = (1 - \lambda)x^i(P) + \lambda x^i(Q)$ with λ varying in $]0, 1[$. Visually, the curve "grows" from P to Q as λ grows in $]0, 1[$. Note further that $x^i(\gamma(\lambda \to 0)) = x^i(P)$ and $x^i(\gamma(\lambda \to 1)) = x^i(Q)$.

Remark 13.72. In the example of the circle of radius R we used for both coordinate systems the same parametrisation of the points of the curve, $(R\cos\phi, R\sin\phi)$; this does not mean we are describing the curve locally with only one coordinate system — it only means that the circle behaves locally in the same way in both coordinate systems, which is why we used the same variable. On the other hand, whenever we describe a curve locally from a Euclidean space by means of a coordinate system $(\gamma,]a,b[\,)$, we shall refer to the curve simply as the map $x^i = x^i(\lambda)$, unless it is necessary to make explicit the interval over which λ varies together with the homeomorphism of that coordinate system. In this case, unlike for the circle, we give a parameter to specify that we are describing the curve locally. The stated notation is warranted by the fact that the coordinates of E_n used to describe the curve depend solely on the coordinate used to describe the curve locally.

Admissible change of parameter

Given a curve $\mathcal{C}$, described by $\boldsymbol{x} = \boldsymbol{x}(\lambda)$, we can perform coordinate changes in our coordinate systems of the form seen in Equation (13.163). A general coordinate transformation may take the form $\bar\lambda = \bar\lambda(\lambda)$, and, as we know, the map

$$\begin{array}{rccc} \bar\lambda: &]a,b[& \longrightarrow &]c,d[\\ & \lambda & \longmapsto & \bar\lambda(\lambda) \end{array}$$

must be a smooth function of λ to guarantee that we possess a differentiable structure. The new coordinate system is then of the form $(\bar\gamma,]c,d[\,)$ where

$$\begin{array}{rccc} \bar\gamma: &]c,d[& \longrightarrow & \mathcal{C} \\ & \bar\lambda & \longmapsto & \bar\gamma(\bar\lambda)\,, \end{array}$$

with $\bar\gamma = \gamma \circ \bar\lambda$.

Definition 13.73 (Admissible change of parameter)**.** In the context of the theory of curves, we call the coordinate transformation $\bar\lambda = \bar\lambda(\lambda)$ an *admissible change of parameter* if and only if

1. $\bar\lambda$ is a function of class C^1 $(]a,b[)$, so as to guarantee the differentiable structure;
2. $\forall\,\lambda \in]a,b[$, $\frac{\mathrm{d}\bar\lambda}{\mathrm{d}\lambda}(\lambda) \neq 0$. This ensures the function has no extrema in $]a,b[$, hence possesses an inverse on the given interval, so that $\lambda = \lambda(\bar\lambda)$ is also a coordinate transformation.

It is important to point out that an admissible change of parameter (a general coordinate transformation of the single coordinate describing the curve locally) must not be confused with a general coordinate transformation of the Euclidean space in which the curve is embedded. There is, however, no problem in performing a general coordinate transformation of the Euclidean space in order to describe the curve. As an example of an admissible change of parameter, let the straight-line curve L_{PQ} with $P, Q \in E_2$ be described by

$$x^i(\lambda) = (1-\lambda)x^i(P) + \lambda x^i(Q) = ((1-\lambda)x(P) + \lambda x(Q),\, (1-\lambda)y(P) + \lambda y(Q))\,,$$

with λ varying in $]0,1[$. We may perform the change of parameter $\bar\lambda(\lambda) = 1-\lambda$, which is clearly admissible, with $\bar\lambda$ still varying in $]0,1[$. The straight line is now described by

$$x^i(\bar\lambda) = \bar\lambda x^i(P) + (1-\bar\lambda)x^i(Q) = (1-\bar\lambda)x^i(Q) + \bar\lambda x^i(P)\,.$$

Visually, this change of parameter makes the curve "grow" from Q to P instead.

Tangent vector

Consider a differentiable curve in E_n described locally by $x^i = x^i(\lambda)$, $i = 1, \dots, n$, with respect to $(\gamma,]a, b[\,)$, or equivalently with respect to the basis $\{\hat{x}_i\}$ of E_n as a vector space. We define the *tangent vector* to the curve at the point $P = \gamma(\lambda_P)$ as the vector

$$\boldsymbol{V}_P = \left.\frac{\mathrm{d}x^i}{\mathrm{d}\lambda}\right|_{\lambda=\lambda_P} \hat{x}_i \,, \tag{13.166}$$

that is, as the variation of the coordinates of the curve as the parameter varies.

Arc element and length of a curve

Section 13.3.1 built the theory of curves *extrinsically*: the curve was a map into $\mathbb{R}^3$, and its tangent, normal and binormal were vectors of the ambient Euclidean space, differentiated componentwise. The same content can be stated using nothing but the metric of the space the curve lives in and the covariant derivative it determines — the *intrinsic* formulation, which is the one that survives when the ambient space is removed. Throughout this stretch (M, g) is a Riemannian manifold of dimension D (Definition 13.117 with $q = 0$), with coordinates x^μ and Levi-Civita connection $\mathring{\Gamma}$ (Theorem 13.150); the reader who prefers a concrete setting may read $M = E_3$ in arbitrary curvilinear coordinates, in which case $g_{\mu\nu}$ is the Euclidean metric written in those coordinates.

The *arc element* is the line element Equation (13.259) of the displacement along the curve,

$$\mathrm{d}s^2 = g_{\mu\nu}\, \mathrm{d}x^\mu \mathrm{d}x^\nu \,, \tag{13.167}$$

which for a surface in E_3 is exactly the first fundamental form Equation (13.61), the metric g_{ij} there being the induced metric Equation (13.261).

Definition 13.74 (Length of a curve)**.** Let $x^\mu(\lambda)$, $\lambda \in]a, b[$, be a differentiable curve in (M, g). Its *length* is

$$L = \int_a^b \sqrt{g_{\mu\nu} \frac{\mathrm{d}x^\mu}{\mathrm{d}\lambda} \frac{\mathrm{d}x^\nu}{\mathrm{d}\lambda}}\; \mathrm{d}\lambda = \int_a^b \left\| \frac{\mathrm{d}x}{\mathrm{d}\lambda} \right\| \mathrm{d}\lambda \,, \tag{13.168}$$

the integrand being the metric norm of the tangent vector Equation (13.177). The curve is *regular* if that norm never vanishes.

Rests on Definitions 13.81, 13.117 and 13.118.

Proposition 13.75 (Invariance of the length)**.** *The length Equation (13.168) is unchanged by a general coordinate transformation of M and by an admissible change of parameter (Definition 13.73).*

Rests on Definitions 13.73, 13.74 and 13.88.

Proof. *Derives Proposition 13.75.*

Under a general coordinate transformation the integrand is a scalar: it is built by contracting $g_{\mu\nu}$, a $(0,2)$ tensor (Definition 13.117), with two copies of the contravariant vector $\mathrm{d}x^\mu/\mathrm{d}\lambda$ (Equation (13.199)), and the Jacobians cancel in pairs exactly as in Equation (13.206). Under a change of parameter $\lambda = \lambda(\bar{\lambda})$ the chain rule gives $\mathrm{d}x^\mu/\mathrm{d}\bar{\lambda} = (\mathrm{d}\lambda/\mathrm{d}\bar{\lambda})\, \mathrm{d}x^\mu/\mathrm{d}\lambda$, so the integrand is multiplied by $\left|\mathrm{d}\lambda/\mathrm{d}\bar{\lambda}\right|$, which is exactly the factor produced by $\mathrm{d}\lambda = (\mathrm{d}\lambda/\mathrm{d}\bar{\lambda})\mathrm{d}\bar{\lambda}$ in the measure, the derivative having a fixed sign by Definition 13.73. □

Definition 13.76 (Arclength parametrisation)**.** For a regular curve, the function

$$s(\lambda) = \int_a^\lambda \sqrt{g_{\mu\nu} \frac{\mathrm{d}x^\mu}{\mathrm{d}\lambda'} \frac{\mathrm{d}x^\nu}{\mathrm{d}\lambda'}}\; \mathrm{d}\lambda' \tag{13.169}$$

has $\mathrm{d}s/\mathrm{d}\lambda > 0$ everywhere and is therefore an admissible change of parameter. In the parameter s the tangent $u^\mu = \mathrm{d}x^\mu/\mathrm{d}s$ is a *unit* vector,

$$g_{\mu\nu} u^\mu u^\nu = 1 \,, \tag{13.170}$$

and we call s the *arclength parameter* and u^μ the *unit tangent*, the intrinsic counterpart of Definition 13.12.

Rests on Definitions 13.73 and 13.74.

Curvature vector, binormal, and torsion

Definition 13.77 (Curvature vector)**.** The *curvature vector* of a curve parametrised by arclength is the covariant derivative of its unit tangent along itself,

$$k^\mu = \frac{\mathrm{D}u^\mu}{\mathrm{d}s} \equiv u^\nu \mathring{\nabla}_\nu u^\mu = \frac{\mathrm{d}^2 x^\mu}{\mathrm{d}s^2} + \mathring{\Gamma}^\mu{}_{\nu\rho} \frac{\mathrm{d}x^\nu}{\mathrm{d}s} \frac{\mathrm{d}x^\rho}{\mathrm{d}s} \,, \tag{13.171}$$

and the *curvature function* is $\kappa = \sqrt{g_{\mu\nu} k^\mu k^\nu}$.

Rests on Definitions 13.76 and 13.145 and Theorem 13.150.

In E_3 referred to Cartesian coordinates the Christoffel symbols vanish and Equation (13.171) collapses to $\mathrm{d}^2\boldsymbol{x}/\mathrm{d}s^2$, which is the extrinsic curvature vector Equation (13.39); comparison with Equations (13.121) and (13.297) shows that the curves with $k^\mu = 0$ are precisely the geodesics.

Proposition 13.78 (The curvature vector is orthogonal to the tangent)**.** $g_{\mu\nu} u^\mu k^\nu = 0$.

Rests on Definitions 13.77 and 13.149 and Equation (13.170).

Proof. *Derives Proposition 13.78.*

Differentiate Equation (13.170) along the curve. The Levi-Civita connection is metric compatible (Definition 13.149), so $\mathring{\nabla}_\lambda g_{\mu\nu} = 0$ and

$$0 = \frac{\mathrm{D}}{\mathrm{d}s} \left(g_{\mu\nu} u^\mu u^\nu \right) = 2\, g_{\mu\nu} u^\mu \frac{\mathrm{D}u^\nu}{\mathrm{d}s} = 2\, g_{\mu\nu} u^\mu k^\nu \,.$$

This is the intrinsic form of Equation (13.40), the ambient differentiation there being replaced by covariant differentiation here. □

Where $\kappa > 0$ we may therefore define the *unit principal normal* $N^\mu = k^\mu/\kappa$, orthogonal to u^μ, in parallel with Definition 13.14. For $D = 3$ — the case treated extrinsically in Section 13.3.1, and the observed spatial dimension — the orthogonal complement of $\langle\{u, N\}\rangle$ in each tangent space is one-dimensional, and we fix the *unit binormal* B^μ as the unique unit vector completing (u, N, B) to a positively oriented orthonormal frame; equivalently, with the Levi-Civita tensor Equation (13.257),

$$B^\mu = g^{\mu\sigma}\, \eta_{\sigma\nu\rho}\, u^\nu N^\rho \,, \tag{13.172}$$

which reduces to the cross product Equation (13.44) in Cartesian coordinates.

Theorem 13.79 (Frenet–Serret equations, covariant form)**.** *Let $D = 3$ and let a curve in (M, g) be parametrised by arclength with $\kappa > 0$. Then there is a function τ, the* torsion*, such that the frame (u, N, B) obeys*

$$\frac{\mathrm{D}u^\mu}{\mathrm{d}s} = \kappa\, N^\mu \,, \tag{13.173}$$

$$\frac{\mathrm{D}N^\mu}{\mathrm{d}s} = \tau\, B^\mu - \kappa\, u^\mu \,, \tag{13.174}$$

$$\frac{\mathrm{D}B^\mu}{\mathrm{d}s} = -\tau\, N^\mu \,. \tag{13.175}$$

In E_3 referred to Cartesian coordinates these are Equations (13.43), (13.46) and (13.47).

Rests on Proposition 13.78, Definition 13.149, and Equation (13.172).

Proof. *Derives Theorem 13.79.*

Write $e_1 = u$, $e_2 = N$, $e_3 = B$ and label the frame with capital indices $A, C \in \{1, 2, 3\}$, so that $g_{\mu\nu} e^\mu_A e^\nu_C = \delta_{AC}$ along the whole curve. Expand the covariant derivative of each frame vector in the frame itself, which is legitimate because the frame is a basis of the tangent space at each point of the curve:

$$\frac{\mathrm{D}e^\mu_C}{\mathrm{d}s} = \omega_{AC}\, e^\mu_A\,, \qquad \omega_{AC} = g_{\mu\nu}\, e^\mu_A\, \frac{\mathrm{D}e^\nu_C}{\mathrm{d}s}\,. \tag{13.176}$$

Differentiating $g_{\mu\nu} e^\mu_A e^\nu_C = \delta_{AC}$ along the curve and using metric compatibility (Definition 13.149) gives $\omega_{AC} + \omega_{CA} = 0$: the matrix ω is antisymmetric, so it has exactly three independent entries. They are fixed one by one. By Definition 13.77 and the definition of N, $\mathrm{D}u^\mu/\mathrm{d}s = \kappa N^\mu$, which is Equation (13.173) and reads $\omega_{21} = \kappa$, $\omega_{11} = \omega_{31} = 0$. Antisymmetry then gives $\omega_{12} = -\kappa$ and $\omega_{13} = 0$. The single entry left undetermined is ω_{32}, which we *define* to be the torsion τ; antisymmetry gives $\omega_{23} = -\tau$. Substituting into Equation (13.176) for $C = 2$ and $C = 3$ yields Equations (13.174) and (13.175). In Cartesian coordinates on E_3 the Christoffel symbols vanish, $\mathrm{D}/\mathrm{d}s$ becomes $\mathrm{d}/\mathrm{d}s$, and the three equations are those obtained extrinsically in Section 13.3.1. □

Remark 13.80. The proof above is shorter than the extrinsic one of Section 13.3.1 because it uses no property of the ambient space: the antisymmetry of ω is metric compatibility and nothing else, and it is what makes the coefficient matrix of the Frenet–Serret system antisymmetric in *any* Riemannian manifold. The same argument in dimension D produces $D-1$ curvature functions and a frame of D vectors. What does *not* carry over unchanged is the fundamental theorem of the theory of curves — Theorem 13.16, that κ and τ determine the curve up to a rigid motion — proved in Section 13.3.1 for E_3. On a general Riemannian manifold prescribed κ and τ still determine the curve uniquely once an initial point and an initial orthonormal frame are fixed, and for as far as the solution extends: the three Frenet equations above, together with $\mathrm{d}x^\mu/\mathrm{d}s = u^\mu$, are a first-order system in which the frame enters linearly. Uniqueness *up to isometry* is a stronger statement, and it needs the isometries of Section 13.7.1 to act transitively on orthonormal frames, so that two solutions with different initial data can be carried onto one another. That is a genuine hypothesis and not a technicality: a generic metric admits no isometry but the identity, and then two curves with the same κ and τ started at different points are simply two different curves. Enough isometries are available exactly on the maximally symmetric spaces of Theorem 13.160, whose curvature is constant, E_3 being the case $\epsilon = 0$.

13.5 Tensor analysis on manifolds

13.5.1 Vectors, covectors, and tensors on a manifold

The definition of a vector on a manifold

The definition of a vector in $\mathbb{R}^N$ is an oriented straight-line segment joining two points. This tells us that a vector as we know it is a *bilocal* object. Would this definition remain consistent if the space no longer had Euclidean geometry — that is, on a general manifold? Consider an n-dimensional manifold $M \subset \mathbb{R}^N$. The Euclidean metric of $\mathbb{R}^N$ allows us to define straight lines joining points on the manifold, but such straight lines are clearly not contained in M.

Along which route, then, should the line between A and B be traced? There is no possible route unless we define beforehand a metric on the space M_n, for without this concept we cannot have a concept of straight line. For this reason we cannot define a vector on the manifold as a bilocal object: we must develop a formalism to understand a vector as a *local* object.

Let $(\gamma,]a, b[\,)$ be a coordinate system describing a curve contained in M. The curve is characterised by the position vectors $\boldsymbol{x}_{\gamma(\lambda)}$ with λ varying in $]a, b[$. Denote by λ_0 the value of the parameter at which the point of the curve is $P = \gamma(\lambda_0) \in M$.

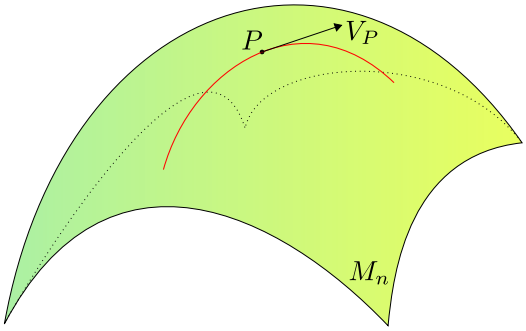

Figure 13.16: A curve through $P = \gamma(\lambda_0)$ on a manifold M: its tangent vector at P does not lie in M but in a tangent plane touching M at P.

We say that the vector $V_P \in \mathbb{R}^N$ is a *tangent vector* to M at P if and only if it is tangent to the curve at P, that is, if its components with respect to the coordinate system $(\gamma,]a, b[\,)$ are

$$V^i(P) = \left.\frac{\mathrm{d}x^i}{\mathrm{d}\lambda}\right|_{\lambda_0} . \tag{13.177}$$

The tangent vector V_P must not be viewed as a displacement lying in M, but as lying in some kind of tangent surface coinciding with M at P. Since M is equipped with an atlas, we can define a differentiable map of the form $f : M \longrightarrow \mathbb{R}$. Then $f \circ x : \mathbb{R} \longrightarrow \mathbb{R}$ is differentiable, being a composition of differentiable maps, and

$$\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}(f \circ x)\right|_{\lambda_0} = \lim_{\lambda \to \lambda_0} \frac{f(x(\lambda)) - f(x(\lambda_0))}{\lambda - \lambda_0} . \tag{13.178}$$

But which map f do we choose? It does not matter. What matters is to see how the curve generates changes in f. Indeed, $f \circ x : \mathbb{R} \longrightarrow \mathbb{R}$ allows us to evaluate the changes in f; these changes are given by the directional derivative (Equation (13.178)) in the direction of the curve, that is, in the direction of the vector V_P.

We may conclude that the operator generating the changes of f in the direction of V_P is $\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda_0}$. By the chain rule and Equation (13.177),

$$\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda_0} = V_P^i \, \partial_i \, .$$

Therefore $\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda_0}$ can be written as a linear combination of the basis $\{\partial_i\}$, with components exactly V_P^i.

Definition 13.81 (Vector on a manifold)**.** We define a *vector* on M_n at P as the operator

$$V_P = V^i(P) \, \frac{\partial}{\partial x^i(P)} = \left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda_0} . \tag{13.179}$$

Rests on Definitions 13.45, 13.48 and 13.71.

Definition 13.82 (Vector field)**.** We say that a *vector field* is an assignment rule that associates a vector with each point of a manifold.

Rests on Definition 13.81.

We must then symbolise a vector field without reference to the point of the manifold, since we are considering all of them. In the context of the definition of a vector, we symbolise a vector field V as

$$V = V^i \partial_i = \frac{\mathrm{d}}{\mathrm{d}\lambda} \,. \tag{13.180}$$

When no reference to the point is made, it is understood that we are speaking of a field.

Tangent space and coordinate basis

Owing to the linearity of the derivative, and since it has the properties of addition and multiplication by a scalar, the set of all vectors tangent to M at P forms an n-dimensional vector space, which we call the *tangent space* and denote $T_M(P)$ (for an arbitrary point, T_M). This may seem inconceivable, but so it is: at each point of the manifold we can define a vector space.

As discussed in the definition of a vector on a manifold, we can write a vector V on M as a linear combination of the vectors ∂_i,

$$V = V^i \partial_i \,. \tag{13.181}$$

This means that the set $\{\partial_i\}_{i=1}^n$ forms a basis of the tangent space, which we call the *coordinate (or holonomic) basis*. We therefore have

$$T_M = \langle \{\partial_i\} \rangle \,, \quad i = 1, \ldots, n \,. \tag{13.182}$$

The vectors of the coordinate basis are tangent to the coordinate lines.

For example, the coordinate-basis vectors of E_2 in Cartesian coordinates are ∂_x and ∂_y, while in polar coordinates they are ∂_r and ∂_ϕ. The relation between the Cartesian and polar coordinates describing E_2 is

$$x = r\cos\phi \,, \quad y = r\sin\phi \,,$$

so that

$$\begin{aligned} \partial_r &= \frac{\partial x}{\partial r}\frac{\partial}{\partial x} + \frac{\partial y}{\partial r}\frac{\partial}{\partial y} \\ &= \cos\phi \, \frac{\partial}{\partial x} + \sin\phi \, \frac{\partial}{\partial y} \,, \end{aligned}$$

and likewise

$$\begin{aligned} \partial_\phi &= \frac{\partial x}{\partial \phi}\frac{\partial}{\partial x} + \frac{\partial y}{\partial \phi}\frac{\partial}{\partial y} \\ &= -r\sin\phi \, \frac{\partial}{\partial x} + r\cos\phi \, \frac{\partial}{\partial y} \,, \end{aligned}$$

whence

$$\partial_r = \cos\phi \, \partial_x + \sin\phi \, \partial_y \,, \qquad \partial_\phi = -r\sin\phi \, \partial_x + r\cos\phi \, \partial_y \,. \tag{13.183}$$

Covectors and the cotangent space

Definition 13.83 (Covector)**.** Let $P \in M$. We define a *covector* at P as a linear functional

$$\begin{array}{rccc} \psi_P : & T_M(P) & \longrightarrow & \mathbb{R} \\ & V_P & \longmapsto & \psi_P(V_P) \,. \end{array}$$

Rests on Definition 13.81.

From the theory of vector spaces we know that the set of all linear functionals defined on a vector space forms a vector space, called the dual. Thus the set of all covectors defined at a point $P \in M$ forms the vector space

$$\mathcal{L}\left(T_M(P), \mathbb{R}\right) = T_M^*(P)\,, \tag{13.184}$$

which we call the *cotangent space* at P. As shown below (Equation (13.239)), the differentials $\mathrm{d}x^i$ furnish the basis dual to the coordinate basis, so that

$$T_M^*(P) = \left\langle \left\{ \mathrm{d}x^i \right\} \right\rangle\,, \quad i = 1, \ldots, n\,. \tag{13.185}$$

Tensors

Definition 13.84 (Tensor)**.** Let $P \in M$, and consider $T_M(P) = \langle\{e_i\}\rangle$ and $T_M^*(P) = \langle\{\omega^i\}\rangle$. We define a *tensor* of type (r, s) at P as a multilinear map

$$T : \underbrace{T_M^*(P) \times \cdots \times T_M^*(P)}_{r \text{ times}} \times \underbrace{T_M(P) \times \cdots \times T_M(P)}_{s \text{ times}} \longrightarrow \mathbb{R}\,,$$

whose components are its values on the basis elements,

$$T\left(\omega^{i_1}, \ldots, \omega^{i_r}, e_{j_1}, \ldots, e_{j_s}\right) = T^{i_1 \ldots i_r}{}_{j_1 \ldots j_s}\,.$$

Rests on Definitions 13.81 and 13.83.

We say that a tensor is *contravariant* if it is of type $(r, 0)$ with $r \in \mathbb{N}$, and *covariant* if it is of type $(0, s)$ with $s \in \mathbb{N}$. For example, a vector is a contravariant tensor of type $(1, 0)$ and a covector is a covariant tensor of type $(0, 1)$.

Pullback and pushforward

If we wished to compare two vectors assigned at distinct points of a differentiable manifold, we could not simply subtract them, since they belong to different vector spaces. We must provide a mechanism that maps one of the vectors into the space of the vector with which we wish to compare it.

Consider a diffeomorphism $f : M \longrightarrow M$. For a point P, the map f induces the *pushforward* $f_* : T_M(P) \longrightarrow T_M(f(P))$. This amounts to taking a tangent vector at P and locating it at $f(P)$.

One also has the *pullback* $f^* : T_M^*(f(P)) \longrightarrow T_M^*(P)$, which to each covector at $f(P)$, say $\omega_{f(P)}$, assigns by definition the covector $f^*(\omega_{f(P)}) = \omega_{f(P)} \circ f_*$ at P. Covectors are linear functionals acting on vectors of the tangent space: for a tangent vector V_P at P,

$$\begin{aligned}\left(f^*(\omega_{f(P)})\right)(V_P) &= \left(\omega_{f(P)} \circ f_*\right)(V_P) \\ &= \omega_{f(P)}\left(f_*(V_P)\right) \\ &= \omega_{f(P)}\left(V_{f(P)}\right)\,.\end{aligned}$$

Vector fields on basic manifolds

Example 13.85 (Euclidean space E_3)**.** The Cartesian chart of Section 13.4.2 is global, so the coordinate frame

$$\{\partial_x, \partial_y, \partial_z\} \tag{13.186}$$

consists of three vector fields defined at every point, and every vector field on E_3 is $V = V^x\partial_x + V^y\partial_y + V^z\partial_z$ with three functions as components. Spherical coordinates,

$$x = r\sin\theta\cos\phi\,, \qquad y = r\sin\theta\sin\phi\,, \qquad z = r\cos\theta\,, \tag{13.187}$$

give a second chart, and the two frames are related by the chain rule, which is the transformation law of a coordinate basis, $\bar{\partial}_i = (\partial x^j/\partial \bar{x}^i)\partial_j$:

$$\partial_r = \sin\theta\cos\phi\,\partial_x + \sin\theta\sin\phi\,\partial_y + \cos\theta\,\partial_z\,, \tag{13.188}$$

$$\partial_\theta = r\cos\theta\cos\phi\,\partial_x + r\cos\theta\sin\phi\,\partial_y - r\sin\theta\,\partial_z\,, \tag{13.189}$$

$$\partial_\phi = -r\sin\theta\sin\phi\,\partial_x + r\sin\theta\cos\phi\,\partial_y\,. \tag{13.190}$$

Two features are worth recording. First, the spherical chart is not global: it degenerates at $r = 0$ and along the polar axis $\sin\theta = 0$, where ∂_ϕ vanishes and ϕ is undefined — the same obstruction met for the circle in Section 13.4.3. Second, the spherical coordinate frame is not orthonormal: Equations (13.188) to (13.190) give $|\partial_r| = 1$, $|\partial_\theta| = r$ and $|\partial_\phi| = r\sin\theta$ in the Euclidean metric Equation (13.159). The normalized frame $\hat{e}_r = \partial_r$, $\hat{e}_\theta = \partial_\theta/r$, $\hat{e}_\phi = \partial_\phi/(r\sin\theta)$ familiar from vector calculus is therefore *not* a coordinate frame: it is an anholonomic frame, with nonvanishing structure functions in the sense of Equation (13.266), and this is the elementary origin of the vielbein of Section 13.8.

Rests on Definition 13.82 and Equation (13.199).

Example 13.86 (A curve)**.** Let $\mathcal{C}$ be a differentiable curve described locally by $(\gamma,]a, b[\,)$ as in Equation (13.163). Its tangent space at every point is one-dimensional, spanned by the single coordinate-basis vector $\mathrm{d}/\mathrm{d}\lambda$, so *every* vector field on $\mathcal{C}$ has the form

$$V = f(\lambda)\,\frac{\mathrm{d}}{\mathrm{d}\lambda}\,, \tag{13.191}$$

with one component function f. Read in the ambient E_n through Equation (13.166), the field $\mathrm{d}/\mathrm{d}\lambda$ is the tangent vector $(\mathrm{d}x^i/\mathrm{d}\lambda)\,\hat{x}_i$ of the curve. Under an admissible change of parameter (Definition 13.73) the chain rule gives $\mathrm{d}/\mathrm{d}\lambda = \left(\mathrm{d}\bar{\lambda}/\mathrm{d}\lambda\right)\mathrm{d}/\mathrm{d}\bar{\lambda}$, the one-dimensional instance of Equation (13.199). Since the coordinate field $\mathrm{d}/\mathrm{d}\lambda$ never vanishes, a curve always carries a nowhere-vanishing vector field; the next example shows that this is a privilege of low dimension and not a general fact.

Rests on Definitions 13.71 and 13.82.

Example 13.87 (The 2-sphere)**.** Let $S_2 \subset E_3$ be the sphere of radius R (Example 13.61) and consider the three rotation generators of E_3,

$$L_1 = y\,\partial_z - z\,\partial_y\,, \qquad L_2 = z\,\partial_x - x\,\partial_z\,, \qquad L_3 = x\,\partial_y - y\,\partial_x\,. \tag{13.192}$$

Each is tangent to S_2, because each annihilates the defining function $F = x^2 + y^2 + z^2$ of Equation (13.147): for instance $L_3 F = x(2y) - y(2x) = 0$. A vector that annihilates F is tangent to the level set, since F is constant along any curve inside it; hence the L_i restrict to vector fields on S_2. In the spherical chart Equation (13.187) with $r = R$ held fixed, so that (θ, ϕ) are coordinates on the sphere, comparison with Equations (13.189) and (13.190) gives

$$L_1 = -\sin\phi\,\partial_\theta - \cot\theta\cos\phi\,\partial_\phi\,, \tag{13.193}$$

$$L_2 = \cos\phi\,\partial_\theta - \cot\theta\sin\phi\,\partial_\phi\,, \tag{13.194}$$

$$L_3 = \partial_\phi\,. \tag{13.195}$$

The last is immediate from Equation (13.190), which reads $\partial_\phi = -y\,\partial_x + x\,\partial_y = L_3$; the other two follow by the same substitution. Computing the Lie brackets Equation (13.273) of the fields Equation (13.192) directly gives

$$[L_i, L_j] = -\varepsilon_{ijk} L_k\,, \tag{13.196}$$

so the three fields span a three-dimensional Lie algebra; it is isomorphic to $\mathfrak{so}(3)$, the sign being absorbed by $L_i \to -L_i$. These are the Killing vectors of the round sphere

(Section 13.9.2), and they saturate the bound $D(D+1)/2 = 3$ of Proposition 13.140 at $D = 2$: the round S_2 is maximally symmetric.

Each of the three fields vanishes somewhere: $L_3 = \partial_\phi$ vanishes at the two poles $\sin\theta = 0$, and L_1, L_2 likewise vanish at the two points of S_2 on their own axis. This is not an accident of the choice. *No continuous vector field on S_2 is nowhere vanishing* — the "hairy ball" theorem. It follows from the Poincaré index theorem, which states that on a compact orientable surface the indices of the isolated zeros of a vector field sum to the Euler characteristic of the surface [1575]; for S_2 that characteristic is 2, so the sum of the indices cannot be zero and zeros cannot be absent. Two consequences are worth naming: S_2 admits no global frame of the kind Equation (13.186) — it is not parallelizable, unlike E_n and unlike the curve of Example 13.86 — and consequently no vielbein (Section 13.8) on S_2 can be defined by a single chart-independent formula valid everywhere. Charts are not a convenience here but a necessity.

Rests on Definitions 13.81 and 13.82 and Example 13.61.

13.5.2 Tensors under general coordinate transformations

General coordinate transformations

We call a *coordinate system* K a set of functions $\{x^i\}_{i=1}^n$ such that the location of a point P is given by $x^i(P)$.

Definition 13.88 (General coordinate transformation)**.** We call *general coordinate transformation* (GCT) a transformation relating the coordinates x^i of a coordinate system K to the coordinates $\bar{x}^i$ of a coordinate system $\bar{K}$, that is, a transformation of the form

$$\bar{x}^i = \bar{x}^i(x^j)\,, \qquad x^i = x^i(\bar{x}^j)\,. \tag{13.197}$$

For practical purposes we assume that these n functions of n variables are of class C^2.

In the context of coordinate systems it is necessary to extend the definition of the *Kronecker delta* to every coordinate system: we define the *Kronecker delta symbol* as the quantities

$$\delta^i{}_j = \begin{cases} 1\,, & i = j \\ 0\,, & i \neq j \end{cases} \tag{13.198}$$

in every coordinate system.

A GCT is *linear* if and only if it can be written as $\bar{x}^i = \Lambda^i{}_j x^j$ with a constant matrix $\Lambda^i{}_j$ (compare Definition 13.2).

Transformation law of a vector

Since a vector field is the coordinate-independent object $V = V^i\partial_i$, its components in two coordinate systems obey

$$V^i\partial_i = \bar{V}^i\bar{\partial}_i\,, \qquad (\bar{x}^j)$$
$$V^i\frac{\partial\bar{x}^j}{\partial x^i} = \bar{V}^i\delta^j{}_i\,,$$

where both sides have been applied to the coordinate function $\bar{x}^j$; hence

$$\bar{V}^i = \frac{\partial\bar{x}^i}{\partial x^j}V^j\,. \tag{13.199}$$

Contravariant, covariant, and mixed tensors

Definition 13.89 (Contravariant and covariant tensors)**.** We define the *components of a contravariant tensor of rank* r as quantities that change coordinate system under the transformation

$$\bar{A}^{i_1\cdots i_r} = \frac{\partial \bar{x}^{i_1}}{\partial x^{j_1}} \cdots \frac{\partial \bar{x}^{i_r}}{\partial x^{j_r}} A^{j_1\cdots j_r} \,, \tag{13.200}$$

placing the indices in the upper position to denote that these indices enumerate the components of a contravariant tensor. Analogously, we define the *components of a covariant tensor of rank* s as quantities that change coordinate system under the transformation

$$\bar{B}_{i_1\cdots i_s} = \frac{\partial x^{j_1}}{\partial \bar{x}^{i_1}} \cdots \frac{\partial x^{j_s}}{\partial \bar{x}^{i_s}} B_{j_1\cdots j_s} \,, \tag{13.201}$$

placing the indices in the lower position.

Rests on Definition 13.88.

Definition 13.90 (Mixed tensor)**.** We define the components of a *mixed tensor of order* $r+s$ as quantities that change coordinate system under the transformation

$$\bar{T}^{i_1\cdots i_r}{}_{l_1\cdots l_s} = \frac{\partial \bar{x}^{i_1}}{\partial x^{j_1}} \cdots \frac{\partial \bar{x}^{i_r}}{\partial x^{j_r}} \frac{\partial x^{k_1}}{\partial \bar{x}^{l_1}} \cdots \frac{\partial x^{k_s}}{\partial \bar{x}^{l_s}} T^{j_1\cdots j_r}{}_{k_1\cdots k_s} \,, \tag{13.202}$$

which we call a tensor of type (r,s) and order $r+s$.

Rests on Definitions 13.88 and 13.89.

We call *contravariant vector* a tensor of type $(1,0)$; from Equation (13.200), its components with respect to another coordinate system are given by

$$\bar{T}^i = \frac{\partial \bar{x}^i}{\partial x^j} T^j \,, \qquad T^j = \frac{\partial x^j}{\partial \bar{x}^i} \bar{T}^i \,. \tag{13.203}$$

We call *covariant vector* a tensor of type $(0,1)$; from Equation (13.201),

$$\bar{T}_i = \frac{\partial x^j}{\partial \bar{x}^i} T_j \,, \qquad T_j = \frac{\partial \bar{x}^i}{\partial x^j} \bar{T}_i \,. \tag{13.204}$$

The displacement vector

For a GCT one cannot say that the coordinates themselves transform as a vector would: under a GCT the coordinates are neither contravariant nor covariant. Differentiating the relations Equation (13.197), however, we see that

$$\mathrm{d}\bar{x}^i = \frac{\partial \bar{x}^i}{\partial x^j} \mathrm{d}x^j \,, \qquad \mathrm{d}x^i = \frac{\partial x^i}{\partial \bar{x}^j} \mathrm{d}\bar{x}^j \,, \tag{13.205}$$

so the differential of the coordinates transforms as a contravariant vector, which we call the *displacement vector*.

Scalars and invariance

The notion of the rank of a tensor under general transformations is the number of indices it carries, and the number of times the Jacobian matrix of the transformation must be applied to carry out a change of coordinates. If we apply this matrix zero times, we obtain the same quantities in both coordinate systems, since we are not transforming them at all. We may extend the definition to *tensors of rank* 0 by defining these *invariant* quantities: quantities that depend on position with respect to a coordinate system but take the same value in every coordinate system. That is,

$$\bar{T}(\bar{x}) = T(x) \,. \tag{13.206}$$

More generally, we call *invariant tensor* a tensor satisfying

$$\bar{T}_{i_1\cdots i_r}(\bar{x}) = T_{i_1\cdots i_r}(x)\,. \tag{13.207}$$

We call *scalar* an invariant tensor of rank 0.

Scalar product

Consider the components of a contravariant vector T^i and of a covariant vector U_l. With respect to $\bar{K}$,

$$\bar{T}^i = \frac{\partial \bar{x}^i}{\partial x^j} T^j\,, \qquad \bar{U}_l = \frac{\partial x^k}{\partial \bar{x}^l} U_k\,.$$

Consider the quantity

$$\begin{aligned}
\bar{T}^i \bar{U}_i &= \frac{\partial \bar{x}^i}{\partial x^j} T^j \frac{\partial x^k}{\partial \bar{x}^i} U_k \\
&= \frac{\partial \bar{x}^i}{\partial x^j} \frac{\partial x^k}{\partial \bar{x}^i}\, T^j U_k \\
&= \frac{\partial x^k}{\partial x^j} T^j U_k \\
&= \delta^k{}_j T^j U_k \\
&= T^j U_j\,,
\end{aligned}$$

from which we see that this type of product is a scalar under GCTs. We call this multiplication of vectors the *scalar product*.

The Kronecker delta as a mixed tensor

From its definition, the Kronecker delta is an invariant tensor. Observe that

$$\begin{aligned}
\bar{\delta}^i{}_l &= \frac{\partial \bar{x}^i}{\partial \bar{x}^l} \\
&= \frac{\partial \bar{x}^i}{\partial x^j} \frac{\partial x^j}{\partial \bar{x}^l} \\
&= \frac{\partial \bar{x}^i}{\partial x^j} \frac{\partial x^k}{\partial \bar{x}^l}\, \delta^j{}_k\,.
\end{aligned}$$

Thus, from Equation (13.202), the Kronecker delta satisfies the definition of a tensor of type $(1,1)$.

Symmetry and antisymmetry

We say that a tensor with components $T^{i_1\cdots i_r}{}_{l_1\cdots l_s}$ is a *tensor symmetric with respect to the indices* i_p and i_q if and only if

$$T^{i_1\cdots i_p\cdots i_q\cdots i_r}{}_{l_1\cdots l_s} = T^{i_1\cdots i_q\cdots i_p\cdots i_r}{}_{l_1\cdots l_s}\,, \tag{13.208}$$

or a *tensor symmetric with respect to the indices* l_p and l_q if and only if

$$T^{i_1\cdots i_r}{}_{l_1\cdots l_p\cdots l_q\cdots l_s} = T^{i_1\cdots i_r}{}_{l_1\cdots l_q\cdots l_p\cdots l_s}\,. \tag{13.209}$$

The quantities so defined are tensors under GCTs, by the permutation of indices. Analogously, the tensor is *antisymmetric* with respect to a pair of upper indices, or a pair of lower indices, if the interchange of the pair produces a minus sign; again the quantities so defined are tensors under GCTs.

Consider now a tensor of type $(1,1)$, and suppose that in some coordinate system

$$T^i{}_j = T^j{}_i \,, \tag{13.210}$$

that is, quantities symmetric with respect to one contravariant and one covariant index. Then

$$\begin{aligned} \bar{T}^i{}_j &= \frac{\partial \bar{x}^i}{\partial x^l}\frac{\partial x^k}{\partial \bar{x}^j} T^l{}_k \\ \text{[Equation (13.210)]} \quad &= \frac{\partial \bar{x}^i}{\partial x^l}\frac{\partial x^k}{\partial \bar{x}^j} T^k_l \,, \end{aligned}$$

from which we see that this type of symmetry does not generate tensors under GCTs. Symmetry or antisymmetry properties must therefore always be taken with respect to two contravariant or two covariant indices; for this reason we display them below only for covariant indices.

The symmetry or antisymmetry of a rank-2 tensor reads

$$S_{ij} = S_{ji} \,, \qquad A_{ij} = -A_{ji} \,, \tag{13.211}$$

which in matrix notation is equivalent to

$$\mathbb{S} = \mathbb{S}^{\mathsf{T}} \,, \qquad \mathbb{A} = -\mathbb{A}^{\mathsf{T}} \,. \tag{13.212}$$

Symmetric and antisymmetric parts

Definition 13.91 (Symmetric and antisymmetric parts)**.** We define the *symmetric part* of a rank-r tensor $T_{i_1\cdots i_r}$ with respect to the indices i_s and i_t as the quantities

$$S_{i_1\cdots(i_s|\cdots|i_t)\cdots i_r} \overset{\text{not.}}{=} \frac{1}{2}\left(T_{i_1\cdots i_s\cdots i_t\cdots i_r} + T_{i_1\cdots i_t\cdots i_s\cdots i_r}\right) \,, \tag{13.213}$$

and analogously the *antisymmetric part*, with respect to the indices i_s and i_t, as the quantities

$$A_{i_1\cdots[i_s|\cdots|i_t]\cdots i_r} \overset{\text{not.}}{=} \frac{1}{2}\left(T_{i_1\cdots i_s\cdots i_t\cdots i_r} - T_{i_1\cdots i_t\cdots i_s\cdots i_r}\right) \,. \tag{13.214}$$

Adding Equations (13.213) and (13.214) we see that

$$T_{i_1\cdots i_r} = S_{i_1\cdots(i_s|\cdots|i_t)\cdots i_r} + A_{i_1\cdots[i_s|\cdots|i_t]\cdots i_r} \,, \tag{13.215}$$

so a rank-r tensor can be decomposed into its symmetric and its antisymmetric part. For a tensor of order 2,

$$S_{ij} = \frac{1}{2}\left(T_{ij} + T_{ji}\right) \,, \qquad A_{ij} = \frac{1}{2}\left(T_{ij} - T_{ji}\right) \,, \qquad T_{ij} = S_{ij} + A_{ij} \,. \tag{13.216}$$

The vector-product tensor

We define the *vector-product tensor* as

$$C_{ij} = A_i B_j - A_j B_i \,. \tag{13.217}$$

From the algebra of tensors, the quantities C_{ij} are the components of a tensor of type $(0,2)$ under GCTs. Moreover, from Equation (13.217),

$$\begin{aligned} C_{ji} &= A_j B_i - A_i B_j \\ &= -\left(A_i B_j - A_j B_i\right) \,, \end{aligned}$$

so that

$$C_{ij} = -C_{ji} \,, \tag{13.218}$$

that is, the vector-product tensor is an antisymmetric tensor of order 2.

Gradient of a scalar

Consider Equation (13.206) and apply the partial derivative with respect to the coordinate $\bar{x}^i$:

$$\begin{aligned} \bar{T} &= T\,, \qquad \frac{\partial}{\partial \bar{x}^i}(\,) \\ \frac{\partial \bar{T}}{\partial \bar{x}^i} &= \frac{\partial T}{\partial \bar{x}^i} \\ &= \frac{\partial T}{\partial x^j}\frac{\partial x^j}{\partial \bar{x}^i}\,, \end{aligned}$$

from which we see that

$$\frac{\partial \bar{T}}{\partial \bar{x}^i} = \frac{\partial x^j}{\partial \bar{x}^i}\frac{\partial T}{\partial x^j}\,, \tag{13.219}$$

that is, the *gradient of a scalar* is a covariant vector under GCTs.

A Jacobian identity

From the chain rule,

$$\begin{aligned} \frac{\partial \bar{x}^i}{\partial \bar{x}^j} &= \delta^i{}_j \\ \frac{\partial \bar{x}^i}{\partial x^k}\frac{\partial x^k}{\partial \bar{x}^j} &= \delta^i{}_j\,, \qquad \det(\,) \\ \left|\frac{\partial \bar{x}}{\partial x}\,\frac{\partial x}{\partial \bar{x}}\right| &= 1\,, \end{aligned} \tag{13.220}$$

where $|\partial\bar{x}/\partial x|$ denotes the Jacobian determinant of the transformation.

13.5.3 Tensor densities

The quantities met so far transform under a GCT by factors of $\partial\bar{x}/\partial x$ alone. A second family of objects, indispensable as soon as one integrates over a manifold, transforms by those factors *and* by a power of the Jacobian determinant.

Definition 13.92 (Tensor density)**.** Write

$$J = \det\left(\frac{\partial \bar{x}^i}{\partial x^j}\right) \tag{13.221}$$

for the Jacobian determinant of the GCT Equation (13.197). Quantities $\mathfrak{T}^{i_1\ldots i_r}{}_{j_1\ldots j_s}$ are the components of a *tensor density of weight* $w \in \mathbb{Z}$, of type (r, s), if under a GCT they transform as

$$\bar{\mathfrak{T}}^{i_1\ldots i_r}{}_{j_1\ldots j_s} = J^{-w}\,\frac{\partial \bar{x}^{i_1}}{\partial x^{k_1}}\cdots\frac{\partial \bar{x}^{i_r}}{\partial x^{k_r}}\,\frac{\partial x^{l_1}}{\partial \bar{x}^{j_1}}\cdots\frac{\partial x^{l_s}}{\partial \bar{x}^{j_s}}\,\mathfrak{T}^{k_1\ldots k_r}{}_{l_1\ldots l_s}\,. \tag{13.222}$$

A density of weight 0 is an ordinary tensor (Equations (13.200) and (13.201)); a density of weight 0 and type $(0, 0)$ is a scalar Equation (13.206). A quantity transforming by $|J|^{-w}$ rather than J^{-w} is a *relative* tensor density of weight w, and the two notions differ only for orientation-reversing transformations.

Rests on Definitions 13.88 and 13.89.

Proposition 13.93 (Algebra of densities)**.** *Densities of the same weight and type form a vector space under pointwise addition; the product of a density of weight w_1 with one of weight w_2 is a density of weight $w_1 + w_2$; contraction of an upper with a lower index preserves the weight; and the quotient of two densities of equal weight, where defined, is an ordinary tensor.*

Rests on Definition 13.92.

Derivation. Derives Proposition 13.93.

Each clause is read off Equation (13.222). Linearity is immediate, since the same factor J^{-w} multiplies both summands. For the product, the Jacobian factors multiply as $J^{-w_1}J^{-w_2} = J^{-(w_1+w_2)}$ while the partial-derivative factors are those of the tensor product. For a contraction, one factor $\partial\bar{x}^i/\partial x^k$ meets one factor $\partial x^l/\partial\bar{x}^i$ and the two collapse to $\delta^l{}_k$ by Equation (13.198), leaving J^{-w} untouched. For the quotient, the factors J^{-w} cancel between numerator and denominator, so the result transforms with no Jacobian factor at all. □

Example 13.94 (The two densities this chapter uses)**.** The Levi-Civita symbol $\varepsilon_{i_1\dots i_n}$, defined to take the values $0, \pm 1$ in *every* coordinate system, is a covariant density of weight -1: expanding the determinant by the Leibniz formula gives

$$\frac{\partial x^{k_1}}{\partial\bar{x}^{i_1}}\cdots\frac{\partial x^{k_n}}{\partial\bar{x}^{i_n}}\,\varepsilon_{k_1\dots k_n} = J^{-1}\,\varepsilon_{i_1\dots i_n}\,, \tag{13.223}$$

which is Equation (13.222) with $w = -1$. Correspondingly $\sqrt{|\det g|}$ is a scalar density of weight $+1$, because $\bar{g}_{ij} = (\partial x^k/\partial\bar{x}^i)(\partial x^l/\partial\bar{x}^j)g_{kl}$ gives $\det\bar{g} = J^{-2}\det g$. Their product $\sqrt{|\det g|}\,\varepsilon_{i_1\dots n}$ has weight 0 and is therefore an honest tensor — the volume form of Section 13.6.7 — and $\sqrt{|\det g|}\,\mathrm{d}^n x$ is invariant, which is what makes an integral over a manifold well defined.

Rests on Definition 13.92 and Proposition 13.93.

The sources develop none of this in general and treat only the following three-dimensional instances.

The pseudo-vector cross product

Consider the vector-product tensor (Equation (13.217)). Since this tensor is totally antisymmetric, we can define the associated dual pseudo-tensor, in three dimensions, as

$$C_i = \frac{1}{2}\varepsilon_{ijk}C_{jk}\,, \tag{13.224}$$

which we call the *pseudo-vector cross product*, or *cross product of two vectors*. From Equation (13.217),

$$\begin{aligned} C_i &= \frac{1}{2}\varepsilon_{ijk}\,(A_jB_k - A_kB_j) \\ &= \frac{1}{2}\varepsilon_{ijk}A_jB_k - \frac{1}{2}\varepsilon_{ijk}A_kB_j \\ &= \frac{1}{2}\varepsilon_{ijk}A_jB_k + \frac{1}{2}\varepsilon_{ikj}A_kB_j \\ &= \frac{1}{2}\varepsilon_{ijk}A_jB_k + \frac{1}{2}\varepsilon_{ijk}A_jB_k\,, \end{aligned}$$

so that

$$C_i = \varepsilon_{ijk}A_jB_k\,. \tag{13.225}$$

The source calls Equation (13.225) a pseudo-vector and stops there. The name records a property, and the property has to be established; the three results below do that, and supply at the same time the elementary identities of the three-dimensional cross product, which the sources use without stating and which the physical parts of this treatise cref constantly.

Proposition 13.95 (The elementary cross-product identities)**.** *For vectors $\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{C}$ of E_3, with $(\boldsymbol{A}\times\boldsymbol{B})_i = \varepsilon_{ijk}A_jB_k$ as in Equation (13.225),*

$$\boldsymbol{A}\cdot(\boldsymbol{B}\times\boldsymbol{C}) = \boldsymbol{B}\cdot(\boldsymbol{C}\times\boldsymbol{A}) = \boldsymbol{C}\cdot(\boldsymbol{A}\times\boldsymbol{B}) = \varepsilon_{ijk}A_iB_jC_k\,, \tag{13.226}$$

$$\boldsymbol{A}\times(\boldsymbol{B}\times\boldsymbol{C}) = \boldsymbol{B}\,(\boldsymbol{A}\cdot\boldsymbol{C}) - \boldsymbol{C}\,(\boldsymbol{A}\cdot\boldsymbol{B})\,, \tag{13.227}$$

$$|\boldsymbol{A}\times\boldsymbol{B}|^2 = |\boldsymbol{A}|^2\,|\boldsymbol{B}|^2 - (\boldsymbol{A}\cdot\boldsymbol{B})^2\,. \tag{13.228}$$

Rests on Proposition 13.6 and Equation (13.225).

Derivation. *Derives Proposition 13.95.*

Equation (13.226): all three scalars equal $\varepsilon_{ijk}A_iB_jC_k$ after renaming the summation indices, because $\varepsilon_{ijk} = \varepsilon_{jki} = \varepsilon_{kij}$ — a cyclic permutation of three symbols is even.

Equation (13.227): by Equation (13.225) and Equation (13.29),

$$\begin{aligned}[\boldsymbol{A}\times(\boldsymbol{B}\times\boldsymbol{C})]_i &= \varepsilon_{ijk}A_j\,\varepsilon_{klm}B_lC_m = \varepsilon_{kij}\varepsilon_{klm}A_jB_lC_m\\ &= (\delta_{il}\delta_{jm} - \delta_{im}\delta_{jl})\,A_jB_lC_m = B_i\,(A_jC_j) - C_i\,(A_jB_j)\,.\end{aligned}$$

Equation (13.228): with the same contraction,

$$|\boldsymbol{A}\times\boldsymbol{B}|^2 = \varepsilon_{ijk}A_jB_k\,\varepsilon_{ilm}A_lB_m = (\delta_{jl}\delta_{km} - \delta_{jm}\delta_{kl})\,A_jB_kA_lB_m\,,$$

which is $A_jA_jB_kB_k - (A_jB_j)^2$. □

Proposition 13.96 (The cross product is an axial vector)**.** *Under an orthogonal coordinate transformation Equation (13.8) with matrix a_{ij}, the quantities Equation (13.225) obey*

$$C'_i = (\det a)\,a_{ij}\,C_j\,. \tag{13.229}$$

They therefore transform as the components of a Cartesian vector (Equation (13.21) with $r = 1$) under a proper *orthogonal transformation,* $\det a = +1$*, and pick up an extra minus sign under an improper one,* $\det a = -1$*: the cross product is a* pseudo-vector*, or* axial vector*, and not a vector.*

Rests on Proposition 13.6, Definition 13.5, and Equation (13.13).

Derivation. *Derives Proposition 13.96.*

Write Equation (13.31) with the index names (i, j, k) on the symbol and (s, l, m) on the free slots, $\varepsilon_{ijk}a_{is}a_{jl}a_{km} = \varepsilon_{slm}\det a$, and contract both sides with a_{ts}, summing over s. On the left the orthogonality condition Equation (13.13) gives $a_{is}a_{ts} = \delta_{it}$, so

$$\varepsilon_{tjk}\,a_{jl}a_{km} = (\det a)\,a_{ts}\,\varepsilon_{slm}\,. \tag{13.230}$$

Now C_{jk} of Equation (13.217) is an ordinary rank-2 tensor, so $C'_{jk} = a_{jl}a_{km}C_{lm}$ by Equation (13.22), and Equation (13.224) with Equation (13.230) gives

$$C'_i = \tfrac{1}{2}\varepsilon_{ijk}C'_{jk} = \tfrac{1}{2}\varepsilon_{ijk}a_{jl}a_{km}C_{lm} = (\det a)\,a_{is}\,\tfrac{1}{2}\varepsilon_{slm}C_{lm} = (\det a)\,a_{is}C_s\,,$$

which is Equation (13.229). The factor $\det a = \pm 1$ of Equation (13.15) is what distinguishes the two cases. □

Stokes' theorem for an antisymmetric tensor field

For an antisymmetric tensor field H_{ij} with associated vector H_i,

$$\frac{1}{2}\int_S H_{ij}\,\mathrm{d}f^{ij} = \oint_{\partial S} H_i\,\mathrm{d}x^i\,, \tag{13.231}$$

where $\mathrm{d}f^{ij}$ is the antisymmetric surface element of S and ∂S its boundary. The source states the relation without derivation; it is the flat three-dimensional instance of the general Stokes theorem for differential forms, and both are proved in the appendix.

Full derivation: Appendix A.29 (p. 2920).

Derives Equation (13.231).

Remark 13.97 (What the statement assumes). The relation between H_{ij} and H_i is left implicit in the source and is worth making explicit, because the identity is false under the other natural reading. It holds when H_{ij} is the *rotor tensor* of H_i,

$$H_{ij} = \partial_i H_j - \partial_j H_i \,, \tag{13.232}$$

and *not* when H_i is the dual pseudo-vector $\frac{1}{2}\varepsilon_{ijk}H_{jk}$ of Equation (13.224): with the latter reading the left-hand side of Equation (13.231) is the flux of H_i through S, which has no reason to equal its circulation around ∂S. With Equation (13.232), and writing the surface element as $\mathrm{d}f^{ij} = \varepsilon^{ijk}\mathrm{d}f_k$, the left-hand side of Equation (13.231) becomes $\frac{1}{2}\varepsilon^{ijk}(\partial_i H_j - \partial_j H_i)\mathrm{d}f_k = (\nabla \times \boldsymbol{H}) \cdot \mathrm{d}\boldsymbol{f}$, so in three dimensions Equation (13.231) is the classical Stokes theorem (Theorem 7.100) transcribed into tensor notation. In the language of Section 13.6 it is the statement $\int_S \mathrm{d}H = \oint_{\partial S} H$ for the one-form $H = H_i \mathrm{d}x^i$, whose exterior derivative has components Equation (13.232). In three dimensions nothing here is owed to the manifold machinery: the classical statement is derived outright in Theorem 7.100 from Green's theorem, with the scope of that derivation set out in Remark 7.102. The general form $\int_M \mathrm{d}\omega = \oint_{\partial M} \omega$ on a compact oriented manifold with boundary, of which Equation (13.231) is the flat three-dimensional instance, is proved in the appendix, and Equation (13.231) is deduced there from it under exactly the hypothesis Equation (13.232) made explicit above. The two derivations are independent — the appendix does not use Theorem 7.100 and Chapter 7 does not use the appendix — so they check each other rather than one resting on the other.

13.6 Differential forms: k-forms and k-vectors

13.6.1 k-forms and k-vectors

Definition 13.98 (k-form)**.** We say that a *k-form* is a totally antisymmetric tensor of type $(0, k)$. In particular, a covector is a 1-form.

Rests on Definitions 13.83 and 13.84.

Definition 13.99 (k-vector)**.** We say that a *k-vector* is a totally antisymmetric tensor of type $(k, 0)$. In particular, a vector is a 1-vector.

Rests on Definitions 13.81 and 13.84.

The set of all k-forms at P forms a vector space, which we denote $\Lambda^k_{M_n}(P)$. Of course,

$$\Lambda^k_{M_n}(P) \subset \underbrace{T^*_{M_n}(P) \otimes \cdots \otimes T^*_{M_n}(P)}_{k \text{ times}} \,. \tag{13.233}$$

Analogously, the set of all k-vectors forms a vector space, denoted ${}^*\Lambda^k_{M_n}(P)$, with

$${}^*\Lambda^k_{M_n}(P) \subset \underbrace{T_{M_n}(P) \otimes \cdots \otimes T_{M_n}(P)}_{k \text{ times}} \,. \tag{13.234}$$

Both assertions, and the dimension of the two spaces, follow from a single count.

Proposition 13.100 (The space of k-forms)**.** *Let M_n be an n-dimensional differentiable manifold and $P \in M_n$. The set $\Lambda^k_{M_n}(P)$ of k-forms at P is a vector subspace of the space of tensors of type $(0, k)$ at P, and*

$$\dim\left(\Lambda^k_{M_n}(P)\right) = \binom{n}{k} = \frac{n!}{(n-k)!\,k!} \quad \text{for } 0 \le k \le n \,, \tag{13.235}$$

while $\Lambda^k_{M_n}(P) = \{0\}$ for $k > n$. The same holds for the space ${}^*\Lambda^k_{M_n}(P)$ of k-vectors, with upper indices throughout.

Rests on Definitions 13.83, 13.84 and 13.98.

Proof. *Derives Proposition 13.100.*

The tensors of type $(0,k)$ at P form a vector space under pointwise addition and scaling of their components (Definition 13.84). Total antisymmetry is the requirement

$$\psi_{i_1\dots i_s\dots i_t\dots i_k} + \psi_{i_1\dots i_t\dots i_s\dots i_k} = 0 \qquad \text{for every pair } s \neq t\,, \tag{13.236}$$

a family of *linear* homogeneous conditions on the components; its solution set is therefore a linear subspace, which is the first assertion. Equivalently: if ψ and φ are totally antisymmetric so is $\alpha\psi + \beta\varphi$, because each condition Equation (13.236) is preserved by linear combination.

For the dimension, fix the coordinate cobasis $\{\mathrm{d}x^i\}$ of $T^*_{M_n}(P)$ (Equation (13.239)) and read a k-form through its components $\psi_{i_1\dots i_k}$. Total antisymmetry has two consequences. First, any component with a repeated index vanishes: exchanging the two equal slots leaves the component unchanged and, by Equation (13.236), reverses its sign. Second, any component whose indices are distinct is determined by the one whose indices are arranged in increasing order, since a permutation σ of the slots multiplies the component by $\operatorname{sgn}\sigma$:

$$\psi_{i_{\sigma(1)}\dots i_{\sigma(k)}} = \operatorname{sgn}(\sigma)\,\psi_{i_1\dots i_k}\,. \tag{13.237}$$

Hence the linear map sending ψ to the family of its *ordered* components $\psi_{i_1\dots i_k}$ with $i_1 < \dots < i_k$ is injective. It is also surjective: given arbitrary numbers assigned to the ordered index sets, Equation (13.237) extends them to a full family of components, and the extension is consistent because sgn is a homomorphism, so the result is a totally antisymmetric tensor with the prescribed ordered components. The map is therefore an isomorphism, and $\dim \Lambda^k_{M_n}(P)$ equals the number of strictly increasing k-tuples drawn from $\{1,\dots,n\}$, that is, the number of k-element subsets of an n-element set: $\binom{n}{k}$, which is Equation (13.235). If $k > n$ no such tuple exists — any k indices taken from n values must repeat one — so every component vanishes and the space is trivial. The argument used nothing but the antisymmetry of the components, so it applies verbatim to k-vectors. □

Remark 13.101. Once the wedge product is available (Definition 13.102), the isomorphism just constructed is realized by an explicit basis: the $\binom{n}{k}$ products $\mathrm{d}x^{i_1}\wedge\dots\wedge\mathrm{d}x^{i_k}$ with $i_1 < \dots < i_k$. Equation (13.235) is the dimension count used in Section 13.6.7 to pair k-forms with $(n-k)$-forms.

13.6.2 The basis of the cotangent space

Let $P \in M_n$, with M_n a differentiable manifold, and let $f : M_n \longrightarrow \mathbb{R}$ be a differentiable map. Consider the map

$$\begin{aligned} \mathrm{d}f &: T_{M_n}(P) \longrightarrow \mathbb{R} \\ V_P = \left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda_0} &\longmapsto \mathrm{d}f(V_P) = \frac{\mathrm{d}f}{\mathrm{d}\lambda}(P)\,. \end{aligned}$$

We claim that $\mathrm{d}f(V_P) = V_P(f)$. Indeed, $\mathrm{d}f$ is defined as

$$\begin{aligned} \mathrm{d}f &= \frac{\partial f}{\partial x^i}\mathrm{d}x^i \\ \mathrm{d}f &= \frac{\partial f}{\partial x^i}\frac{\mathrm{d}x^i}{\mathrm{d}\lambda}\mathrm{d}\lambda \\ \frac{\mathrm{d}f}{\mathrm{d}\lambda}(P) &= \frac{\partial f}{\partial x^i}\frac{\mathrm{d}x^i}{\mathrm{d}\lambda} \\ \mathrm{d}f(V_P) &= V_P^i\,\partial_i f\,, \end{aligned}$$

and, recalling the discussion of the definition of a vector, $\{\partial_i\}$ is a basis of the tangent space at P. Thus

$$\mathrm{d}f(V_P) = V_P(f)\,. \tag{13.238}$$

From Equation (13.238), taking the vectors $\partial_i \in T_{M_n}(P)$ and $f = x^j$, we see that

$$\mathrm{d}x^j(\partial_i) = \delta^j{}_i\,, \tag{13.239}$$

so $\{\mathrm{d}x^i\}$ is the basis dual to $\{\partial_i\}$, that is,

$$T^*_{M_n}(P) = \left\langle \left\{ \mathrm{d}x^i \right\}_{i=1}^n \right\rangle\,,$$

and in particular the $\mathrm{d}x^i$ are covectors, that is, 1-forms. From this we see that for the set of all tensors of type $(0,k)$,

$$\underbrace{T^*_{M_n}(P) \otimes \cdots \otimes T^*_{M_n}(P)}_{k \text{ times}} = \left\langle \left\{ \mathrm{d}x^{i_1} \otimes \cdots \otimes \mathrm{d}x^{i_k} \right\} \right\rangle\,. \tag{13.240}$$

13.6.3 The wedge product

Wedge product and change of basis

Observe the following. The space of all 2-forms, $\Lambda^2_{M_n}(P)$, can be generated by the basis $\{\mathrm{d}x^i \otimes \mathrm{d}x^j\}$, but we must be careful: the direct product of two 2-forms is not necessarily a 4-form, since the result is a tensor of type $(0,4)$ that is not necessarily antisymmetric; that is, it can happen that

$$\psi \otimes \varphi \notin \Lambda^4_{M_n}(P)\,, \qquad \psi, \varphi \in \Lambda^2_{M_n}(P)\,.$$

For closure — referring to the antisymmetry property — we must define a new type of product. As we now show, this can be achieved by a change of basis. In the basis already discussed for the cotangent space,

$$\begin{aligned}
\psi &= \psi_{ij}\,\mathrm{d}x^i \otimes \mathrm{d}x^j \\
&= \frac{1}{2}\left(\psi_{ij} + \psi_{ij}\right)\mathrm{d}x^i \otimes \mathrm{d}x^j \\
&= \frac{1}{2}\left(\psi_{ij} - \psi_{ji}\right)\mathrm{d}x^i \otimes \mathrm{d}x^j \\
&= \frac{1}{2}\left(\psi_{ij}\,\mathrm{d}x^i \otimes \mathrm{d}x^j - \psi_{ji}\,\mathrm{d}x^i \otimes \mathrm{d}x^j\right) \\
&= \frac{1}{2}\left(\psi_{ij}\,\mathrm{d}x^i \otimes \mathrm{d}x^j - \psi_{ij}\,\mathrm{d}x^j \otimes \mathrm{d}x^i\right) \\
&= \frac{1}{2}\psi_{ij}\left(\mathrm{d}x^i \otimes \mathrm{d}x^j - \mathrm{d}x^j \otimes \mathrm{d}x^i\right)\,,
\end{aligned}$$

where the antisymmetry of ψ_{ij} was used in the second step.

Definition 13.102 (Wedge product)**.** As we have seen, the $\mathrm{d}x^i$ are 1-forms. We define the *wedge product* as the binary operation on the basis elements

$$\begin{aligned}
\wedge : \Lambda^1_{M_n}(P) \times \Lambda^1_{M_n}(P) &\longrightarrow \Lambda^2_{M_n}(P) \\
(\mathrm{d}x^i, \mathrm{d}x^j) &\longmapsto \mathrm{d}x^i \wedge \mathrm{d}x^j = \mathrm{d}x^i \otimes \mathrm{d}x^j - \mathrm{d}x^j \otimes \mathrm{d}x^i\,.
\end{aligned}$$

Rests on Definition 13.98 and Equation (13.239).

Therefore

$$\psi = \frac{1}{2}\psi_{ij}\,\mathrm{d}x^i \wedge \mathrm{d}x^j\,.$$

In short, we have performed the change of basis

$$\left\{ \mathrm{d}x^i \otimes \mathrm{d}x^j \right\}_{i,j}^n \;\longrightarrow\; \left\{ \mathrm{d}x^i \wedge \mathrm{d}x^j \right\}_{i,j}^n\,.$$

Antisymmetry

From the definition of the wedge product it is immediate that

$$\mathrm{d}x^i \wedge \mathrm{d}x^j = -\mathrm{d}x^j \wedge \mathrm{d}x^i \,, \tag{13.241}$$

and clearly, taking $j = i$ (no sum),

$$\mathrm{d}x^i \wedge \mathrm{d}x^i = 0 \,. \tag{13.242}$$

Powers of a k-form

We introduce the notation

$$\underbrace{\psi \wedge \cdots \wedge \psi}_{m \text{ times}} = \psi^m \,,$$

which we call the m-th *power* of a k-form, with respect to the wedge product.

Commutation rule

Having defined the wedge product explicitly, we can analyse its commutativity. Let ψ be a k-form and φ an l-form. In the basis discussed above,

$$\begin{aligned}
\psi \wedge \varphi &= \left(\frac{1}{k!}\psi_{i_1\ldots i_k}\mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k}\right) \wedge \left(\frac{1}{l!}\varphi_{j_1\ldots j_l}\mathrm{d}x^{j_1} \wedge \cdots \wedge \mathrm{d}x^{j_l}\right) \\
&= \frac{1}{k!\,l!}\psi_{i_1\ldots i_k}\varphi_{j_1\ldots j_l}\,\mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k} \wedge \mathrm{d}x^{j_1} \wedge \cdots \wedge \mathrm{d}x^{j_l} \\
\text{[Equation (13.241)]} \quad &= -\frac{1}{k!\,l!}\psi_{i_1\ldots i_k}\varphi_{j_1\ldots j_l}\,\mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_{k-1}} \wedge \mathrm{d}x^{j_1} \wedge \mathrm{d}x^{i_k} \wedge \mathrm{d}x^{j_2} \wedge \cdots \wedge \mathrm{d}x^{j_l} \\
&= (-1)^k \frac{1}{k!\,l!}\psi_{i_1\ldots i_k}\varphi_{j_1\ldots j_l}\,\mathrm{d}x^{j_1} \wedge \mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k} \wedge \cdots \wedge \mathrm{d}x^{j_l} \\
&= \left((-1)^k\right)^l \frac{1}{k!\,l!}\psi_{i_1\ldots i_k}\varphi_{j_1\ldots j_l}\,\mathrm{d}x^{j_1} \wedge \cdots \wedge \mathrm{d}x^{j_l} \wedge \mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k} \\
&= (-1)^{kl}\left(\frac{1}{l!}\varphi_{j_1\ldots j_l}\mathrm{d}x^{j_1} \wedge \cdots \wedge \mathrm{d}x^{j_l}\right) \wedge \left(\frac{1}{k!}\psi_{i_1\ldots i_k}\mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k}\right) .
\end{aligned}$$

We thus obtain the commutation rule

$$\psi \wedge \varphi = (-1)^{kl}\,\varphi \wedge \psi \,. \tag{13.243}$$

Various properties follow from this relation by simple arithmetic. For example, consider the case $\varphi = \psi$ with k odd. Since the square of an odd number is odd,

$$\begin{aligned}
\psi^2 &= (-1)^{k^2}\psi^2 \\
&= -\psi^2 \,,
\end{aligned}$$

hence

$$\psi^2 = 0 \,. \tag{13.244}$$

13.6.4 The exterior derivative

Definition 13.103 (Exterior derivative)**.** We define the *exterior derivative* as the map

$$\begin{aligned}
\mathrm{d} : \Lambda^k_{M_n}(P) &\longrightarrow \Lambda^{k+1}_{M_n}(P) \\
\psi &\longmapsto \mathrm{d}\psi = \frac{1}{k!}\,\partial_j\psi_{i_1\ldots i_k}\,\mathrm{d}x^j \wedge \mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k} \,.
\end{aligned}$$

Rests on Definitions 13.98 and 13.102.

It is clear that the exterior derivative is a linear operator, owing to the linearity of the ordinary derivative ∂_j.

Nilpotency

Let ψ be a k-form. Then

$$\mathrm{d}(\mathrm{d}\psi) = \frac{1}{k!}\,\partial_i\partial_j\psi_{i_1\dots i_k}\,\mathrm{d}x^i\wedge\mathrm{d}x^j\wedge\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}\,.$$

Now, if $\psi_{i_1\dots i_k}$ is of sufficiently high differentiability class, $\partial_i\partial_j$ is symmetric in i and j, while $\mathrm{d}x^i\wedge\mathrm{d}x^j$ is antisymmetric in those indices; hence their contraction vanishes. Thus

$$\mathrm{d}(\mathrm{d}\psi) = 0\,. \tag{13.245}$$

Leibniz rule

Let ψ be a k-form and φ an l-form. Then

$$\begin{aligned}
\mathrm{d}(\psi\wedge\varphi) &= \mathrm{d}\left(\left(\frac{1}{k!}\psi_{i_1\dots i_k}\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}\right)\wedge\left(\frac{1}{l!}\varphi_{j_1\dots j_l}\mathrm{d}x^{j_1}\wedge\cdots\wedge\mathrm{d}x^{j_l}\right)\right)\\
&= \frac{1}{k!\,l!}\,\partial_j\left(\psi_{i_1\dots i_k}\varphi_{j_1\dots j_l}\right)\mathrm{d}x^j\wedge\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}\wedge\mathrm{d}x^{j_1}\wedge\cdots\wedge\mathrm{d}x^{j_l}\\
&= \frac{1}{k!\,l!}\left(\partial_j(\psi_{i_1\dots i_k})\varphi_{j_1\dots j_l}+\psi_{i_1\dots i_k}\partial_j\varphi_{j_1\dots j_l}\right)\mathrm{d}x^j\wedge\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}\wedge\mathrm{d}x^{j_1}\wedge\cdots\wedge\mathrm{d}x^{j_l}\\
&= \mathrm{d}\psi\wedge\varphi+\frac{1}{k!\,l!}\,\psi_{i_1\dots i_k}\partial_j\varphi_{j_1\dots j_l}\,\mathrm{d}x^j\wedge\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}\wedge\mathrm{d}x^{j_1}\wedge\cdots\wedge\mathrm{d}x^{j_l}\\
&= \mathrm{d}\psi\wedge\varphi+\frac{(-1)^k}{k!\,l!}\,\psi_{i_1\dots i_k}\partial_j\varphi_{j_1\dots j_l}\,\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}\wedge\mathrm{d}x^j\wedge\mathrm{d}x^{j_1}\wedge\cdots\wedge\mathrm{d}x^{j_l}\,,
\end{aligned}$$

where in the last step the 1-form $\mathrm{d}x^j$ was carried through the k factors $\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_k}$ at the cost of a factor $(-1)^k$, by Equation (13.241). We conclude the identity

$$\mathrm{d}(\psi\wedge\varphi) = \mathrm{d}\psi\wedge\varphi+(-1)^k\,\psi\wedge\mathrm{d}\varphi\,, \tag{13.246}$$

known as the *Leibniz rule* for differential forms.

Remark 13.104. All the properties of the exterior derivative mentioned above are consequences of the properties of the ordinary derivative. This is because this special derivative is only a definition designed to deal with differential forms; the essential object is the derivative we all know.

13.6.5 Closed and exact forms

Definition 13.105 (Closed form)**.** Let ψ be a k-form. We say that ψ is *closed* if and only if

$$\mathrm{d}\psi = 0\,.$$

Rests on Definitions 13.98 and 13.103.

Definition 13.106 (Exact form)**.** Let $\psi\in\Lambda^k_{M_n}(P)$ be a k-form. We say that ψ is *exact* if and only if there exists a $(k-1)$-form $\varphi\in\Lambda^{k-1}_{M_n}(P)$ such that

$$\psi = \mathrm{d}\varphi\,.$$

Rests on Definitions 13.98 and 13.103.

Lemma 13.107 (Poincaré lemma)**.** *If a k-form is exact, then it is closed.*
Rests on Definitions 13.105 and 13.106 and Equation (13.245).

Derivation. Derives Lemma 13.107.

Immediate from the nilpotency of the exterior derivative, Equation (13.245): if $\psi=\mathrm{d}\varphi$ then $\mathrm{d}\psi=\mathrm{d}(\mathrm{d}\varphi)=0$. □

The converse is not automatic, and its validity depends on the topology of the domain. Two statements settle the matter for everything this treatise needs: on a star-shaped domain the converse holds outright, and in general it fails, with a completely explicit counterexample.

Definition 13.108 (Star-shaped domain)**.** An open set $U \subseteq \mathbb{R}^n$ is *star-shaped* about $x_0 \in U$ if and only if the segment from x_0 to x lies in U for every $x \in U$. A ball is star-shaped about its centre, and every point of every open set has a star-shaped neighbourhood.

Rests on Definition 6.2 and Equation (6.12).

Theorem 13.109 (Converse of the Poincaré lemma on a star-shaped domain)**.** *Let $U \subseteq \mathbb{R}^n$ be open and star-shaped about the origin, and let ψ be a closed k-form on U with $k \geq 1$. Then ψ is exact: $\psi = \mathrm{d}\varphi$ with φ the $(k-1)$-form*

$$\varphi_{i_2 \ldots i_k}(x) = \int_0^1 t^{k-1}\, x^j\, \psi_{j\, i_2 \ldots i_k}(tx)\, \mathrm{d}t\,. \tag{13.247}$$

Consequently a closed form is locally *exact on any manifold, each point having a chart domain that may be taken star-shaped.*

Rests on Definitions 13.105, 13.106 and 13.108.

Proof. *Derives Theorem 13.109.*

Write $h\psi$ for the $(k-1)$-form Equation (13.247); it is defined because $tx \in U$ for $t \in [0,1]$, and it is totally antisymmetric in $i_2, \ldots, i_k$ because ψ is. We prove the *homotopy identity*

$$\mathrm{d}\,(h\psi) + h\,(\mathrm{d}\psi) = \psi\,, \tag{13.248}$$

from which the theorem follows by putting $\mathrm{d}\psi = 0$.

In the convention of Definition 13.103 the components of the exterior derivative of an l-form χ are $(\mathrm{d}\chi)_{i_1 \ldots i_{l+1}} = (l+1)\, \partial_{[i_1} \chi_{i_2 \ldots i_{l+1}]}$, the brackets denoting total antisymmetrization. Differentiating Equation (13.247) under the integral sign, the derivative falls either on the explicit factor x^j or on the argument tx:

$$[\mathrm{d}\,(h\psi)]_{i_1 \ldots i_k} = k \int_0^1 t^{k-1} \psi_{i_1 \ldots i_k}(tx)\, \mathrm{d}t + k \int_0^1 t^k x^j \left(\partial_{[i_1} \psi_{|j|\, i_2 \ldots i_k]}\right)(tx)\, \mathrm{d}t\,, \tag{13.249}$$

the first term arising from $\delta^j_{[i_1} \psi_{|j| i_2 \ldots i_k]} = \psi_{[i_1 i_2 \ldots i_k]} = \psi_{i_1 \ldots i_k}$, and the vertical bars excluding j from the antisymmetrization. For the second term of Equation (13.248),

$$[h\,(\mathrm{d}\psi)]_{i_1 \ldots i_k} = (k+1) \int_0^1 t^k x^j \left(\partial_{[j} \psi_{i_1 \ldots i_k]}\right)(tx)\, \mathrm{d}t\,. \tag{13.250}$$

Separating the first slot from a total antisymmetrization over $k+1$ indices gives the algebraic identity

$$(k+1)\, \partial_{[j} \psi_{i_1 \ldots i_k]} = \partial_j \psi_{i_1 \ldots i_k} - k\, \partial_{[i_1} \psi_{|j|\, i_2 \ldots i_k]}\,, \tag{13.251}$$

which for $k = 1$ reads $\partial_j \psi_i - \partial_i \psi_j = \partial_j \psi_i - \partial_i \psi_j$ and in general is the statement that antisymmetrizing over $k+1$ slots may be performed by holding the first slot and antisymmetrizing the k transpositions that move j into it. Adding Equations (13.249) and (13.250) through Equation (13.251), the two terms carrying $\partial_{[i_1} \psi_{|j| \ldots]}$ cancel and

$$[\mathrm{d}(h\psi) + h(\mathrm{d}\psi)]_{i_1 \ldots i_k} = \int_0^1 \left[k\, t^{k-1} \psi_{i_1 \ldots i_k}(tx) + t^k x^j \left(\partial_j \psi_{i_1 \ldots i_k}\right)(tx)\right] \mathrm{d}t\,.$$

By the chain rule the bracket is exactly $\frac{\mathrm{d}}{\mathrm{d}t}\left[t^k \psi_{i_1 \ldots i_k}(tx)\right]$, so the integral is $\left[t^k \psi_{i_1 \ldots i_k}(tx)\right]_0^1 = \psi_{i_1 \ldots i_k}(x)$, the lower limit vanishing because $k \geq 1$. That is Equation (13.248). □

Example 13.110 (Closed but not exact: the angle form)**.** On $U = \mathbb{R}^2 \setminus \{0\}$, which is not star-shaped, put

$$\alpha = \frac{-y\,\mathrm{d}x + x\,\mathrm{d}y}{x^2 + y^2}\,. \tag{13.252}$$

It is closed: with $\alpha_1 = -y/(x^2+y^2)$ and $\alpha_2 = x/(x^2+y^2)$, both $\partial_1\alpha_2$ and $\partial_2\alpha_1$ equal $(y^2-x^2)/(x^2+y^2)^2$, so $\mathrm{d}\alpha = 0$. It is not exact: on the unit circle $x = \cos s$, $y = \sin s$ one computes $\oint \alpha = \int_0^{2\pi} \mathrm{d}s = 2\pi$, whereas an exact form $\mathrm{d}f$ integrates to zero around any closed curve, since $\oint \mathrm{d}f = \int_0^{2\pi} \frac{\mathrm{d}}{\mathrm{d}s} f\,(\gamma(s))\,\mathrm{d}s = f(\gamma(2\pi)) - f(\gamma(0)) = 0$ by the fundamental theorem of calculus (Theorem 7.43). So the converse of Lemma 13.107 genuinely fails, and what fails is topological: α is exact on any star-shaped subset of U — there it is d of a branch of the polar angle — but no branch is single-valued on the whole punctured plane.

Rests on Theorem 13.109 and Definition 13.106.

The symmetric-tensor analogue of Theorem 13.109 is the result that decides which strain fields of a continuum are realisable by an actual displacement, and it follows from the antisymmetric one by applying it twice.

Definition 13.111 (Linearised curvature of a symmetric field)**.** For a C^2 symmetric field $e_{ij} = e_{ji}$ on an open set of $\mathbb{R}^n$, put

$$\mathcal{R}_{jlkm}(e) = \partial_l\partial_k e_{jm} + \partial_j\partial_m e_{lk} - \partial_l\partial_m e_{jk} - \partial_j\partial_k e_{lm}\,. \tag{13.253}$$

It is antisymmetric under $j \leftrightarrow l$ and under $k \leftrightarrow m$ and symmetric under the exchange of the two pairs — the index symmetries of the curvature tensor (Proposition 13.154), which is what it is: the linearisation of Equation (13.95) about a flat metric in the perturbation e. The equations $\mathcal{R}(e) = 0$ are the *Saint-Venant compatibility conditions*.

Rests on Definition 13.91 and Proposition 13.154.

Theorem 13.112 (Symmetric analogue of the converse Poincaré lemma)**.** *Let $U \subseteq \mathbb{R}^n$ be open and star-shaped and let e_{ij} be a symmetric field of class C^2 on U. Then*

$$\mathcal{R}_{jlkm}(e) = 0 \quad \text{on } U \quad\Longleftrightarrow\quad e_{jk} = \tfrac{1}{2}\,(\partial_j u_k + \partial_k u_j) \quad \text{for some } C^3 \text{ field } u\,. \tag{13.254}$$

The field u is unique up to $u_j \mapsto u_j + a_j + \Omega_{jk}x^k$ with a constant and Ω a constant antisymmetric array — an infinitesimal rigid motion.

Rests on Theorem 13.109, Definition 13.111, and Proposition 7.73.

Proof. *Derives Theorem 13.112.*

Necessity. Substituting $e_{jm} = \frac{1}{2}\,(\partial_j u_m + \partial_m u_j)$ into Equation (13.253) and commuting partial derivatives freely (Proposition 7.73), the eight third derivatives cancel in four pairs: $\partial_l\partial_k\partial_j u_m$ against $\partial_j\partial_k\partial_l u_m$, $\partial_l\partial_k\partial_m u_j$ against $\partial_l\partial_m\partial_k u_j$, $\partial_j\partial_m\partial_l u_k$ against $\partial_l\partial_m\partial_j u_k$, and $\partial_j\partial_m\partial_k u_l$ against $\partial_j\partial_k\partial_m u_l$.

Sufficiency, first application. For each fixed pair (j,l) consider the one-form on U

$$\alpha^{(jl)} = (\partial_l e_{jk} - \partial_j e_{lk})\,\mathrm{d}x^k\,, \tag{13.255}$$

antisymmetric in (j,l). Its exterior derivative has components $\partial_m\,(\partial_l e_{jk} - \partial_j e_{lk}) - \partial_k\,(\partial_l e_{jm} - \partial_j e_{lm}) = -\mathcal{R}_{jlkm}(e)$, which vanishes by hypothesis. By Theorem 13.109 there are functions w_{jl} with $\partial_k w_{jl} = \partial_l e_{jk} - \partial_j e_{lk}$; since the right-hand side changes sign under $j \leftrightarrow l$, the function $w_{jl} + w_{lj}$ has vanishing gradient and is therefore a constant on the connected set U (Corollary 7.36), which may be subtracted, so w may be taken antisymmetric.

Second application. For each fixed j consider $\beta^{(j)} = (e_{jk} + w_{jk})\,\mathrm{d}x^k$. Its exterior derivative has components

$$\begin{aligned}\partial_m\,(e_{jk} + w_{jk}) - \partial_k\,(e_{jm} + w_{jm}) &= \partial_m e_{jk} - \partial_k e_{jm} + (\partial_k e_{jm} - \partial_j e_{km}) - (\partial_m e_{jk} - \partial_j e_{mk}) \\ &= \partial_j\,(e_{mk} - e_{km}) = 0\end{aligned}$$

by the symmetry of e. So $\beta^{(j)} = \mathrm{d}u_j$ for some function u_j, again by Theorem 13.109; that is $\partial_k u_j = e_{jk} + w_{jk}$, and symmetrizing in (j,k) kills w and returns $e_{jk} = \tfrac{1}{2}(\partial_j u_k + \partial_k u_j)$. The field u is C^3 because its first derivatives are C^2.

Uniqueness. If two solutions differ by u with $\partial_j u_k + \partial_k u_j = 0$, then

$$\partial_k \partial_l u_j = -\partial_k \partial_j u_l = -\partial_j \partial_k u_l = \partial_j \partial_l u_k = \partial_l \partial_j u_k = -\partial_l \partial_k u_j = -\partial_k \partial_l u_j \,,$$

so all second derivatives vanish and u is affine, $u_j = a_j + \Omega_{jk} x^k$; the condition then forces $\Omega_{jk} + \Omega_{kj} = 0$. □

Proposition 13.113 (Product of a closed and an exact form)**.** *If ψ is a closed form and φ is an exact form, then $\psi \wedge \varphi$ is a closed form.*

Rests on Definitions 13.105 and 13.106, Lemma 13.107, and Equation (13.246)*.*

Derivation. *Derives Proposition 13.113.*

Let ψ be a closed k-form and φ an exact l-form. By the Poincaré lemma, φ is moreover closed; then by the Leibniz rule

$$\mathrm{d}(\psi \wedge \varphi) = \mathrm{d}\psi \wedge \varphi + (-1)^k \, \psi \wedge \mathrm{d}\varphi$$

vanishes. □

13.6.6 The volume form

Definition 13.114 (Volume form)**.** We define the *volume form* as

$$\eta = \sqrt{g}\; \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n \,, \tag{13.256}$$

where g is the determinant of the metric tensor (Section 13.7).

Rests on Definitions 13.102 and 13.117.

η is in fact an n-form, since

$$\begin{aligned} \eta &= \sqrt{g}\; \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n \\ &= \frac{\sqrt{g}}{n!}\, \delta^{1\ldots n}_{i_1 \ldots i_n}\, \mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_n} \\ &= \frac{1}{n!} \sqrt{g}\; \varepsilon_{i_1 \ldots i_n}\, \mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_n} \,, \end{aligned}$$

where $\delta^{1\ldots n}_{i_1\ldots i_n}$ is the generalised Kronecker delta and $\varepsilon_{i_1\ldots i_n}$ the Levi-Civita symbol. Hence η is an n-form with components

$$\eta_{i_1 \ldots i_n} = \sqrt{g}\; \varepsilon_{i_1 \ldots i_n} \,. \tag{13.257}$$

Remark 13.115. For a metric of signature (p,q) with $D = p+q$ the determinant g carries the sign $(-1)^q$, and the volume form is written with $\sqrt{|g|}$ in place of $\sqrt{g}$; the source treats the Riemannian case $q = 0$.

13.6.7 The Hodge dual

Consider a differentiable manifold M_n. Recall that at each point P of the manifold there exist a tangent space $T_{M_n}(P)$ and a cotangent space $T^*_{M_n}(P)$, which are n-dimensional vector spaces, and that the set of all k-forms is a vector space $\Lambda^k_{M_n}(P)$ with (Proposition 13.100)

$$\dim\left(\Lambda^k_{M_n}(P)\right) = \frac{n!}{(n-k)!\,k!} \,,$$

and likewise for the set of all k-vectors, ${}^*\Lambda^k_{M_n}(P)$. Owing to the fact that

$$\binom{n}{k} = \binom{n}{n-k},$$

we can associate four $\binom{n}{k}$-dimensional vector spaces with each point of the manifold: the space of k-forms, the space of $(n-k)$-forms, the space of k-vectors, and the space of $(n-k)$-vectors. Recalling that two vector spaces of the same dimension are isomorphic, the four spaces mentioned are isomorphic; that is, we can guarantee that isomorphisms exist among them.

Which are the isomorphisms that move us between these spaces? The answer to this question is not in itself essential: we define the maps and prove their quality as isomorphisms when necessary.

Definition 13.116 (Hodge dual)**.** Let T be a k-vector with components $T^{i_1\dots i_k}$. We define the *Hodge operator* (*duality operator*, or *star operator*) as

$$\begin{aligned} *\,:\, {}^*\Lambda^k_{M_n}(P) &\longrightarrow \Lambda^{n-k}_{M_n}(P) \\ T &\longmapsto {}^*T = \frac{1}{(n-k)!}\underbrace{\frac{1}{k!}\,\eta_{i_1\dots i_k i_{k+1}\dots i_n} T^{i_1\dots i_k}}_{{}^*T_{i_{k+1}\dots i_n}}\,\mathrm{d}x^{i_{k+1}}\wedge\cdots\wedge\mathrm{d}x^{i_n}\,. \end{aligned}$$

Rests on Definitions 13.98, 13.99 and 13.114.

We see that the change of components is given by

$${}^*T_{i_{k+1}\dots i_n} = \frac{1}{k!}\,\eta_{i_1\dots i_n} T^{i_1\dots i_k}\,. \tag{13.258}$$

13.7 The metric tensor

A manifold, as defined so far, knows nearness but not distance: the charts of Section 13.4.1 let us differentiate, but nothing yet measures lengths, areas, volumes, or angles. As the source manuscript asks: the ambient $\mathbb{R}^N$ of an embedded manifold carries the Euclidean metric, but can that law serve an arbitrary manifold? It cannot — a vector on a manifold lives in the tangent space at its point (Section 13.5.1), and each point carries its own. The remedy is a field that equips every tangent space with its own scalar product.

Definition 13.117 (Metric tensor of signature (p,q))**.** A *metric* on a D-dimensional manifold M, $D = p+q$, is a $(0,2)$ tensor field $g = g_{\mu\nu}\,\mathrm{d}x^\mu \otimes \mathrm{d}x^\nu$ that is symmetric, $g_{\mu\nu} = g_{\nu\mu}$, and nondegenerate, $\det g_{\mu\nu} \neq 0$, and whose matrix at every point has p positive and q negative eigenvalues (*signature* (p,q); the counts are point-independent on a connected manifold by continuity of the eigenvalues). The inverse metric $g^{\mu\nu}$ is defined by $g^{\mu\lambda}g_{\lambda\nu} = \delta^\mu{}_\nu$. The pair (M,g) is a *pseudo-Riemannian manifold* (Riemannian iff $q=0$).

Rests on Definitions 13.48 and 13.84.

Definition 13.118 (Line element)**.** The *invariant line element* of a displacement $\mathrm{d}x^\mu$ is

$$\mathrm{d}s^2 = g_{\mu\nu}\,\mathrm{d}x^\mu \mathrm{d}x^\nu\,. \tag{13.259}$$

It is a scalar under general coordinate transformations (Section 13.5.2), because the transformation Jacobians of $g_{\mu\nu}$ and of the two $\mathrm{d}x$'s cancel. For $q \neq 0$ the line element is not positive definite: displacements split into those with $\mathrm{d}s^2 > 0$, $\mathrm{d}s^2 = 0$, and $\mathrm{d}s^2 < 0$, the geometric germ of the causal structure of Part IV.

Rests on Definition 13.117.

The metric and its inverse convert between the tangent and cotangent spaces — they *lower and raise indices*, $V_\mu = g_{\mu\nu}V^\nu$, $\omega^\mu = g^{\mu\nu}\omega_\nu$ — and define the invariant volume element

$$\mathrm{d}V = \sqrt{|g|}\,\mathrm{d}^D x\,, \qquad g \equiv \det g_{\mu\nu}\,, \tag{13.260}$$

whose invariance follows from the Jacobian transformation of $\det g$ (Section 13.5.3: $\sqrt{|g|}$ is a scalar density of weight one).

Definition 13.119 (Induced metric)**.** Let $\Sigma \subset M$ be a submanifold described by the embedding $x^\mu(\xi^i)$. The *induced metric* on Σ is the pullback of g,

$$h_{ij} = g_{\mu\nu}\,\frac{\partial x^\mu}{\partial \xi^i}\,\frac{\partial x^\nu}{\partial \xi^j}\,, \tag{13.261}$$

generalizing the first fundamental form of surface theory (Section 13.3.2), which is exactly Equation (13.261) for a surface in Euclidean $\mathbb{R}^3$.

Rests on Definition 13.117.

13.7.1 Isometries

Definition 13.120 (Isometry)**.** A diffeomorphism $f : M \longrightarrow M$ is an *isometry* iff the metric at P has the same value as the metric at $f(P)$, compared by pulling back:

$$f^* g_{f(P)} = g_P\,. \tag{13.262}$$

Rests on Definition 13.117.

Proposition 13.121 (The isometry group)**.** *The set of all isometries of (M, g) forms a group under composition, denoted* $\mathrm{Isom}(M, g)$.

Rests on Definition 13.120.

Proof. *Derives Proposition 13.121.*

Closure: for isometries f and h, the pullback of a composition is the composition of pullbacks in reverse order (Section 13.5.1), so

$$\begin{aligned}(h \circ f)^* g_{(h\circ f)(P)} &= f^*\left(h^* g_{h(f(P))}\right)\\ &= f^* g_{f(P)}\\ &= g_P\,.\end{aligned} \tag{13.263}$$

Associativity is inherited from composition of maps. The identity id_M is an isometry, $\mathrm{id}_M^*\, g_P = g_P$. Inverses: an isometry is a diffeomorphism, so f^{-1} exists, and applying $(f^{-1})^*$ to both sides of Equation (13.262) at the point $f^{-1}(Q)$ gives $(f^{-1})^* g_{f^{-1}(Q)} = g_Q$, i.e. f^{-1} is an isometry. □

The infinitesimal version of Equation (13.262) — the Killing equation — is derived in Section 13.9.2, and the manifolds whose isometry groups are as large as possible are classified in Section 13.13: they are precisely the flat, anti-de Sitter, and de Sitter geometries of Table 13.1.

13.8 Vielbein and local frames

The coordinate basis ∂_μ diagonalizes differentiation, not the metric. For the physics of Part V — and for spinors, which transform under no representation of the diffeomorphism group — one needs at each point a basis in which the metric is the flat η_{ab} of Equation (13.1). Indices $a, b, \ldots$ follow the conventions of Section 13.1.

Definition 13.122 (Vielbein)**.** A *vielbein* (frame field) is a set of D one-forms $e^a = e^a{}_\mu \, \mathrm{d}x^\mu$ such that

$$g_{\mu\nu} = \eta_{ab} \, e^a{}_\mu \, e^b{}_\nu \, . \tag{13.264}$$

The dual frame vectors $e_a = e_a{}^\mu \partial_\mu$ satisfy $e^a{}_\mu e_b{}^\mu = \delta^a_b$ and $e^a{}_\mu e_a{}^\nu = \delta_\mu{}^\nu$; frame indices are raised and lowered with η_{ab}, coordinate indices with $g_{\mu\nu}$, and the vielbein converts one type into the other, $V^a = e^a{}_\mu V^\mu$. Taking determinants of Equation (13.264), $e \equiv \det e^a{}_\mu = \sqrt{|g|}$ (up to orientation), so the volume element Equation (13.260) is $e \, \mathrm{d}^D x$.

Rests on Definition 13.117 and Equation (13.1).

Proposition 13.123 (Local Lorentz freedom)**.** *The vielbein of a given metric is unique up to*

$$e^a{}_\mu(x) \longrightarrow \Lambda^a{}_b(x) \, e^b{}_\mu(x) \, , \qquad \Lambda^a{}_c \, \Lambda^b{}_d \, \eta_{ab} = \eta_{cd} \, , \tag{13.265}$$

a local *(point-dependent) transformation with values in the Lorentz group* $\mathrm{L}_{p+q} = \mathrm{SO}(p,q)$ *of Table 13.1.*

Rests on Definition 13.122.

Proof. *Derives Proposition 13.123.*

If e and $\tilde{e}$ both satisfy Equation (13.264), then $\Lambda^a{}_b \equiv \tilde{e}^a{}_\mu e_b{}^\mu$ maps one to the other, and substituting into Equation (13.264) for both sides forces $\eta_{ab}\Lambda^a{}_c\Lambda^b{}_d = \eta_{cd}$, which is the defining condition of $\mathrm{O}(p,q)$; continuity and choice of orientation restrict to $\mathrm{SO}(p,q)$. Conversely any such $\Lambda(x)$ preserves Equation (13.264). □

Geometry in the frame formulation therefore has *two* covariances, acting on different indices per Section 13.1: diffeomorphisms on $\mu, \nu, \ldots$ and local Lorentz transformations on $a, b, \ldots$ — the structure that makes gravity resemble a gauge theory (Section 13.12).

Unlike the coordinate basis, the frame e_a is in general *anholonomic*: its Lie brackets (Section 13.9) do not vanish,

$$[e_a, e_b] = C^c{}_{ab} \, e_c \, , \qquad C^c{}_{ab} = e_a{}^\mu e_b{}^\nu \left(\partial_\mu e^c{}_\nu - \partial_\nu e^c{}_\mu \right) \, , \tag{13.266}$$

and the $C^c{}_{ab}$ measure the failure of the frame to come from coordinates.

13.9 Flows, the Lie derivative, and Killing vectors

A vector field $\boldsymbol{\xi} = \xi^\mu \partial_\mu$ generates a flow: the one-parameter family of diffeomorphisms ϕ_t obtained by sliding every point along the integral curves $\frac{\mathrm{d}x^\mu}{\mathrm{d}t} = \xi^\mu(x)$. The *Lie derivative* measures the rate of change of a tensor field as it is dragged by this flow, comparing the dragged tensor with the actual one:

$$\mathcal{L}_\xi T = \lim_{t \to 0} \frac{\phi_t^* \, T_{\phi_t(P)} - T_P}{t} \, . \tag{13.267}$$

It requires no metric and no connection — only the differentiable structure.

That opening sentence asserts something, and the assertion is a theorem: that a smooth vector field *has* a flow, that the flow is unique, that it is smooth in the point as well as in the parameter, and that each ϕ_t is a diffeomorphism. Everything in this section, and the Frobenius theorem of Section 13.9.1 below, rests on it.

Definition 13.124 (Integral curve; complete vector field)**.** An *integral curve* of a smooth vector field X on M_n is a smooth curve γ with $\dot{\gamma}(t) = X\left(\gamma(t)\right)$ for every t in its domain. X is *complete* if and only if through every point there is an integral curve defined on all of $\mathbb{R}$.

Rests on Definitions 13.71 and 13.82.

Theorem 13.125 (Existence, uniqueness and smoothness of the flow)**.** *Let X be a smooth vector field on M_n and $P \in M_n$. Then there are an open set $U \ni P$, a number $\varepsilon > 0$ and a smooth map*

$$\phi :]-\varepsilon, \varepsilon[\times U \longrightarrow M_n , \qquad \frac{\mathrm{d}}{\mathrm{d}t}\phi_t(x) = X\left(\phi_t(x)\right) , \qquad \phi_0 = \mathrm{id}_U , \tag{13.268}$$

such that each ϕ_t is a diffeomorphism of U onto an open subset of M_n. Two integral curves of X that agree at one parameter value agree on the intersection of their domains; consequently

$$\phi_{t+s} = \phi_t \circ \phi_s \tag{13.269}$$

wherever both sides are defined, and $\phi_t^{-1} = \phi_{-t}$. If X is complete, ϕ is defined on all of $\mathbb{R} \times M_n$ and $t \mapsto \phi_t$ is a one-parameter group of diffeomorphisms of M_n.

Rests on Definition 13.124 and Theorems 9.8 and A.74.

Proof. *Derives Theorem 13.125.*

Work in a chart around P, in which X becomes a smooth map $X : V \longrightarrow \mathbb{R}^n$ on an open $V \subseteq \mathbb{R}^n$ and P becomes x_0. Smoothness makes X bounded and Lipschitz on any closed box inside V (Theorem 7.24 and Theorem 7.35 applied componentwise), so Theorem 9.8 gives a unique integral curve c with $c(0) = x_0$ on some interval, and we fix $T > 0$ with $c\left([-T, T]\right) \subset V$.

Reduction to a field that vanishes at a point. For $s \in [0,1]$ and z in the open set $O = \{z \in \mathbb{R}^n \mid z + c(Ts) \in V \text{ for all } s \in [0,1]\}$, which contains 0 because $c([0,T])$ is compact and V open, put

$$Z_s(z) = T\left[X\left(z + c(Ts)\right) - X\left(c(Ts)\right)\right] . \tag{13.270}$$

This is smooth in (s, z) and $Z_s(0) = 0$ for every s, which is exactly the hypothesis of Theorem A.74. That theorem supplies a ball $B \ni 0$ and a smooth $\zeta : [0,1] \times B \longrightarrow O$ with $\partial_s \zeta_s(z) = Z_s\left(\zeta_s(z)\right)$, $\zeta_0 = \mathrm{id}$, each ζ_s a diffeomorphism onto an open set. Define, for $x \in U := x_0 + B$ and $t \in [0, T]$,

$$\phi_t(x) = \zeta_{t/T}(x - x_0) + c(t) . \tag{13.271}$$

Then $\phi_0(x) = (x - x_0) + x_0 = x$, and by Equation (13.270)

$$\frac{\mathrm{d}}{\mathrm{d}t}\phi_t(x) = \frac{1}{T}\, Z_{t/T}\left(\zeta_{t/T}(x - x_0)\right) + \dot{c}(t) = X\left(\phi_t(x)\right) - X\left(c(t)\right) + X\left(c(t)\right) ,$$

which is Equation (13.268). Each ϕ_t is a diffeomorphism onto an open set, being $\zeta_{t/T}$ composed with two translations, and ϕ is smooth in (t, x) jointly because ζ and c are. Negative t is covered by running the same construction for $-X$, whose integral curves are those of X traversed backwards; taking ε smaller than both times obtained gives Equation (13.268) on $]-\varepsilon, \varepsilon[\times U$.

Uniqueness and the group law. Two integral curves agreeing at t_1 satisfy the same initial value problem there, so they agree near t_1 by Theorem 9.8; the set where they agree is therefore open, and it is closed by continuity, so it is the whole of the (connected) intersection of their domains. Now fix s and x: both $t \mapsto \phi_{t+s}(x)$ and $t \mapsto \phi_t\left(\phi_s(x)\right)$ are integral curves of X taking the value $\phi_s(x)$ at $t = 0$, whence Equation (13.269); putting $s = -t$ gives $\phi_t \circ \phi_{-t} = \mathrm{id}$. Completeness removes the restriction on the interval, and Equation (13.269) then says that $t \mapsto \phi_t$ is a homomorphism of $(\mathbb{R}, +)$ into the diffeomorphisms of M_n. □

Remark 13.126 (What the proof imports, and what it does not). Only two things: the Picard–Lindelöf theorem of Chapter 9, for existence and uniqueness, and the flow theorem proved in the appendix for Moser's trick (Theorem A.74), for smooth dependence on the initial point. The latter is stated there for a time-dependent field vanishing at a point,

which looks like a special case and is not: subtracting the value of X along the integral curve through P, as Equation (13.270) does, turns *any* smooth field into one of that kind, at the cost of making it time-dependent — which the appendix theorem already allows. No fixed-point theorem and no compactness argument beyond Theorem 7.24 enters.

Proposition 13.127 (Component formulas)**.** *For a scalar, a vector, a covector, and a* $(0,2)$ *tensor,*

$$\mathcal{L}_\xi f = \xi^\mu \partial_\mu f \,, \tag{13.272}$$

$$(\mathcal{L}_\xi V)^\mu = \xi^\nu \partial_\nu V^\mu - V^\nu \partial_\nu \xi^\mu = [\xi, V]^\mu \,, \tag{13.273}$$

$$(\mathcal{L}_\xi \omega)_\mu = \xi^\nu \partial_\nu \omega_\mu + \omega_\nu \partial_\mu \xi^\nu \,, \tag{13.274}$$

$$(\mathcal{L}_\xi g)_{\mu\nu} = \xi^\lambda \partial_\lambda g_{\mu\nu} + g_{\lambda\nu} \partial_\mu \xi^\lambda + g_{\mu\lambda} \partial_\nu \xi^\lambda \,, \tag{13.275}$$

with one drag term per index in general. All partial derivatives may be replaced by covariant derivatives of any torsion-free connection: the connection terms cancel pairwise.

Rests on Equation (13.267) *and Definitions 13.89 and 13.90.*

Proof. *Derives Proposition 13.127.*

Expand ϕ_t to first order, $x'^\mu = x^\mu + t\,\xi^\mu$, in the transformation law of each tensor type (Section 13.5.2), and differentiate at $t = 0$: the Jacobian $\partial x'^\mu / \partial x^\nu = \delta^\mu{}_\nu + t\,\partial_\nu \xi^\mu$ contributes the drag terms with the signs shown (one $+$ per lower index, one $-$ per upper index), and the argument shift contributes the transport term $\xi \cdot \partial$. The cancellation of connection terms is a direct check using the symmetry $\Gamma^\lambda{}_{\mu\nu} = \Gamma^\lambda{}_{\nu\mu}$ of a torsion-free connection. □

On differential forms (Section 13.6) the Lie derivative has a purely exterior expression:

Proposition 13.128 (Cartan's magic formula)**.** *On any* k*-form* α*,*

$$\mathcal{L}_\xi \alpha = \mathrm{d}\,(i_\xi \alpha) + i_\xi\,(\mathrm{d}\alpha) \,, \tag{13.276}$$

where i_ξ *is the interior product,* $(i_\xi \alpha)_{\mu_2 \ldots \mu_k} = \xi^{\mu_1} \alpha_{\mu_1 \mu_2 \ldots \mu_k}$*.*

Rests on Proposition 13.127, Definition 13.103, and Equations (13.245) *and* (13.246)*.*

Proof. *Derives Proposition 13.128.*

On functions, $i_\xi f \equiv 0$ and $i_\xi \mathrm{d}f = \xi^\mu \partial_\mu f = \mathcal{L}_\xi f$. On the coordinate differentials, $\mathcal{L}_\xi \mathrm{d}x^\mu = \mathrm{d}\xi^\mu = \mathrm{d}(i_\xi \mathrm{d}x^\mu) + i_\xi \mathrm{d}(\mathrm{d}x^\mu)$, using $\mathrm{d}^2 = 0$ (Section 13.6.4). Both sides of Equation (13.276) are derivations of the exterior algebra (they obey the graded Leibniz rule — for the right side this follows from the graded Leibniz rules of d and i_ξ), and a derivation is fixed by its action on functions and their differentials, which generate all forms locally. The two sides agree there, hence everywhere. □

The three operators $\mathcal{L}$, d and i close on one another, and Equation (13.276) is only the first of the identities they satisfy. The second is the one that lets a computation move an interior product past a Lie derivative, which is what makes many arguments with forms one line long instead of a component calculation.

Proposition 13.129 (Commutation of Lie derivative and interior product)**.** *For any smooth vector fields* X, Y *and any* k*-form* α*,*

$$\mathcal{L}_X\, i_Y \alpha - i_Y\, \mathcal{L}_X \alpha = i_{[X,Y]} \alpha \,. \tag{13.277}$$

Rests on Propositions 13.127 and 13.128 and Definition 13.98.

Proof. *Derives Proposition 13.129.*

Both sides are $(k-1)$-forms; compare components. Write $\beta = i_Y\alpha$, so $\beta_{\mu_2\dots\mu_k} = Y^\nu\alpha_{\nu\mu_2\dots\mu_k}$ by the convention of Proposition 13.128, and use the general component formula of Proposition 13.127 — transport term plus one drag term per lower index:

$$(\mathcal{L}_X\beta)_{\mu_2\dots\mu_k} = X^\lambda\partial_\lambda\left(Y^\nu\alpha_{\nu\mu_2\dots\mu_k}\right) + \sum_{i=2}^{k} Y^\nu\alpha_{\nu\dots\lambda\dots\mu_k}\,\partial_{\mu_i}X^\lambda\,,$$

$$(i_Y\mathcal{L}_X\alpha)_{\mu_2\dots\mu_k} = Y^\nu\left[X^\lambda\partial_\lambda\alpha_{\nu\mu_2\dots\mu_k} + \alpha_{\lambda\mu_2\dots\mu_k}\partial_\nu X^\lambda + \sum_{i=2}^{k}\alpha_{\nu\dots\lambda\dots\mu_k}\,\partial_{\mu_i}X^\lambda\right],$$

where in each sum λ sits in the i-th slot. Subtracting, the transport terms of α and all the drag terms carried by $\mu_2,\dots,\mu_k$ cancel, leaving

$$\left(X^\lambda\partial_\lambda Y^\nu - Y^\lambda\partial_\lambda X^\nu\right)\alpha_{\nu\mu_2\dots\mu_k} = [X,Y]^\nu\,\alpha_{\nu\mu_2\dots\mu_k}\,,$$

by Equation (13.273), and that is $\left(i_{[X,Y]}\alpha\right)_{\mu_2\dots\mu_k}$. □

13.9.1 Distributions and the Frobenius theorem

A single vector field, by Theorem 13.125, threads the manifold with curves: through every point passes one integral curve, and the curves fill the manifold. The question of this subsection is what happens when a k-dimensional field of tangent planes is prescribed instead of a field of tangent lines. Does a k-dimensional surface pass through each point with the prescribed tangent plane everywhere? For $k=1$ the answer is always yes; for $k\geq 2$ it is yes precisely when an algebraic condition on brackets holds, and that is the Frobenius theorem. It is the theorem behind the symplectic foliation of a Poisson manifold, behind the counting of gauge degrees of freedom generated by first-class constraints, and behind the very meaning of the word *nonholonomic*: a constraint is nonholonomic exactly when the distribution it defines fails the condition below.

Definition 13.130 (Distribution; involutive; integrable)**.** A *distribution of rank k* on M_n is an assignment $P\mapsto D_P\subseteq T_PM_n$ of a k-dimensional subspace to each point which is *smooth*: every point has a neighbourhood on which there are smooth vector fields $X_1,\dots,X_k$ spanning D_Q at each Q of it. A vector field X *belongs to* D iff $X_Q\in D_Q$ everywhere. The distribution is

1. *involutive* iff $[X,Y]$ belongs to D whenever X and Y do;
2. *integrable* iff through each $P\in M_n$ there passes an *integral manifold*: an embedded k-dimensional submanifold $S\ni P$ (Definition 13.54) with $T_QS = D_Q$ for every $Q\in S$.

Rests on Definitions 13.54 and 13.82 and Equation (13.273).

Proposition 13.131 (Commuting fields have commuting flows)**.** *Let X and Y be smooth vector fields with flows ϕ_t and η_s. If $[X,Y]=0$ then $(\phi_t)_*Y = Y$ and*

$$\phi_t\circ\eta_s = \eta_s\circ\phi_t \tag{13.278}$$

wherever both sides are defined.

Rests on Theorem 13.125 and Equations (13.267) and (13.273).

Proof. *Derives Proposition 13.131.*

Fix x and put $W(t) = (\phi_{-t})_*\,Y_{\phi_t(x)}\in T_xM_n$, a smooth curve in one fixed vector space. By the group law Equation (13.269), for any t_0,

$$W(t_0+h) = (\phi_{-t_0})_*\left[(\phi_{-h})_*\,Y_{\phi_h(y)}\right],\qquad y=\phi_{t_0}(x)\,,$$

so differentiating at $h = 0$ and using the definition Equation (13.267) of the Lie derivative together with Equation (13.273), $\frac{\mathrm{d}W}{\mathrm{d}t}(t_0) = (\phi_{-t_0})_* (\mathcal{L}_X Y)_y = (\phi_{-t_0})_* [X, Y]_y = 0$. Hence $W(t) = W(0) = Y_x$, i.e. $(\phi_t)_* Y_x = Y_{\phi_t(x)}$ for every t and x.

A diffeomorphism that carries Y to Y carries integral curves of Y to integral curves of Y: if $\dot\gamma = Y \circ \gamma$ then $\frac{\mathrm{d}}{\mathrm{d}s}(\phi_t \circ \gamma) = (\phi_t)_* Y_\gamma = Y_{\phi_t(\gamma)}$. So $s \mapsto \phi_t(\eta_s(x))$ is the integral curve of Y through $\phi_t(x)$, which is $s \mapsto \eta_s(\phi_t(x))$ by the uniqueness clause of Theorem 13.125. That is Equation (13.278). □

Proposition 13.132 (Simultaneous straightening of commuting fields)**.** *Let $Y_1, \dots, Y_k$ be smooth vector fields on M_n, pairwise commuting, $[Y_a, Y_b] = 0$, and linearly independent at P. Then there is a chart $(u^1, \dots, u^n)$ around P in which*

$$Y_a = \frac{\partial}{\partial u^a}, \qquad a = 1, \dots, k. \tag{13.279}$$

Rests on Proposition 13.131, Theorem 13.125, and Corollary A.292.

Proof. *Derives Proposition 13.132.*

Take any chart around P sending P to the origin of $\mathbb{R}^n$, and follow it by the linear change of coordinates that sends $Y_1(P), \dots, Y_k(P)$ — independent by hypothesis, hence extendable to a basis — to the first k coordinate vectors. Write ϕ^a for the flow of Y_a (Theorem 13.125) and, for u in a small neighbourhood of 0 in $\mathbb{R}^n$, set

$$\Psi\left(u^1, \dots, u^n\right) = \left(\phi^1_{u^1} \circ \cdots \circ \phi^k_{u^k}\right)\left(0, \dots, 0, u^{k+1}, \dots, u^n\right), \tag{13.280}$$

the argument on the right being the point of the slice $u^1 = \cdots = u^k = 0$. This is defined and smooth near 0, each flow being smooth in both arguments.

Its differential at 0 is invertible: all parameters vanish there, so $\partial\Psi/\partial u^a\big|_0 = Y_a(P)$ for $a \le k$, while $\partial\Psi/\partial u^j\big|_0 = \partial/\partial x^j\big|_P$ for $j > k$, and these n vectors are a basis by the choice of the initial chart. By the inverse function theorem (Corollary A.292) Ψ is a diffeomorphism of a neighbourhood of 0 onto a neighbourhood of P, and we take Ψ^{-1} as the chart.

Finally, fix a. Because the flows commute (Proposition 13.131), the composition in Equation (13.280) may be reordered to put ϕ^a outermost, and then $\partial\Psi/\partial u^a$ is the velocity of the integral curve of Y_a through $\Psi(u)$, that is $Y_a(\Psi(u))$. Hence $\Psi_*(\partial/\partial u^a) = Y_a$, which is Equation (13.279). □

Theorem 13.133 (Frobenius)**.** *A smooth distribution D of constant rank k on M_n is integrable if and only if it is involutive. When it is, every point has a chart $(u^1, \dots, u^n)$ in which*

$$D = \operatorname{span}\left\{\frac{\partial}{\partial u^1}, \dots, \frac{\partial}{\partial u^k}\right\}, \tag{13.281}$$

so that the slices $u^{k+1} = const, \dots, u^n = const$ are integral manifolds: the chart domain is foliated by them, and every connected integral manifold inside it lies in one slice.

Rests on Definition 13.130, Proposition 13.132, and Equation (13.273).

Proof. *Derives Theorem 13.133.*

Integrable implies involutive. Let X, Y belong to D and let $P \in M_n$ lie on an integral manifold S. Both fields are tangent to S, hence restrict to vector fields on S; the bracket Equation (13.273) of two fields tangent to an embedded submanifold is again tangent to it, since in a chart adapted to S both fields have vanishing components transverse to S and Equation (13.273) differentiates those components only along directions inside S. So $[X, Y]_P \in T_P S = D_P$.

Involutive implies integrable. Fix P and a local spanning frame $X_1, \dots, X_k$ of D (Definition 13.130). Choose a chart around P with coordinates $(x^1, \dots, x^n)$ such that D_P is transverse to the span of $\partial/\partial x^{k+1}, \dots, \partial/\partial x^n$; equivalently, writing $X_a = X_a{}^i \partial/\partial x^i$, the

$k \times k$ block $A_a{}^b = X_a{}^b$ with $b \le k$ is invertible at P, hence on a neighbourhood. Replace the frame by

$$Y_a = \left(A^{-1}\right)_a{}^b X_b = \frac{\partial}{\partial x^a} + \sum_{j>k} Y_a{}^j \frac{\partial}{\partial x^j}\,, \tag{13.282}$$

still a frame for D, since the change is by an invertible matrix of functions.

Now compute $[Y_a, Y_b]$ from Equation (13.273). The components of Y_a along $\partial/\partial x^c$ with $c \le k$ are the constants δ_a^c, so every derivative of them vanishes and the bracket has *no* component along $\partial/\partial x^1, \dots, \partial/\partial x^k$:

$$[Y_a, Y_b] = \sum_{j>k} \left(Y_a\left(Y_b{}^j\right) - Y_b\left(Y_a{}^j\right)\right) \frac{\partial}{\partial x^j}\,. \tag{13.283}$$

By involutivity the left side belongs to D, so it is a combination $\lambda^a Y_a$; comparing the components along $\partial/\partial x^c$, $c \le k$, which are λ^c on the right and zero on the left by Equation (13.283), gives $\lambda^c = 0$ and hence

$$[Y_a, Y_b] = 0\,. \tag{13.284}$$

The frame $Y_1, \dots, Y_k$ is therefore commuting and pointwise independent, and Proposition 13.132 supplies a chart in which $Y_a = \partial/\partial u^a$. Since the Y_a span D, this is Equation (13.281), and the slices $u^{k+1}, \dots, u^n = \text{const}$ are embedded k-dimensional submanifolds whose tangent space at each point is exactly D: integral manifolds through every point of the chart domain.

For the last clause, let S be a connected integral manifold inside the chart domain. On S each function u^j with $j > k$ has vanishing differential, because $T_Q S = D_Q$ is spanned by the $\partial/\partial u^a$ with $a \le k$; a function with vanishing differential on a connected manifold is constant (Corollary 7.36 applied along paths in a chart). So S lies in one slice. □

The dual formulation is the one that appears whenever the planes are prescribed by equations rather than by spanning fields — a mechanical constraint written as a set of one-forms annihilating the admissible velocities is exactly that situation.

Corollary 13.134 (Frobenius for a Pfaffian system)**.** *Let D have rank k and let $\theta^1, \dots, \theta^{n-k}$ be pointwise independent one-forms whose common kernel is D, so that a vector v lies in D if and only if $\theta^\alpha(v) = 0$ for every α. Then D is integrable if and only if the ideal generated by the θ^α is closed under exterior differentiation, i.e. iff there are one-forms $\eta^\alpha{}_\beta$ with*

$$\mathrm{d}\theta^\alpha = \sum_\beta \eta^\alpha{}_\beta \wedge \theta^\beta\,, \tag{13.285}$$

equivalently iff $\mathrm{d}\theta^\alpha \wedge \theta^1 \wedge \cdots \wedge \theta^{n-k} = 0$ for every α.

Rests on Theorem 13.133 and Definitions 13.103 and 13.130.

Proof. *Derives Corollary 13.134.*

For a one-form $\theta = \theta_\mu \mathrm{d}x^\mu$, the components of $\mathrm{d}\theta$ are $\partial_\mu\theta_\nu - \partial_\nu\theta_\mu$ (Definition 13.103), and for any vector fields X, Y

$$\left(\partial_\mu\theta_\nu - \partial_\nu\theta_\mu\right) X^\mu Y^\nu = X(\theta(Y)) - Y(\theta(X)) - \theta([X,Y])\,, \tag{13.286}$$

as expanding the three terms on the right with Equation (13.273) shows: the terms carrying a derivative of X or of Y cancel in pairs and only the derivatives of θ survive. If X and Y belong to D, the first two terms on the right of Equation (13.286) vanish, so

$$\left(\mathrm{d}\theta^\alpha\right)_{\mu\nu} X^\mu Y^\nu = -\,\theta^\alpha([X,Y])\,. \tag{13.287}$$

Involutivity says the right-hand side vanishes for every α and every X, Y in D — because the θ^α detect exactly membership of D — and that is the statement that each $\mathrm{d}\theta^\alpha$ annihilates

$D \times D$. Completing the θ^α to a coframe by one-forms σ^a dual to a frame of D, a two-form annihilating $D \times D$ has no $\sigma^a \wedge \sigma^b$ term, i.e. every term carries at least one factor θ^β, which is Equation (13.285); and a two-form of that shape wedges to zero against $\theta^1 \wedge \cdots \wedge \theta^{n-k}$, while conversely a $\sigma^a \wedge \sigma^b$ term would survive that wedge. The three conditions are therefore equivalent, and by Theorem 13.133 each is equivalent to integrability. □

Remark 13.135 (Constant rank is a hypothesis, not a formality). Theorem 13.133 assumes the rank of D is the same at every point, and the hypothesis is doing work: Equation (13.282) needs a local frame of fixed size, and Equation (13.281) asserts a fixed number of slice coordinates. Distributions whose rank jumps do occur — a bivector field may be invertible on the complement of a point and vanish at it, so that the distribution it spans has rank 2 almost everywhere and rank 0 there — and at such a point the conclusion above says nothing whatever, not even that a leaf of some smaller dimension passes through. This treatise establishes no generalisation covering that case, and nothing in it rests on one; the limitation is recorded here so that an appeal to Theorem 13.133 elsewhere in the book can be checked against its hypothesis rather than against its name.

Lemma 13.136 (Discrete subgroups of $\mathbb{R}^f$)**.** *Let Γ be a subgroup of $\left(\mathbb{R}^f, +\right)$ which is* discrete*, i.e. $\Gamma \cap B_r(0) = \{0\}$ for some $r > 0$. Then there are $m \leq f$ linearly independent vectors $w_1, \ldots, w_m \in \Gamma$ with*

$$\Gamma = \mathbb{Z}w_1 \oplus \cdots \oplus \mathbb{Z}w_m \,, \tag{13.288}$$

and m is the dimension of the linear span of Γ.

Rests on Definitions 5.13 and 6.9.

Proof. *Derives Lemma 13.136.*

First, a bounded set meets Γ in finitely many points: two distinct elements of Γ differ by a nonzero element of Γ, hence by at least r, so a ball of radius R can contain at most finitely many of them.

Induct on $m = \dim \operatorname{span} \Gamma$. For $m = 0$, $\Gamma = \{0\}$. Let $m \geq 1$ and choose linearly independent $v_1, \ldots, v_m \in \Gamma$ spanning that span. Put $W = \operatorname{span}\{v_1, \ldots, v_{m-1}\}$. The subgroup $\Gamma' = \Gamma \cap W$ is discrete with span exactly W, so by the induction hypothesis $\Gamma' = \mathbb{Z}w_1 \oplus \cdots \oplus \mathbb{Z}w_{m-1}$ with the w_i linearly independent, hence a basis of W.

Every $x \in \Gamma$ decomposes uniquely as $x = \sum_{i<m} a_i w_i + t\, v_m$ with a_i, t real. Let

$$S = \{x \in \Gamma \mid 0 \leq a_i < 1 \text{ for all } i < m, \quad 0 < t \leq 1\} \,,$$

a bounded set, hence finite, and non-empty: subtracting from v_m suitable integer multiples of the w_i — which are in Γ — brings its a_i into $[0, 1[$ without changing $t = 1$. Choose $w_m \in S$ with $t = t_0$ minimal.

Let $x \in \Gamma$ have v_m-coefficient t, put $n = \lfloor t/t_0 \rfloor$ and consider $x - n\, w_m \in \Gamma$, whose v_m-coefficient is $t - nt_0 \in [0, t_0[$. If it were positive, subtracting integer multiples of the w_i would produce an element of S with a v_m-coefficient smaller than t_0, contradicting minimality. So $t = nt_0$ and $x - n\, w_m \in \Gamma \cap W = \Gamma'$. Hence $\Gamma = \Gamma' + \mathbb{Z}w_m$, the sum is direct because $w_m \notin W$, and $w_1, \ldots, w_m$ are linearly independent. Finally $m \leq f$, being the number of independent vectors in $\mathbb{R}^f$. □

Theorem 13.137 (Commuting complete fields on a compact manifold)**.** *Let M_f be a compact connected manifold of dimension f carrying f complete, pairwise commuting vector fields $Y_1, \ldots, Y_f$ that are linearly independent at every point. Then the map*

$$\Theta : \mathbb{R}^f \times M_f \longrightarrow M_f \,, \qquad \Theta\,(t, x) = \left(\phi^1_{t^1} \circ \cdots \circ \phi^f_{t^f}\right)(x) \tag{13.289}$$

is a smooth action of the abelian group $\left(\mathbb{R}^f, +\right)$ which is transitive, and M_f is diffeomorphic to the torus $T^f = \mathbb{R}^f / \mathbb{Z}^f$.

Rests on Propositions 13.131 and 13.132 and Theorem 13.125.

Proof. *Derives Theorem 13.137.*

Each ϕ^a is defined for all parameters by completeness (Definition 13.124 and Theorem 13.125) and the f flows commute in pairs (Proposition 13.131), so Equation (13.289) does not depend on the order of composition and $\Theta(t, \Theta(s, x)) = \Theta(t + s, x)$: it is a smooth action of $\mathbb{R}^f$.

The orbits are open, hence there is one. Fix x and apply Proposition 13.132 with $k = f = n$: near x there is a chart in which $Y_a = \partial/\partial u^a$, and in it $\Theta(\cdot, x)$ is $t \mapsto u = t$ near $t = 0$. So the orbit of x contains a neighbourhood of x; being a union of such, every orbit is open. The orbits partition M_f, and M_f is connected, so there is exactly one: the action is transitive. The same computation shows that $\Theta(\cdot, x)$ is a local diffeomorphism at every t, by the group law.

The stabiliser is a lattice. Let $\Gamma = \left\{ t \in \mathbb{R}^f \mid \Theta(t, x) = x \right\}$, a subgroup of $\mathbb{R}^f$; since $\Theta(\cdot, x)$ is injective near 0, Γ meets some neighbourhood of 0 only in 0, so Γ is discrete, and by transitivity $\Theta(\cdot, x)$ descends to a bijection $\mathbb{R}^f/\Gamma \longrightarrow M_f$, a diffeomorphism because $\Theta(\cdot, x)$ is a local diffeomorphism everywhere. By Lemma 13.136, $\Gamma = \mathbb{Z}w_1 \oplus \cdots \oplus \mathbb{Z}w_m$ with $w_1, \ldots, w_m$ linearly independent; completing them to a basis of $\mathbb{R}^f$ and using that basis as coordinates identifies $\mathbb{R}^f/\Gamma$ with $T^m \times \mathbb{R}^{f-m}$. Compactness of M_f forces $m = f$, since $\mathbb{R}^{f-m}$ is non-compact for $m < f$, and the same change of basis carries Γ to $\mathbb{Z}^f$. Hence $M_f \cong \mathbb{R}^f/\mathbb{Z}^f = T^f$. □

Remark 13.138 (Where this is used). Theorem 13.137 is the differential-topological half of the Liouville–Arnold theorem of Hamiltonian mechanics: an integrable system with f degrees of freedom supplies, on a compact connected level set of its f commuting conserved quantities, exactly f commuting independent vector fields, and the theorem then says the level set is a torus. The symplectic half — that the resulting angle coordinates are canonical — belongs to the mechanics part and is not a statement about manifolds alone.

13.9.2 Killing vectors

Definition 13.139 (Killing vector)**.** $\boldsymbol{\xi}$ is a *Killing vector* of (M, g) iff its flow consists of isometries, i.e. iff $\mathcal{L}_\xi g = 0$.

Rests on Definition 13.120 and Equation (13.267).

Proposition 13.140 (Killing's equation)**.** *With ∇ the Levi-Civita connection of g (Theorem 13.150),*

$$\mathcal{L}_\xi g = 0 \quad \Longleftrightarrow \quad \nabla_\mu \xi_\nu + \nabla_\nu \xi_\mu = 0\,. \tag{13.290}$$

A D-dimensional manifold admits at most $D(D+1)/2$ linearly independent Killing vectors.

Rests on Definitions 13.139 and 13.149, Proposition 13.127, and Theorems 13.150 and 13.152.

Proof. *Derives Proposition 13.140.*

Replace ∂ by ∇ in Equation (13.275) (Proposition 13.127) and use metricity $\nabla_\lambda g_{\mu\nu} = 0$: the transport term drops and the drag terms become $\nabla_\mu \xi_\nu + \nabla_\nu \xi_\mu$. For the count: differentiating Equation (13.290) and commuting derivatives (Section 13.11) yields $\nabla_\mu \nabla_\nu \xi_\lambda = R^\rho{}_{\mu\nu\lambda}\, \xi_\rho$ (torsion-free), so a Killing vector is determined everywhere by the D values $\xi_\mu(P)$ and the $D(D-1)/2$ values $\nabla_{[\mu}\xi_{\nu]}(P)$ at a single point: $D + D(D-1)/2 = D(D+1)/2$. □

A Killing vector is worth having because it gives a conserved quantity, and the conservation law — not the symmetry — is what a physical chapter actually uses. It is one line from Killing's equation.

Proposition 13.141 (The invariant of a Killing vector along a geodesic)**.** *Let $\boldsymbol{\xi}$ be a Killing vector of (M, g) and let γ be an affinely parametrized geodesic of the Levi-Civita connection, with tangent $u^\mu = \frac{\mathrm{d}x^\mu}{\mathrm{d}t}$ and $u^\nu \nabla_\nu u^\mu = 0$. Then*

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\xi_\mu u^\mu\right) = 0\,, \tag{13.291}$$

that is, $\xi_\mu u^\mu$ is constant along γ.
Rests on Proposition 13.140 and Definitions 13.146 and 13.149.

Proof. *Derives Proposition 13.141.*
The derivative along the curve of a scalar is $u^\nu\nabla_\nu$ of it, so

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\xi_\mu u^\mu\right) = u^\nu u^\mu \nabla_\nu \xi_\mu + \xi_\mu\, u^\nu \nabla_\nu u^\mu \,.$$

The second term vanishes by the geodesic equation (Equation (13.297) with $\Gamma = \mathring{\Gamma}$). In the first, $u^\nu u^\mu$ is symmetric under $\mu \leftrightarrow \nu$, so only the symmetric part of $\nabla_\nu \xi_\mu$ contributes:

$$u^\nu u^\mu \nabla_\nu \xi_\mu = \tfrac{1}{2} u^\nu u^\mu \left(\nabla_\nu \xi_\mu + \nabla_\mu \xi_\nu\right) \,,$$

and the bracket vanishes by Killing's equation Equation (13.290). □

Not every geodesic invariant comes from an isometry. The object that produces the rest is the symmetric-tensor generalisation of a Killing vector.

Definition 13.142 (Killing tensor)**.** A *Killing tensor of rank r* on (M, g) is a totally symmetric tensor field $K_{\mu_1\ldots\mu_r}$ satisfying

$$\nabla_{(\lambda} K_{\mu_1\ldots\mu_r)} = 0 \,, \tag{13.292}$$

the round brackets denoting here the *total* symmetrization over the $r+1$ indices they enclose — the average over all $(r+1)!$ orderings of them — which extends to any number of indices the two-index convention Equation (13.213) of Definition 13.91. For $r = 1$, Equation (13.292) is Killing's equation Equation (13.290).
Rests on Definitions 13.91, 13.139 and 13.149.

Theorem 13.143 (Killing tensors and geodesic invariants)**.** *Let K be a Killing tensor of rank r and γ an affinely parametrized geodesic with tangent u^μ. Then*

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(K_{\mu_1\ldots\mu_r}\, u^{\mu_1}\cdots u^{\mu_r}\right) = 0 \,. \tag{13.293}$$

Conversely, a function on the tangent bundle that is a homogeneous polynomial of degree r in u and constant along every geodesic has totally symmetric coefficients obeying Equation (13.292).
Rests on Definitions 13.142 and 13.146 and Proposition 13.141.

Proof. *Derives Theorem 13.143.*
Differentiating along the curve and using $u^\nu\nabla_\nu u^\mu = 0$ for each of the r factors,

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(K_{\mu_1\ldots\mu_r} u^{\mu_1}\cdots u^{\mu_r}\right) = \left(\nabla_\lambda K_{\mu_1\ldots\mu_r}\right) u^\lambda u^{\mu_1}\cdots u^{\mu_r} \,.$$

The product $u^\lambda u^{\mu_1}\cdots u^{\mu_r}$ is totally symmetric in its $r+1$ indices, so contracting it with any tensor picks out that tensor's totally symmetric part; the right-hand side is therefore $\left(\nabla_{(\lambda} K_{\mu_1\ldots\mu_r)}\right) u^\lambda u^{\mu_1}\cdots u^{\mu_r}$, which vanishes by Equation (13.292).

For the converse, the same computation shows that the derivative along every geodesic is $\left(\nabla_{(\lambda} K_{\mu_1\ldots\mu_r)}\right) u^\lambda u^{\mu_1}\cdots u^{\mu_r}$, and through a given point a geodesic may be started with any tangent u (Equation (13.297) is a second-order equation with arbitrary initial position and velocity, solvable by Theorem 9.8). A totally symmetric tensor whose contraction with $u^{\otimes(r+1)}$ vanishes for every u is zero, by polarization: the contraction is a homogeneous polynomial in the components of u whose coefficients are exactly the independent components of the symmetric tensor. □

Example 13.144 (The two Killing tensors every metric carries)**.** The metric itself is a Killing tensor of rank 2: metricity (Definition 13.149) gives $\nabla_\lambda g_{\mu\nu} = 0$, so Equation (13.292) holds trivially, and the invariant Equation (13.293) is $g_{\mu\nu}u^\mu u^\nu$ — the statement that a geodesic keeps the norm of its tangent, i.e. that timelike, null and spacelike geodesics stay so. Symmetrized products of Killing vectors are Killing tensors too: if ξ and χ are Killing vectors then $K_{\mu\nu} = \xi_{(\mu}\chi_{\nu)}$ obeys Equation (13.292), since Equation (13.290) makes each $\nabla_{(\lambda}\xi_{\mu)}$ vanish. A Killing tensor is called *irreducible* when it is not a combination of the metric and such products; an irreducible one gives a constant of the motion that no isometry accounts for, which is why the bound $D(D+1)/2$ of Proposition 13.140 does not bound the number of geodesic invariants.

Rests on Definitions 13.142 and 13.149 and Proposition 13.140.

Metrics that saturate this bound are *maximally symmetric* (Section 13.13). Relaxing isometry to angle preservation defines the conformal Killing vectors, $\mathcal{L}_\xi g = 2\sigma g$ with $\sigma = \nabla_\mu \xi^\mu / D$; for flat space of signature (p, q) with $D > 2$ their maximal number is $(D+1)(D+2)/2$, the dimension of the conformal group $\mathrm{C}_{p+q} = \mathrm{SO}(p+1, q+1)$ (Section 13.13.1).

13.10 Connections, parallel transport, and torsion

In Euclidean geometry a homogeneous (constant) vector field is one whose derivative with respect to position vanishes; its vectors are parallel and of equal length. How does this notion extend to an arbitrary manifold? The partial derivative fails: differentiating the vector transformation law $V'^\mu = (\partial x'^\mu/\partial x^\nu)V^\nu$ gives

$$\partial'_\nu V'^\mu = \frac{\partial x^\rho}{\partial x'^\nu}\frac{\partial x'^\mu}{\partial x^\sigma}\,\partial_\rho V^\sigma + \frac{\partial x^\rho}{\partial x'^\nu}\frac{\partial^2 x'^\mu}{\partial x^\rho \partial x^\sigma}\,V^\sigma\,, \tag{13.294}$$

whose second, inhomogeneous term spoils tensoriality whenever the coordinate change is nonlinear. The covariant derivative is the repair, and it is the concept on which the whole of theoretical physics leans.

Definition 13.145 (Affine connection)**.** An *affine connection* ∇ assigns to vector fields the $(1,1)$-tensor-valued derivative

$$\nabla_\mu V^\lambda = \partial_\mu V^\lambda + \Gamma^\lambda{}_{\mu\nu} V^\nu\,, \tag{13.295}$$

extended to covectors by $\nabla_\mu \omega_\nu = \partial_\mu \omega_\nu - \Gamma^\lambda{}_{\mu\nu}\omega_\lambda$ (so that $\nabla(V^\mu\omega_\mu)$ obeys the Leibniz rule and reduces to ∂), and to arbitrary (r, s) tensors with one $+\Gamma$ term per upper and one $-\Gamma$ term per lower index. The connection coefficients are *not* tensor components: requiring Equation (13.295) to transform as a tensor forces

$$\Gamma'^\lambda{}_{\mu\nu} = \frac{\partial x'^\lambda}{\partial x^\rho}\frac{\partial x^\sigma}{\partial x'^\mu}\frac{\partial x^\tau}{\partial x'^\nu}\,\Gamma^\rho{}_{\sigma\tau} + \frac{\partial x'^\lambda}{\partial x^\rho}\frac{\partial^2 x^\rho}{\partial x'^\mu \partial x'^\nu}\,, \tag{13.296}$$

the inhomogeneous term cancelling that of Equation (13.294).

Rests on Definitions 13.82 and 13.90.

Definition 13.146 (Parallel transport and autoparallels)**.** A tensor T is *parallelly transported* along a curve with tangent $u^\mu = \frac{\mathrm{d}x^\mu}{\mathrm{d}t}$ iff $u^\mu \nabla_\mu T = 0$. A curve is an *autoparallel* iff it parallelly transports its own tangent,

$$\frac{\mathrm{d}^2 x^\lambda}{\mathrm{d}t^2} + \Gamma^\lambda{}_{\mu\nu}\frac{\mathrm{d}x^\mu}{\mathrm{d}t}\frac{\mathrm{d}x^\nu}{\mathrm{d}t} = 0\,, \tag{13.297}$$

generalizing the geodesics of surface theory (Section 13.3.3). Only the symmetric part $\Gamma^\lambda{}_{(\mu\nu)}$ enters Equation (13.297).

Rests on Definition 13.145.

Definition 13.147 (Torsion)**.** The *torsion* of a connection is

$$T^{\lambda}{}_{\mu\nu} = \Gamma^{\lambda}{}_{\mu\nu} - \Gamma^{\lambda}{}_{\nu\mu}\,. \tag{13.298}$$

Rests on Definition 13.145.

Proposition 13.148. *$T^{\lambda}{}_{\mu\nu}$ is a tensor, although $\Gamma^{\lambda}{}_{\mu\nu}$ is not.*
Rests on Definitions 13.90 and 13.147, Equation (13.296), and Proposition 7.73.

Proof. *Derives Proposition 13.148.*
The inhomogeneous term of Equation (13.296) is symmetric in $\mu\nu$ (mixed second partials commute, Proposition 7.73), so it cancels in the antisymmetrization Equation (13.298), leaving the homogeneous tensor law. □

Geometrically, torsion measures the failure of infinitesimal parallelograms to close: transporting $\mathrm{d}x_{(1)}$ along $\mathrm{d}x_{(2)}$ and vice versa, the two endpoints differ by $T^{\lambda}{}_{\mu\nu}\,\mathrm{d}x^{\mu}_{(1)}\mathrm{d}x^{\nu}_{(2)}$. In Section 13.12 it becomes one of the two field strengths of the geometry.

Definition 13.149 (Metric compatibility)**.** A connection is *metric compatible* iff $\nabla_{\lambda} g_{\mu\nu} = 0$: parallel transport preserves lengths and angles.
Rests on Definitions 13.117, 13.145 and 13.146.

Theorem 13.150 (Levi-Civita connection and contorsion)**.** *On a pseudo-Riemannian manifold there is exactly one metric-compatible connection for each prescribed torsion. Lowering the first index, $\Gamma_{\lambda\mu\nu} = g_{\lambda\rho}\Gamma^{\rho}{}_{\mu\nu}$,*

$$\Gamma_{\lambda\mu\nu} = \underbrace{\tfrac{1}{2}\left(\partial_{\mu} g_{\nu\lambda} + \partial_{\nu} g_{\lambda\mu} - \partial_{\lambda} g_{\mu\nu}\right)}_{\mathring{\Gamma}_{\lambda\mu\nu}} + \underbrace{\tfrac{1}{2}\left(T_{\lambda\mu\nu} + T_{\mu\lambda\nu} + T_{\nu\lambda\mu}\right)}_{K_{\lambda\mu\nu}}, \tag{13.299}$$

with $T_{\lambda\mu\nu} = g_{\lambda\rho}T^{\rho}{}_{\mu\nu}$. The torsion-free case $K = 0$ is the Levi-Civita connection $\mathring{\Gamma}$ *(the Christoffel symbols, generalizing Section 13.3.2); the* contorsion $K_{\lambda\mu\nu}$ *is a tensor, antisymmetric in its outer pair, $K_{\lambda\mu\nu} = -K_{\nu\mu\lambda}$.*
Rests on Definitions 13.117, 13.145, 13.147 and 13.149.

Proof. *Derives Theorem 13.150.*
Write metricity three times with cyclically permuted indices,

$$\begin{aligned} \partial_{\lambda} g_{\mu\nu} &= \Gamma_{\mu\lambda\nu} + \Gamma_{\nu\lambda\mu}\,, \\ \partial_{\mu} g_{\nu\lambda} &= \Gamma_{\nu\mu\lambda} + \Gamma_{\lambda\mu\nu}\,, \\ \partial_{\nu} g_{\lambda\mu} &= \Gamma_{\lambda\nu\mu} + \Gamma_{\mu\nu\lambda}\,, \end{aligned} \tag{13.300}$$

and form the combination (second) + (third) − (first). Grouping with the torsion Equation (13.298), $\Gamma_{\lambda\mu\nu} + \Gamma_{\lambda\nu\mu} = 2\Gamma_{\lambda\mu\nu} - T_{\lambda\mu\nu}$, $\Gamma_{\nu\mu\lambda} - \Gamma_{\nu\lambda\mu} = T_{\nu\mu\lambda}$, and $\Gamma_{\mu\nu\lambda} - \Gamma_{\mu\lambda\nu} = T_{\mu\nu\lambda}$, so that

$$\partial_{\mu} g_{\nu\lambda} + \partial_{\nu} g_{\lambda\mu} - \partial_{\lambda} g_{\mu\nu} = 2\Gamma_{\lambda\mu\nu} - T_{\lambda\mu\nu} + T_{\nu\mu\lambda} + T_{\mu\nu\lambda}\,. \tag{13.301}$$

Solving for $\Gamma_{\lambda\mu\nu}$ and using the antisymmetry $T_{\nu\mu\lambda} = -T_{\nu\lambda\mu}$, $T_{\mu\nu\lambda} = -T_{\mu\lambda\nu}$ to reorder gives Equation (13.299). Uniqueness is manifest: the metric determines $\mathring{\Gamma}$, the prescribed torsion determines K. The outer antisymmetry of K is a two-line check using $T_{\lambda\mu\nu} = -T_{\lambda\nu\mu}$, and it is precisely the condition that the contorsion contribution preserve metricity. □

Remark 13.151 (Geodesics versus autoparallels). Curves that extremize the length functional $\int \sqrt{|\mathrm{d}s^2|}$ obey Equation (13.297) with $\mathring{\Gamma}$ (the variational computation of Chapter 21 applied to the line element). Since $K^{\lambda}{}_{(\mu\nu)} \neq 0$ in general, autoparallels of a torsionful connection differ from geodesics of its metric: straightest and shortest part ways.

13.10.1 The spin connection

Frame-indexed fields need their own connection: local Lorentz transformations Equation (13.265) are point-dependent, so $\partial_\mu V^a$ is not covariant. The *spin connection* $\omega_\mu{}^a{}_b$ enters as

$$\nabla_\mu V^a = \partial_\mu V^a + \omega_\mu{}^a{}_b V^b \,, \tag{13.302}$$

and the requirement that frame and coordinate descriptions agree — the *vielbein postulate*, total covariant constancy of the vielbein — ties it to Γ:

$$\nabla_\mu e^a{}_\nu = \partial_\mu e^a{}_\nu + \omega_\mu{}^a{}_b\, e^b{}_\nu - \Gamma^\lambda{}_{\mu\nu}\, e^a{}_\lambda = 0 \,. \tag{13.303}$$

Metricity of Γ is then equivalent to $\omega_{\mu ab} = -\omega_{\mu ba}$: the spin connection takes values in the Lorentz algebra $\mathfrak{so}(p,q)$ (Chapter 14). Under a local Lorentz transformation it transforms inhomogeneously,

$$\omega_\mu \longrightarrow \Lambda\, \omega_\mu\, \Lambda^{-1} - (\partial_\mu \Lambda)\, \Lambda^{-1} \,, \tag{13.304}$$

exactly like a gauge potential — the observation the Cartan formalism turns into machinery (Section 13.12).

13.11 Curvature

In the theory of curves a curve is characterized by its curvatures, built from first and second derivatives (Section 13.3.1); the curvature of a manifold must likewise live in the first and second derivatives of the metric, and vanish for Euclidean space. The correct object measures the failure of parallel transport around a closed loop, i.e. the non-commutativity of covariant derivatives.

Theorem 13.152 (Riemann tensor; Ricci identity with torsion)**.** *For any affine connection and any vector field,*

$$[\nabla_\mu, \nabla_\nu]\, V^\lambda = R^\lambda{}_{\rho\mu\nu}\, V^\rho - T^\rho{}_{\mu\nu}\, \nabla_\rho V^\lambda \,, \tag{13.305}$$

with

$$R^\lambda{}_{\rho\mu\nu} = \partial_\mu \Gamma^\lambda{}_{\nu\rho} - \partial_\nu \Gamma^\lambda{}_{\mu\rho} + \Gamma^\lambda{}_{\mu\sigma}\Gamma^\sigma{}_{\nu\rho} - \Gamma^\lambda{}_{\nu\sigma}\Gamma^\sigma{}_{\mu\rho} \,. \tag{13.306}$$

$R^\lambda{}_{\rho\mu\nu}$ *is a tensor: the* Riemann curvature tensor.

Rests on Definitions 13.145 and 13.147 and Proposition 7.73.

Proof. *Derives Theorem 13.152.*

Expand $\nabla_\mu \nabla_\nu V^\lambda = \partial_\mu(\nabla_\nu V^\lambda) + \Gamma^\lambda{}_{\mu\sigma}\nabla_\nu V^\sigma - \Gamma^\rho{}_{\mu\nu}\nabla_\rho V^\lambda$ (the middle slot of $\nabla_\nu V^\lambda$ is a covector index) and antisymmetrize in $\mu\nu$. The $\partial\partial V$ terms cancel by equality of mixed partials; the terms with one Γ and one ∂V cancel except for those coming from the last piece, which assemble into $-T^\rho{}_{\mu\nu}\nabla_\rho V^\lambda$ by Equation (13.298); the remaining terms contain no derivatives of V and define Equation (13.306). Tensoriality follows because the left side of Equation (13.305) and the torsion term are tensors for arbitrary V. □

Definition 13.153 (Contractions)**.** The *Ricci tensor* and *curvature scalar* are

$$R_{\mu\nu} = R^\lambda{}_{\mu\lambda\nu} \,, \qquad R = g^{\mu\nu} R_{\mu\nu} \,. \tag{13.307}$$

For a surface ($D = 2$, torsion-free) $R = 2K$ with K the Gaussian curvature of Section 13.3.3, closing the circle with the classical theory.

Rests on Theorem 13.152 and Definition 13.117.

Proposition 13.154 (Symmetries of the curvature)**.** *Always:* $R^{\lambda}{}_{\rho\mu\nu} = -R^{\lambda}{}_{\rho\nu\mu}$. *With metricity:* $R_{\lambda\rho\mu\nu} = -R_{\rho\lambda\mu\nu}$. *For the Levi-Civita connection additionally*

$$R_{\lambda\rho\mu\nu} = R_{\mu\nu\lambda\rho}\,, \qquad R^{\lambda}{}_{[\rho\mu\nu]} = 0\,, \qquad \nabla_{[\sigma}R^{\lambda}{}_{|\rho|\mu\nu]} = 0\,, \tag{13.308}$$

(first and second Bianchi identities). With torsion the last two acquire torsion terms, displayed in form language in Proposition 13.157.

Rests on Theorems 13.150 and 13.152, Definition 13.149, and Proposition 13.157.

Proof. *Derives Proposition 13.154.*

The first is manifest from Equation (13.306). The second: apply Equation (13.305) to the scalar $g_{\lambda\rho}V^{\lambda}W^{\rho}$ and use metricity. The torsion-free identities follow from Equation (13.306) with $\Gamma^{\lambda}{}_{[\mu\nu]} = 0$ by direct cyclic summation — carried out most efficiently in the Cartan formalism below (Proposition 13.157 with $T^{a} = 0$); the pair-exchange symmetry is an algebraic consequence of the other three. □

Proposition 13.155 (Geodesic deviation; Jacobi equation)**.** *Let* $x^{\lambda}(\tau, s)$ *be a smooth one-parameter family of geodesics of a torsion-free connection, with tangent* $u^{\lambda} = \partial x^{\lambda}/\partial\tau$ *and connecting field* $\xi^{\lambda} = \partial x^{\lambda}/\partial s$. *Then* ξ *obeys the* Jacobi equation

$$\frac{\mathrm{D}^2\xi^{\lambda}}{\mathrm{d}\tau^2} = R^{\lambda}{}_{\rho\mu\nu}\,u^{\rho}\,u^{\mu}\,\xi^{\nu}\,, \tag{13.309}$$

with $\mathrm{D}/\mathrm{d}\tau = u^{\mu}\nabla_{\mu}$ *the covariant derivative along the curve.*

Rests on Theorem 13.152 and Definition 13.146.

Proof. *Derives Proposition 13.155.*

The coordinate fields commute: $[u,\xi]^{\lambda} = u^{\mu}\partial_{\mu}\xi^{\lambda} - \xi^{\mu}\partial_{\mu}u^{\lambda} = \partial_{\tau}\partial_{s}x^{\lambda} - \partial_{s}\partial_{\tau}x^{\lambda} = 0$. For any connection, $\nabla_{u}\xi^{\lambda} - \nabla_{\xi}u^{\lambda} = [u,\xi]^{\lambda} + T^{\lambda}{}_{\mu\nu}u^{\mu}\xi^{\nu}$ by Equation (13.298), so with $T = 0$ the two mixed derivatives agree, $\nabla_{u}\xi = \nabla_{\xi}u$. Hence

$$\frac{\mathrm{D}^2\xi^{\lambda}}{\mathrm{d}\tau^2} = \nabla_{u}\nabla_{u}\xi^{\lambda} = \nabla_{u}\nabla_{\xi}u^{\lambda} = \nabla_{\xi}\nabla_{u}u^{\lambda} + R^{\lambda}{}_{\rho\mu\nu}\,u^{\rho}u^{\mu}\xi^{\nu}\,,$$

the exchange being the Ricci identity Equation (13.305) applied to the pair (u,ξ): the commutator term $\nabla_{[u,\xi]}$ vanishes because $[u,\xi] = 0$, and the torsion term because $T = 0$. The first term on the right vanishes because every member of the family is a geodesic — $\nabla_{u}u = 0$ identically in s, and ∇_{ξ} differentiates that identity. □

13.12 The Cartan formalism

The results of Sections 13.8, 13.10 and 13.11 compress into two lines when written in the language of differential forms (Section 13.6), with all coordinate indices hidden. The dynamical variables are the vielbein one-forms e^{a} and the $\mathfrak{so}(p,q)$-valued *connection one-form*

$$\omega^{a}{}_{b} = \omega_{\mu}{}^{a}{}_{b}\,\mathrm{d}x^{\mu}\,, \qquad \omega^{ab} = -\omega^{ba}\,, \tag{13.310}$$

and the *Lorentz-covariant exterior derivative* acts on frame-indexed forms as $\mathrm{D}\alpha^{a} = \mathrm{d}\alpha^{a} + \omega^{a}{}_{b}\wedge\alpha^{b}$ (one ω term per frame index).

Theorem 13.156 (Cartan structure equations)**.** *The torsion and curvature of Definition 13.147 and Theorem 13.152 are the two-forms*

$$T^{a} = \mathrm{d}e^{a} + \omega^{a}{}_{b}\wedge e^{b} = \mathrm{D}e^{a} = \tfrac{1}{2}\,T^{a}{}_{\mu\nu}\,\mathrm{d}x^{\mu}\wedge\mathrm{d}x^{\nu}\,, \tag{13.311}$$

$$R^{a}{}_{b} = \mathrm{d}\omega^{a}{}_{b} + \omega^{a}{}_{c}\wedge\omega^{c}{}_{b} = \tfrac{1}{2}\,R^{a}{}_{b\mu\nu}\,\mathrm{d}x^{\mu}\wedge\mathrm{d}x^{\nu}\,, \tag{13.312}$$

with $T^{a}{}_{\mu\nu} = e^{a}{}_{\lambda}T^{\lambda}{}_{\mu\nu}$ *and* $R^{a}{}_{b\mu\nu} = e^{a}{}_{\lambda}\,e_{b}{}^{\rho}\,R^{\lambda}{}_{\rho\mu\nu}$.

Rests on Definitions 13.102, 13.103, 13.122 and 13.147, Equation (13.303), and Theorem 13.152.

Proof. *Derives Theorem 13.156.*

For Equation (13.311): by the vielbein postulate Equation (13.303), $\partial_\mu e^a{}_\nu + \omega_\mu{}^a{}_b e^b{}_\nu = \Gamma^\lambda{}_{\mu\nu} e^a{}_\lambda$; antisymmetrizing in $\mu\nu$, the left side gives the components of $\mathrm{d}e^a + \omega^a{}_b \wedge e^b$ and the right side gives $\frac{1}{2}(\Gamma^\lambda{}_{\mu\nu} - \Gamma^\lambda{}_{\nu\mu}) e^a{}_\lambda = \frac{1}{2} T^\lambda{}_{\mu\nu} e^a{}_\lambda$. For Equation (13.312): solve Equation (13.303) for $\omega_\mu{}^a{}_b$ in terms of Γ and e, insert into $\mathrm{d}\omega + \omega \wedge \omega$, and the inhomogeneous ∂e contributions cancel, leaving exactly the components Equation (13.306) converted with two vielbeins. (Equivalently: $\mathrm{D}^2 V^a = R^a{}_b V^b$ for any zero-form V^a, by a two-line computation, which identifies Equation (13.312) as the frame version of the Ricci identity Equation (13.305).) □

Proposition 13.157 (Bianchi identities)**.** *Applying* d *to the structure equations,*

$$\mathrm{D}T^a = R^a{}_b \wedge e^b \,, \tag{13.313}$$

$$\mathrm{D}R^a{}_b = 0 \,. \tag{13.314}$$

In the torsion-free case, Equation (13.313) *reduces to the first Bianchi identity* $R^a{}_b \wedge e^b = 0$*, i.e.* $R^\lambda{}_{[\rho\mu\nu]} = 0$*, and Equation* (13.314) *is the second identity of Equation* (13.308)*.*

Rests on Theorem 13.156 and Equations (13.245) *and* (13.246)*.*

Proof. *Derives Proposition 13.157.*

Differentiate Equation (13.311) with $\mathrm{d}^2 = 0$ (Section 13.6.4):

$$\begin{aligned} \mathrm{d}T^a &= \mathrm{d}\omega^a{}_b \wedge e^b - \omega^a{}_b \wedge \mathrm{d}e^b \\ &= (R^a{}_b - \omega^a{}_c \wedge \omega^c{}_b) \wedge e^b - \omega^a{}_b \wedge \left(T^b - \omega^b{}_c \wedge e^c\right) \\ &= R^a{}_b \wedge e^b - \omega^a{}_b \wedge T^b \,, \end{aligned} \tag{13.315}$$

which is Equation (13.313) after moving the $\omega \wedge T$ term to the left as part of $\mathrm{D}T^a$. Differentiating Equation (13.312) likewise, $\mathrm{d}R^a{}_b = \mathrm{d}\omega^a{}_c \wedge \omega^c{}_b - \omega^a{}_c \wedge \mathrm{d}\omega^c{}_b = R^a{}_c \wedge \omega^c{}_b - \omega^a{}_c \wedge R^c{}_b$ (the $\omega \wedge \omega \wedge \omega$ terms cancel pairwise), which is $\mathrm{D}R^a{}_b = 0$. □

Proposition 13.158 (The connection determined by vielbein and torsion)**.** *Given* e^a *and a prescribed torsion two-form* T^a*, the first structure equation Equation* (13.311) *determines* $\omega^{ab} = -\omega^{ba}$ *uniquely; for* $T^a = 0$*,* $\omega = \omega(e)$ *is the frame form of the Levi-Civita connection, with the contorsion one-form* $K^a{}_b$ *(*$T^a = K^a{}_b \wedge e^b$*) supplying the general case, in exact parallel with Equation* (13.299)*.*

Rests on Theorems 13.150 and 13.156 and Equation (13.266)*.*

Proof. *Derives Proposition 13.158.*

Counting: $\omega_\mu{}^{ab}$ has $D \cdot D(D-1)/2$ independent components, exactly the number of components of the two-form system Equation (13.311); the explicit solution repeats the cyclic permutation trick of Theorem 13.150 on the anholonomy coefficients Equation (13.266),

$$\omega_{\mu ab} = \tfrac{1}{2}\, e_\mu{}^c \,(C_{abc} - C_{bca} - C_{cab}) + K_{\mu ab} \quad \text{with } C_{abc} = \eta_{cd}\, C^d{}_{ab} \,, \tag{13.316}$$

whose verification is the same computation as in Theorem 13.150 transcribed to frame indices. □

Remark 13.159 (Gravity as gauge geometry). Equations Equations (13.304), (13.311) and (13.312) exhibit the frame bundle of (M, g) as a gauge structure with group $\mathrm{L}_{p+q} = \mathrm{SO}(p, q)$: ω is the gauge potential, R its field strength, and e a Lorentz-vector-valued one-form whose field strength is the torsion. The fibre-bundle formulation is taken up in Chapter 14; the physical instantiation is general relativity (Part V), where the Einstein–Hilbert action becomes

$$S_{\mathrm{EH}} = \frac{1}{2\kappa\,(D-2)!} \int \epsilon_{a_1 \ldots a_D}\, R^{a_1 a_2} \wedge e^{a_3} \wedge \cdots \wedge e^{a_D} = \frac{1}{2\kappa} \int \mathrm{d}^D x \, \sqrt{|g|}\, R \,, \tag{13.317}$$

the equality of the two integrands being proven in Appendix A.8 and used in Chapter 43.

13.13 Maximally symmetric spaces and the symmetry ladder

The spaces admitting the full complement of $D(D+1)/2$ Killing vectors (Proposition 13.140) are characterized by a curvature built from the metric alone, with one constant:

$$R_{\lambda\rho\mu\nu} = \frac{\epsilon}{\ell^2}\left(g_{\lambda\mu}g_{\rho\nu} - g_{\lambda\nu}g_{\rho\mu}\right), \qquad \epsilon \in \{+1,\, 0,\, -1\}\,, \tag{13.318}$$

with $T^a = 0$ and ℓ a length (for $\epsilon = 0$ the curvature vanishes and ℓ drops out). In form language, $R^{ab} = (\epsilon/\ell^2)\, e^a \wedge e^b$.

Theorem 13.160 (Maximal symmetry forces constant curvature)**.** *Let (M, g) be a connected pseudo-Riemannian manifold of dimension $D \geq 2$ with the Levi-Civita connection, and suppose it admits the maximal number $D(D+1)/2$ of linearly independent Killing vectors. Then its curvature has the form Equation (13.318), with*

$$\frac{\epsilon}{\ell^2} = \frac{R}{D(D-1)}\,, \tag{13.319}$$

R being the constant curvature scalar of Equation (13.307).

Rests on Propositions 13.140 and 13.154 and Definition 13.153.

Proof. *Derives Theorem 13.160.*

Step 1: the data a Killing vector may carry at a point. The proof of Proposition 13.140 showed that a Killing vector is determined throughout M by the D numbers $\xi_\mu(P)$ and the $D(D-1)/2$ numbers $\nabla_{[\mu}\xi_{\nu]}(P)$ at one point P; that is, the linear map sending ξ to this data is injective. By hypothesis its domain has dimension $D(D+1)/2$, which is exactly the dimension of its target, so the map is a bijection: for *every* vector v_μ and every antisymmetric $A_{\mu\nu}$ there is a Killing vector with $\xi_\mu(P) = v_\mu$ and $\nabla_\mu\xi_\nu(P) = A_{\mu\nu}$, the latter being antisymmetric already by Killing's equation Equation (13.290).

Step 2: isotropy of the curvature. The flow of a Killing vector consists of isometries (Definition 13.139), and the Riemann tensor is built from the metric by a rule that commutes with diffeomorphisms, so $\phi_t^* R[g] = R[\phi_t^* g] = R[g]$; differentiating at $t = 0$ gives $\mathcal{L}_\xi R = 0$. Writing the Lie derivative of a $(0,4)$ tensor with covariant derivatives, which is legitimate for a torsion-free connection (Proposition 13.127),

$$\begin{aligned} 0 = \xi^\sigma\nabla_\sigma R_{\lambda\rho\mu\nu} + (\nabla_\lambda\xi^\sigma)\, R_{\sigma\rho\mu\nu} + (\nabla_\rho\xi^\sigma)\, R_{\lambda\sigma\mu\nu} \\ + (\nabla_\mu\xi^\sigma)\, R_{\lambda\rho\sigma\nu} + (\nabla_\nu\xi^\sigma)\, R_{\lambda\rho\mu\sigma}\,. \end{aligned} \tag{13.320}$$

Evaluate at P on a Killing vector with $\xi(P) = 0$ and $\nabla_\mu\xi_\nu(P) = A_{\mu\nu}$, which Step 1 provides for arbitrary antisymmetric A. The transport term drops and

$$A_\lambda{}^\sigma R_{\sigma\rho\mu\nu} + A_\rho{}^\sigma R_{\lambda\sigma\mu\nu} + A_\mu{}^\sigma R_{\lambda\rho\sigma\nu} + A_\nu{}^\sigma R_{\lambda\rho\mu\sigma} = 0 \tag{13.321}$$

holds at P for every antisymmetric A.

Step 3: the algebra. Fix two indices α, β and take $A_{\sigma\tau} = g_{\sigma\alpha}g_{\tau\beta} - g_{\sigma\beta}g_{\tau\alpha}$, so that $A_\lambda{}^\sigma = g_{\lambda\alpha}\delta^\sigma{}_\beta - g_{\lambda\beta}\delta^\sigma{}_\alpha$. Then Equation (13.321) becomes

$$\begin{aligned} g_{\lambda\alpha}R_{\beta\rho\mu\nu} - g_{\lambda\beta}R_{\alpha\rho\mu\nu} + g_{\rho\alpha}R_{\lambda\beta\mu\nu} - g_{\rho\beta}R_{\lambda\alpha\mu\nu} \\ + g_{\mu\alpha}R_{\lambda\rho\beta\nu} - g_{\mu\beta}R_{\lambda\rho\alpha\nu} + g_{\nu\alpha}R_{\lambda\rho\mu\beta} - g_{\nu\beta}R_{\lambda\rho\mu\alpha} = 0\,. \end{aligned} \tag{13.322}$$

Contract Equation (13.322) with $g^{\lambda\alpha}$. The first term gives $D\, R_{\beta\rho\mu\nu}$; the second and the third give $-R_{\beta\rho\mu\nu}$ each, the third after using $R_{\rho\beta\mu\nu} = -R_{\beta\rho\mu\nu}$ (Proposition 13.154); the fourth vanishes by the same antisymmetry; the sixth and eighth produce Ricci tensors

(Definition 13.153), $-g_{\mu\beta}R_{\rho\nu}$ and $+g_{\nu\beta}R_{\rho\mu}$; the fifth and seventh survive as $R_{\mu\rho\beta\nu}$ and $R_{\nu\rho\mu\beta}$. Hence

$$(D-2)R_{\beta\rho\mu\nu} + R_{\mu\rho\beta\nu} + R_{\nu\rho\mu\beta} = g_{\mu\beta}R_{\rho\nu} - g_{\nu\beta}R_{\rho\mu}\,. \tag{13.323}$$

Use the pair-exchange symmetry of Equation (13.308) to write $R_{\mu\rho\beta\nu} = R_{\beta\nu\mu\rho}$ and $R_{\nu\rho\mu\beta} = -R_{\beta\mu\nu\rho}$, both with β in the first slot, and then the first Bianchi identity $R_{\beta[\rho\mu\nu]} = 0$ in the form $R_{\beta\nu\mu\rho} = R_{\beta\rho\mu\nu} + R_{\beta\mu\nu\rho}$. The last two terms of the left side of Equation (13.323) collapse to $R_{\beta\rho\mu\nu}$, leaving

$$(D-1)R_{\lambda\rho\mu\nu} = g_{\lambda\mu}R_{\rho\nu} - g_{\lambda\nu}R_{\rho\mu}\,, \tag{13.324}$$

after renaming β to λ.

The left side of Equation (13.324) is antisymmetric under $\lambda \leftrightarrow \rho$, so the right side must be too:

$$g_{\lambda\mu}R_{\rho\nu} - g_{\lambda\nu}R_{\rho\mu} = -g_{\rho\mu}R_{\lambda\nu} + g_{\rho\nu}R_{\lambda\mu}\,.$$

Contracting this with $g^{\lambda\mu}$ gives $(D-1)R_{\rho\nu} = -R_{\rho\nu} + g_{\rho\nu}R$, that is

$$R_{\rho\nu} = \frac{R}{D}\,g_{\rho\nu}\,. \tag{13.325}$$

Substituting Equation (13.325) into Equation (13.324),

$$R_{\lambda\rho\mu\nu} = \frac{R}{D(D-1)}\left(g_{\lambda\mu}g_{\rho\nu} - g_{\lambda\nu}g_{\rho\mu}\right)\,, \tag{13.326}$$

which is the tensor structure of Equation (13.318) at the point P, and P was arbitrary.

Step 4: the coefficient is constant. By Step 1 there is, at each point P and for each vector v, a Killing vector with $\xi(P) = v$. Since R is a scalar built from the metric and the flow of ξ consists of isometries, $\mathcal{L}_\xi R = \xi^\sigma \partial_\sigma R = 0$ (Equation (13.272)), so $v^\sigma \partial_\sigma R = 0$ at P for every v, whence $\partial_\sigma R = 0$ there. As P was arbitrary and M is connected, R is constant. Writing that constant as Equation (13.319) — with $\epsilon = 0$ when $R = 0$, and otherwise $\epsilon = \pm 1$ the sign of R and $\ell = \left(|R|\,/D(D-1)\right)^{-1/2}$ the associated length — turns Equation (13.326) into Equation (13.318). □

Remark 13.161. Step 4 did not need the second Bianchi identity, only homogeneity. Where a space is isotropic about every point but the full Killing count is not assumed, Equation (13.326) still holds with a function $K(x)$ in place of the constant, and inserting it into the second Bianchi identity of Equation (13.308) and contracting twice yields $(D-1)(D-2)\nabla_\sigma K = 0$: for $D > 2$ pointwise isotropy alone already forces K to be constant. This is Schur's theorem, and it is the reason the three cases below exhaust the possibilities.

The three cases realize the groups of Table 13.1:

Flat space ($\epsilon = 0$). The manifold is $\mathbb{R}^{p,q}$ with metric $\eta_{\mu\nu}$; the Killing vectors are the D translations ∂_μ (group T_{p+q}, abelian) and the $D(D-1)/2$ pseudo-rotations $x_\mu\partial_\nu - x_\nu\partial_\mu$ (group $\mathrm{L}_{p+q} = \mathrm{SO}(p,q)$), closing into the Poincaré group $\mathrm{P}_{p+q} = \mathrm{ISO}(p,q)$, the semidirect product of the two.

Anti-de Sitter space ($\epsilon = -1$). AdS_{p+q} is the quadric

$$\eta_{AB}\,X^A X^B = -\ell^2 \tag{13.327}$$

in the flat $(p+q+1)$-dimensional space of signature $(p, q+1)$, with embedding coordinates X^m and frame metric η_{AB} per the conventions of Section 13.1. The induced metric (Definition 13.119) satisfies Equation (13.318) with $\epsilon = -1$, by Proposition 13.162 below. Every linear transformation of X^m preserving η_{AB} preserves the quadric and its induced metric, so $\mathrm{Isom}(\mathrm{AdS}_{p+q}) \supseteq \mathrm{SO}(p, q+1)$; its dimension $(D+1)D/2$ saturates the Killing bound, so equality holds (connected component).

de Sitter space ($\epsilon = +1$). Identically, dS_{p+q} is the quadric $\eta_{AB}X^A X^B = +\ell^2$ in signature $(p+1, q)$, with isometry group $\mathrm{SO}(p+1, q)$.

The curvature of the two quadrics is computed once, for both signs at once, by the Gauss equation of Section 13.3.2 transcribed to a pseudo-Riemannian hypersurface of a flat space.

Proposition 13.162 (Curvature induced on the quadric)**.** *Let η_{AB} be the flat metric of a $(D+1)$-dimensional space with Cartesian coordinates X^A, let $\sigma = \pm 1$, and let Σ be the quadric*

$$\eta_{AB}\, X^A X^B = \sigma\, \ell^2 \,, \tag{13.328}$$

described by an embedding $X^A(\xi^i)$, $i = 1, \dots, D$. Then the metric h_{ij} induced on Σ (Definition 13.119) has curvature

$$R_{ijkl} = \frac{\sigma}{\ell^2}\left(h_{ik}h_{jl} - h_{il}h_{jk}\right) , \tag{13.329}$$

that is, Equation (13.318) with $\epsilon = \sigma$.

Rests on Definition 13.119, Equation (13.83), and Theorem 13.152.

Proof. *Derives Proposition 13.162.*

Write $e_i^A = \partial X^A/\partial\xi^i$ for the tangent vectors, so that $h_{ij} = \eta_{AB}e_i^A e_j^B$ by Equation (13.261). Differentiating Equation (13.328) along Σ gives $\eta_{AB}X^A e_i^B = 0$: the position vector is normal to the quadric. Hence

$$N^A = \frac{X^A}{\ell} \,, \qquad \eta_{AB}N^A N^B = \sigma \,, \qquad \frac{\partial N^A}{\partial \xi^i} = \frac{e_i^A}{\ell} \,, \tag{13.330}$$

the last relation because X^A is itself the embedding.

At each point the $D+1$ vectors $\left\{e_i^A, N^A\right\}$ are a basis of the ambient space, so we may expand, exactly as in the Gauss equations Equation (13.83),

$$\frac{\partial e_j^A}{\partial \xi^i} = \Gamma^k{}_{ij}\, e_k^A + \sigma\, b_{ij}\, N^A \,, \qquad b_{ij} = \eta_{AB}N^A \frac{\partial e_j^B}{\partial \xi^i} \,, \tag{13.331}$$

the factor σ being what makes the stated formula for b_{ij} follow from Equation (13.330) on contracting with $\eta_{AB}N^B$; contracting instead with $\eta_{AB}e_k^B$ identifies $\Gamma^k{}_{ij}$ as the Levi-Civita connection of h_{ij}, by the same computation that produced Equation (13.87) from Equation (13.83). Differentiating $\eta_{AB}N^A e_j^B = 0$ with respect to ξ^i and using Equation (13.330),

$$b_{ij} = -\eta_{AB}\left(\frac{\partial N^A}{\partial \xi^i}\right) e_j^B = -\frac{h_{ij}}{\ell} \,. \tag{13.332}$$

The second fundamental form of the quadric is thus proportional to its first: every direction is a curvature direction, which is the analytic form of the statement that the quadric looks the same from every side.

The ambient space is flat and referred to Cartesian coordinates, so $\partial_i\partial_j e_k^A$ is symmetric in i and j. Differentiating Equation (13.331) once more and antisymmetrizing in i, j, the component along e_m^A must vanish:

$$\partial_i\Gamma^m{}_{jk} - \partial_j\Gamma^m{}_{ik} + \Gamma^m{}_{il}\Gamma^l{}_{jk} - \Gamma^m{}_{jl}\Gamma^l{}_{ik} + \frac{\sigma}{\ell}\left(b_{jk}\delta^m_{\ i} - b_{ik}\delta^m_{\ j}\right) = 0 \,,$$

the last bracket arising from the terms $\sigma b_{jk}\partial_i N^A$ through Equation (13.330). The first four terms are precisely $R^m{}_{kij}$ of the induced metric, in the convention Equation (13.306). Inserting Equation (13.332),

$$R^m{}_{kij} = -\frac{\sigma}{\ell}\left(b_{jk}\delta^m_{\ i} - b_{ik}\delta^m_{\ j}\right) = \frac{\sigma}{\ell^2}\left(h_{jk}\delta^m_{\ i} - h_{ik}\delta^m_{\ j}\right) \,,$$

and lowering the first index with h_{lm} and renaming gives Equation (13.329).

For anti-de Sitter space Equation (13.327) has $\sigma = -1$, so $\epsilon = -1$; for de Sitter space $\sigma = +1$, so $\epsilon = +1$. In both cases the induced metric is nondegenerate of the signature stated, because the normal direction Equation (13.330) carries the extra sign σ of the ambient metric and is removed from it. □

In the limit $\ell \to \infty$ both quadrics flatten and their isometry groups contract to P_{p+q} — the İnönü–Wigner contraction, treated algebraically in Chapter 14.

13.13.1 The conformal group

Relaxing isometry to angle preservation, $f^*g = \Omega^2(x)\, g$, enlarges the symmetry. For flat space of signature (p, q), $D = p + q > 2$, the conformal Killing vectors are

$$\begin{aligned} \text{translations}: &\quad \xi^\mu = a^\mu && (D)\,, \\ \text{pseudo-rotations}: &\quad \xi^\mu = \lambda^\mu{}_\nu x^\nu,\ \lambda_{\mu\nu} = -\lambda_{\nu\mu} && (D(D-1)/2)\,, \\ \text{dilatation}: &\quad \xi^\mu = x^\mu && (1)\,, \\ \text{special conformal}: &\quad \xi^\mu = 2(b\cdot x)x^\mu - x^2 b^\mu && (D)\,, \end{aligned} \tag{13.333}$$

for a total of $(D+1)(D+2)/2$ generators. That this list is complete is the content of the following proposition.

Proposition 13.163 (Integration of the conformal Killing equation)**.** *Let $\eta_{\mu\nu}$ be the flat metric of signature (p, q) in Cartesian coordinates, $D = p + q > 2$. Every solution of the conformal Killing equation*

$$\partial_\mu \xi_\nu + \partial_\nu \xi_\mu = 2\sigma\, \eta_{\mu\nu}\,, \qquad \sigma = \frac{1}{D}\,\partial_\lambda \xi^\lambda\,, \tag{13.334}$$

is a polynomial of degree at most two in x, and the solution space is spanned by the vector fields Equation (13.333); its dimension is $(D+1)(D+2)/2$.

Rests on Equations (13.275) and (13.333) and Definition 13.139.

Proof. *Derives Proposition 13.163.*

Equation (13.334) is $\mathcal{L}_\xi \eta = 2\sigma\eta$ written out with Equation (13.275), the trace of which fixes σ as stated.

Step 1: second derivatives in terms of σ. Put $E_{\mu\nu} = \partial_\mu\xi_\nu + \partial_\nu\xi_\mu - 2\sigma\eta_{\mu\nu}$, so that $E_{\mu\nu} = 0$. Form the combination $\partial_\rho E_{\mu\nu} + \partial_\mu E_{\nu\rho} - \partial_\nu E_{\rho\mu} = 0$. Six of the eight derivative terms cancel in pairs because partial derivatives commute, and what survives is

$$\partial_\mu\partial_\rho\xi_\nu = \eta_{\mu\nu}\partial_\rho\sigma + \eta_{\nu\rho}\partial_\mu\sigma - \eta_{\rho\mu}\partial_\nu\sigma\,. \tag{13.335}$$

Step 2: σ is affine. Apply ∂^ν to Equation (13.335). On the left this gives $\partial_\mu\partial_\rho\,(\partial^\nu\xi_\nu) = D\,\partial_\mu\partial_\rho\sigma$, and on the right $2\partial_\mu\partial_\rho\sigma - \eta_{\rho\mu}\Box\sigma$ with $\Box = \partial^\nu\partial_\nu$, whence

$$(D-2)\,\partial_\mu\partial_\rho\sigma = -\eta_{\mu\rho}\,\Box\sigma\,. \tag{13.336}$$

Tracing Equation (13.336) gives $(D-2)\Box\sigma = -D\,\Box\sigma$, that is $\Box\sigma = 0$ for $D \neq 1$; and then Equation (13.336) itself gives $\partial_\mu\partial_\rho\sigma = 0$, since $D > 2$. Hence σ is an affine function, which we write

$$\sigma(x) = \lambda + 2\,b_\mu x^\mu\,, \tag{13.337}$$

with λ and b_μ constant, the factor 2 chosen for later convenience. This is the only place where $D > 2$ is used, and it is where the argument genuinely fails in two dimensions, whose conformal algebra is infinite-dimensional.

Step 3: ξ is quadratic. With $\partial\partial\sigma = 0$ the right-hand side of Equation (13.335) is constant, so all third derivatives of ξ vanish and its Taylor expansion about the origin terminates:

$$\xi_\nu(x) = a_\nu + b_{\nu\mu}x^\mu + \tfrac{1}{2}\left(\partial_\mu\partial_\rho\xi_\nu\right)x^\mu x^\rho\,, \qquad a_\nu = \xi_\nu(0)\,, \quad b_{\nu\mu} = \partial_\mu\xi_\nu(0)\,. \tag{13.338}$$

Step 4: the three orders. Each order of Equation (13.338) is constrained separately, because Equation (13.334) must hold identically in x.

1. *Constant part.* a_ν is unconstrained: D parameters, the translations $\xi^\mu = a^\mu$.
2. *Linear part.* Here Equation (13.334) reads $b_{\nu\mu} + b_{\mu\nu} = 2\lambda\eta_{\mu\nu}$, so $b_{\nu\mu} = \lambda\eta_{\nu\mu} + \lambda_{\nu\mu}$ with $\lambda_{\nu\mu} = -\lambda_{\mu\nu}$ arbitrary: one parameter for the dilatation $\xi^\mu = \lambda\, x^\mu$ and $D(D-1)/2$ for the pseudo-rotations $\xi^\mu = \lambda^\mu{}_\nu x^\nu$.
3. *Quadratic part.* By Equations (13.335) and (13.337), $\partial_\mu\partial_\rho\xi_\nu = 2\left(\eta_{\mu\nu}b_\rho + \eta_{\nu\rho}b_\mu - \eta_{\rho\mu}b_\nu\right)$, so the last term of Equation (13.338) is

$$\left(\eta_{\mu\nu}b_\rho + \eta_{\nu\rho}b_\mu - \eta_{\rho\mu}b_\nu\right)x^\mu x^\rho = 2\,(b\cdot x)\,x_\nu - x^2 b_\nu\,,$$

   which is the special conformal transformation of Equation (13.333): D parameters b_μ.

Conversely each of the four families satisfies Equation (13.334) by direct substitution — for the last, with $\sigma = 2\,b\cdot x$ — so the solution space is exactly their span. The parameters are independent, being the coefficients of distinct powers of x together with the irreducible pieces of $b_{\nu\mu}$, and they number

$$D + 1 + \frac{D(D-1)}{2} + D = \frac{(D+1)(D+2)}{2}\,, \tag{13.339}$$

which is the dimension of $\mathrm{SO}(p+1, q+1)$ quoted below. □

These close into the conformal group $\mathrm{C}_{p+q} = \mathrm{SO}(p+1, q+1)$ of Table 13.1, realized *linearly* on the $(p+q+2)$-dimensional flat space of signature $(p+1, q+1)$: flat (p,q)-space is identified with rays of the null cone

$$\eta_{MN}\,X^M X^N = 0\,, \tag{13.340}$$

(projective light-cone construction), on which $\mathrm{SO}(p+1, q+1)$ acts by its defining representation, indices M, N and I, J per Section 13.1. The dimension matches: $\dim \mathrm{SO}(p+1, q+1) = (D+1)(D+2)/2$.

13.13.2 The observed case

Physics instantiates this chapter at $p+q = 3+1$. The kinematics of Part IV is the flat row of Table 13.1; general relativity (Part V) is the torsion-free, Levi-Civita case of Sections 13.10 to 13.12, tested by the experiments recorded there; and the accelerating expansion of the Universe (Chapter 48) makes the de Sitter row observationally relevant. Torsion, by contrast, is retained in this chapter as mathematics: no experiment to date requires $T^a \neq 0$, and the physical parts of this treatise accordingly set it to zero — the scope rule of Chapter 1 applied to geometry itself.

Chapter 14

Lie Groups, Lie Algebras, and Fibre Bundles

A continuous symmetry of a physical system is described by a group whose elements depend smoothly on a set of real parameters: a Lie group. This chapter introduces Lie groups and their generators, builds the universal enveloping algebra and the Casimir operators that label an irreducible representation, and works out the rotation group $\mathrm{SO}(2,\mathbb{R})$ as the fundamental example. It then constructs the three compact groups on which the Standard Model rests — $\mathrm{SO}(3,\mathbb{R})$, its double cover $\mathrm{SU}(2)$, and $\mathrm{SU}(3)$ — together with their irreducible representations, and the Lie algebras $\mathfrak{t}(D)$ and $\mathfrak{so}(p,q)$ with the algebras built from them: Lorentz, Poincaré, (anti-)de Sitter and conformal, in general dimension $D = p + q$ and signature (p, q). The two Casimir invariants of the Poincaré algebra, which are mass and spin, are obtained in the observed $3 + 1$ dimensions. The closing sections develop invariant polynomials on a principal fibre bundle and prove the Chern–Weil theorem, from which the transgression and Chern–Simons forms follow.

Notation 14.1. Throughout this chapter $D = p + q$ denotes the dimension of the underlying pseudo-Euclidean space; capital Latin indices $A, B, C, \ldots$ run from 1 to D; and $\eta_{AB} = \mathrm{diag}(\underbrace{+1,\ldots,+1}_{p},\underbrace{-1,\ldots,-1}_{q})$ is the flat metric of signature (p, q), used to raise and lower indices, $x_A = \eta_{AB}\, x^B$. The upright symbol D denotes the covariant exterior derivative and must not be confused with the italic dimension D.

14.1 Lie groups

14.1.1 Definition and generators

Lie group

Definition 14.2 (Lie group)**.** Consider an n-dimensional differentiable manifold G. To denote the points of the manifold we introduce the differentiable operator g, with $g(\theta^a) \in G$, where the θ^a, $a = 1, \ldots, M$, are real parameters. We say that G is a *Lie group* if and only if

1. the algebraic structure $(G, \circ)$ is a group;
2. the operator g is of class C^∞ in the parameters θ^a.

Thus, in order to characterise a continuous-group transformation, the transformation must be a function of the old coordinates and of the parameters θ^a; that is, continuous-group transformations take the form

$$\bar{x}^i = f^i(\theta^a, x^i)\,. \tag{14.1}$$

Generator of a Lie group

Consider an infinitesimal continuous-group transformation in a Lie group G,

$$\bar{x}^i = f^i(\delta\theta^a, x^i)\,.$$

Since with no variation of the parameters the coordinates do not change, we may write

$$x^i = f^i(0, x^i)\,,$$

so the infinitesimal variation of the coordinates is given by

$$\begin{aligned}\delta\bar{x}^i &= \bar{x}^i - x^i \\ &= f^i(\delta\theta^a, x^i) - f^i(0, x^i) \\ &\approx f^i(0, x^i) + \left.\frac{\partial f^i}{\partial\theta^a}\right|_{\theta^a=0} \delta\theta^a - f^i(0, x^i) \\ &= \left.\frac{\partial f^i}{\partial\theta^a}\right|_{\theta^a=0} \delta\theta^a\,. \end{aligned} \tag{14.2}$$

Consider now the variation of a field $F = F(x)$ defined on G between two infinitesimally close points P and Q:

$$\begin{aligned}\delta F &= F(Q) - F(P) \\ &= F(x + \delta x) - F(x) \\ &\approx F(x) + \frac{\partial F}{\partial x^i}\,\delta x^i - F(x) \\ &= \frac{\partial F}{\partial x^i}\,\delta x^i \\ \text{[Equation (14.2)]} \quad &= \frac{\partial F}{\partial x^i}\,\left.\frac{\partial f^i}{\partial\theta^a}\right|_{\theta^a=0} \delta\theta^a \\ &= \left(\left.\frac{\partial f^i}{\partial\theta^a}\right|_{\theta^a=0} \partial_i\right) F\,\delta\theta^a\,. \end{aligned}$$

We define the *generators of the Lie group* as the operators

$$J_a = \left.\frac{\partial f^i}{\partial\theta^a}\right|_{\theta^a=0} \partial_i\,, \tag{14.3}$$

so that

$$\delta F = J_a F\,\delta\theta^a\,. \tag{14.4}$$

From Equations (14.2) and (14.3) (insert the infinitesimal coordinate variation into the variation of the field and read off the operator acting on it).

The generators of a Lie group owe their name to the fact that they generate the variation of a field, as Equation (14.4) shows. They are mathematical objects that can always be assigned to a Lie group, and they are of fundamental importance in physics for the study of the symmetries of a system, as the physical parts of this treatise will show at length.

Geometric interpretation of the Lie bracket

In the preceding setting, let us examine what happens when we apply the variations along different paths leading from P to Q. Let θ_1^a and θ_2^a be the two sets of parameters used to follow the two distinct paths. From Equation (14.4) we have

$$\delta_1 F = J_a F\,\delta\theta_1^a\,, \qquad \delta_2 F = J_b F\,\delta\theta_2^b\,.$$

Then

$$\delta_2\delta_1 F = J_b J_a F\, \delta\theta_1^a \delta\theta_2^b\,, \qquad \delta_1\delta_2 F = J_a J_b F\, \delta\theta_2^b \delta\theta_1^a\,,$$

so that the variation of the variations becomes

$$\begin{aligned}\delta_1\delta_2 F - \delta_2\delta_1 F &= J_a J_b F\, \delta\theta_2^b \delta\theta_1^a - J_b J_a F\, \delta\theta_1^a \delta\theta_2^b \\ &= [J_a, J_b]\, F\, \delta\theta_1^a \delta\theta_2^b\,.\end{aligned}$$

Hence, for the quantity $\delta_1\delta_2 F - \delta_2\delta_1 F$ to be, indeed, a variation of F leading from P to Q — that is, of the form Equation (14.4) — the operator $[J_a, J_b]$ must be a linear combination of the generators:

$$[J_a, J_b] = C^c{}_{ab}\, J_c\,. \tag{14.5}$$

From Equation (14.4) (demanding that the commutator of two variations be itself a variation of the same form).

Exponentiation of the generators

A finite transformation is obtained by exponentiating the generators:

$$g(\theta^a) = \mathrm{e}^{J_a \theta^a}\,. \tag{14.6}$$

The source asserts Equation (14.6) without derivation. Two statements are hidden in it and they are of different kinds. That a *one-parameter* family of transformations closing under composition is an exponential is a theorem, proved next. That a *many*-parameter family can be written as the single exponential Equation (14.6) is a statement about the choice of parameters, and is discussed in Remark 14.4.

Proposition 14.3 (A one-parameter subgroup is an exponential)**.** *Let $\mathbb{V}$ be a finite-dimensional real or complex vector space and let $t \mapsto g(t)$ be a differentiable curve of linear operators on $\mathbb{V}$ satisfying*

$$g(s+t) = g(s)\, g(t)\,, \qquad g(0) = \mathbb{1}\,. \tag{14.7}$$

Then, with $J = \left.\frac{\mathrm{d}g}{\mathrm{d}t}\right|_{t=0}$,

$$\boxed{g(t) = \mathrm{e}^{tJ} = \sum_{n=0}^{\infty} \frac{t^n}{n!}\, J^n}\,, \tag{14.8}$$

the series converging absolutely for every t. In particular $g(t)$ is invertible, with $g(t)^{-1} = g(-t)$.

Rests on Definition 14.2 and Equation (14.3).

Proof. *Derives Proposition 14.3.*

Fix any submultiplicative norm on the operators of $\mathbb{V}$, so that $\|J^n\| \le \|J\|^n$. Then $\sum_n |t|^n \|J\|^n / n! = \mathrm{e}^{|t|\|J\|} < \infty$, so the series Equation (14.8) converges absolutely in the finite-dimensional — hence complete — space of operators, term by term differentiation is legitimate, and $\frac{\mathrm{d}}{\mathrm{d}t}\mathrm{e}^{tJ} = J\mathrm{e}^{tJ} = \mathrm{e}^{tJ} J$.

Differentiate Equation (14.7) with respect to s at $s = 0$, holding t fixed. The left-hand side gives $\frac{\mathrm{d}g}{\mathrm{d}t}(t)$ and the right-hand side gives $g(t)\left.\frac{\mathrm{d}g}{\mathrm{d}s}\right|_{s=0} = g(t)J$, so

$$\frac{\mathrm{d}g}{\mathrm{d}t} = g(t)\, J\,, \qquad g(0) = \mathbb{1}\,. \tag{14.9}$$

Put $h(t) = g(t)\mathrm{e}^{-tJ}$. Since J commutes with e^{-tJ},

$$\frac{\mathrm{d}h}{\mathrm{d}t} = g(t)J\mathrm{e}^{-tJ} - g(t)J\mathrm{e}^{-tJ} = 0\,,$$

so h is constant and equal to $h(0) = \mathbb{1}$. Multiplying on the right by e^{tJ} gives Equation (14.8). Finally $g(t)g(-t) = g(0) = \mathbb{1}$ by Equation (14.7). □

Remark 14.4 (What the exponential formula asserts, and what it does not). For several parameters, $\mathrm{e}^{\theta^a J_a}$ is a well-defined operator for every choice of the θ^a, and for fixed θ^a the curve $t \mapsto \mathrm{e}^{t\theta^a J_a}$ is a one-parameter subgroup by Proposition 14.3. The map $\theta^a \mapsto \mathrm{e}^{\theta^a J_a}$ is smooth, and its differential at $\theta^a = 0$ sends θ^a to $\theta^a J_a$, which is injective because the generators are linearly independent; by the inverse function theorem the map is therefore a diffeomorphism of a neighbourhood of the origin in parameter space onto a neighbourhood of the identity in G. Equation (14.6) is the statement that the parameters θ^a of Definition 14.2 have been chosen to be those coordinates — the *canonical coordinates of the first kind*. Three things it does *not* say. It does not say that parameters compose additively: unless the generators commute, $\mathrm{e}^{X}\mathrm{e}^{Y} \neq \mathrm{e}^{X+Y}$, the leading correction to the exponent being $\tfrac{1}{2}[X,Y]$. It does not say that every element of a connected Lie group is a single exponential; what is true, and is all that Corollary 14.18 uses, is that the exponentials cover a neighbourhood of the identity and that a connected group is generated by any such neighbourhood. And when the generators are realized as the differential operators Equation (14.3) rather than as matrices, $\mathrm{e}^{\theta^a J_a}$ is to be read as the flow of the vector field $\theta^a J_a$, which exists locally by the existence and uniqueness theorem for ordinary differential equations and obeys Equation (14.7) for that reason.

Alternative expression for the generators

From Equation (14.6) we see that, differentiating with respect to θ^a,

$$\begin{aligned}\frac{\mathrm{d}g}{\mathrm{d}\theta^a} &= \mathrm{e}^{J_b\theta^b}\,\frac{\mathrm{d}}{\mathrm{d}\theta^a}\left(J_c\theta^c\right)\\ &= \mathrm{e}^{J_b\theta^b} J_c\,\delta^c{}_a\\ &= \mathrm{e}^{J_b\theta^b} J_a\,,\end{aligned}$$

and evaluating at $\theta^a = 0$ we obtain

$$J_a = \left.\frac{\mathrm{d}g}{\mathrm{d}\theta^a}\right|_{\theta^a=0}. \tag{14.10}$$

From Equation (14.6) (differentiate the exponential with respect to a parameter and evaluate at the identity).

The universal enveloping algebra

The bracket Equation (14.5) is not an associative product. The juxtaposition J_aJ_b has no meaning in the Lie algebra itself; it acquires one only inside a representation, where the generators are operators and juxtaposition is composition. Yet the quantities that label the states of a physical system — the squared angular momentum, the squared four-momentum — are polynomials of exactly that kind. Before they can be discussed once and for all, rather than representation by representation, they must be given a home.

Definition 14.5 (Universal enveloping algebra)**.** Let $\mathfrak{g}$ be a Lie algebra over $\mathbb{R}$ with basis $\{T_a\}$, $a = 1, \dots, \dim\mathfrak{g}$, and structure constants fixed as in Equation (14.5),

$$[T_a, T_b] = C^c{}_{ab}\,T_c\,. \tag{14.11}$$

Its *universal enveloping algebra* $U(\mathfrak{g})$ is the associative algebra with unit generated by the symbols T_a subject to the relations

$$\boxed{T_aT_b - T_bT_a = C^c{}_{ab}\,T_c}\,, \tag{14.12}$$

equivalently the quotient of the tensor algebra of the vector space $\mathfrak{g}$ by the two-sided ideal generated by all elements $X \otimes Y - Y \otimes X - [X,Y]$ with $X, Y \in \mathfrak{g}$.

Rests on Equation (14.5).

Remark 14.6 (What $U(\mathfrak{g})$ is for). Every linear representation D of $\mathfrak{g}$ on a vector space $\mathbb{V}$ — that is, every linear map with $D([X,Y]) = D(X)D(Y) - D(Y)D(X)$ — extends uniquely to a homomorphism of associative algebras $U(\mathfrak{g}) \to \mathrm{End}(\mathbb{V})$, because Equation (14.12) is precisely the relation the operators $D(T_a)$ already satisfy. This is the sense in which $U(\mathfrak{g})$ is *universal*, and it is what makes a statement proved once in $U(\mathfrak{g})$ a statement about every representation at once.

Theorem 14.7 (Poincaré–Birkhoff–Witt)**.** *The ordered monomials $T_1^{n_1} T_2^{n_2} \cdots T_M^{n_M}$, with $M = \dim \mathfrak{g}$ and $n_a \in \mathbb{N} \cup \{0\}$, form a basis of $U(\mathfrak{g})$ as a vector space. In particular $\mathfrak{g}$ embeds in $U(\mathfrak{g})$, and no relation holds among the generators beyond those forced by Equation (14.12).*

Rests on Definition 14.5.
